&-(y^2-4\,\mathrm{e}^x)^{\frac{3}{2}}\,a_3-\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3+2y^3a_3-4\,\mathrm{e}^x xa_2-12\,\mathrm{e}^x ya_3 \\
&\quad-2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2+2xyb_2+2y^2a_2-4\,\mathrm{e}^x a_1 \\
&\quad-8\,\mathrm{e}^x a_2+8\,\mathrm{e}^x b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}+2yb_1=0
\end{aligned}
\tag{6E}
$$

Simplifying the above gives

$$
\begin{aligned}
&-(y^2-4\,\mathrm{e}^x)^{\frac{3}{2}}\,a_3+2(y^2-4\,\mathrm{e}^x)\,ya_3-\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3-4\,\mathrm{e}^x xa_2-4\,\mathrm{e}^x ya_3 \\
&\quad+2(y^2-4\,\mathrm{e}^x)\,a_2-2(y^2-4\,\mathrm{e}^x)\,b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2 \\
&\quad+2xyb_2+2y^2b_3-4\,\mathrm{e}^x a_1-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}+2yb_1=0
\end{aligned}
\tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&-2\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3+2y^3a_3-4\,\mathrm{e}^x xa_2+4\,\mathrm{e}^x\sqrt{y^2-4\,\mathrm{e}^x}\,a_3-12\,\mathrm{e}^x ya_3 \\
&\quad-2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2+2xyb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2+2y^2a_2-4\,\mathrm{e}^x a_1 \\
&\quad-8\,\mathrm{e}^x a_2+8\,\mathrm{e}^x b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}+2yb_1=0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$
\left\{x,y,\sqrt{y^2-4\,\mathrm{e}^x},\mathrm{e}^x\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{y^2 - 4\,\mathrm{e}^x} = v_3, \mathrm{e}^x = v_4\right\}$$

The above PDE (6E) now becomes

$$2v_2^3 a_3 - 2v_3 v_2^2 a_3 - 4v_4 v_1 a_2 + 2v_2^2 a_2 - 2v_3 v_2 a_2 - 12v_4 v_2 a_3 + 4v_4 v_3 a_3 + 2v_1 v_2 b_2 - 2v_3 v_1 b_2 - 4v_4 a_1 - 8v_4 a_2 + 2v_2 b_1 - 2v_3 b_1 + 4b_2 v_3 + 8v_4 b_3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$2v_1 v_2 b_2 - 2v_3 v_1 b_2 - 4v_4 v_1 a_2 + 2v_2^3 a_3 - 2v_3 v_2^2 a_3 + 2v_2^2 a_2 - 2v_3 v_2 a_2 - 12v_4 v_2 a_3 + 2v_2 b_1 + 4v_4 v_3 a_3 + (-2b_1 + 4b_2)\, v_3 + (-4a_1 - 8a_2 + 8b_3)\, v_4 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-4a_2 &= 0 \\
-2a_2 &= 0 \\
2a_2 &= 0 \\
-12a_3 &= 0 \\
-2a_3 &= 0 \\
2a_3 &= 0 \\
4a_3 &= 0 \\
2b_1 &= 0 \\
-2b_2 &= 0 \\
2b_2 &= 0 \\
-2b_1 + 4b_2 &= 0 \\
-4a_1 - 8a_2 + 8b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 2b_3 \\
a_2 &= 0 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= 2 \\
\eta &= y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y - \left(\frac{y}{2} - \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right) (2) \\
&= \sqrt{y^2 - 4\,\mathrm{e}^x} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\sqrt{y^2 - 4\,\mathrm{e}^x}} dy
\end{aligned}$$

Which results in

$$S = \ln\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{2}-\frac{\sqrt{y^{2}-4\,\mathrm{e}^{x}}}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1\\
R_y &= 0\\
S_x &= -\frac{2\,\mathrm{e}^{x}}{\sqrt{y^{2}-4\,\mathrm{e}^{x}}\,\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right)}\\
S_y &= \frac{1}{\sqrt{y^{2}-4\,\mathrm{e}^{x}}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right) = c_1$$

Which simplifies to

$$\ln\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right) = c_{1}$$

Which gives

$$y = \frac{\left(\mathrm{e}^{2c_{1}}+4\,\mathrm{e}^{x}\right)\mathrm{e}^{-c_{1}}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\mathrm{e}^{2c_{1}}+4\,\mathrm{e}^{x}\right)\mathrm{e}^{-c_{1}}}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\left(\mathrm{e}^{2c_{1}}+4\,\mathrm{e}^{x}\right)\mathrm{e}^{-c_{1}}}{2}$$

Verified OK.

Problem number: 273.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_homogeneous, `class A`], _rational, _dAlembert]`

$$\boxed{3xy'^2 - 6yy' + 2y = -x}$$

11.14.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$3x\,p^2 - 6yp + 2y = -x$$

Solving for y from the above results in

$$y = \frac{x(3p^2 + 1)}{6p - 2} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= \frac{3p^2 + 1}{6p - 2} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p - \frac{3p^2 + 1}{6p - 2} = x\left(\frac{6p}{6p - 2} - \frac{6(3p^2 + 1)}{(6p - 2)^2}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - \frac{3p^2 + 1}{6p - 2} = 0
$$

Solving for p from the above gives

$$
\begin{aligned}
p &= 1 \\
p &= -\frac{1}{3}
\end{aligned}
$$

Substituting these in (1A) gives

$$
\begin{aligned}
y &= x \\
y &= -\frac{x}{3}
\end{aligned}
$$

The general solution is found when $\frac{dp}{dx} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - \frac{3p(x)^2 + 1}{6p(x) - 2}}{x\left(\frac{6p(x)}{6p(x) - 2} - \frac{6\left(3p(x)^2 + 1\right)}{(6p(x) - 2)^2}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
p'(x) + p(x)p(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= -\frac{1}{3x}
\end{aligned}
$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = -\frac{1}{3x}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)\left(-\frac{1}{3x}\right) \\ \frac{d}{dx}\left(\frac{p}{x}\right) &= \left(\frac{1}{x}\right)\left(-\frac{1}{3x}\right) \\ d\left(\frac{p}{x}\right) &= \left(-\frac{1}{3x^2}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{p}{x} &= \int -\frac{1}{3x^2} dx \\ \frac{p}{x} &= \frac{1}{3x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = \frac{1}{3} + c_1 x$$

Substituing the above solution for p in (2A) gives

$$y = \frac{3\left(\frac{1}{3} + c_1 x\right)^2 + 1}{6c_1}$$

Summary

The solution(s) found are the following

$$y = x \tag{1}$$

$$y = -\frac{x}{3} \tag{2}$$

$$y = \frac{3\left(\frac{1}{3} + c_1 x\right)^2 + 1}{6c_1} \tag{3}$$

Verification of solutions

$$y = x$$

Verified OK.

$$y = -\frac{x}{3}$$

Verified OK.

$$y = \frac{3\left(\frac{1}{3} + c_1 x\right)^2 + 1}{6c_1}$$

Verified OK.

Problem number: 274.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _rational, _Clairaut]`

$$\boxed{y - xy' - \sqrt{a^2 y'^2 + b^2} = 0}$$

11.15.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - \sqrt{a^2 p^2 + b^2} = 0$$

Solving for y from the above results in

$$y = xp + \sqrt{a^2 p^2 + b^2} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + \sqrt{a^2 p^2 + b^2} \\ &= xp + \sqrt{a^2 p^2 + b^2} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = \sqrt{a^2p^2 + b^2}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1x + \sqrt{a^2c_1^2 + b^2}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = \sqrt{a^2p^2 + b^2}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + \frac{a^2p}{\sqrt{a^2p^2 + b^2}} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$
\begin{aligned}
p_1 &= \frac{xb}{\sqrt{a^2 - x^2}\, a} \\
p_2 &= -\frac{xb}{\sqrt{a^2 - x^2}\, a}
\end{aligned}
$$

Substituting the above back in (1) results in

$$
\begin{aligned}
y_1 &= \frac{\sqrt{\frac{a^2 b^2}{a^2 - x^2}}\, \sqrt{a^2 - x^2}\, a + b\, x^2}{\sqrt{a^2 - x^2}\, a} \\
y_2 &= \frac{\sqrt{\frac{a^2 b^2}{a^2 - x^2}}\, \sqrt{a^2 - x^2}\, a - b\, x^2}{\sqrt{a^2 - x^2}\, a}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x + \sqrt{a^2 c_1^2 + b^2} \tag{1}
$$

$$
y = \frac{\sqrt{\frac{a^2 b^2}{a^2 - x^2}}\, \sqrt{a^2 - x^2}\, a + b\, x^2}{\sqrt{a^2 - x^2}\, a} \tag{2}
$$

$$
y = \frac{\sqrt{\frac{a^2 b^2}{a^2 - x^2}}\, \sqrt{a^2 - x^2}\, a - b\, x^2}{\sqrt{a^2 - x^2}\, a} \tag{3}
$$

Verification of solutions

$$
y = c_1 x + \sqrt{a^2 c_1^2 + b^2}
$$

Verified OK.

$$
y = \frac{\sqrt{\frac{a^2 b^2}{a^2 - x^2}}\, \sqrt{a^2 - x^2}\, a + b\, x^2}{\sqrt{a^2 - x^2}\, a}
$$

Verified OK.

$$
y = \frac{\sqrt{\frac{a^2 b^2}{a^2 - x^2}}\, \sqrt{a^2 - x^2}\, a - b\, x^2}{\sqrt{a^2 - x^2}\, a}
$$

Problem number: 275.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _Riccati]
```

$$\boxed{y' - (-y + x)^2 = 1}$$

12.1.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = x^2 - 2xy + y^2 + 1$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}&b_2 + (x^2 - 2xy + y^2 + 1)(b_3 - a_2) - (x^2 - 2xy + y^2 + 1)^2 a_3 \\ &- (2x - 2y)(xa_2 + ya_3 + a_1) - (-2x + 2y)(xb_2 + yb_3 + b_1) = 0\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\begin{aligned}&-x^4a_3 + 4x^3ya_3 - 6x^2y^2a_3 + 4x\,y^3a_3 - y^4a_3 - 3x^2a_2 - 2x^2a_3 + 2x^2b_2 + x^2b_3 + 4xya_2 \\ &+ 2xya_3 - 2xyb_2 - y^2a_2 - y^2b_3 - 2xa_1 + 2xb_1 + 2ya_1 - 2yb_1 - a_2 - a_3 + b_2 + b_3 = 0\end{aligned}$$

Setting the numerator to zero gives

$$\begin{aligned}&-x^4a_3 + 4x^3ya_3 - 6x^2y^2a_3 + 4x\,y^3a_3 - y^4a_3 - 3x^2a_2 - 2x^2a_3 \\ &+ 2x^2b_2 + x^2b_3 + 4xya_2 + 2xya_3 - 2xyb_2 - y^2a_2 - y^2b_3 \\ &- 2xa_1 + 2xb_1 + 2ya_1 - 2yb_1 - a_2 - a_3 + b_2 + b_3 = 0\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}&-a_3v_1^4 + 4a_3v_1^3v_2 - 6a_3v_1^2v_2^2 + 4a_3v_1v_2^3 - a_3v_2^4 - 3a_2v_1^2 + 4a_2v_1v_2 \\ &- a_2v_2^2 - 2a_3v_1^2 + 2a_3v_1v_2 + 2b_2v_1^2 - 2b_2v_1v_2 + b_3v_1^2 - b_3v_2^2 \\ &- 2a_1v_1 + 2a_1v_2 + 2b_1v_1 - 2b_1v_2 - a_2 - a_3 + b_2 + b_3 = 0\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$-a_3v_1^4 + 4a_3v_1^3v_2 - 6a_3v_1^2v_2^2 + (-3a_2 - 2a_3 + 2b_2 + b_3)\,v_1^2 \\ + 4a_3v_1v_2^3 + (4a_2 + 2a_3 - 2b_2)\,v_1v_2 + (-2a_1 + 2b_1)\,v_1 - a_3v_2^4 \\ + (-a_2 - b_3)\,v_2^2 + (2a_1 - 2b_1)\,v_2 - a_2 - a_3 + b_2 + b_3 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -6a_3 &= 0 \\ -a_3 &= 0 \\ 4a_3 &= 0 \\ -2a_1 + 2b_1 &= 0 \\ 2a_1 - 2b_1 &= 0 \\ -a_2 - b_3 &= 0 \\ 4a_2 + 2a_3 - 2b_2 &= 0 \\ -3a_2 - 2a_3 + 2b_2 + b_3 &= 0 \\ -a_2 - a_3 + b_2 + b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= b_1 \\ a_2 &= -b_3 \\ a_3 &= 0 \\ b_1 &= b_1 \\ b_2 &= -2b_3 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 1 \\ \eta &= 1 \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x,y)\,\xi \\ &= 1 - \left(x^2 - 2xy + y^2 + 1\right)(1) \\ &= -x^2 + 2xy - y^2 \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{-x^2 + 2xy - y^2} dy \end{aligned}$$

Which results in

$$S = \frac{1}{-x + y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = x^2 - 2xy + y^2 + 1$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{(x - y)^2} \\ S_y &= -\frac{1}{(x - y)^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{1}{-x+y} = -x + c_1$$

Which simplifies to

$$\frac{1}{-x+y} = -x + c_1$$

Which gives

$$y = \frac{c_1 x - x^2 + 1}{-x + c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = x^2 - 2xy + y^2 + 1$ 	$R = x$ $S = \frac{1}{-x + y}$	$\frac{dS}{dR} = -1$ 
<u>Summary</u>

The solution(s) found are the following

$$y = \frac{c_1 x - x^2 + 1}{-x + c_1} \tag{1}$$

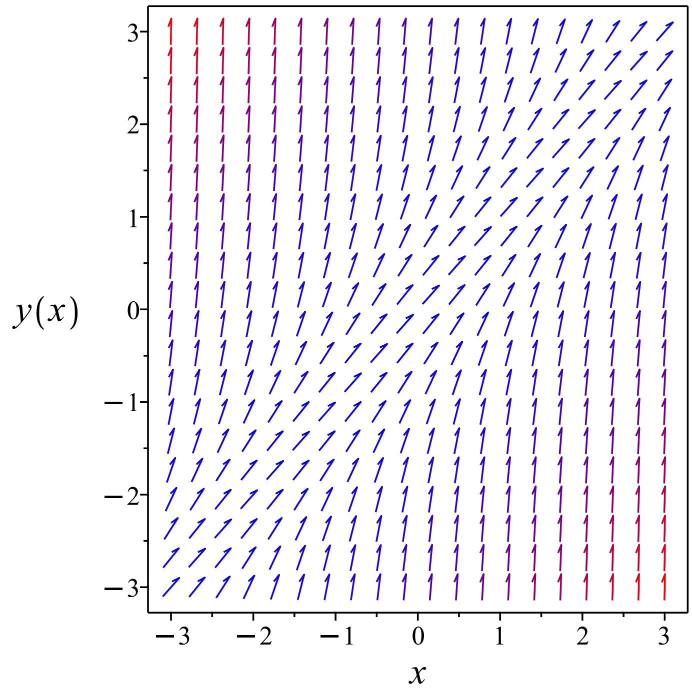

Figure 339: Slope field plot

Verification of solutions

$$y = \frac{c_1 x - x^2 + 1}{-x + c_1}$$

Verified OK.

12.1.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= x^2 - 2xy + y^2 + 1 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x^2 - 2xy + y^2 + 1$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = x^2 + 1$, $f_1(x) = -2x$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= -2x \\ f_2^2 f_0 &= x^2 + 1 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + 2xu'(x) + \left(x^2 + 1\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{e}^{-\frac{x^2}{2}} (c_2 x + c_1)$$

The above shows that

$$u'(x) = \mathrm{e}^{-\frac{x^2}{2}} \left(-c_2 x^2 - c_1 x + c_2\right)$$

Using the above in (1) gives the solution

$$y = -\frac{-c_2 x^2 - c_1 x + c_2}{c_2 x + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{c_3 x + x^2 - 1}{c_3 + x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_3 x + x^2 - 1}{c_3 + x} \tag{1}$$

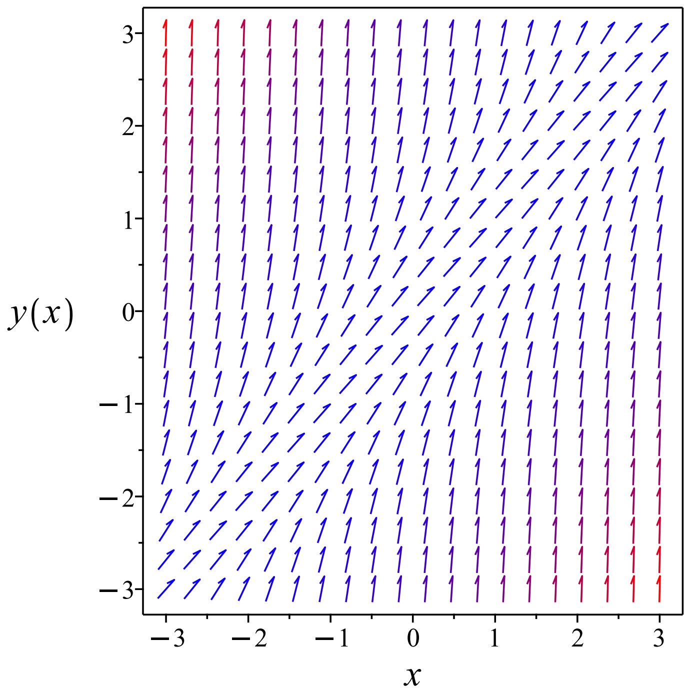

Figure 340: Slope field plot

Verification of solutions

$$y = \frac{c_3 x + x^2 - 1}{c_3 + x}$$

Problem number: 276.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{x \sin(x) y' + (\sin(x) - \cos(x) x) y = \sin(x) \cos(x) - x}$$

12.2.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{x \cot(x) - 1}{x}$$
$$q(x) = \frac{\cos(x) - x \csc(x)}{x}$$

Hence the ode is

$$y' - \frac{(x \cot(x) - 1) y}{x} = \frac{\cos(x) - x \csc(x)}{x}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{x\cot(x)-1}{x}dx}$$
$$= e^{-\ln(\sin(x))+\ln(x)}$$

Which simplifies to

$$\mu = \frac{x}{\sin(x)}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{\cos(x) - x\csc(x)}{x}\right)$$
$$\frac{d}{dx}\left(\frac{xy}{\sin(x)}\right) = \left(\frac{x}{\sin(x)}\right)\left(\frac{\cos(x) - x\csc(x)}{x}\right)$$
$$d\left(\frac{xy}{\sin(x)}\right) = \left(\cot(x) - x\csc(x)^2\right)\,dx$$

Integrating gives

$$\frac{xy}{\sin(x)} = \int \cot(x) - x\csc(x)^2\,dx$$
$$\frac{xy}{\sin(x)} = x\cot(x) + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{x}{\sin(x)}$ results in

$$y = \sin(x)\cot(x) + \frac{c_1\sin(x)}{x}$$

which simplifies to

$$y = \cos(x) + \frac{c_1\sin(x)}{x}$$

Summary

The solution(s) found are the following

$$y = \cos(x) + \frac{c_1\sin(x)}{x} \tag{1}$$

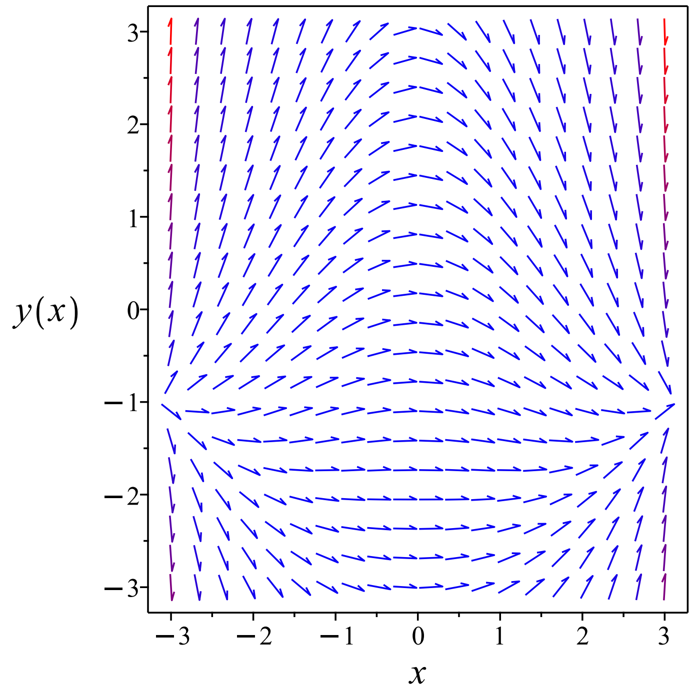

Figure 341: Slope field plot

Verification of solutions

$$y = \cos(x) + \frac{c_1 \sin(x)}{x}$$

Verified OK.

12.2.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{\cos(x) xy + \sin(x) \cos(x) - y \sin(x) - x}{\sin(x) x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 274: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \mathrm{e}^{\ln(\sin(x))-\ln(x)}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\ln(\sin(x))-\ln(x)}} dy \end{aligned}$$

Which results in

$$S = \frac{xy}{\sin(x)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\cos(x)\,xy + \sin(x)\cos(x) - y\sin(x) - x}{\sin(x)\,x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -y\csc(x)\,(x\cot(x) - 1) \\ S_y &= x\csc(x) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cot(x) - x\csc(x)^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cot(R) - R\csc(R)^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R\cot(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{yx}{\sin(x)} = x\cot(x) + c_1$$

Which simplifies to

$$\frac{yx}{\sin(x)} = x\cot(x) + c_1$$

Which gives

$$y = \frac{\sin(x)\,(x\cot(x) + c_1)}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\cos(x)xy+\sin(x)\cos(x)-y\sin(x)-x}{\sin(x)x}$ 	$R = x$ $S = \frac{xy}{\sin(x)}$	$\frac{dS}{dR} = \cot(R) - R\csc(R)^2$ 
Summary

The solution(s) found are the following

$$y = \frac{\sin(x)(x\cot(x)+c_1)}{x} \tag{1}$$

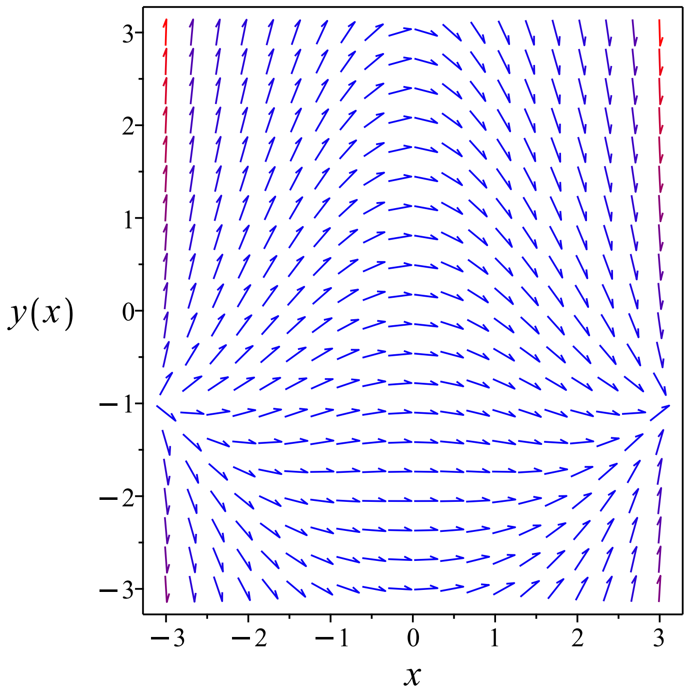

Figure 342: Slope field plot

Verification of solutions

$$y = \frac{\sin(x)(x\cot(x)+c_1)}{x}$$

Verified OK.

12.2.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$(x\sin(x))\,\mathrm{d}y=(-(\sin(x)-\cos(x)\,x)\,y+\sin(x)\cos(x)$$

$$((\sin(x)-\cos(x)\,x)\,y-\sin(x)\cos(x)+x)\,\mathrm{d}x+(x\sin(x))\,\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=(\sin(x)-\cos(x)\,x)\,y-\sin(x)\cos(x)+x\\ N(x,y)&=x\sin(x)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}((\sin(x)-\cos(x)\,x)\,y-\sin(x)\cos(x)+x)\\ &=\sin(x)-\cos(x)\,x\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x \sin(x)) \\
&= \sin(x) + \cos(x) x
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{\csc(x)}{x}((\sin(x) - \cos(x) x) - (\sin(x) + \cos(x) x)) \\
&= -2\cot(x)
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -2\cot(x) \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-2\ln(\sin(x))} \\
&= \csc(x)^2
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \csc(x)^2 ((\sin(x) - \cos(x) x) y - \sin(x)\cos(x) + x) \\
&= x\csc(x)^2 + y(-x\cot(x) + 1)\csc(x) - \cot(x)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \csc(x)^2 (x \sin(x)) \\
&= x\csc(x)
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(x\csc(x)^2 + y(-x\cot(x) + 1)\csc(x) - \cot(x)\right) + (x\csc(x))\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int x \csc(x)^2 + y(-x \cot(x) + 1) \csc(x) - \cot(x) \, \mathrm{d}x$$
$$\phi = x(\csc(x)\, y - \cot(x)) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x \csc(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x \csc(x)$. Therefore equation (4) becomes

$$x \csc(x) = x \csc(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = x(\csc(x)\, y - \cot(x)) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(\csc(x)\, y - \cot(x))$$

The solution becomes

$$y = \frac{x \cot(x) + c_1}{x \csc(x)}$$

Summary

The solution(s) found are the following

$$y = \frac{x \cot(x) + c_1}{x \csc(x)} \tag{1}$$

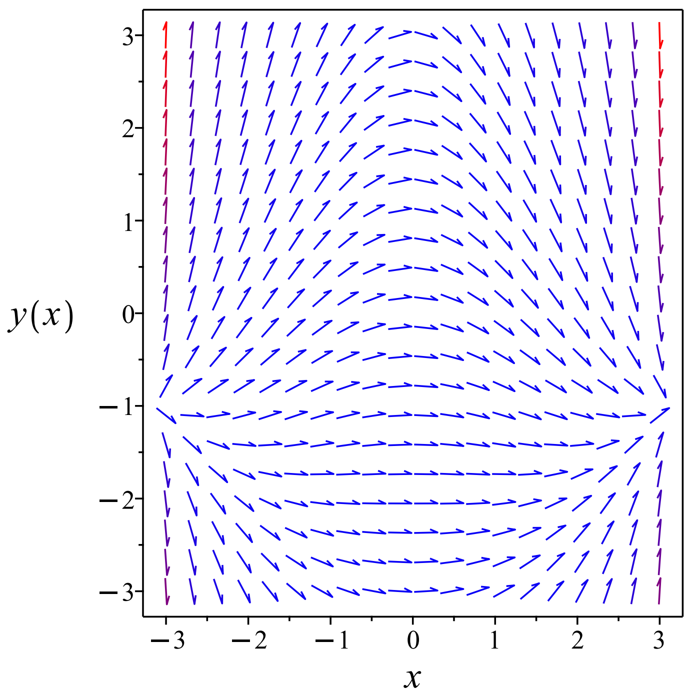

Figure 343: Slope field plot

Verification of solutions

$$y = \frac{x \cot(x) + c_1}{x \csc(x)}$$

Verified OK.

12.2.4 Maple step by step solution

Let's solve

$x \sin(x) y' + (\sin(x) - \cos(x) x) y = \sin(x) \cos(x) - x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{(\cos(x)x - \sin(x))y}{\sin(x)x} + \frac{\sin(x)\cos(x) - x}{\sin(x)x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{(\cos(x)x - \sin(x))y}{\sin(x)x} = \frac{\sin(x)\cos(x) - x}{\sin(x)x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{(\cos(x)x - \sin(x))y}{\sin(x)x}\right) = \frac{\mu(x)(\sin(x)\cos(x) - x)}{\sin(x)x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' - \frac{(\cos(x)x - \sin(x))y}{\sin(x)x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)(\cos(x)x - \sin(x))}{\sin(x)x}$

- Solve to find the integrating factor

  $\mu(x) = \frac{x}{\sin(x)}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)(\sin(x)\cos(x) - x)}{\sin(x)x} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)(\sin(x)\cos(x) - x)}{\sin(x)x} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)(\sin(x)\cos(x) - x)}{\sin(x)x} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{x}{\sin(x)}$

  $y = \frac{\sin(x)\left(\int \frac{\sin(x)\cos(x) - x}{\sin(x)^2} dx + c_1\right)}{x}$

- Evaluate the integrals on the rhs

  $y = \frac{\sin(x)(x\cot(x) + c_1)}{x}$

- Simplify

  $y = \frac{\cos(x)x+\sin(x)c_1}{x}$

The type(s) of ODE detected by this program : **"bernoulli", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_Bernoulli]`

$$\boxed{y' + \cos(x)\, y - y^n \sin(2x) = 0}$$

12.3.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -y\cos(x) + y^n \sin(2x) \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 277: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= y^n \mathrm{e}^{(n-1)\sin(x)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{y^n \mathrm{e}^{(n-1)\sin(x)}} dy \end{aligned}$$

Which results in

$$S = -\frac{y\, y^{-n} \mathrm{e}^{-(n-1)\sin(x)}}{n-1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -y\cos(x) + y^n \sin(2x)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y^{-n+1} \cos(x)\, \mathrm{e}^{-(n-1)\sin(x)} \\ S_y &= y^{-n} \mathrm{e}^{-(n-1)\sin(x)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2\,\mathrm{e}^{-(n-1)\sin(x)} \cos(x)\sin(x) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2\,\mathrm{e}^{-(n-1)\sin(R)} \cos(R)\sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{c_1(n-1)^2 - 2\,\mathrm{e}^{-(n-1)\sin(R)}(1+(n-1)\sin(R))}{(n-1)^2} \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{y^{-n+1}\mathrm{e}^{-(n-1)\sin(x)}}{n-1} = \frac{c_1(n-1)^2 - 2\,\mathrm{e}^{-(n-1)\sin(x)}(1+(n-1)\sin(x))}{(n-1)^2}$$

Which simplifies to

$$\frac{((-n+1)\,y^{-n+1} + 2 + (2n-2)\sin(x))\,\mathrm{e}^{-(n-1)\sin(x)} - c_1(n-1)^2}{(n-1)^2} = 0$$

Which gives

$$y = \mathrm{e}^{-\frac{\sin(x)n+\ln\left(\frac{2\sin(x)\mathrm{e}^{-(n-1)\sin(x)}n - c_1n^2 - 2\sin(x)\mathrm{e}^{-(n-1)\sin(x)} + 2c_1n + 2\,\mathrm{e}^{-(n-1)\sin(x)} - c_1}{n-1}\right) - \sin(x)}{n-1}}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{\sin(x)n+\ln\left(\frac{2\sin(x)\mathrm{e}^{-(n-1)\sin(x)}n - c_1n^2 - 2\sin(x)\mathrm{e}^{-(n-1)\sin(x)} + 2c_1n + 2\,\mathrm{e}^{-(n-1)\sin(x)} - c_1}{n-1}\right) - \sin(x)}{n-1}} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-\frac{\sin(x)n+\ln\left(\frac{2\sin(x)\mathrm{e}^{-(n-1)\sin(x)}n - c_1n^2 - 2\sin(x)\mathrm{e}^{-(n-1)\sin(x)} + 2c_1n + 2\,\mathrm{e}^{-(n-1)\sin(x)} - c_1}{n-1}\right) - \sin(x)}{n-1}}$$

Verified OK.

12.3.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -y\cos(x) + y^n\sin(2x) \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\cos(x)\,y + 2\sin(x)\cos(x)\,y^n \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\cos(x) \\ f_1(x) &= 2\sin(x)\cos(x) \\ n &= n \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^n$ gives

$$y'y^{-n} = -\cos(x)\, y^{-n+1} + 2\sin(x)\cos(x) \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^{-n+1} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = (-n+1)\, y^{-n}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{-n+1} &= -\cos(x)\, w(x) + 2\sin(x)\cos(x) \\ w' &= -(-n+1)\cos(x)\, w + 2(-n+1)\sin(x)\cos(x) \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -(n-1)\cos(x) \\
q(x) &= -(n-1)\sin(2x)
\end{aligned}
$$

Hence the ode is

$$
w'(x) - (n-1)\cos(x)\, w(x) = -(n-1)\sin(2x)
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -(n-1)\cos(x)dx} \\
&= \mathrm{e}^{\sin(x)(-n+1)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \mathrm{e}^{-(n-1)\sin(x)}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu w) &= (\mu)\left(-(n-1)\sin(2x)\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-(n-1)\sin(x)} w\right) &= \left(\mathrm{e}^{-(n-1)\sin(x)}\right)\left(-(n-1)\sin(2x)\right) \\
\mathrm{d}\left(\mathrm{e}^{-(n-1)\sin(x)} w\right) &= \left(-(n-1)\sin(2x)\,\mathrm{e}^{-(n-1)\sin(x)}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-(n-1)\sin(x)} w &= \int -(n-1)\sin(2x)\,\mathrm{e}^{-(n-1)\sin(x)}\,\mathrm{d}x \\
\mathrm{e}^{-(n-1)\sin(x)} w &= \frac{2\,\mathrm{e}^{\sin(x)(-n+1)}(-n+1)\sin(x) - 2\,\mathrm{e}^{\sin(x)(-n+1)}}{-n+1} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-(n-1)\sin(x)}$ results in

$$
w(x) = \frac{2\,\mathrm{e}^{(n-1)\sin(x)}\left(\mathrm{e}^{\sin(x)(-n+1)}(-n+1)\sin(x) - \mathrm{e}^{\sin(x)(-n+1)}\right)}{-n+1} + c_1 \mathrm{e}^{(n-1)\sin(x)}
$$

which simplifies to

$$
w(x) = \frac{(n-1)\,c_1 \mathrm{e}^{(n-1)\sin(x)} + 2 + (2n-2)\sin(x)}{n-1}
$$

Replacing w in the above by y^{-n+1} using equation (5) gives the final solution.

$$
y^{-n+1} = \frac{(n-1)\,c_1 \mathrm{e}^{(n-1)\sin(x)} + 2 + (2n-2)\sin(x)}{n-1}
$$

Summary

The solution(s) found are the following

$$y^{-n+1} = \frac{(n-1)\, c_1 \mathrm{e}^{(n-1)\sin(x)} + 2 + (2n-2)\sin(x)}{n-1} \tag{1}$$

Verification of solutions

$$y^{-n+1} = \frac{(n-1)\, c_1 \mathrm{e}^{(n-1)\sin(x)} + 2 + (2n-2)\sin(x)}{n-1}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 12. Miscellaneous problems. Exercises page 93
Problem number: 278.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, _dAlembert]
```

$$\boxed{-3y^2x + \left(y^3 - 3yx^2\right) y' = -x^3}$$

12.4.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$-3u(x)^2\, x^3 + \left(u(x)^3\, x^3 - 3u(x)\, x^3\right) \left(u'(x)\, x + u(x)\right) = -x^3$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^4 - 6u^2 + 1}{ux\,(u^2 - 3)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^4-6u^2+1}{u(u^2-3)}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{u^4-6u^2+1}{u(u^2-3)}}\,du &= -\frac{1}{x}\,dx \\
\int \frac{1}{\frac{u^4-6u^2+1}{u(u^2-3)}}\,du &= \int -\frac{1}{x}\,dx \\
\frac{\ln\left(u^4-6u^2+1\right)}{4} &= -\ln\left(x\right)+c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
\left(u^4-6u^2+1\right)^{\frac{1}{4}} = \mathrm{e}^{-\ln(x)+c_2}
$$

Which simplifies to

$$
\left(u^4-6u^2+1\right)^{\frac{1}{4}} = \frac{c_3}{x}
$$

Which simplifies to

$$
\left(u(x)^4-6u(x)^2+1\right)^{\frac{1}{4}} = \frac{c_3\mathrm{e}^{c_2}}{x}
$$

The solution is

$$
\left(u(x)^4-6u(x)^2+1\right)^{\frac{1}{4}} = \frac{c_3\mathrm{e}^{c_2}}{x}
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\left(\frac{y^4}{x^4}-\frac{6y^2}{x^2}+1\right)^{\frac{1}{4}} &= \frac{c_3\mathrm{e}^{c_2}}{x} \\
\left(\frac{y^4-6y^2x^2+x^4}{x^4}\right)^{\frac{1}{4}} &= \frac{c_3\mathrm{e}^{c_2}}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\left(\frac{y^4-6y^2x^2+x^4}{x^4}\right)^{\frac{1}{4}} = \frac{c_3\mathrm{e}^{c_2}}{x} \tag{1}
$$

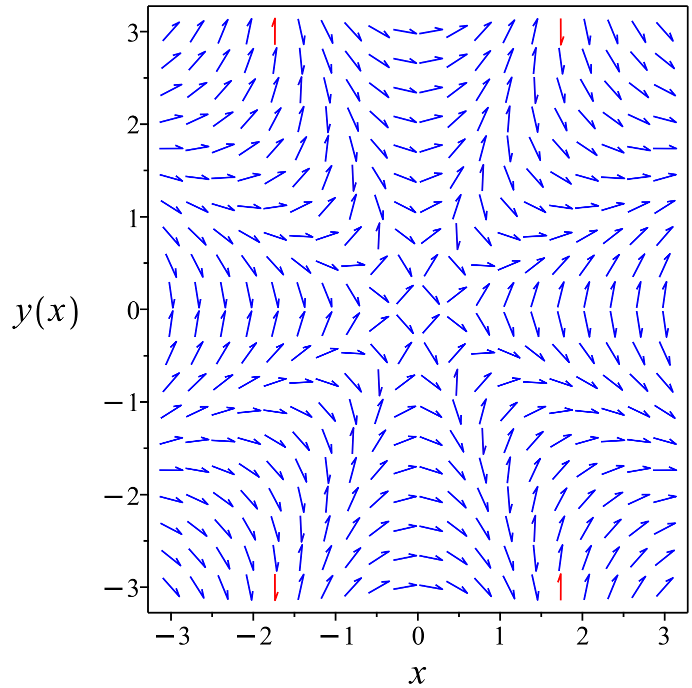

Figure 344: Slope field plot

Verification of solutions

$$\left(\frac{y^4-6y^2x^2+x^4}{x^4}\right)^{\frac{1}{4}}=\frac{c_3 e^{c_2}}{x}$$

Verified OK.

12.4.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{x(-x^2+3y^2)}{y\,(-3x^2+y^2)}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&b_2+\frac{x(-x^2+3y^2)\,(b_3-a_2)}{y\,(-3x^2+y^2)}-\frac{x^2(-x^2+3y^2)^2\,a_3}{y^2\,(-3x^2+y^2)^2}\\
&-\left(\frac{-x^2+3y^2}{y\,(-3x^2+y^2)}-\frac{2x^2}{y\,(-3x^2+y^2)}+\frac{6x^2(-x^2+3y^2)}{y\,(-3x^2+y^2)^2}\right)(xa_2+ya_3+a_1)\\
&-\left(\frac{6x}{-3x^2+y^2}-\frac{x(-x^2+3y^2)}{y^2\,(-3x^2+y^2)}-\frac{2x(-x^2+3y^2)}{(-3x^2+y^2)^2}\right)(xb_2+yb_3+b_1)=0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^6a_3-3x^6b_2+6x^5ya_2-6x^5yb_3-3x^4y^2a_3-15x^4y^2b_2-4x^3y^3a_2+4x^3y^3b_3+15x^2y^4a_3+3x^2y^4b_2+6x}{y^2\,(3x^2-y^2)^2}$$
$$=0$$

Setting the numerator to zero gives

$$\begin{aligned}
&-x^6a_3+3x^6b_2-6x^5ya_2+6x^5yb_3+3x^4y^2a_3+15x^4y^2b_2+4x^3y^3a_2\\
&-4x^3y^3b_3-15x^2y^4a_3-3x^2y^4b_2-6x\,y^5a_2+6x\,y^5b_3-3y^6a_3+y^6b_2\\
&+3x^5b_1-3x^4ya_1+6x^3y^2b_1-6x^2y^3a_1+3x\,y^4b_1-3y^5a_1=0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&-6a_2v_1^5v_2+4a_2v_1^3v_2^3-6a_2v_1v_2^5-a_3v_1^6+3a_3v_1^4v_2^2-15a_3v_1^2v_2^4-3a_3v_2^6\\
&+3b_2v_1^6+15b_2v_1^4v_2^2-3b_2v_1^2v_2^4+b_2v_2^6+6b_3v_1^5v_2-4b_3v_1^3v_2^3+6b_3v_1v_2^5\\
&-3a_1v_1^4v_2-6a_1v_1^2v_2^3-3a_1v_2^5+3b_1v_1^5+6b_1v_1^3v_2^2+3b_1v_1v_2^4=0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}(-a_3+3b_2)\,v_1^6+(-6a_2+6b_3)\,v_1^5v_2+3b_1v_1^5+(3a_3+15b_2)\,v_1^4v_2^2\\-3a_1v_1^4v_2+(4a_2-4b_3)\,v_1^3v_2^3+6b_1v_1^3v_2^2+(-15a_3-3b_2)\,v_1^2v_2^4\\-6a_1v_1^2v_2^3+(-6a_2+6b_3)\,v_1v_2^5+3b_1v_1v_2^4+(-3a_3+b_2)\,v_2^6-3a_1v_2^5=0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}-6a_1&=0\\-3a_1&=0\\3b_1&=0\\6b_1&=0\\-6a_2+6b_3&=0\\4a_2-4b_3&=0\\-15a_3-3b_2&=0\\-3a_3+b_2&=0\\-a_3+3b_2&=0\\3a_3+15b_2&=0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1&=0\\a_2&=b_3\\a_3&=0\\b_1&=0\\b_2&=0\\b_3&=b_3\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi&=x\\\eta&=y\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{x(-x^2+3y^2)}{y\,(-3x^2+y^2)}\right)(x) \\
&= \frac{-x^4+6x^2y^2-y^4}{3x^2y-y^3} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-x^4+6x^2y^2-y^4}{3x^2y-y^3}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln\left(x^4-6x^2y^2+y^4\right)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x(-x^2+3y^2)}{y\,(-3x^2+y^2)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{x(x^2 - 3y^2)}{(x^2 + 2xy - y^2)(x^2 - 2xy - y^2)} \\
S_y &= \frac{-3x^2y + y^3}{(x^2 + 2xy - y^2)(x^2 - 2xy - y^2)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(x^2 + 2yx - y^2)}{4} + \frac{\ln(x^2 - 2yx - y^2)}{4} = c_1$$

Which simplifies to

$$\frac{\ln(x^2 + 2yx - y^2)}{4} + \frac{\ln(x^2 - 2yx - y^2)}{4} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x(-x^2+3y^2)}{y(-3x^2+y^2)}$ 	$R = x$ $S = \frac{\ln(x^2+2xy-y^2)}{4} +$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(x^2+2yx-y^2)}{4} + \frac{\ln(x^2-2yx-y^2)}{4} = c_1 \tag{1}$$

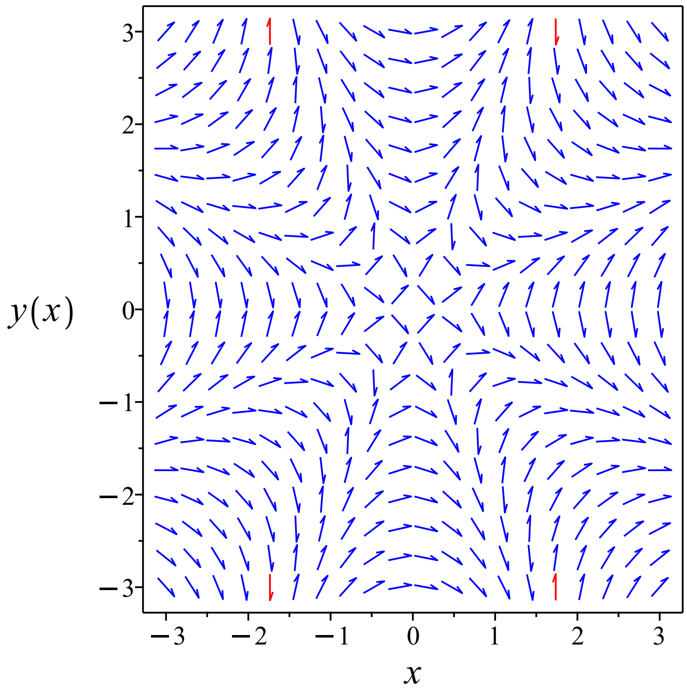

Figure 345: Slope field plot

Verification of solutions

$$\frac{\ln(x^2+2yx-y^2)}{4}+\frac{\ln(x^2-2yx-y^2)}{4}=c_1$$

Verified OK.

12.4.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
(-3x^2y + y^3) \, \mathrm{d}y &= (-x^3 + 3x \, y^2) \, \mathrm{d}x \\
(x^3 - 3x \, y^2) \, \mathrm{d}x + (-3x^2y + y^3) \, \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= x^3 - 3x \, y^2 \\
N(x, y) &= -3x^2y + y^3
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^3 - 3x \, y^2) \\
&= -6xy
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-3x^2y + y^3) \\
&= -6xy
\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int x^3 - 3x\,y^2 \mathrm{d}x$$
$$\phi = \frac{(x^2-3y^2)^2}{4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -3\left(x^2-3y^2\right)y + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -3x^2y + y^3$. Therefore equation (4) becomes

$$-3x^2y + y^3 = -3\left(x^2-3y^2\right)y + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -8y^3$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(-8y^3\right) \mathrm{d}y$$
$$f(y) = -2y^4 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(x^2-3y^2)^2}{4} - 2y^4 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(x^2 - 3y^2)^2}{4} - 2y^4$$

Summary

The solution(s) found are the following

$$\frac{(x^2 - 3y^2)^2}{4} - 2y^4 = c_1 \tag{1}$$

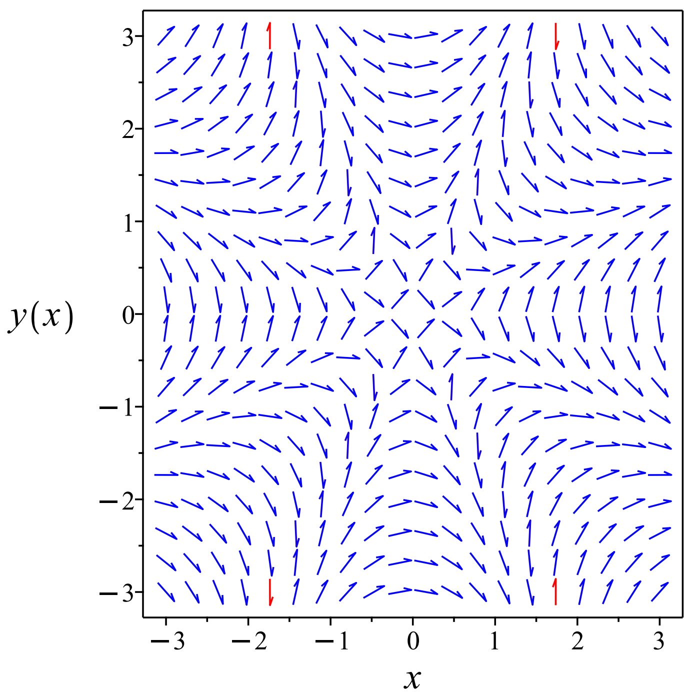

Figure 346: Slope field plot

Verification of solutions

$$\frac{(x^2 - 3y^2)^2}{4} - 2y^4 = c_1$$

Verified OK.

12.4.4 Maple step by step solution

Let's solve

$-3y^2x+(y^3-3yx^2)\,y'=-x^3$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$

  - Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

  - Evaluate derivatives

    $-6xy=-6xy$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int(x^3-3x\,y^2)\,dx+f_1(y)$

- Evaluate integral

  $F(x,y)=\frac{(x^2-3y^2)^2}{4}+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $-3x^2y+y^3=-3(x^2-3y^2)\,y+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=3(x^2-3y^2)\,y-3x^2y+y^3$

- Solve for $f_1(y)$

  $f_1(y)=-2y^4$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$F(x,y) = \frac{(x^2-3y^2)^2}{4} - 2y^4$

- Substitute $F(x,y)$ into the solution of the ODE

  $\frac{(x^2-3y^2)^2}{4} - 2y^4 = c_1$

- Solve for y

  $\left\{y = \sqrt{3x^2 - 2\sqrt{2x^4+c_1}}, y = \sqrt{3x^2 + 2\sqrt{2x^4+c_1}}, y = -\sqrt{3x^2 - 2\sqrt{2x^4+c_1}}, y = -\sqrt{3x^2 + 2\right.$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 12. Miscellaneous problems. Exercises page 93
Problem number: 279.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, _dAlembert]
```

$$\boxed{5yx - 4y^2 + \left(y^2 - 8yx + \frac{5x^2}{2}\right) y' = 6x^2}$$

12.5.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$5u(x)\,x^2 - 4u(x)^2\,x^2 + \left(u(x)^2\,x^2 - 8u(x)\,x^2 + \frac{5x^2}{2}\right)(u'(x)\,x + u(x)) = 6x^2$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u^3 - 24u^2 + 15u - 12}{x\,(2u^2 - 16u + 5)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{2u^3-24u^2+15u-12}{2u^2-16u+5}$. Integrating both sides gives

$$\frac{1}{\frac{2u^3-24u^2+15u-12}{2u^2-16u+5}} du = -\frac{1}{x} dx$$
$$\int \frac{1}{\frac{2u^3-24u^2+15u-12}{2u^2-16u+5}} du = \int -\frac{1}{x} dx$$
$$\frac{\ln(2u^3 - 24u^2 + 15u - 12)}{3} = -\ln(x) + c_2$$

Raising both side to exponential gives

$$(2u^3 - 24u^2 + 15u - 12)^{\frac{1}{3}} = e^{-\ln(x)+c_2}$$

Which simplifies to

$$(2u^3 - 24u^2 + 15u - 12)^{\frac{1}{3}} = \frac{c_3}{x}$$

Which simplifies to

$$(2u(x)^3 - 24u(x)^2 + 15u(x) - 12)^{\frac{1}{3}} = \frac{c_3 e^{c_2}}{x}$$

The solution is

$$(2u(x)^3 - 24u(x)^2 + 15u(x) - 12)^{\frac{1}{3}} = \frac{c_3 e^{c_2}}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\left(\frac{2y^3}{x^3} - \frac{24y^2}{x^2} + \frac{15y}{x} - 12\right)^{\frac{1}{3}} = \frac{c_3 e^{c_2}}{x}$$
$$\left(\frac{2y^3 - 24y^2x + 15yx^2 - 12x^3}{x^3}\right)^{\frac{1}{3}} = \frac{c_3 e^{c_2}}{x}$$

Summary

The solution(s) found are the following

$$\left(\frac{2y^3 - 24y^2x + 15yx^2 - 12x^3}{x^3}\right)^{\frac{1}{3}} = \frac{c_3 e^{c_2}}{x} \tag{1}$$

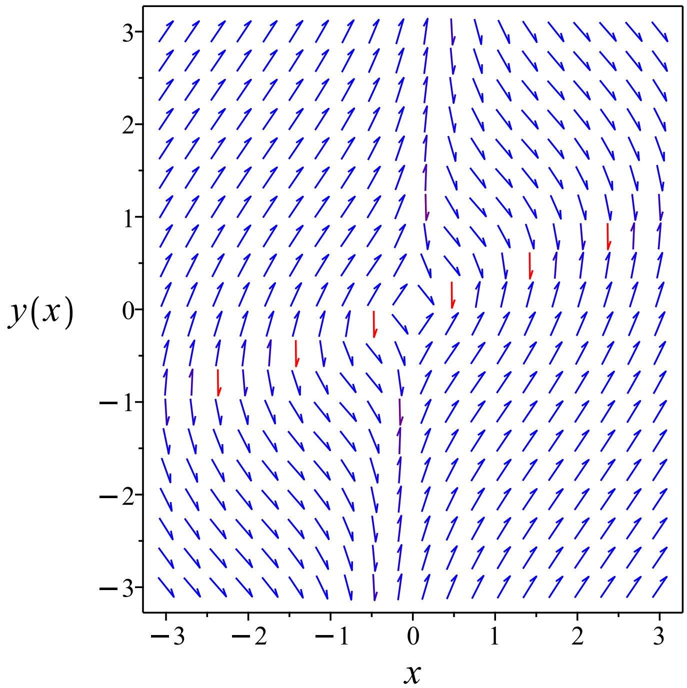

Figure 347: Slope field plot

Verification of solutions

$$\left(\frac{2y^3-24y^2x+15yx^2-12x^3}{x^3}\right)^{\frac{1}{3}}=\frac{c_3\mathrm{e}^{c_2}}{x}$$

Verified OK.

12.5.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{12x^2-10xy+8y^2}{5x^2-16xy+2y^2}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{2(6x^2 - 5xy + 4y^2)(b_3 - a_2)}{5x^2 - 16xy + 2y^2} - \frac{4(6x^2 - 5xy + 4y^2)^2 a_3}{(5x^2 - 16xy + 2y^2)^2} \\ & - \left(\frac{24x - 10y}{5x^2 - 16xy + 2y^2} - \frac{2(6x^2 - 5xy + 4y^2)(10x - 16y)}{(5x^2 - 16xy + 2y^2)^2}\right)(xa_2 + ya_3 + a_1) \\ & - \left(\frac{-10x + 16y}{5x^2 - 16xy + 2y^2} \right. \\ & \left. - \frac{2(6x^2 - 5xy + 4y^2)(-16x + 4y)}{(5x^2 - 16xy + 2y^2)^2}\right)(xb_2 + yb_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{60x^4a_2 + 144x^4a_3 + 117x^4b_2 - 60x^4b_3 - 384x^3ya_2 - 240x^3ya_3 + 192x^3yb_2 + 384x^3yb_3 + 192x^2y^2a_2 + 1}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} & -60x^4a_2 - 144x^4a_3 - 117x^4b_2 + 60x^4b_3 + 384x^3ya_2 + 240x^3ya_3 - 192x^3yb_2 \\ & - 384x^3yb_3 - 192x^2y^2a_2 - 150x^2y^2a_3 + 384x^2y^2b_2 + 192x^2y^2b_3 + 40x\,y^3a_2 \\ & + 192x\,y^3a_3 - 64x\,y^3b_2 - 40x\,y^3b_3 - 16y^4a_2 - 172y^4a_3 + 4y^4b_2 + 16y^4b_3 \\ & - 142x^3b_1 + 142x^2ya_1 - 32x^2yb_1 + 32x\,y^2a_1 + 108x\,y^2b_1 - 108y^3a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-60a_2v_1^4+384a_2v_1^3v_2-192a_2v_1^2v_2^2+40a_2v_1v_2^3-16a_2v_2^4\\
&-144a_3v_1^4+240a_3v_1^3v_2-150a_3v_1^2v_2^2+192a_3v_1v_2^3-172a_3v_2^4\\
&-117b_2v_1^4-192b_2v_1^3v_2+384b_2v_1^2v_2^2-64b_2v_1v_2^3+4b_2v_2^4+60b_3v_1^4\\
&-384b_3v_1^3v_2+192b_3v_1^2v_2^2-40b_3v_1v_2^3+16b_3v_2^4+142a_1v_1^2v_2\\
&+32a_1v_1v_2^2-108a_1v_2^3-142b_1v_1^3-32b_1v_1^2v_2+108b_1v_1v_2^2=0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&(-60a_2-144a_3-117b_2+60b_3)\,v_1^4+(384a_2+240a_3-192b_2-384b_3)\,v_1^3v_2\\
&-142b_1v_1^3+(-192a_2-150a_3+384b_2+192b_3)\,v_1^2v_2^2\\
&+(142a_1-32b_1)\,v_1^2v_2+(40a_2+192a_3-64b_2-40b_3)\,v_1v_2^3\\
&+(32a_1+108b_1)\,v_1v_2^2+(-16a_2-172a_3+4b_2+16b_3)\,v_2^4-108a_1v_2^3=0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-108a_1&=0\\
-142b_1&=0\\
32a_1+108b_1&=0\\
142a_1-32b_1&=0\\
-192a_2-150a_3+384b_2+192b_3&=0\\
-60a_2-144a_3-117b_2+60b_3&=0\\
-16a_2-172a_3+4b_2+16b_3&=0\\
40a_2+192a_3-64b_2-40b_3&=0\\
384a_2+240a_3-192b_2-384b_3&=0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1&=0\\
a_2&=b_3\\
a_3&=0\\
b_1&=0\\
b_2&=0\\
b_3&=b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = x$$
$$\eta = y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{12x^2 - 10xy + 8y^2}{5x^2 - 16xy + 2y^2}\right)(x) \\
&= \frac{-12x^3 + 15x^2y - 24x\,y^2 + 2y^3}{5x^2 - 16xy + 2y^2} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-12x^3 + 15x^2y - 24x\,y^2 + 2y^3}{5x^2 - 16xy + 2y^2}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln\left(-12x^3 + 15x^2y - 24x\,y^2 + 2y^3\right)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{12x^2 - 10xy + 8y^2}{5x^2 - 16xy + 2y^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{12x^2 - 10xy + 8y^2}{12x^3 - 15x^2y + 24x\,y^2 - 2y^3} \\ S_y &= \frac{-5x^2 + 16xy - 2y^2}{12x^3 - 15x^2y + 24x\,y^2 - 2y^3} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(2y^3 - 24y^2x + 15yx^2 - 12x^3)}{3} = c_1$$

Which simplifies to

$$\frac{\ln(2y^3 - 24y^2x + 15yx^2 - 12x^3)}{3} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{12x^2-10xy+8y^2}{5x^2-16xy+2y^2}$ 	$R = x$ $S = \frac{\ln(-12x^3+15x^2y-}{3}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(2y^3-24y^2x+15yx^2-12x^3)}{3} = c_1 \tag{1}$$

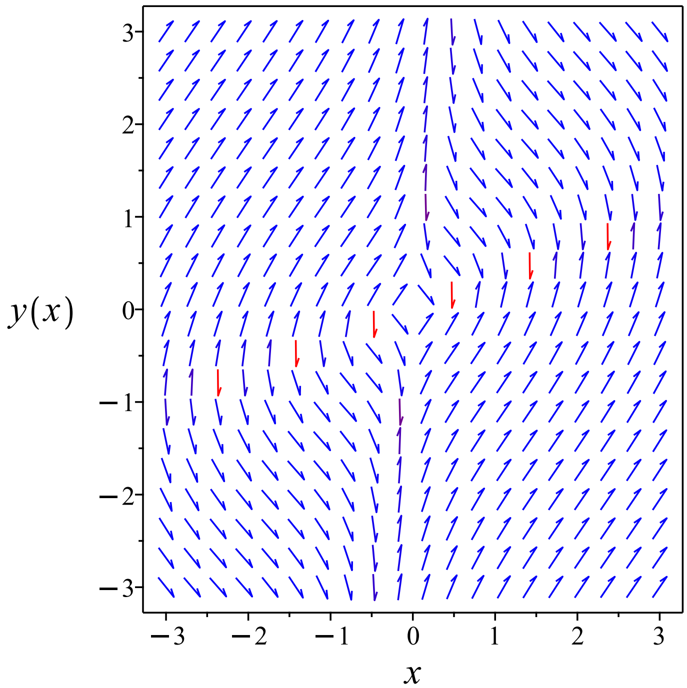

Figure 348: Slope field plot

Verification of solutions

$$\frac{\ln (2y^3 - 24y^2x + 15yx^2 - 12x^3)}{3} = c_1$$

Verified OK.

12.5.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(y^2 - 8xy + \frac{5}{2}x^2\right)\mathrm{d}y = \left(6x^2 - 5xy + 4y^2\right)\mathrm{d}x$$
$$\left(-6x^2 + 5xy - 4y^2\right)\mathrm{d}x + \left(y^2 - 8xy + \frac{5}{2}x^2\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -6x^2 + 5xy - 4y^2$$
$$N(x,y) = y^2 - 8xy + \frac{5}{2}x^2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-6x^2 + 5xy - 4y^2\right)\\ &= 5x - 8y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(y^2 - 8xy + \frac{5}{2}x^2\right)\\ &= 5x - 8y\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int -6x^2 + 5xy - 4y^2\,\mathrm{d}x$$

$$\phi = -2\left(x^2 - \frac{5}{4}xy + 2y^2\right)x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -2\left(-\frac{5x}{4} + 4y\right)x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^2 - 8xy + \frac{5}{2}x^2$. Therefore equation (4) becomes

$$y^2 - 8xy + \frac{5}{2}x^2 = \frac{(5x - 16y)\,x}{2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y^2$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (y^2)\,\mathrm{d}y$$

$$f(y) = \frac{y^3}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -2\left(x^2 - \frac{5}{4}xy + 2y^2\right)x + \frac{y^3}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -2\left(x^2 - \frac{5}{4}xy + 2y^2\right)x + \frac{y^3}{3}$$

Summary

The solution(s) found are the following

$$-2\left(x^2 - \frac{5yx}{4} + 2y^2\right)x + \frac{y^3}{3} = c_1 \tag{1}$$

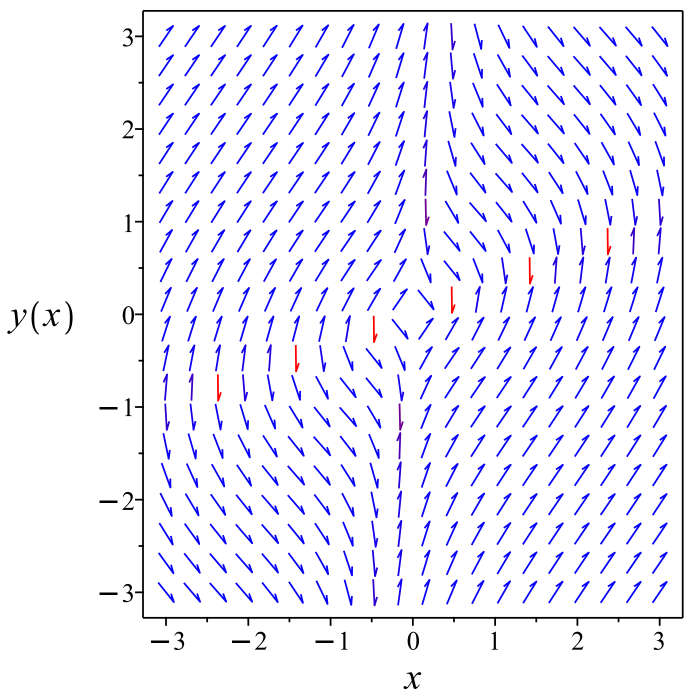

Figure 349: Slope field plot

Verification of solutions

$$-2\left(x^{2}-\frac{5yx}{4}+2y^{2}\right)x+\frac{y^{3}}{3}=c_{1}$$

Verified OK.

12.5.4 Maple step by step solution

Let's solve

$5yx-4y^{2}+\left(y^{2}-8yx+\frac{5x^{2}}{2}\right)y'=6x^{2}$

- Highest derivative means the order of the ODE is 1

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

```
[_exact, _rational]
```

$$\boxed{3y^2x + (3yx^2 - 6y^2 - 1)\, y' = x^2}$$

12.6.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(3x^2y - 6y^2 - 1\right)\mathrm{d}y &= \left(-3x\,y^2 + x^2\right)\mathrm{d}x\\ \left(3x\,y^2 - x^2\right)\mathrm{d}x + \left(3x^2y - 6y^2 - 1\right)\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 3x\,y^2 - x^2\\ N(x, y) &= 3x^2y - 6y^2 - 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(3x\,y^2 - x^2\right)\\ &= 6xy\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(3x^2y - 6y^2 - 1\right)\\ &= 6xy\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 3x\, y^2 - x^2 \, \mathrm{d}x$$
$$\phi = \frac{3}{2}x^2y^2 - \frac{1}{3}x^3 + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 3x^2y + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3x^2y - 6y^2 - 1$. Therefore equation (4) becomes

$$3x^2y - 6y^2 - 1 = 3x^2y + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -6y^2 - 1$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(-6y^2 - 1\right) \mathrm{d}y$$
$$f(y) = -2y^3 - y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{3}{2}x^2y^2 - \frac{1}{3}x^3 - 2y^3 - y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{3}{2}x^2y^2 - \frac{1}{3}x^3 - 2y^3 - y$$

Summary
The solution(s) found are the following

$$\frac{3y^2x^2}{2} - \frac{x^3}{3} - 2y^3 - y = c_1 \tag{1}$$

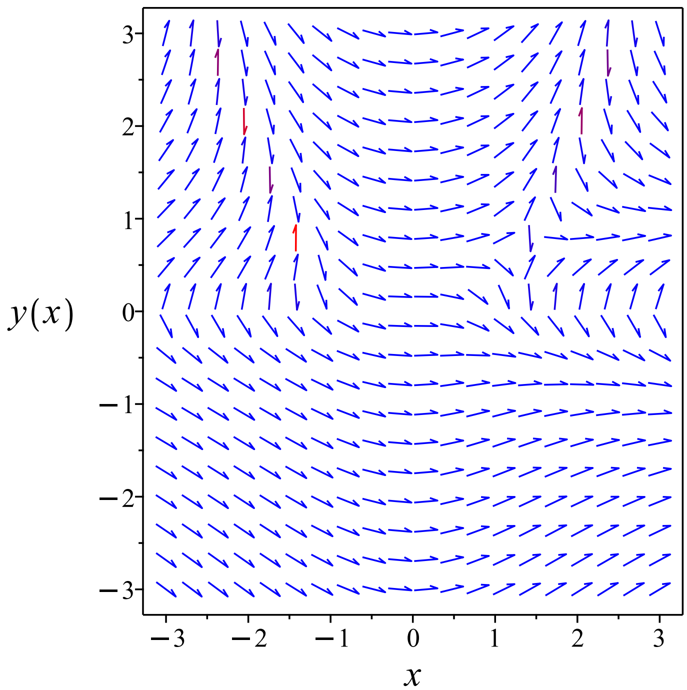

Figure 350: Slope field plot

Verification of solutions

$$\frac{3y^2x^2}{2} - \frac{x^3}{3} - 2y^3 - y = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati", "bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_Bernoulli]
```

$$\boxed{y - x y^2 \ln(x) + x y' = 0}$$

12.7.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{y(\ln(x)\, xy - 1)}{x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 282: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= x\,y^2
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x\,y^2} dy \end{aligned}$$

Which results in

$$S = -\frac{1}{xy}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y(\ln(x)\,xy - 1)}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{x^2 y} \\ S_y &= \frac{1}{x\,y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\ln(x)}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{\ln(R)}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{\ln(R)^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{xy} = \frac{\ln(x)^2}{2} + c_1$$

Which simplifies to

$$-\frac{1}{xy} = \frac{\ln(x)^2}{2} + c_1$$

Which gives

$$y = -\frac{2}{x\left(\ln(x)^2 + 2c_1\right)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y(\ln(x)xy-1)}{x}$ 	$R = x$ $S = -\frac{1}{xy}$	$\frac{dS}{dR} = \frac{\ln(R)}{R}$ 
Summary
The solution(s) found are the following

$$y = -\frac{2}{x\left(\ln\left(x\right)^{2}+2c_1\right)} \tag{1}$$

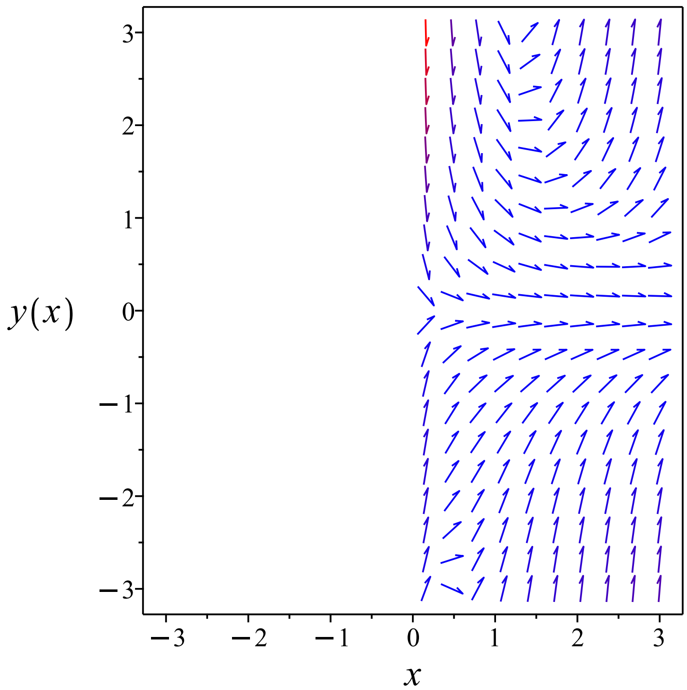

Figure 351: Slope field plot

Verification of solutions

$$y = -\frac{2}{x\left(\ln\left(x\right)^{2}+2c_1\right)}$$

Verified OK.

12.7.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{y(\ln\left(x\right)xy-1)}{x} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{x}y+\ln\left(x\right)y^{2} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{1}{x} \\ f_1(x) &= \ln(x) \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = -\frac{1}{xy} + \ln(x) \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(x) &= -\frac{w(x)}{x} + \ln(x) \\ w' &= \frac{w}{x} - \ln(x) \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= -\ln(x)
\end{aligned}
$$

Hence the ode is

$$
w'(x) - \frac{w(x)}{x} = -\ln(x)
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu w) &= (\mu)(-\ln(x)) \\
\frac{d}{dx}\left(\frac{w}{x}\right) &= \left(\frac{1}{x}\right)(-\ln(x)) \\
d\left(\frac{w}{x}\right) &= \left(-\frac{\ln(x)}{x}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{w}{x} &= \int -\frac{\ln(x)}{x} dx \\
\frac{w}{x} &= -\frac{\ln(x)^2}{2} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$
w(x) = -\frac{\ln(x)^2 x}{2} + c_1 x
$$

which simplifies to

$$
w(x) = x\left(-\frac{\ln(x)^2}{2} + c_1\right)
$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$
\frac{1}{y} = x\left(-\frac{\ln(x)^2}{2} + c_1\right)
$$

Or

$$y = \frac{1}{x\left(-\frac{\ln(x)^2}{2} + c_1\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{x\left(-\frac{\ln(x)^2}{2} + c_1\right)} \tag{1}$$

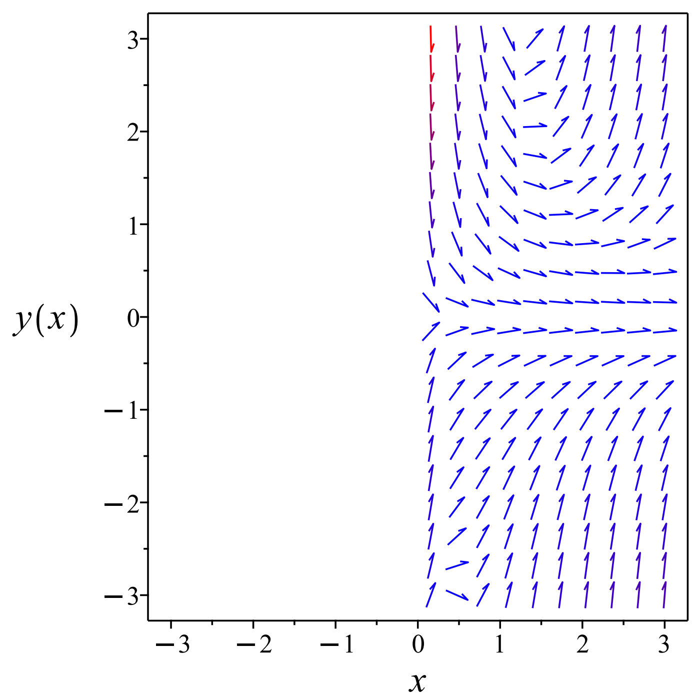

Figure 352: Slope field plot

Verification of solutions

$$y = \frac{1}{x\left(-\frac{\ln(x)^2}{2} + c_1\right)}$$

Verified OK.

12.7.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y&=\left(-y+x\,y^2\ln(x)\right)\mathrm{d}x\\ \left(-x\,y^2\ln(x)+y\right)\mathrm{d}x+(x)\,\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-x\,y^2\ln(x)+y\\ N(x,y)&=x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x\, y^{2} \ln \left(x \right)+y\right)\\ &= -2 \ln \left(x \right) x y +1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{x}\left(\left(-2 \ln \left(x \right) x y +1\right) - (1)\right)\\ &= -2 y \ln \left(x \right)\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\\ &= -\frac{1}{y \left(\ln \left(x \right) x y -1\right)}\left((1) - \left(-2 \ln \left(x \right) x y +1\right)\right)\\ &= -\frac{2 \ln \left(x \right) x}{\ln \left(x \right) x y -1}\end{aligned}$$

Since B depends on x, it can not be used to obtain an integrating factor.We will now try a third method to find an integrating factor. Let

$$R = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{x M - y N}$$

R is now checked to see if it is a function of only $t = xy$. Therefore

$$
\begin{aligned}
R &= \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN} \\
&= \frac{(1) - (-2\ln(x)\,xy + 1)}{x\,(-x\,y^2 \ln(x) + y) - y\,(x)} \\
&= -\frac{2}{xy}
\end{aligned}
$$

Replacing all powers of terms xy by t gives

$$
R = -\frac{2}{t}
$$

Since R depends on t only, then it can be used to find an integrating factor. Let the integrating factor be μ then

$$
\begin{aligned}
\mu &= e^{\int R \,\mathrm{d}t} \\
&= e^{\int \left(-\frac{2}{t}\right) \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-2\ln(t)} \\
&= \frac{1}{t^2}
\end{aligned}
$$

Now t is replaced back with xy giving

$$
\mu = \frac{1}{x^2 y^2}
$$

Multiplying M and N by this integrating factor gives new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^2 y^2}\left(-x\,y^2 \ln(x) + y\right) \\
&= \frac{-\ln(x)\,xy + 1}{x^2 y}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^2 y^2}(x) \\
&= \frac{1}{x\,y^2}
\end{aligned}
$$

A modified ODE is now obtained from the original ODE, which is exact and can solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\frac{-\ln(x)\,xy + 1}{x^2 y}\right) + \left(\frac{1}{x\,y^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{-\ln(x)\,xy + 1}{x^2 y}\,\mathrm{d}x$$
$$\phi = -\frac{\ln(x)^2}{2} - \frac{1}{xy} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{1}{x\,y^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{x\,y^2}$. Therefore equation (4) becomes

$$\frac{1}{x\,y^2} = \frac{1}{x\,y^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x)^2}{2} - \frac{1}{xy} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x)^2}{2} - \frac{1}{xy}$$

The solution becomes

$$y = -\frac{2}{x\left(\ln(x)^2 + 2c_1\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{2}{x\left(\ln(x)^2 + 2c_1\right)} \tag{1}$$

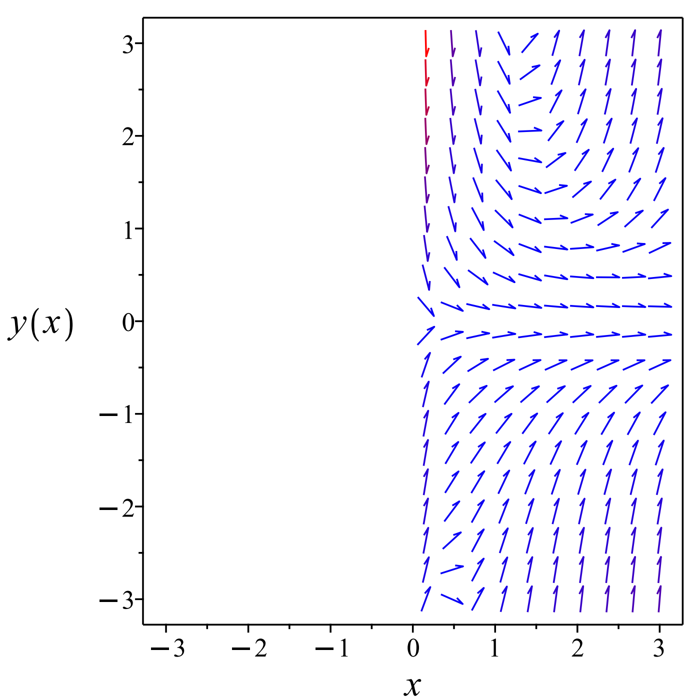

Figure 353: Slope field plot

Verification of solutions

$$y = -\frac{2}{x\left(\ln(x)^2 + 2c_1\right)}$$

Verified OK.

12.7.4 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{y(\ln(x)\, xy - 1)}{x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 \ln(x) - \frac{y}{x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = -\frac{1}{x}$ and $f_2(x) = \ln(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\ln(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= \frac{1}{x} \\ f_1 f_2 &= -\frac{\ln(x)}{x} \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\ln(x)\, u''(x) - \left(\frac{1}{x} - \frac{\ln(x)}{x}\right) u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + \ln(x)^2 c_2$$

The above shows that

$$u'(x) = \frac{2\ln(x) c_2}{x}$$

Using the above in (1) gives the solution

$$y = -\frac{2c_2}{x\left(c_1 + \ln(x)^2 c_2\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{2}{x\left(c_3 + \ln(x)^2\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{2}{x\left(c_3 + \ln(x)^2\right)} \tag{1}$$

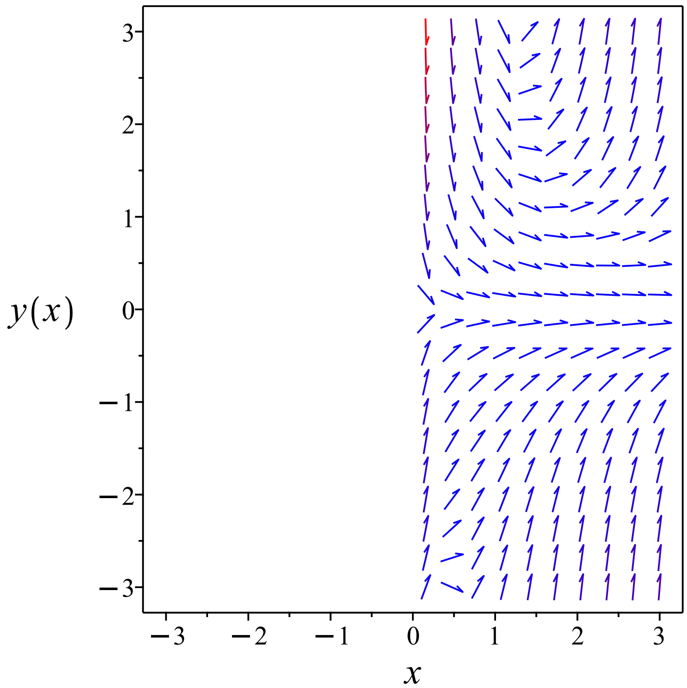

Figure 354: Slope field plot

Verification of solutions

$$y = -\frac{2}{x\left(c_3 + \ln\left(x\right)^2\right)}$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2xy\,\mathrm{e}^{x^2}+\mathrm{e}^{x^2}y' = x\sin(x)}$$

12.8.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2x \\ q(x) &= \mathrm{e}^{-x^2} x\sin(x) \end{aligned}$$

Hence the ode is

$$y' + 2yx = \mathrm{e}^{-x^2} x\sin(x)$$

The integrating factor μ is

$$\mu = e^{\int 2x dx}$$
$$= e^{x^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(e^{-x^2} x \sin(x)\right)$$
$$\frac{d}{dx}\left(y e^{x^2}\right) = \left(e^{x^2}\right)\left(e^{-x^2} x \sin(x)\right)$$
$$d\left(y e^{x^2}\right) = (x \sin(x)) dx$$

Integrating gives

$$y e^{x^2} = \int x \sin(x) dx$$
$$y e^{x^2} = \sin(x) - \cos(x) x + c_1$$

Dividing both sides by the integrating factor $\mu = e^{x^2}$ results in

$$y = e^{-x^2}(\sin(x) - \cos(x) x) + c_1 e^{-x^2}$$

which simplifies to

$$y = e^{-x^2}(\sin(x) - \cos(x) x + c_1)$$

Summary

The solution(s) found are the following

$$y = e^{-x^2}(\sin(x) - \cos(x) x + c_1) \tag{1}$$

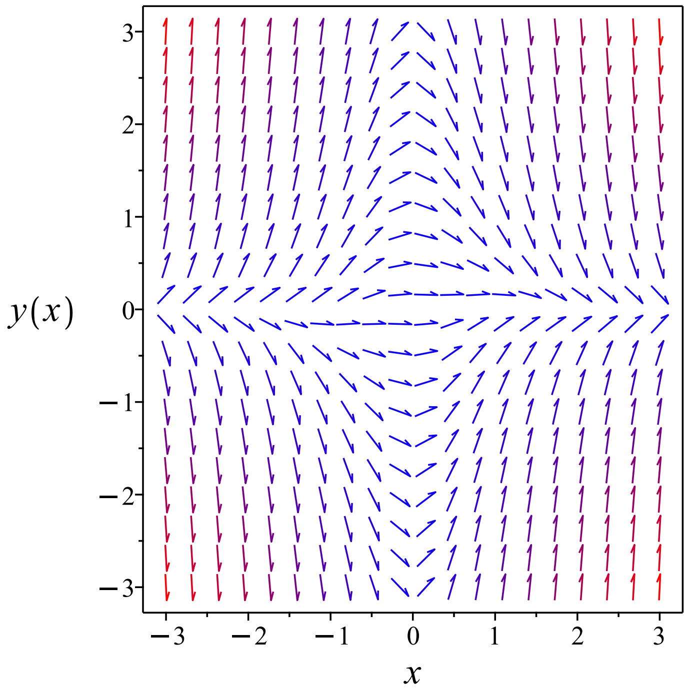

Figure 355: Slope field plot

Verification of solutions

$$y = e^{-x^2}(\sin(x) - \cos(x)\,x + c_1)$$

Verified OK.

12.8.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -x\left(2y\,e^{x^2} - \sin(x)\right)e^{-x^2} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 284: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-x^2}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-x^2}} dy \end{aligned}$$

Which results in

$$S = y\,\mathrm{e}^{x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -x\left(2y\,\mathrm{e}^{x^2} - \sin(x)\right)\mathrm{e}^{-x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= 2xy\,\mathrm{e}^{x^2} \\ S_y &= \mathrm{e}^{x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x\sin(x) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R\sin(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \sin(R) - R\cos(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{x^2} y = \sin(x) - \cos(x)\, x + c_1$$

Which simplifies to

$$e^{x^2} y = \sin(x) - \cos(x)\, x + c_1$$

Which gives

$$y = e^{-x^2}\left(\sin(x) - \cos(x)\, x + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -x\left(2y\, e^{x^2} - \sin(x)\right) e^{-x^2}$ 	$R = x$ $S = y\, e^{x^2}$	$\frac{dS}{dR} = R\sin(R)$ 
Summary
The solution(s) found are the following

$$y = e^{-x^2}\left(\sin(x) - \cos(x)\, x + c_1\right) \tag{1}$$

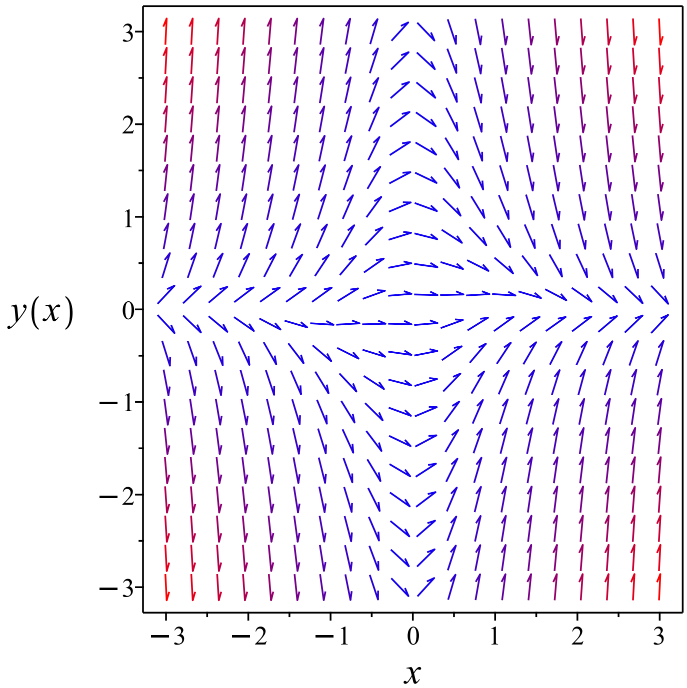

Figure 356: Slope field plot

Verification of solutions

$$y = e^{-x^2}(\sin(x) - \cos(x)\,x + c_1)$$

Verified OK.

12.8.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\mathrm{e}^{x^2}\right) \mathrm{d}y &= \left(-2xy\,\mathrm{e}^{x^2} + x\sin(x)\right) \mathrm{d}x \\ \left(2xy\,\mathrm{e}^{x^2} - x\sin(x)\right) \mathrm{d}x + \left(\mathrm{e}^{x^2}\right) \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 2xy\,\mathrm{e}^{x^2} - x\sin(x) \\ N(x, y) &= \mathrm{e}^{x^2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2xy\,\mathrm{e}^{x^2} - x\sin(x)\right) \\ &= 2x\,\mathrm{e}^{x^2}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\mathrm{e}^{x^2}\right) \\ &= 2x\,\mathrm{e}^{x^2}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 2xy \, \mathrm{e}^{x^2} - x \sin(x) \, \mathrm{d}x$$
$$\phi = \cos(x) \, x - \sin(x) + y \, \mathrm{e}^{x^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{x^2}$. Therefore equation (4) becomes

$$\mathrm{e}^{x^2} = \mathrm{e}^{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \cos(x) \, x - \sin(x) + y \, \mathrm{e}^{x^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \cos(x) \, x - \sin(x) + y \, \mathrm{e}^{x^2}$$

The solution becomes

$$y = e^{-x^2}(\sin(x) - \cos(x)\, x + c_1)$$

Summary

The solution(s) found are the following

$$y = e^{-x^2}(\sin(x) - \cos(x)\, x + c_1) \tag{1}$$

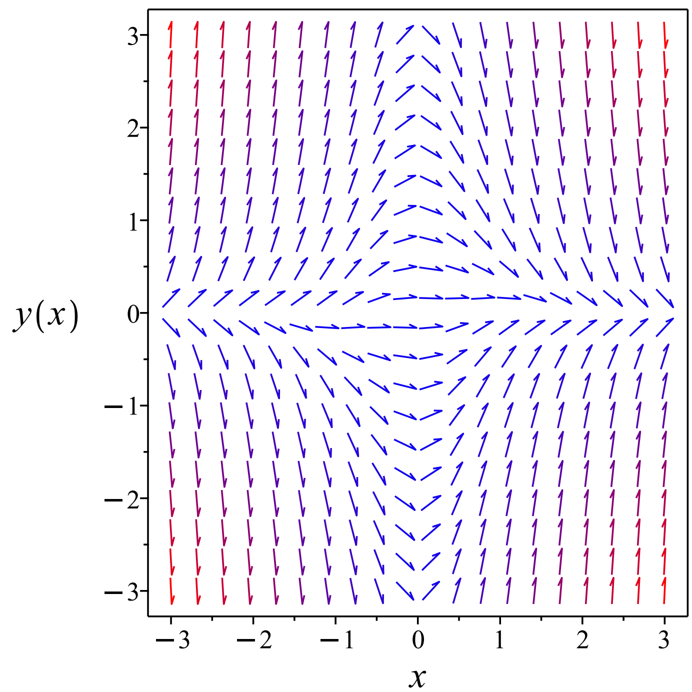

Figure 357: Slope field plot

Verification of solutions

$$y = e^{-x^2}(\sin(x) - \cos(x)\, x + c_1)$$

Verified OK.

12.8.4 Maple step by step solution

Let's solve

$2xy\,\mathrm{e}^{x^2}+\mathrm{e}^{x^2}y'=x\sin\left(x\right)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=-2yx+\frac{x\sin(x)}{\mathrm{e}^{x^2}}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y'+2yx=\frac{x\sin(x)}{\mathrm{e}^{x^2}}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y'+2yx\right)=\frac{\mu(x)x\sin(x)}{\mathrm{e}^{x^2}}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'+2yx\right)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x)=2\mu(x)\,x$

- Solve to find the integrating factor

  $\mu(x)=\left(\mathrm{e}^{x^2}\right)^2\mathrm{e}^{-x^2}$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\frac{\mu(x)x\sin(x)}{\mathrm{e}^{x^2}}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\frac{\mu(x)x\sin(x)}{\mathrm{e}^{x^2}}dx+c_1$

- Solve for y

  $y=\frac{\int\frac{\mu(x)x\sin(x)}{\mathrm{e}^{x^2}}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\left(\mathrm{e}^{x^2}\right)^2\mathrm{e}^{-x^2}$

  $y=\frac{\int\mathrm{e}^{-x^2}x\sin(x)\mathrm{e}^{x^2}dx+c_1}{\left(\mathrm{e}^{x^2}\right)^2\mathrm{e}^{-x^2}}$

- Evaluate the integrals on the rhs

$$y = \frac{\sin(x) - \cos(x) x + c_1}{\left(e^{x^2}\right)^2 e^{-x^2}}$$

- Simplify

$$y = e^{-x^2} (\sin(x) - \cos(x) x + c_1)$$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_exponential_symmetries]]
```

$$\boxed{y' - \frac{1}{2x - y^2} = 0}$$

12.9.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{1}{y^2 - 2x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{b_3 - a_2}{y^2 - 2x} - \frac{a_3}{(y^2 - 2x)^2} + \frac{2xa_2 + 2ya_3 + 2a_1}{(y^2 - 2x)^2} - \frac{2y(xb_2 + yb_3 + b_1)}{(y^2 - 2x)^2} = 0 \quad (5E)$$

Putting the above in normal form gives

$$\frac{y^4 b_2 - 4x\, y^2 b_2 + 4x^2 b_2 - 2xyb_2 + y^2 a_2 - 3y^2 b_3 + 2xb_3 + 2ya_3 - 2yb_1 + 2a_1 - a_3}{(-y^2 + 2x)^2} = 0$$

Setting the numerator to zero gives

$$y^4 b_2 - 4x\, y^2 b_2 + 4x^2 b_2 - 2xyb_2 + y^2 a_2 - 3y^2 b_3 + 2xb_3 + 2ya_3 - 2yb_1 + 2a_1 - a_3 = 0 \quad (6E)$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$b_2 v_2^4 - 4b_2 v_1 v_2^2 + a_2 v_2^2 + 4b_2 v_1^2 - 2b_2 v_1 v_2 - 3b_3 v_2^2 + 2a_3 v_2 - 2b_1 v_2 + 2b_3 v_1 + 2a_1 - a_3 = 0 \quad (7E)$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$4b_2 v_1^2 - 4b_2 v_1 v_2^2 - 2b_2 v_1 v_2 + 2b_3 v_1 + b_2 v_2^4 + (a_2 - 3b_3)\, v_2^2 + (2a_3 - 2b_1)\, v_2 + 2a_1 - a_3 = 0 \quad (8E)$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
b_2 &= 0 \\
-4b_2 &= 0 \\
-2b_2 &= 0 \\
4b_2 &= 0 \\
2b_3 &= 0 \\
2a_1 - a_3 &= 0 \\
a_2 - 3b_3 &= 0 \\
2a_3 - 2b_1 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= a_1 \\
a_2 &= 0 \\
a_3 &= 2a_1 \\
b_1 &= 2a_1 \\
b_2 &= 0 \\
b_3 &= 0
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 2y + 1 \\
\eta &= 2
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= 2 - \left(-\frac{1}{y^2 - 2x}\right)(2y + 1) \\
&= \frac{-2y^2 + 4x - 2y - 1}{-y^2 + 2x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-2y^2+4x-2y-1}{-y^2+2x}} dy \end{aligned}$$

Which results in

$$S = \frac{y}{2} - \frac{\ln(2y^2 - 4x + 2y + 1)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{1}{y^2 - 2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{2y^2 - 4x + 2y + 1} \\ S_y &= \frac{-y^2 + 2x}{-2y^2 + 4x - 2y - 1} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{2} - \frac{\ln(2y^2 - 4x + 2y + 1)}{4} = c_1$$

Which simplifies to

$$\frac{y}{2} - \frac{\ln(2y^2 - 4x + 2y + 1)}{4} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{1}{y^2-2x}$ 	$R = x$ $S = \frac{y}{2} - \frac{\ln(2y^2 - 4x + 2}{4}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$\frac{y}{2}-\frac{\ln\left(2y^{2}-4x+2y+1\right)}{4}=c_1 \tag{1}$$

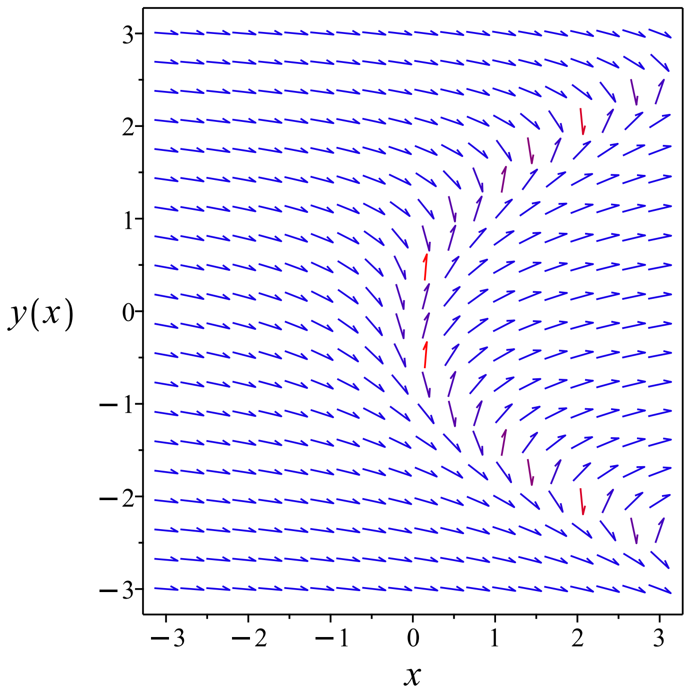

Figure 358: Slope field plot

Verification of solutions

$$\frac{y}{2}-\frac{\ln\left(2y^{2}-4x+2y+1\right)}{4}=c_1$$

Verified OK.

12.9.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(y^2-2x)\,\mathrm{d}y&=(-1)\,\mathrm{d}x\\ (1)\,\mathrm{d}x+(y^2-2x)\,\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=1\\ N(x,y)&=y^2-2x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(1)\\ &=0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y^2 - 2x)\\ &= -2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{y^2 - 2x}((0) - (-2))\\ &= -\frac{2}{-y^2 + 2x}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\\ &= 1((-2) - (0))\\ &= -2\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}\mu &= e^{\int B \, \mathrm{d}y}\\ &= e^{\int -2 \, \mathrm{d}y}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2y}\\ &= \mathrm{e}^{-2y}\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{-2y}(1)\\ &= \mathrm{e}^{-2y}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-2y}\left(y^2 - 2x\right) \\
&= \left(y^2 - 2x\right)\mathrm{e}^{-2y}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\mathrm{e}^{-2y}\right) + \left(\left(y^2 - 2x\right)\mathrm{e}^{-2y}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \mathrm{e}^{-2y}\,\mathrm{d}x \\
\phi &= \mathrm{e}^{-2y}x + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -2\,\mathrm{e}^{-2y}x + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \left(y^2 - 2x\right)\mathrm{e}^{-2y}$. Therefore equation (4) becomes

$$
\left(y^2 - 2x\right)\mathrm{e}^{-2y} = -2\,\mathrm{e}^{-2y}x + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \mathrm{e}^{-2y}y^2
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\mathrm{e}^{-2y}y^2\right)\mathrm{d}y$$

$$f(y) = -\frac{(2y^2+2y+1)\,\mathrm{e}^{-2y}}{4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \mathrm{e}^{-2y}x - \frac{(2y^2+2y+1)\,\mathrm{e}^{-2y}}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \mathrm{e}^{-2y}x - \frac{(2y^2+2y+1)\,\mathrm{e}^{-2y}}{4}$$

Summary

The solution(s) found are the following

$$\mathrm{e}^{-2y}x - \frac{(2y^2+2y+1)\,\mathrm{e}^{-2y}}{4} = c_1 \tag{1}$$

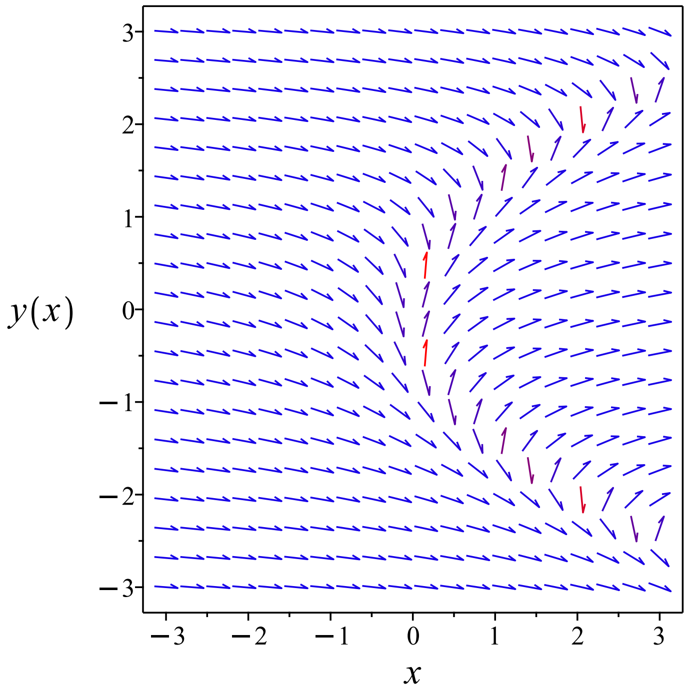

Figure 359: Slope field plot

Verification of solutions

$$
e^{-2y}x - \frac{(2y^2 + 2y + 1)\, e^{-2y}}{4} = c_1
$$

Verified OK.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{xy' - y' = -x^2 + 3x}$$

12.10.1 Solving as quadrature ode

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{x(x-3)}{x-1}\, dx \\ &= -\frac{x^2}{2} + 2x + 2\ln(x-1) + c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{x^2}{2} + 2x + 2\ln(x-1) + c_1 \tag{1}$$

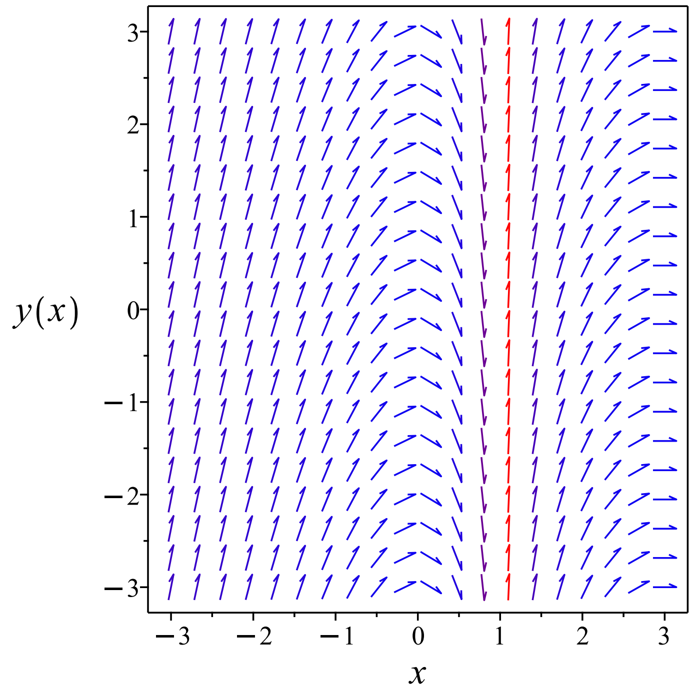

Figure 360: Slope field plot

Verification of solutions

$$y = -\frac{x^2}{2} + 2x + 2\ln(x-1) + c_1$$

Verified OK.

12.10.2 Maple step by step solution

Let's solve

$xy' - y' = -x^2 + 3x$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y' = \frac{-x^2+3x}{x-1}$

- Integrate both sides with respect to x

  $\int y' dx = \int \frac{-x^2+3x}{x-1} dx + c_1$

- Evaluate integral

$$y = -\frac{x^2}{2} + 2x + 2\ln(x-1) + c_1$$

- Solve for y

$$y = -\frac{x^2}{2} + 2x + 2\ln(x-1) + c_1$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _rational, _Bernoulli]
```

$$\boxed{y'yx - y^2 = x^4}$$

12.11.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x + u(x))\,u(x)\,x^2 - u(x)^2\,x^2 = x^4$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{x}{u} \end{aligned}$$

Where $f(x) = x$ and $g(u) = \frac{1}{u}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{1}{u}}\,du &= x\,dx \\
\int \frac{1}{\frac{1}{u}}\,du &= \int x\,dx \\
\frac{u^2}{2} &= \frac{x^2}{2} + c_2
\end{aligned}
$$

The solution is

$$
\frac{u(x)^2}{2} - \frac{x^2}{2} - c_2 = 0
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\frac{y^2}{2x^2} - \frac{x^2}{2} - c_2 = 0 \\
\frac{y^2}{2x^2} - \frac{x^2}{2} - c_2 = 0
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\frac{y^2}{2x^2} - \frac{x^2}{2} - c_2 = 0 \tag{1}
$$

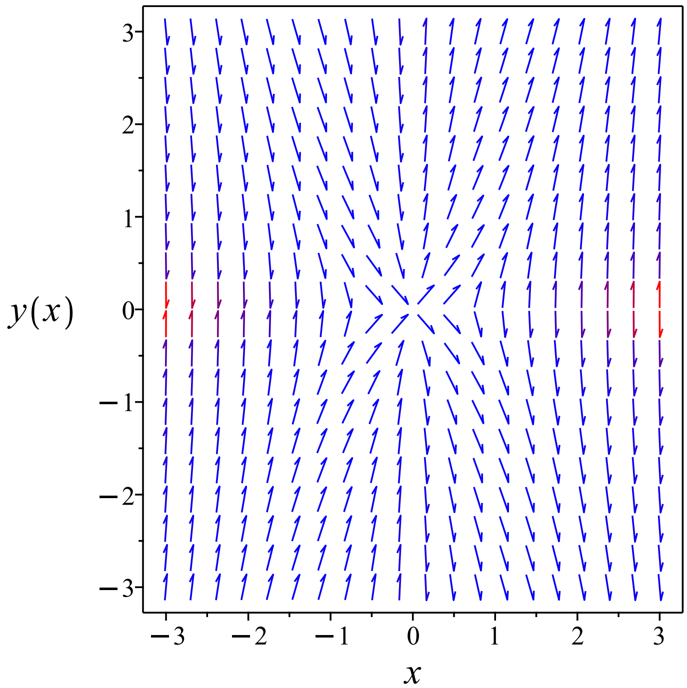

Figure 361: Slope field plot

Verification of solutions

$$\frac{y^2}{2x^2} - \frac{x^2}{2} - c_2 = 0$$

Verified OK.

12.11.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^4 + y^2}{yx}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 288: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x, y) = 0$$
$$\eta(x, y) = \frac{x^2}{y} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2}{2x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^4 + y^2}{yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y^2}{x^3} \\ S_y &= \frac{y}{x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x^2} = \frac{x^2}{2} + c_1$$

Which simplifies to

$$\frac{y^2}{2x^2} = \frac{x^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^4+y^2}{yx}$ 	$R = x$ $S = \frac{y^2}{2x^2}$	$\frac{dS}{dR} = R$ 
Summary
The solution(s) found are the following

$$\frac{y^2}{2x^2} = \frac{x^2}{2} + c_1 \tag{1}$$

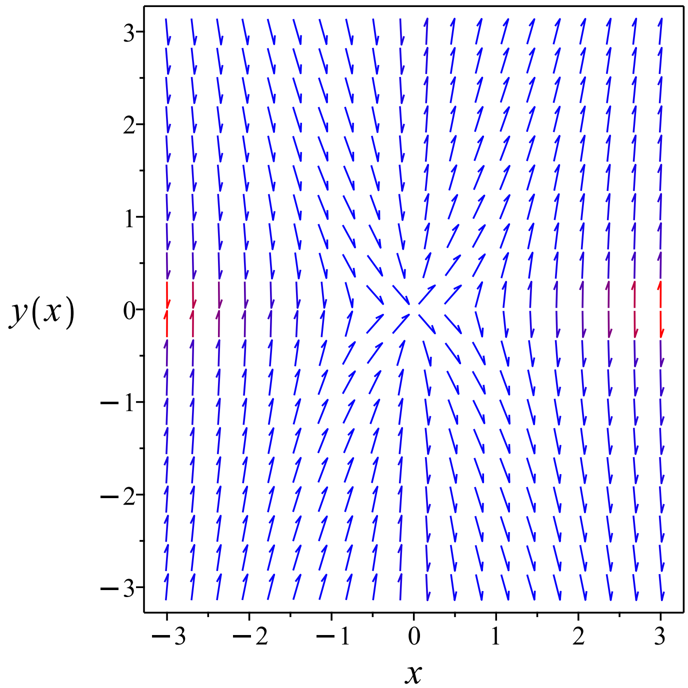

Figure 362: Slope field plot

Verification of solutions

$$\frac{y^2}{2x^2} = \frac{x^2}{2} + c_1$$

Verified OK.

12.11.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^4 + y^2}{yx} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{x}y + x^3\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{1}{x} \\ f_1(x) &= x^3 \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = \frac{y^2}{x} + x^3 \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= \frac{w(x)}{x} + x^3 \\ w' &= \frac{2w}{x} + 2x^3 \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= 2x^3 \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{2w(x)}{x} = 2x^3$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu w) &= (\mu)\left(2x^3\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{w}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(2x^3\right) \\ \mathrm{d}\left(\frac{w}{x^2}\right) &= (2x)\ \mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^2} &= \int 2x\,\mathrm{d}x \\ \frac{w}{x^2} &= x^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$w(x) = x^4 + c_1 x^2$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = x^4 + c_1 x^2$$

Solving for y gives

$$\begin{aligned}y(x) &= \sqrt{x^2 + c_1}\,x \\ y(x) &= -\sqrt{x^2 + c_1}\,x\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{x^2 + c_1}\,x \tag{1}$$

$$y = -\sqrt{x^2 + c_1}\,x \tag{2}$$

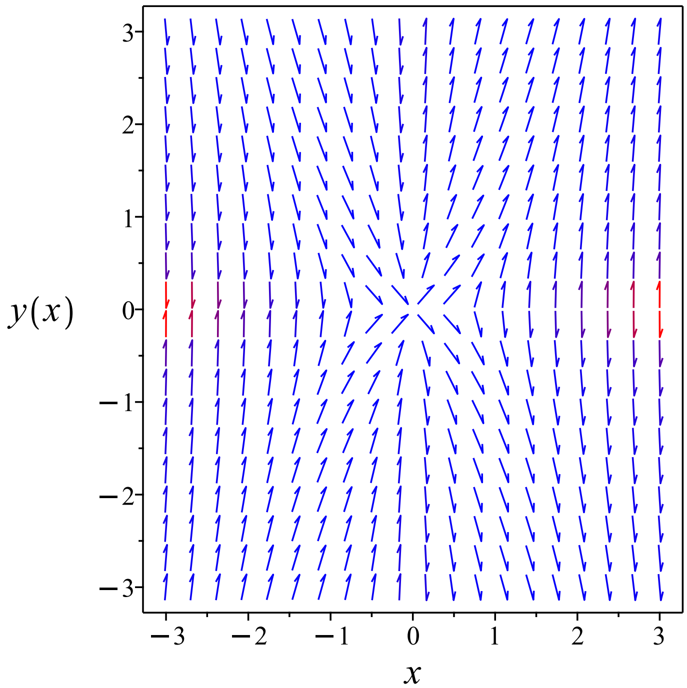

Figure 363: Slope field plot

Verification of solutions

$$y = \sqrt{x^2 + c_1}\, x$$

Verified OK.

$$y = -\sqrt{x^2 + c_1}\, x$$

Verified OK.

12.11.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(xy) \, \mathrm{d}y &= \left(x^4 + y^2\right) \mathrm{d}x \\ \left(-x^4 - y^2\right) \mathrm{d}x + (xy) \, \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x^4 - y^2 \\ N(x, y) &= xy\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^4 - y^2\right) \\ &= -2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(xy)\\ &= y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{xy}((-2y) - (y))\\ &= -\frac{3}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}x}\\ &= e^{\int -\frac{3}{x} \,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-3\ln(x)}\\ &= \frac{1}{x^3}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^3}(-x^4 - y^2)\\ &= \frac{-x^4 - y^2}{x^3}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{x^3}(xy)\\ &= \frac{y}{x^2}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\frac{-x^4 - y^2}{x^3}\right) + \left(\frac{y}{x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{-x^4 - y^2}{x^3}\,\mathrm{d}x$$
$$\phi = \frac{-x^4 + y^2}{2x^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{y}{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y}{x^2}$. Therefore equation (4) becomes

$$\frac{y}{x^2} = \frac{y}{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{-x^4 + y^2}{2x^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{-x^4 + y^2}{2x^2}$$

Summary

The solution(s) found are the following

$$\frac{-x^4 + y^2}{2x^2} = c_1 \tag{1}$$

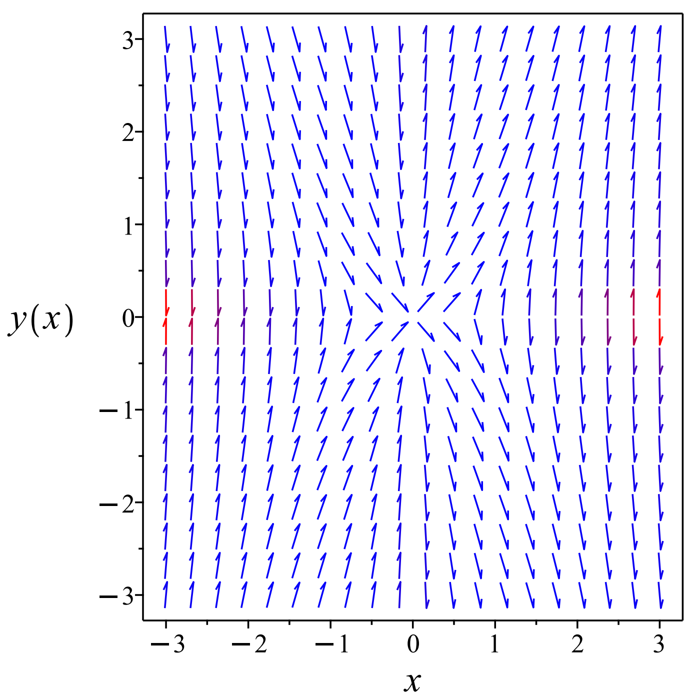

Figure 364: Slope field plot

Verification of solutions

$$\frac{-x^4 + y^2}{2x^2} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{\frac{1}{x^2 - yx + y^2} - \frac{y'}{2y^2 - yx} = 0}$$

12.12.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$\frac{1}{x^2 - u(x)\,x^2 + u(x)^2\,x^2} - \frac{u'(x)\,x + u(x)}{2u(x)^2\,x^2 - u(x)\,x^2} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u(u^2 - 3u + 2)}{(u^2 - u + 1)\,x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u(u^2-3u+2)}{u^2-u+1}$. Integrating both sides gives

$$\frac{1}{\frac{u(u^2-3u+2)}{u^2-u+1}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{u(u^2-3u+2)}{u^2-u+1}}\,du = \int -\frac{1}{x}\,dx$$

$$\frac{\ln(u)}{2} - \ln(u-1) + \frac{3\ln(u-2)}{2} = -\ln(x) + c_2$$

Raising both side to exponential gives

$$e^{\frac{\ln(u)}{2} - \ln(u-1) + \frac{3\ln(u-2)}{2}} = e^{-\ln(x)+c_2}$$

Which simplifies to

$$\frac{\sqrt{u}\,(u-2)^{\frac{3}{2}}}{u-1} = \frac{c_3}{x}$$

Therefore the solution y is

$$\begin{aligned} y &= xu \\ &= \frac{c_3^2\left(\operatorname{RootOf}\left(x^2\_Z^8 + 2x^2\_Z^6 - \_Z^4c_3^2 - 2\_Z^2c_3^2 - c_3^2\right)^2 + 1\right)^2}{x\operatorname{RootOf}\left(x^2\_Z^8 + 2x^2\_Z^6 - \_Z^4c_3^2 - 2\_Z^2c_3^2 - c_3^2\right)^6} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_3^2\left(\operatorname{RootOf}\left(x^2\_Z^8 + 2x^2\_Z^6 - \_Z^4c_3^2 - 2\_Z^2c_3^2 - c_3^2\right)^2 + 1\right)^2}{x\operatorname{RootOf}\left(x^2\_Z^8 + 2x^2\_Z^6 - \_Z^4c_3^2 - 2\_Z^2c_3^2 - c_3^2\right)^6} \tag{1}$$

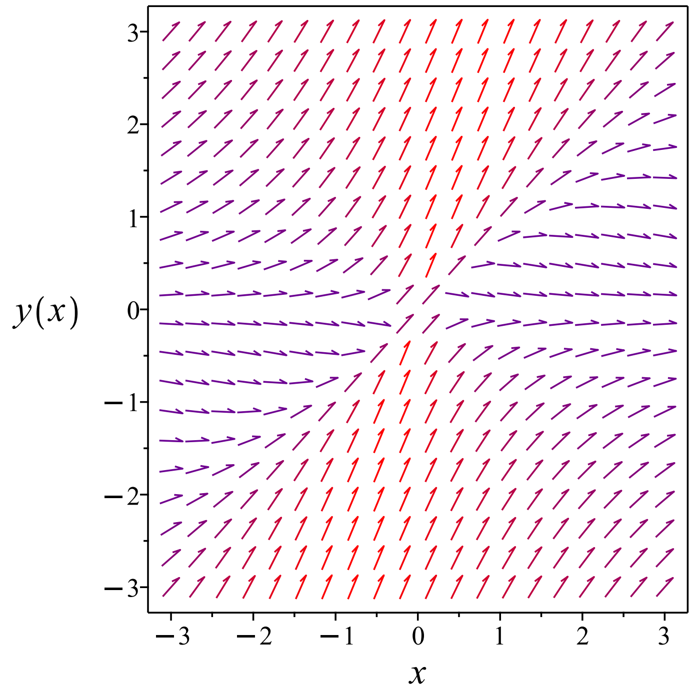

Figure 365: Slope field plot

Verification of solutions

$$y = \frac{c_3^2\left(\operatorname{RootOf}\left(x^2\_Z^8 + 2x^2\_Z^6 - \_Z^4c_3^2 - 2\_Z^2c_3^2 - c_3^2\right)^2 + 1\right)^2}{x \operatorname{RootOf}\left(x^2\_Z^8 + 2x^2\_Z^6 - \_Z^4c_3^2 - 2\_Z^2c_3^2 - c_3^2\right)^6}$$

Verified OK.

12.12.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{y(-x + 2y)}{x^2 - xy + y^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 + \frac{y(-x+2y)(b_3-a_2)}{x^2-xy+y^2} - \frac{y^2(-x+2y)^2 a_3}{(x^2-xy+y^2)^2} \\
&- \left(-\frac{y}{x^2-xy+y^2} - \frac{y(-x+2y)(2x-y)}{(x^2-xy+y^2)^2}\right)(x a_2 + y a_3 + a_1) \\
&- \left(\frac{-x+2y}{x^2-xy+y^2} + \frac{2y}{x^2-xy+y^2} - \frac{y(-x+2y)^2}{(x^2-xy+y^2)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
\frac{2x^4b_2 - 6x^3yb_2 + x^2y^2a_2 - 2x^2y^2a_3 + 4x^2y^2b_2 - x^2y^2b_3 + 2x\,y^3a_2 + 8x\,y^3a_3 - 2x\,y^3b_2 - 2x\,y^3b_3 - 2y^4a_2 -}{(x^2-xy+y^2)^2}
$$

$$
= 0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
&2x^4b_2 - 6x^3yb_2 + x^2y^2a_2 - 2x^2y^2a_3 + 4x^2y^2b_2 - x^2y^2b_3 + 2x\,y^3a_2 \\
&+ 8x\,y^3a_3 - 2x\,y^3b_2 - 2x\,y^3b_3 - 2y^4a_2 - 5y^4a_3 + y^4b_2 + 2y^4b_3 \\
&+ x^3b_1 - x^2ya_1 - 4x^2yb_1 + 4x\,y^2a_1 + x\,y^2b_1 - y^3a_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\{x, y\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\{x = v_1, y = v_2\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&a_2v_1^2v_2^2 + 2a_2v_1v_2^3 - 2a_2v_2^4 - 2a_3v_1^2v_2^2 + 8a_3v_1v_2^3 - 5a_3v_2^4 + 2b_2v_1^4 \\
&- 6b_2v_1^3v_2 + 4b_2v_1^2v_2^2 - 2b_2v_1v_2^3 + b_2v_2^4 - b_3v_1^2v_2^2 - 2b_3v_1v_2^3 + 2b_3v_2^4 \\
&- a_1v_1^2v_2 + 4a_1v_1v_2^2 - a_1v_2^3 + b_1v_1^3 - 4b_1v_1^2v_2 + b_1v_1v_2^2 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} &2b_2v_1^4 - 6b_2v_1^3v_2 + b_1v_1^3 + (a_2 - 2a_3 + 4b_2 - b_3)\, v_1^2v_2^2 \\ &+ (-a_1 - 4b_1)\, v_1^2v_2 + (2a_2 + 8a_3 - 2b_2 - 2b_3)\, v_1v_2^3 \\ &+ (4a_1 + b_1)\, v_1v_2^2 + (-2a_2 - 5a_3 + b_2 + 2b_3)\, v_2^4 - a_1v_2^3 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} b_1 &= 0 \\ -a_1 &= 0 \\ -6b_2 &= 0 \\ 2b_2 &= 0 \\ -a_1 - 4b_1 &= 0 \\ 4a_1 + b_1 &= 0 \\ -2a_2 - 5a_3 + b_2 + 2b_3 &= 0 \\ a_2 - 2a_3 + 4b_2 - b_3 &= 0 \\ 2a_2 + 8a_3 - 2b_2 - 2b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi \\ &= y - \left(\frac{y(-x+2y)}{x^2 - xy + y^2}\right)(x) \\ &= \frac{2x^2 y - 3x\,y^2 + y^3}{x^2 - xy + y^2} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{2x^2 y - 3x\,y^2 + y^3}{x^2 - xy + y^2}} dy\end{aligned}$$

Which results in

$$S = -\ln(-x+y) + \frac{\ln(y)}{2} + \frac{3\ln(y-2x)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y(-x+2y)}{x^2 - xy + y^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{-x+y} - \frac{3}{y-2x} \\
S_y &= \frac{1}{x-y} + \frac{1}{2y} - \frac{3}{4x-2y}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\ln(-x+y) + \frac{\ln(y)}{2} + \frac{3\ln(y-2x)}{2} = c_1
$$

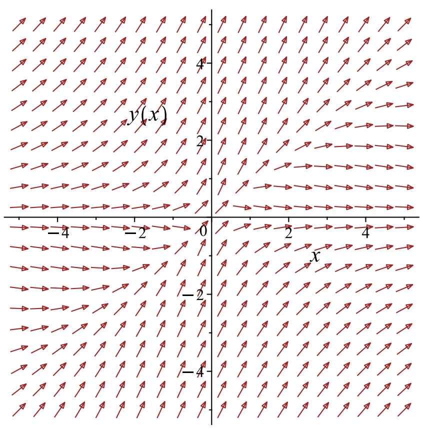
Which simplifies to

$$
-\ln(-x+y) + \frac{\ln(y)}{2} + \frac{3\ln(y-2x)}{2} = c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>

$\frac{dy}{dx} = \frac{y(-x+2y)}{x^2-xy+y^2}$



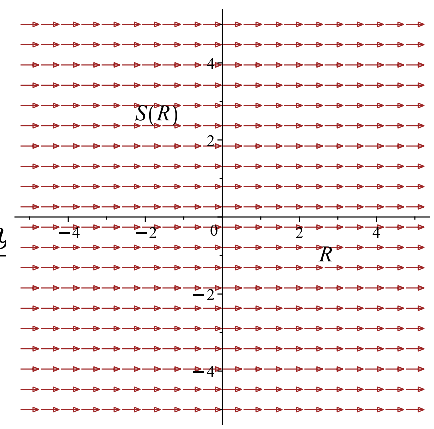
</td><td>

$R = x$

$S = -\ln(-x+y) + \frac{\ln(y}{2}$

</td><td>

$\frac{dS}{dR} = 0$



</td></tr>
</table>

Summary

The solution(s) found are the following

$$-\ln(-x+y) + \frac{\ln(y)}{2} + \frac{3\ln(y-2x)}{2} = c_1 \tag{1}$$

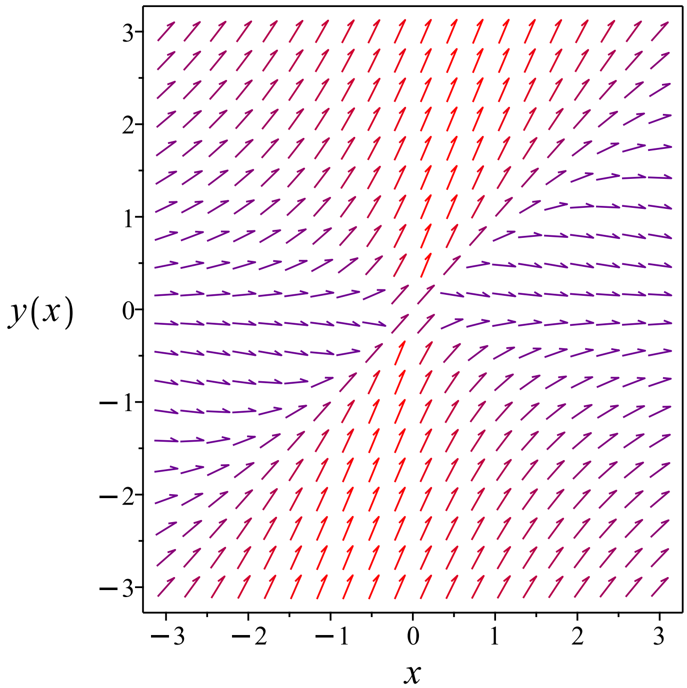


Figure 366: Slope field plot

Verification of solutions

$$-\ln(-x+y)+\frac{\ln(y)}{2}+\frac{3\ln(y-2x)}{2}=c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{(2x-1)\,y'-2y=\frac{1-4x}{x^2}}$$

12.13.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$p(x)=-\frac{2}{2x-1}$$
$$q(x)=\frac{1-4x}{(2x-1)\,x^2}$$

Hence the ode is

$$y'-\frac{2y}{2x-1}=\frac{1-4x}{(2x-1)\,x^2}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -\frac{2}{2x-1}dx} \\
&= \frac{1}{2x-1}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{1-4x}{(2x-1)\,x^2}\right) \\
\frac{d}{dx}\left(\frac{y}{2x-1}\right) &= \left(\frac{1}{2x-1}\right)\left(\frac{1-4x}{(2x-1)\,x^2}\right) \\
d\left(\frac{y}{2x-1}\right) &= \left(\frac{1-4x}{(2x-1)^2\,x^2}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y}{2x-1} &= \int \frac{1-4x}{(2x-1)^2\,x^2}\, dx \\
\frac{y}{2x-1} &= -\frac{1}{x}+\frac{2}{2x-1}+c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{2x-1}$ results in

$$
y = (2x-1)\left(-\frac{1}{x}+\frac{2}{2x-1}\right)+c_1(2x-1)
$$

which simplifies to

$$
y = \frac{2c_1x^2-c_1x+1}{x}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \frac{2c_1x^2-c_1x+1}{x} \tag{1}
$$

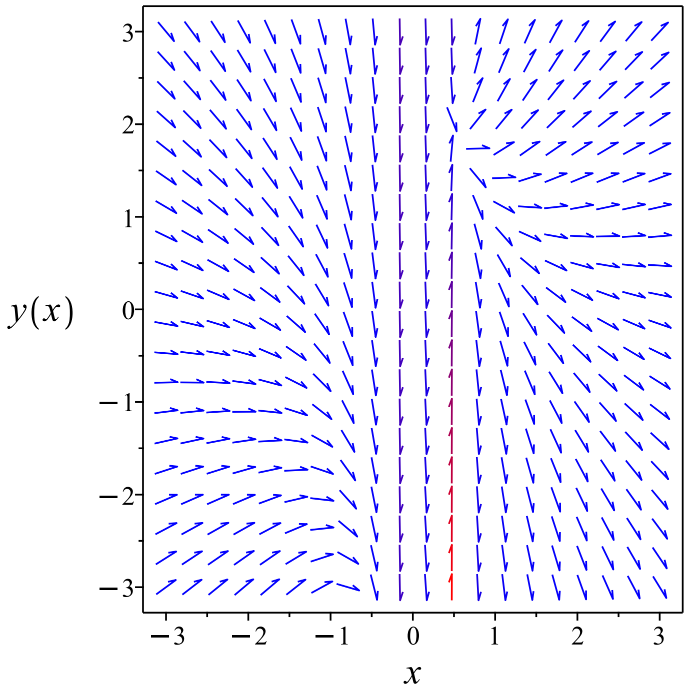

Figure 367: Slope field plot

Verification of solutions

$$y = \frac{2c_1x^2 - c_1x + 1}{x}$$

Verified OK.

12.13.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{2x^2y - 4x + 1}{(2x - 1)\,x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 290: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= 2x - 1
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{2x-1} dy
\end{aligned}$$

Which results in

$$S = \frac{y}{2x-1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2x^2 y - 4x + 1}{(2x-1)\, x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{2y}{(2x-1)^2} \\
S_y &= \frac{1}{2x-1}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1-4x}{(2x-1)^2\, x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1-4R}{(2R-1)^2\, R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + \frac{2}{2R-1} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{2x-1} = -\frac{1}{x} + \frac{2}{2x-1} + c_1$$

Which simplifies to

$$\frac{y}{2x-1} = -\frac{1}{x} + \frac{2}{2x-1} + c_1$$

Which gives

$$y = \frac{2c_1x^2 - c_1x + 1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2x^2y-4x+1}{(2x-1)x^2}$ 	$R = x$ $S = \frac{y}{2x-1}$	$\frac{dS}{dR} = \frac{1-4R}{(2R-1)^2R^2}$ 
Summary

The solution(s) found are the following

$$y = \frac{2c_1x^2 - c_1x + 1}{x} \tag{1}$$

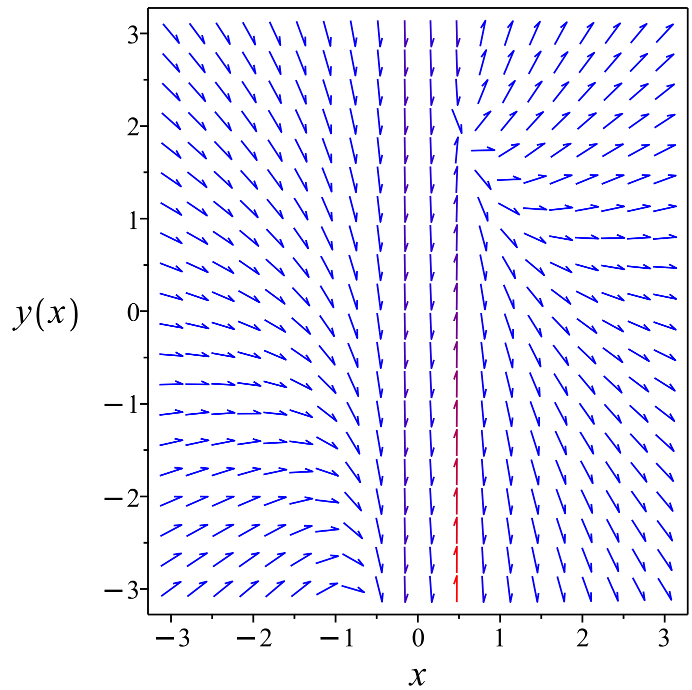

Figure 368: Slope field plot

Verification of solutions

$$y = \frac{2c_1x^2 - c_1x + 1}{x}$$

Verified OK.

12.13.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2x-1)\,\mathrm{d}y &= \left(2y + \frac{1-4x}{x^2}\right)\mathrm{d}x\\ \left(-2y - \frac{1-4x}{x^2}\right)\mathrm{d}x + (2x-1)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -2y - \frac{1-4x}{x^2}\\ N(x,y) &= 2x-1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-2y - \frac{1-4x}{x^2}\right)\\ &= -2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x-1)\\ &= 2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x-1}((-2)-(2))\\ &= -\frac{4}{2x-1}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int -\frac{4}{2x-1}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(2x-1)}\\ &= \frac{1}{(2x-1)^2}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{(2x-1)^2}\left(-2y - \frac{1-4x}{x^2}\right)\\ &= \frac{-2x^2y+4x-1}{(2x-1)^2\,x^2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{(2x-1)^2}(2x-1)\\ &= \frac{1}{2x-1}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{-2x^2y+4x-1}{\left(2x-1\right)^2x^2}\right)+\left(\frac{1}{2x-1}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial\phi}{\partial x}=\overline{M} \tag{1}
$$

$$
\frac{\partial\phi}{\partial y}=\overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x \\
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\frac{-2x^2y+4x-1}{\left(2x-1\right)^2x^2}\,\mathrm{d}x \\
\phi &= \frac{xy-1}{\left(2x-1\right)x}+f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial\phi}{\partial y}=\frac{1}{2x-1}+f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial\phi}{\partial y}=\frac{1}{2x-1}$. Therefore equation (4) becomes

$$
\frac{1}{2x-1}=\frac{1}{2x-1}+f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y)=0
$$

Therefore

$$
f(y)=c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{xy-1}{(2x-1)\,x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{xy-1}{(2x-1)\,x}$$

The solution becomes

$$y = \frac{2c_1x^2 - c_1x + 1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{2c_1x^2 - c_1x + 1}{x} \tag{1}$$

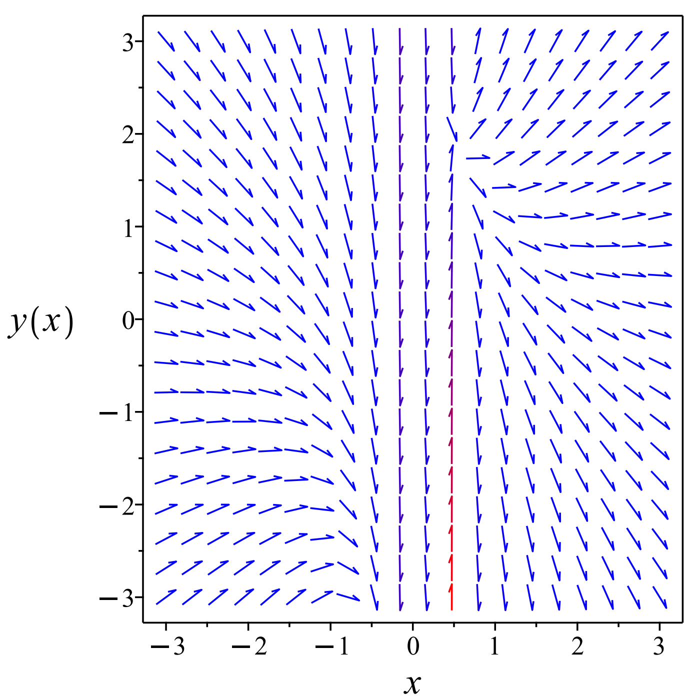

Figure 369: Slope field plot

Verification of solutions

$$y = \frac{2c_1x^2 - c_1x + 1}{x}$$

Verified OK.

12.13.4 Maple step by step solution

Let's solve

$(2x-1)\,y' - 2y = \frac{1-4x}{x^2}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{2y}{2x-1} - \frac{-1+4x}{(2x-1)x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{2y}{2x-1} = -\frac{-1+4x}{(2x-1)x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{2y}{2x-1}\right) = -\frac{\mu(x)(-1+4x)}{(2x-1)x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' - \frac{2y}{2x-1}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{2\mu(x)}{2x-1}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{2x-1}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int -\frac{\mu(x)(-1+4x)}{(2x-1)x^2} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int -\frac{\mu(x)(-1+4x)}{(2x-1)x^2} dx + c_1$

- Solve for y

  $y = \frac{\int -\frac{\mu(x)(-1+4x)}{(2x-1)x^2} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{2x-1}$

$$y = (2x-1)\left(\int -\frac{-1+4x}{(2x-1)^2 x^2}dx + c_1\right)$$

- Evaluate the integrals on the rhs

$$y = (2x-1)\left(-\frac{1}{x} + \frac{2}{2x-1} + c_1\right)$$

- Simplify

$$y = \frac{2c_1x^2 - c_1x + 1}{x}$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 12. Miscellaneous problems. Exercises page 93
Problem number: 288.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{-y + (3x + y + 1)\, y' = -x - 3}$$

12.14.1 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{-X - x_0 + Y(X) + y_0 - 3}{3X + 3x_0 + Y(X) + y_0 + 1}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = -1$$
$$y_0 = 2$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{-X + Y(X)}{3X + Y(X)}$$

In canonical form, the ODE is

$$
\begin{aligned}
Y' &= F(X,Y) \\
&= \frac{-X+Y}{3X+Y}
\end{aligned} \tag{1}
$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$
f(t^n X, t^n Y) = t^n f(X,Y)
$$

In this case, it can be seen that both $M = -X+Y$ and $N = 3X+Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$
\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u
$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$
\begin{aligned}
\frac{\mathrm{d}u}{\mathrm{d}X}X + u &= \frac{u-1}{u+3} \\
\frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{\frac{u(X)-1}{u(X)+3} - u(X)}{X}
\end{aligned}
$$

Or

$$
\frac{d}{dX}u(X) - \frac{\frac{u(X)-1}{u(X)+3} - u(X)}{X} = 0
$$

Or

$$
\left(\frac{d}{dX}u(X)\right) Xu(X) + 3\left(\frac{d}{dX}u(X)\right) X + u(X)^2 + 2u(X) + 1 = 0
$$

Or

$$
X(u(X)+3)\left(\frac{d}{dX}u(X)\right) + (u(X)+1)^2 = 0
$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(X,u) \\
&= f(X)g(u) \\
&= -\frac{(u+1)^2}{X\,(u+3)}
\end{aligned}
$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{(u+1)^2}{u+3}$. Integrating both sides gives

$$\frac{1}{\frac{(u+1)^2}{u+3}}\,du = -\frac{1}{X}\,dX$$

$$\int \frac{1}{\frac{(u+1)^2}{u+3}}\,du = \int -\frac{1}{X}\,dX$$

$$-\frac{2}{u+1} + \ln(u+1) = -\ln(X) + c_2$$

The solution is

$$-\frac{2}{u(X)+1} + \ln(u(X)+1) + \ln(X) - c_2 = 0$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$-\frac{2}{\frac{Y(X)}{X}+1} + \ln\left(\frac{Y(X)}{X}+1\right) + \ln(X) - c_2 = 0$$

Using the solution for $Y(X)$

$$-\frac{2X}{Y(X)+X} + \ln\left(\frac{Y(X)+X}{X}\right) + \ln(X) - c_2 = 0$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y + 2$$
$$X = x - 1$$

Then the solution in y becomes

$$-\frac{2(1+x)}{y-1+x} + \ln\left(\frac{y-1+x}{1+x}\right) + \ln(1+x) - c_2 = 0$$

Summary

The solution(s) found are the following

$$-\frac{2(1+x)}{y-1+x} + \ln\left(\frac{y-1+x}{1+x}\right) + \ln(1+x) - c_2 = 0 \tag{1}$$

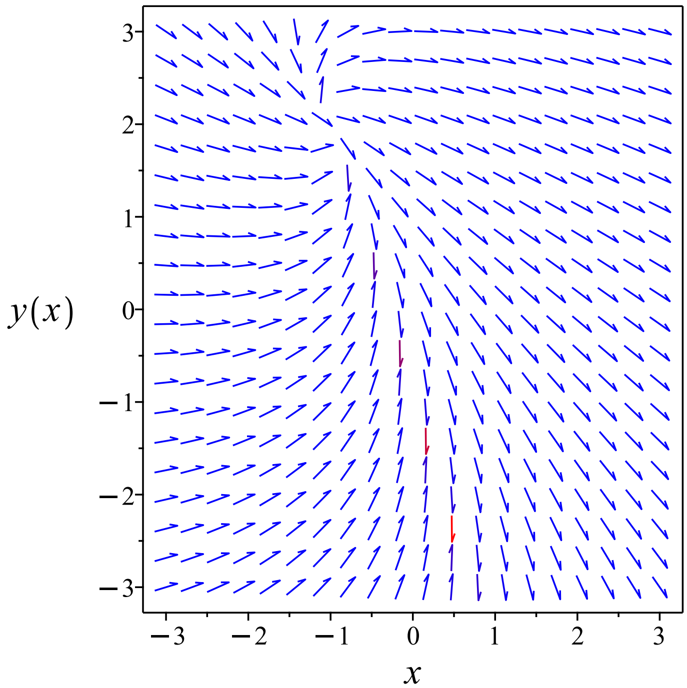

Figure 370: Slope field plot

Verification of solutions

$$-\frac{2(1+x)}{y-1+x}+\ln\left(\frac{y-1+x}{1+x}\right)+\ln(1+x)-c_2=0$$

Verified OK.

12.14.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{-x+y-3}{3x+y+1}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{(-x+y-3)(b_3-a_2)}{3x+y+1} - \frac{(-x+y-3)^2 a_3}{(3x+y+1)^2} - \left(-\frac{1}{3x+y+1} - \frac{3(-x+y-3)}{(3x+y+1)^2}\right)(x a_2 + y a_3 + a_1) - \left(\frac{1}{3x+y+1} - \frac{-x+y-3}{(3x+y+1)^2}\right)(x b_2 + y b_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{3x^2a_2 - x^2a_3 + 5x^2b_2 - 3x^2b_3 + 2xya_2 + 2xya_3 + 6xyb_2 - 2xyb_3 - y^2a_2 + 3y^2a_3 + y^2b_2 + y^2b_3 + 2xa_2 - 6}{(3x+y+} = 0$$

Setting the numerator to zero gives

$$3x^2a_2 - x^2a_3 + 5x^2b_2 - 3x^2b_3 + 2xya_2 + 2xya_3 + 6xyb_2 - 2xyb_3 - y^2a_2 + 3y^2a_3 + y^2b_2 + y^2b_3 + 2xa_2 - 6xa_3 - 4xb_1 + 2xb_2 - 10xb_3 + 4ya_1 + 2ya_2 - 2ya_3 + 2yb_2 - 6yb_3 - 8a_1 + 3a_2 - 9a_3 - 4b_1 + b_2 - 3b_3 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$3a_2v_1^2 + 2a_2v_1v_2 - a_2v_2^2 - a_3v_1^2 + 2a_3v_1v_2 + 3a_3v_2^2 + 5b_2v_1^2 + 6b_2v_1v_2 + b_2v_2^2 - 3b_3v_1^2 - 2b_3v_1v_2 + b_3v_2^2 + 4a_1v_2 + 2a_2v_1 + 2a_2v_2 - 6a_3v_1 - 2a_3v_2 - 4b_1v_1 + 2b_2v_1 + 2b_2v_2 - 10b_3v_1 - 6b_3v_2 - 8a_1 + 3a_2 - 9a_3 - 4b_1 + b_2 - 3b_3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}&(3a_2 - a_3 + 5b_2 - 3b_3)\, v_1^2 + (2a_2 + 2a_3 + 6b_2 - 2b_3)\, v_1 v_2 \\ &+ (2a_2 - 6a_3 - 4b_1 + 2b_2 - 10b_3)\, v_1 + (-a_2 + 3a_3 + b_2 + b_3)\, v_2^2 \\ &+ (4a_1 + 2a_2 - 2a_3 + 2b_2 - 6b_3)\, v_2 - 8a_1 + 3a_2 - 9a_3 - 4b_1 + b_2 - 3b_3 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}-a_2 + 3a_3 + b_2 + b_3 &= 0\\ 2a_2 + 2a_3 + 6b_2 - 2b_3 &= 0\\ 3a_2 - a_3 + 5b_2 - 3b_3 &= 0\\ 4a_1 + 2a_2 - 2a_3 + 2b_2 - 6b_3 &= 0\\ 2a_2 - 6a_3 - 4b_1 + 2b_2 - 10b_3 &= 0\\ -8a_1 + 3a_2 - 9a_3 - 4b_1 + b_2 - 3b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= b_3\\ a_2 &= -2b_2 + b_3\\ a_3 &= -b_2\\ b_1 &= b_2 - 2b_3\\ b_2 &= b_2\\ b_3 &= b_3\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= 1 + x\\ \eta &= y - 2\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\, \xi\\ &= y - 2 - \left(\frac{-x + y - 3}{3x + y + 1}\right)(1 + x)\\ &= \frac{x^2 + 2xy + y^2 - 2x - 2y + 1}{3x + y + 1}\\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2+2xy+y^2-2x-2y+1}{3x+y+1}} dy \end{aligned}$$

Which results in

$$S = \ln(x + y - 1) - \frac{2x + 2}{x + y - 1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{-x + y - 3}{3x + y + 1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{x - y + 3}{(x + y - 1)^2} \\ S_y &= \frac{3x + y + 1}{(x + y - 1)^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{(y-1+x)\ln(y-1+x)-2x-2}{y-1+x} = c_1$$

Which simplifies to

$$\frac{(y-1+x)\ln(y-1+x)-2x-2}{y-1+x} = c_1$$

Which gives

$$y = e^{\text{LambertW}\left(2(1+x)e^{-c_1}\right)+c_1} - x + 1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{-x+y-3}{3x+y+1}$ 	$R = x$ $S = \frac{(x+y-1)\ln(x+y}{x+y-}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$y = e^{\mathrm{LambertW}\left(2(1+x)e^{-c_1}\right)+c_1} - x + 1 \tag{1}$$

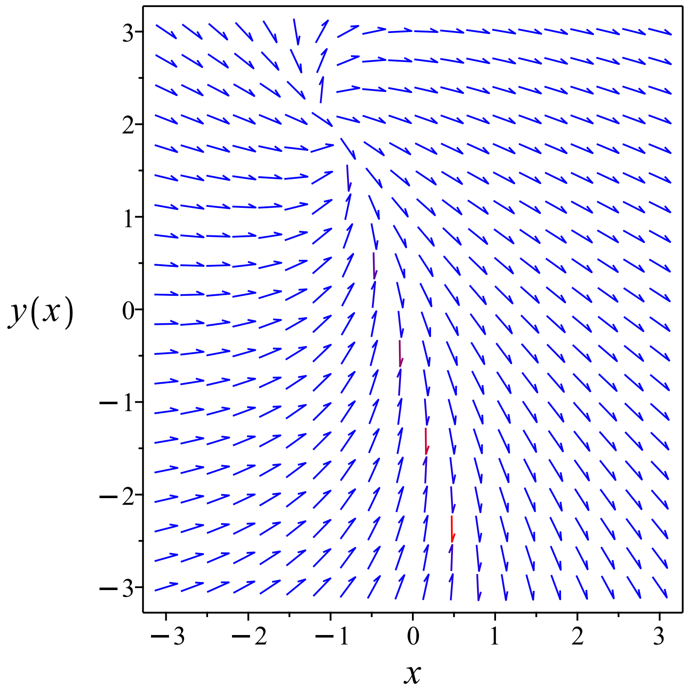

Figure 371: Slope field plot

Verification of solutions

$$y = e^{\mathrm{LambertW}\left(2(1+x)e^{-c_1}\right)+c_1} - x + 1$$

Verified OK.

Section: Section 12. Miscellaneous problems. Exercises page 93
Problem number: 289.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' + \cos\left(\frac{y}{2} + \frac{x}{2}\right) - \cos\left(-\frac{y}{2} + \frac{x}{2}\right) = 0}$$

12.15.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= 2\sin\left(\frac{y}{2}\right)\sin\left(\frac{x}{2}\right) \end{aligned}$$

Where $f(x) = 2\sin\left(\frac{x}{2}\right)$ and $g(y) = \sin\left(\frac{y}{2}\right)$. Integrating both sides gives

$$\frac{1}{\sin\left(\frac{y}{2}\right)}\, dy = 2\sin\left(\frac{x}{2}\right)\, dx$$

$$\int \frac{1}{\sin\left(\frac{y}{2}\right)}\, dy = \int 2\sin\left(\frac{x}{2}\right)\, dx$$

$$2\ln\left(\csc\left(\frac{y}{2}\right) - \cot\left(\frac{y}{2}\right)\right) = -4\cos\left(\frac{x}{2}\right) + c_1$$

Raising both side to exponential gives

$$\left(\csc\left(\frac{y}{2}\right)-\cot\left(\frac{y}{2}\right)\right)^{2}=\mathrm{e}^{-4\cos\left(\frac{x}{2}\right)+c_1}$$

Which simplifies to

$$\frac{1-\cos\left(\frac{y}{2}\right)}{\cos\left(\frac{y}{2}\right)+1}=c_2\mathrm{e}^{-4\cos\left(\frac{x}{2}\right)}$$

Summary

The solution(s) found are the following

$$y=2\pi-2\arccos\left(\frac{c_2\mathrm{e}^{-4\cos\left(\frac{x}{2}\right)+c_1}-1}{1+c_2\mathrm{e}^{-4\cos\left(\frac{x}{2}\right)+c_1}}\right) \tag{1}$$

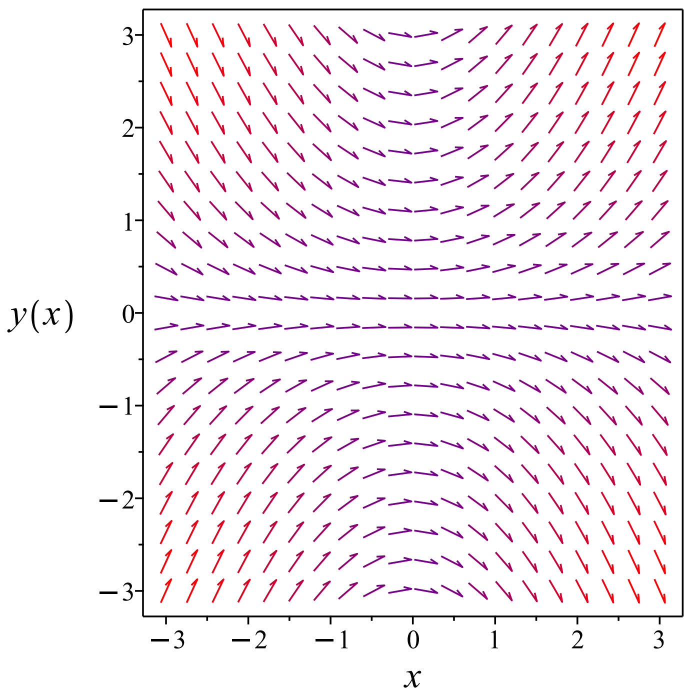

Figure 372: Slope field plot

Verification of solutions

$$y=2\pi-2\arccos\left(\frac{c_2\mathrm{e}^{-4\cos\left(\frac{x}{2}\right)+c_1}-1}{1+c_2\mathrm{e}^{-4\cos\left(\frac{x}{2}\right)+c_1}}\right)$$

Verified OK.

12.15.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\cos\left(\frac{y}{2}+\frac{x}{2}\right)+\cos\left(-\frac{y}{2}+\frac{x}{2}\right) \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 293: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x,y) = \frac{1}{2\sin\left(\frac{x}{2}\right)}$$
$$\eta(x,y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{2\sin\left(\frac{x}{2}\right)}} dx \end{aligned}$$

Which results in

$$S = -4\cos\left(\frac{x}{2}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\cos\left(\frac{y}{2} + \frac{x}{2}\right) + \cos\left(-\frac{y}{2} + \frac{x}{2}\right)$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= 2\sin\left(\frac{x}{2}\right) \\
S_y &= 0
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \csc\left(\frac{y}{2}\right) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \csc\left(\frac{R}{2}\right)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -2\ln\left(\csc\left(\frac{R}{2}\right) + \cot\left(\frac{R}{2}\right)\right) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-4\cos\left(\frac{x}{2}\right) = -2\ln\left(\csc\left(\frac{y}{2}\right) + \cot\left(\frac{y}{2}\right)\right) + c_1$$

Which simplifies to

$$-4\cos\left(\frac{x}{2}\right) = -2\ln\left(\csc\left(\frac{y}{2}\right) + \cot\left(\frac{y}{2}\right)\right) + c_1$$

Which gives

$$y = 2\arctan\left(\frac{2\,\mathrm{e}^{2\cos\left(\frac{x}{2}\right)+\frac{c_1}{2}}}{\mathrm{e}^{c_1+4\cos\left(\frac{x}{2}\right)} + 1}, \frac{\mathrm{e}^{c_1+4\cos\left(\frac{x}{2}\right)} - 1}{\mathrm{e}^{c_1+4\cos\left(\frac{x}{2}\right)} + 1}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\cos\left(\frac{y}{2}+\frac{x}{2}\right)+\cos\left(-\frac{y}{2}+\frac{x}{2}\right)$ 	$R = y$ $S = -4\cos\left(\frac{x}{2}\right)$	$\frac{dS}{dR} = \csc\left(\frac{R}{2}\right)$ 
Summary

The solution(s) found are the following

$$y = 2\arctan\left(\frac{2\,e^{2\cos\left(\frac{x}{2}\right)+\frac{c_1}{2}}}{e^{c_1+4\cos\left(\frac{x}{2}\right)}+1}, \frac{e^{c_1+4\cos\left(\frac{x}{2}\right)}-1}{e^{c_1+4\cos\left(\frac{x}{2}\right)}+1}\right) \tag{1}$$

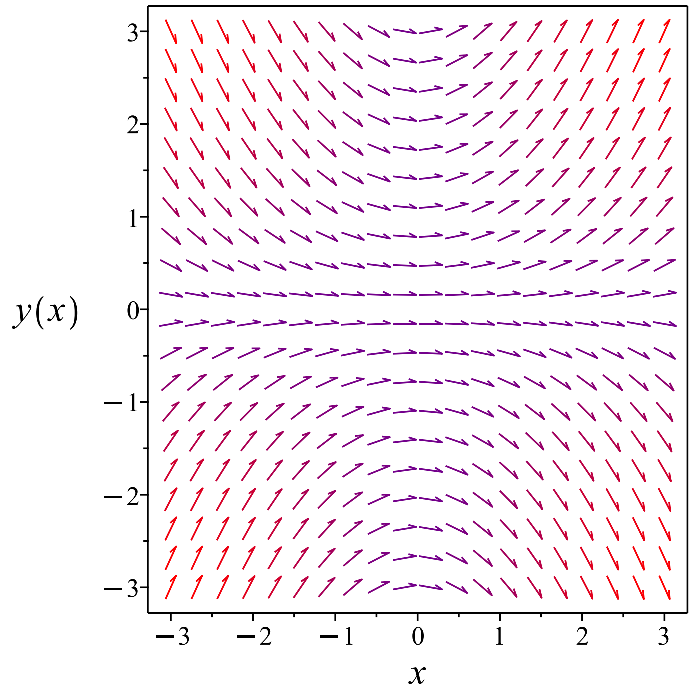

Figure 373: Slope field plot

Verification of solutions

$$y = 2 \arctan\left(\frac{2\,\mathrm{e}^{2\cos\left(\frac{x}{2}\right)+\frac{c_1}{2}}}{\mathrm{e}^{c_1+4\cos\left(\frac{x}{2}\right)}+1}, \frac{\mathrm{e}^{c_1+4\cos\left(\frac{x}{2}\right)}-1}{\mathrm{e}^{c_1+4\cos\left(\frac{x}{2}\right)}+1}\right)$$

Verified OK.

12.15.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, dx + N(x, y) \, dy = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{2 \sin\left(\frac{y}{2}\right)}\right) dy = \left(\sin\left(\frac{x}{2}\right)\right) dx$$
$$\left(-\sin\left(\frac{x}{2}\right)\right) dx + \left(\frac{1}{2 \sin\left(\frac{y}{2}\right)}\right) dy = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\sin\left(\frac{x}{2}\right)$$
$$N(x, y) = \frac{1}{2 \sin\left(\frac{y}{2}\right)}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\sin\left(\frac{x}{2}\right)\right) \\ &= 0 \end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2\sin\left(\frac{y}{2}\right)}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\sin\left(\frac{x}{2}\right)\mathrm{d}x\end{aligned}$$

$$\phi = 2\cos\left(\frac{x}{2}\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2\sin\left(\frac{y}{2}\right)}$. Therefore equation (4) becomes

$$\frac{1}{2\sin\left(\frac{y}{2}\right)} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$\begin{aligned}f'(y) &= \frac{1}{2\sin\left(\frac{y}{2}\right)}\\ &= \frac{\csc\left(\frac{y}{2}\right)}{2}\end{aligned}$$

Integrating the above w.r.t y results in

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{\csc\left(\frac{y}{2}\right)}{2}\right)\mathrm{d}y$$

$$f(y) = -\ln\left(\csc\left(\frac{y}{2}\right) + \cot\left(\frac{y}{2}\right)\right) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = 2\cos\left(\frac{x}{2}\right) - \ln\left(\csc\left(\frac{y}{2}\right) + \cot\left(\frac{y}{2}\right)\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 2\cos\left(\frac{x}{2}\right) - \ln\left(\csc\left(\frac{y}{2}\right) + \cot\left(\frac{y}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$2\cos\left(\frac{x}{2}\right) - \ln\left(\csc\left(\frac{y}{2}\right) + \cot\left(\frac{y}{2}\right)\right) = c_1 \tag{1}$$

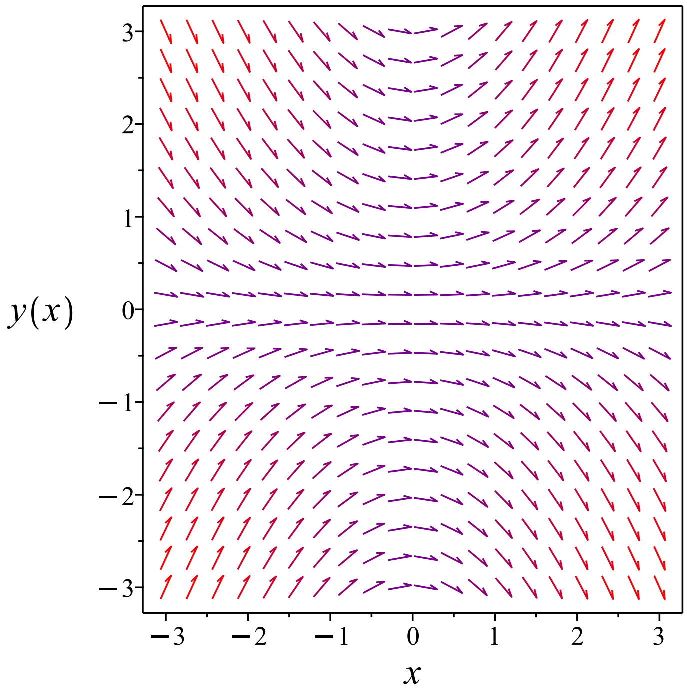

Figure 374: Slope field plot

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y'(3x^2-2x)-y(6x-2)=0}$$

12.16.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{2y(3x-1)}{x(3x-2)} \end{aligned}$$

Where $f(x) = \frac{6x-2}{x(3x-2)}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= \frac{6x-2}{x\,(3x-2)}\,dx \\
\int \frac{1}{y}\,dy &= \int \frac{6x-2}{x\,(3x-2)}\,dx \\
\ln\left(y\right) &= \ln\left(x(3x-2)\right) + c_1 \\
y &= \mathrm{e}^{\ln(x(3x-2))+c_1} \\
&= c_1 x(3x-2)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 x(3x-2) \tag{1}$$

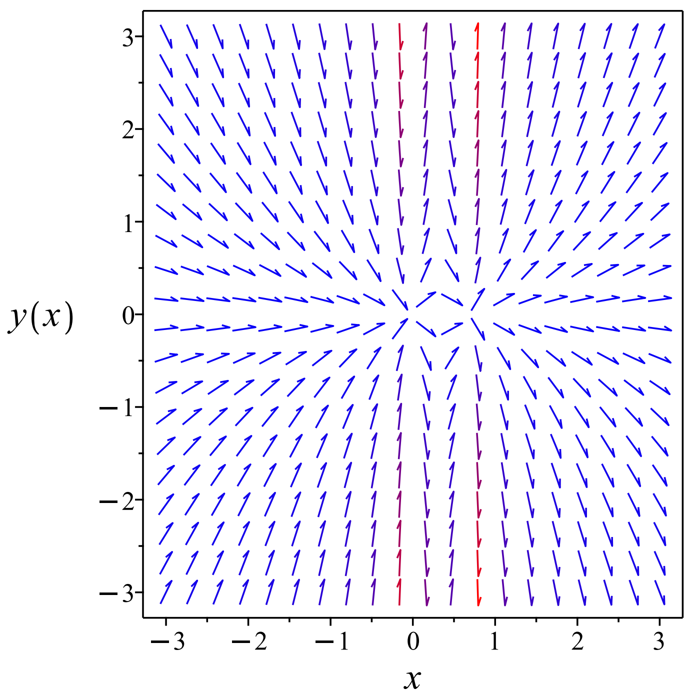

Figure 375: Slope field plot

Verification of solutions

$$y = c_1 x(3x-2)$$

Verified OK.

12.16.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{6x-2}{x(3x-2)} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - \frac{(6x-2)\, y}{x(3x-2)} = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{6x-2}{x(3x-2)}dx} \\ &= \frac{1}{x(3x-2)} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}\mu y &= 0 \\ \frac{d}{dx}\left(\frac{y}{x(3x-2)}\right) &= 0 \end{aligned}$$

Integrating gives

$$\frac{y}{x(3x-2)} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x(3x-2)}$ results in

$$y = c_1(3x^2 - 2x)$$

which simplifies to

$$y = c_1 x(3x-2)$$

Summary

The solution(s) found are the following

$$y = c_1 x(3x-2) \tag{1}$$

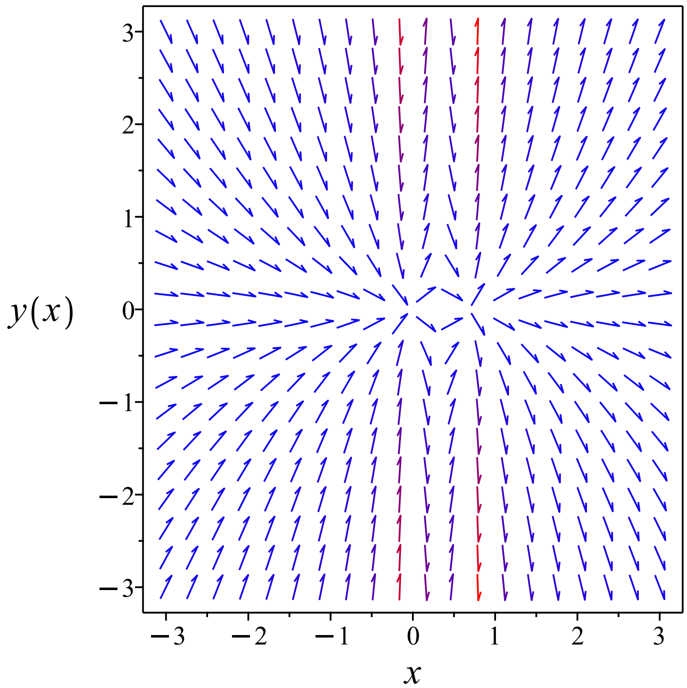

Figure 376: Slope field plot

Verification of solutions

$$y = c_1 x(3x - 2)$$

Verified OK.

12.16.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x + u(x))\,(3x^2 - 2x) - u(x)\,x(6x - 2) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= \frac{3u}{3x - 2} \end{aligned}$$

Where $f(x) = \frac{3}{3x-2}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{3}{3x-2}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{3}{3x-2}\,dx \\
\ln(u) &= \ln(3x-2) + c_2 \\
u &= \mathrm{e}^{\ln(3x-2)+c_2} \\
&= c_2(3x-2)
\end{aligned}$$

Therefore the solution y is

$$\begin{aligned}
y &= xu \\
&= xc_2(3x-2)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = xc_2(3x-2) \tag{1}$$

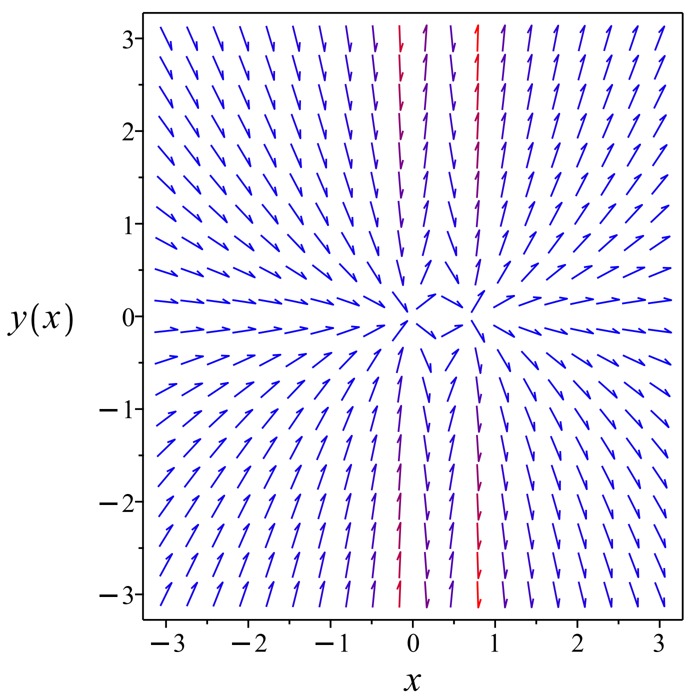

Figure 377: Slope field plot

Verification of solutions

$$y = xc_2(3x - 2)$$

Verified OK.

12.16.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{2y(3x-1)}{x\,(3x-2)} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 295: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= x(3x-2) \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x(3x-2)} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x(3x-2)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2y(3x-1)}{x(3x-2)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2y(3x-1)}{x^2(3x-2)^2} \\ S_y &= \frac{1}{x(3x-2)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x(3x-2)} = c_1$$

Which simplifies to

$$\frac{y}{x(3x-2)} = c_1$$

Which gives

$$y = c_1 x(3x-2)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2y(3x-1)}{x(3x-2)}$ 	$R = x$ $S = \frac{y}{x(3x-2)}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$y = c_1 x(3x-2) \tag{1}$$

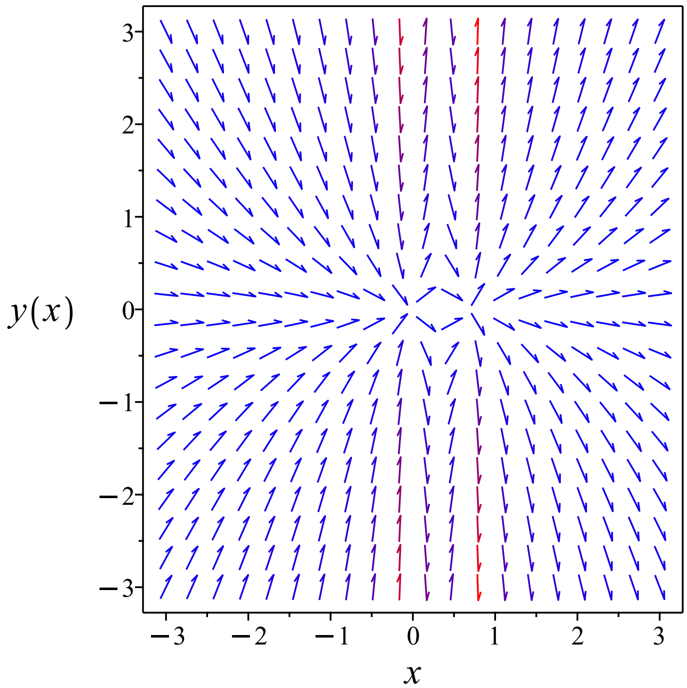

Figure 378: Slope field plot

Verification of solutions

$$y = c_1 x(3x - 2)$$

Verified OK.

12.16.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{2y}\right) \mathrm{d}y = \left(\frac{3x - 1}{x (3x - 2)}\right) \mathrm{d}x$$
$$\left(-\frac{3x - 1}{x (3x - 2)}\right) \mathrm{d}x + \left(\frac{1}{2y}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{3x - 1}{x (3x - 2)}$$
$$N(x, y) = \frac{1}{2y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{3x - 1}{x (3x - 2)}\right) \\ &= 0 \end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{align}
\frac{\partial \phi}{\partial x} &= M \tag{1} \\
\frac{\partial \phi}{\partial y} &= N \tag{2}
\end{align}
$$

Integrating (1) w.r.t. x gives

$$
\begin{align}
\int \frac{\partial \phi}{\partial x} \, dx &= \int M \, dx \nonumber \\
\int \frac{\partial \phi}{\partial x} \, dx &= \int -\frac{3x-1}{x(3x-2)} \, dx \nonumber \\
\phi &= -\frac{\ln(3x^2 - 2x)}{2} + f(y) \tag{3}
\end{align}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2y}$. Therefore equation (4) becomes

$$
\frac{1}{2y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{2y}
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{2y}\right) \mathrm{d}y$$

$$f(y) = \frac{\ln (y)}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln (3x^2 - 2x)}{2} + \frac{\ln (y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln (3x^2 - 2x)}{2} + \frac{\ln (y)}{2}$$

The solution becomes

$$y = \mathrm{e}^{2c_1} x(3x - 2)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2c_1} x(3x - 2) \tag{1}$$

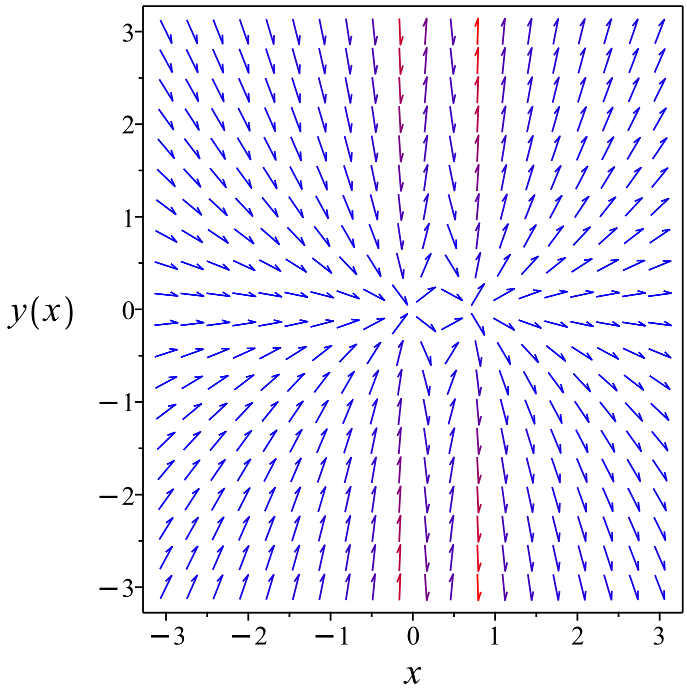

Figure 379: Slope field plot

Verification of solutions

$$y = e^{2c_1}x(3x - 2)$$

Verified OK.

12.16.6 Maple step by step solution

Let's solve

$y'(3x^2 - 2x) - y(6x - 2) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{6x-2}{3x^2-2x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int \frac{6x-2}{3x^2-2x}dx + c_1$

- Evaluate integral

$$\ln(y) = \ln(x(3x-2)) + c_1$$

- Solve for y

$$y = e^{c_1} x(3x-2)$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 12. Miscellaneous problems. Exercises page 93
Problem number: 291.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _rational, _Bernoulli]
```

$$\boxed{xy^2y' - y^3 = \frac{x^4}{3}}$$

12.17.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$x^3 u(x)^2 \left(u'(x)\, x + u(x)\right) - u(x)^3\, x^3 = \frac{x^4}{3}$$

Integrating both sides gives

$$\int 3u^2 du = x + c_2$$
$$u^3 = x + c_2$$

Solving for u gives these solutions

$$
\begin{aligned}
u_1 &= (x+c_2)^{\frac{1}{3}} \\
u_2 &= -\frac{(x+c_2)^{\frac{1}{3}}}{2} - \frac{i\sqrt{3}\,(x+c_2)^{\frac{1}{3}}}{2} \\
u_3 &= -\frac{(x+c_2)^{\frac{1}{3}}}{2} + \frac{i\sqrt{3}\,(x+c_2)^{\frac{1}{3}}}{2}
\end{aligned}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= xu \\
&= x(x+c_2)^{\frac{1}{3}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x(x+c_2)^{\frac{1}{3}} \tag{1}
$$

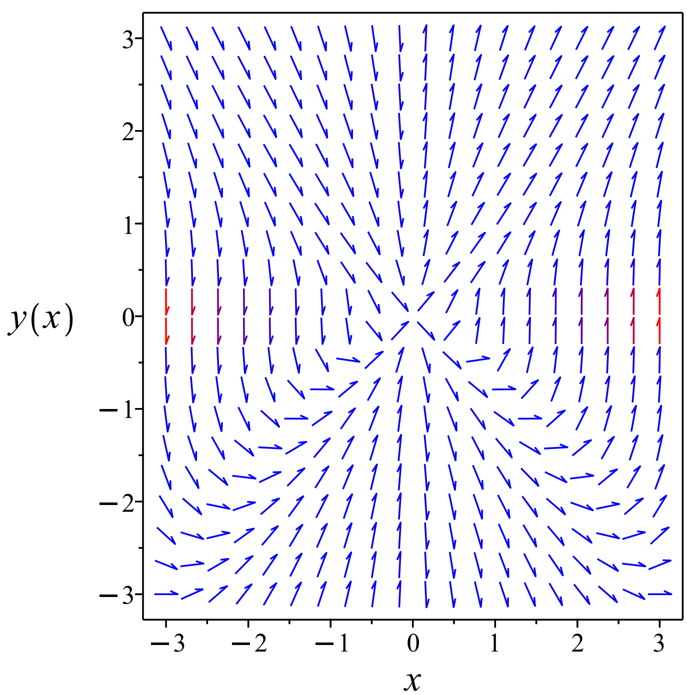

Figure 380: Slope field plot

Verification of solutions

$$
y = x(x+c_2)^{\frac{1}{3}}
$$

Verified OK.

12.17.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^4 + 3y^3}{3x\,y^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 298: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \frac{x^3}{y^2}\end{aligned}\tag{A1}$$

The next step is to determine the canonical coordinates R,S. The canonical coordinates map $(x,y)\to(R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi}=\frac{dy}{\eta}=dS\tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R=x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta}dy\\ &= \int \frac{1}{\frac{x^3}{y^2}}dy\end{aligned}$$

Which results in

$$S=\frac{y^3}{3x^3}$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR}=\frac{S_x+\omega(x,y)S_y}{R_x+\omega(x,y)R_y}\tag{2}$$

Where in the above R_x,R_y,S_x,S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y)=\frac{x^4+3y^3}{3x\,y^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{y^3}{x^4} \\
S_y &= \frac{y^2}{x^3}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{3} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{3}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{R}{3} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{y^3}{3x^3} = \frac{x}{3} + c_1
$$

Which simplifies to

$$
\frac{y^3}{3x^3} = \frac{x}{3} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^4+3y^3}{3x\,y^2}$ 	$R = x$ $S = \frac{y^3}{3x^3}$	$\frac{dS}{dR} = \frac{1}{3}$ 
Summary

The solution(s) found are the following

$$\frac{y^3}{3x^3} = \frac{x}{3} + c_1 \tag{1}$$

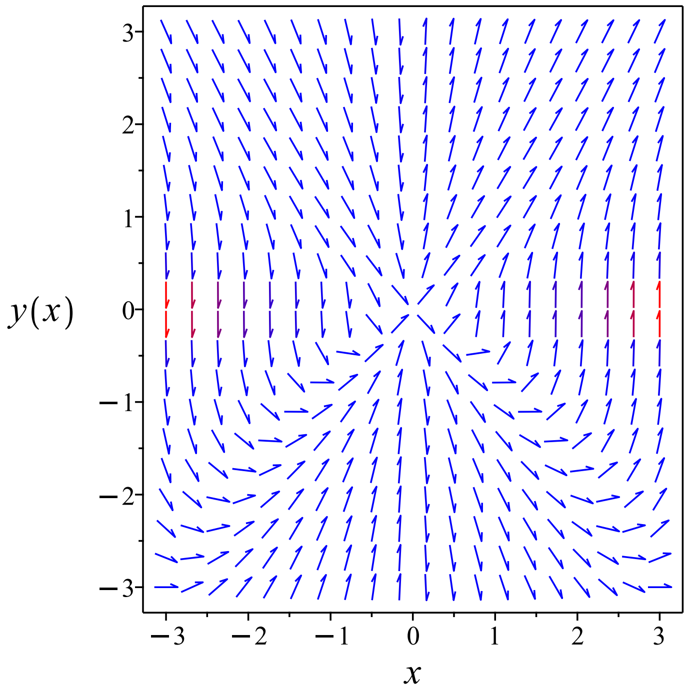

Figure 381: Slope field plot

Verification of solutions

$$\frac{y^3}{3x^3} = \frac{x}{3} + c_1$$

Verified OK.

12.17.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^4 + 3y^3}{3x\,y^2} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{x}y + \frac{x^3}{3}\frac{1}{y^2} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= \frac{1}{x} \\
f_1(x) &= \frac{x^3}{3} \\
n &= -2
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y^2}$ gives

$$
y'y^2 = \frac{y^3}{x} + \frac{x^3}{3} \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= y^3
\end{aligned} \tag{5}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = 3y^2y' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
\frac{w'(x)}{3} &= \frac{w(x)}{x} + \frac{x^3}{3} \\
w' &= \frac{3w}{x} + x^3
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{3}{x} \\
q(x) &= x^3
\end{aligned}
$$

Hence the ode is

$$w'(x) - \frac{3w(x)}{x} = x^3$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{3}{x}dx} \\ &= \frac{1}{x^3}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)\left(x^3\right) \\ \frac{d}{dx}\left(\frac{w}{x^3}\right) &= \left(\frac{1}{x^3}\right)\left(x^3\right) \\ d\left(\frac{w}{x^3}\right) &= dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^3} &= \int dx \\ \frac{w}{x^3} &= x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$w(x) = c_1 x^3 + x^4$$

which simplifies to

$$w(x) = x^3(x + c_1)$$

Replacing w in the above by y^3 using equation (5) gives the final solution.

$$y^3 = x^3(x + c_1)$$

Solving for y gives

$$\begin{aligned}y(x) &= (x + c_1)^{\frac{1}{3}}\, x \\ y(x) &= \frac{(x + c_1)^{\frac{1}{3}}\left(i\sqrt{3} - 1\right) x}{2} \\ y(x) &= -\frac{(x + c_1)^{\frac{1}{3}}\left(1 + i\sqrt{3}\right) x}{2}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = (x + c_1)^{\frac{1}{3}} x \tag{1}$$

$$y = \frac{(x + c_1)^{\frac{1}{3}} \left(i\sqrt{3} - 1\right) x}{2} \tag{2}$$

$$y = -\frac{(x + c_1)^{\frac{1}{3}} \left(1 + i\sqrt{3}\right) x}{2} \tag{3}$$

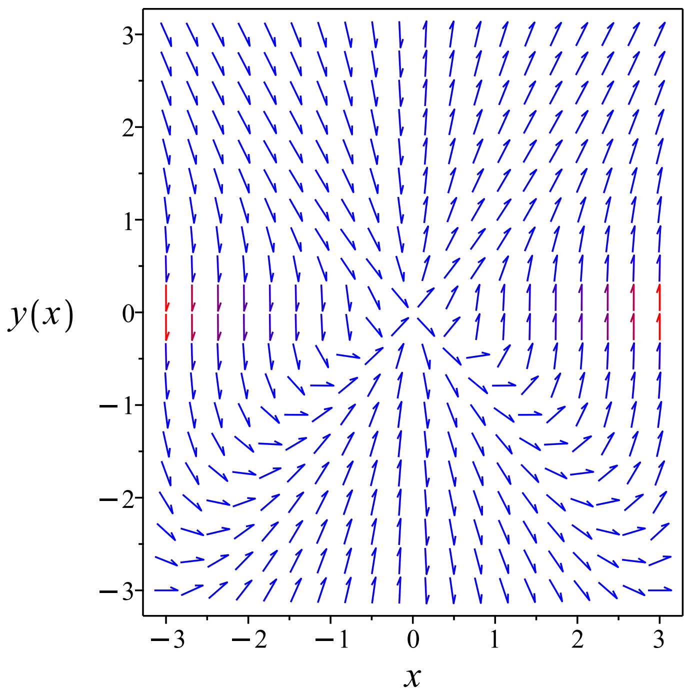

Figure 382: Slope field plot

Verification of solutions

$$y = (x + c_1)^{\frac{1}{3}} x$$

Verified OK.

$$y = \frac{(x + c_1)^{\frac{1}{3}} \left(i\sqrt{3} - 1\right) x}{2}$$

Verified OK.

$$y = -\frac{(x + c_1)^{\frac{1}{3}} \left(1 + i\sqrt{3}\right) x}{2}$$

Verified OK.

12.17.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition

$\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x\,y^2)\,\mathrm{d}y = \left(y^3 + \frac{x^4}{3}\right)\mathrm{d}x$$

$$\left(-y^3 - \frac{x^4}{3}\right)\mathrm{d}x + (x\,y^2)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -y^3 - \frac{x^4}{3}\\ N(x,y) &= x\,y^2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y^3 - \frac{x^4}{3}\right)\\ &= -3y^2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x\,y^2)\\ &= y^2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{x\,y^2}\left(\left(-3y^2\right) - \left(y^2\right)\right)\\ &= -\frac{4}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\frac{4}{x} \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-4\ln(x)} \\ &= \frac{1}{x^4}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \frac{1}{x^4}\left(-y^3 - \frac{x^4}{3}\right) \\ &= \frac{-x^4 - 3y^3}{3x^4}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \frac{1}{x^4}(x\,y^2) \\ &= \frac{y^2}{x^3}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{-x^4 - 3y^3}{3x^4}\right) + \left(\frac{y^2}{x^3}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \frac{-x^4 - 3y^3}{3x^4} \, \mathrm{d}x$$

$$\phi = -\frac{x}{3} + \frac{y^3}{3x^3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{y^2}{x^3} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y^2}{x^3}$. Therefore equation (4) becomes

$$\frac{y^2}{x^3} = \frac{y^2}{x^3} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x}{3} + \frac{y^3}{3x^3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x}{3} + \frac{y^3}{3x^3}$$

Summary

The solution(s) found are the following

$$-\frac{x}{3} + \frac{y^3}{3x^3} = c_1 \tag{1}$$

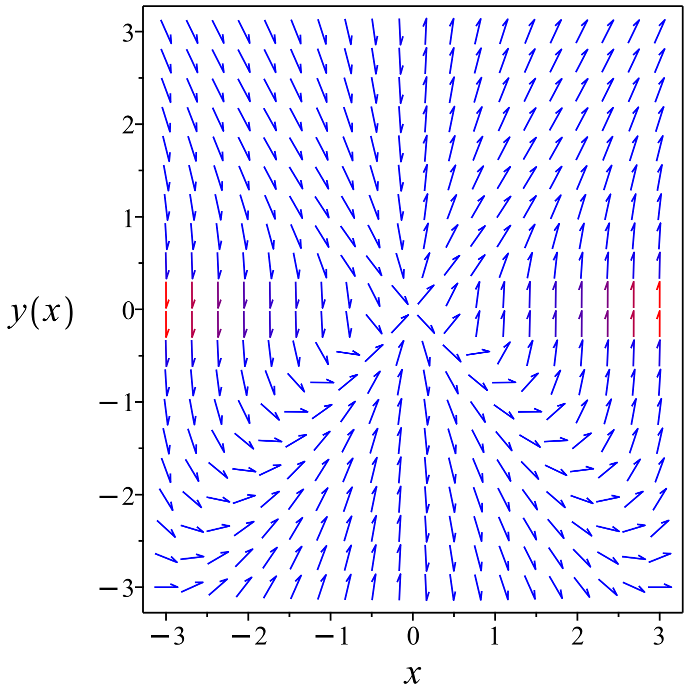

Figure 383: Slope field plot

Verification of solutions

$$-\frac{x}{3}+\frac{y^3}{3x^3}=c_1$$

Verified OK.

$$[y(1)=1]$$

12.18.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned}
y' &= f(x,y)\\
&= -\frac{y\left(e^{\frac{x}{y}}+1\right)e^{-\frac{x}{y}}}{-x+y}
\end{aligned}$$

The x domain of $f(x,y)$ when $y=1$ is

$$\{x<1\vee 1<x\}$$

But the point $x_0=1$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

12.18.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$e^{\frac{1}{u(x)}}+e^{\frac{1}{u(x)}}\left(1-\frac{1}{u(x)}\right)(u'(x)\,x+u(x))=-1$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= -\frac{u\left(e^{-\frac{1}{u}}+u\right)}{x(u-1)}
\end{aligned}$$

Where $f(x)=-\frac{1}{x}$ and $g(u)=\frac{\left(e^{-\frac{1}{u}}+u\right)u}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{\left(e^{-\frac{1}{u}}+u\right)u}{u-1}}\,du=-\frac{1}{x}\,dx$$

$$\int\frac{1}{\frac{\left(e^{-\frac{1}{u}}+u\right)u}{u-1}}\,du=\int-\frac{1}{x}\,dx$$

$$\frac{1}{u}+\ln\left(e^{-\frac{1}{u}}+u\right)=-\ln(x)+c_2$$

The solution is

$$\frac{1}{u(x)}+\ln\left(e^{-\frac{1}{u(x)}}+u(x)\right)+\ln(x)-c_2=0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{x}{y}+\ln\left(e^{-\frac{x}{y}}+\frac{y}{x}\right)+\ln(x)-c_2=0$$

$$\frac{\ln\left(\frac{e^{-\frac{x}{y}}x+y}{x}\right)y+(-c_2+\ln(x))\,y+x}{y}=0$$

Substituting initial conditions and solving for c_2 gives $c_2 = 1+\ln\left(e^{-1}+1\right)$. Hence the so-
Summary
The solution(s) found are the following
lution becomes

$$\frac{\ln\left(\frac{e^{-\frac{x}{y}}x+y}{x}\right)y+\left(-1-\ln\left(e^{-1}+1\right)+\ln\left(x\right)\right)y+x}{y}=0 \tag{1}$$

Verification of solutions

$$\frac{\ln\left(\frac{e^{-\frac{x}{y}}x+y}{x}\right)y+\left(-1-\ln\left(e^{-1}+1\right)+\ln\left(x\right)\right)y+x}{y}=0$$

Verified OK.

12.18.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{y\left(e^{\frac{x}{y}}+1\right)e^{-\frac{x}{y}}}{-x+y} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1,a_2,a_3,b_1,b_2,b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 - \frac{y\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}(b_3-a_2)}{-x+y} - \frac{y^2\left(\mathrm{e}^{\frac{x}{y}}+1\right)^2\mathrm{e}^{-\frac{2x}{y}}a_3}{(-x+y)^2} \\
&- \left(-\frac{1}{-x+y} + \frac{\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}}{-x+y} - \frac{y\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}}{(-x+y)^2}\right)(xa_2+ya_3+a_1) \\
&- \left(-\frac{\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}}{-x+y} + \frac{x}{y(-x+y)} - \frac{\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}x}{y(-x+y)} \right. \\
&\left. + \frac{y\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}}{(-x+y)^2}\right)(xb_2+yb_3+b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{\left(2\,\mathrm{e}^{\frac{2x}{y}}x\,y^2b_2 - \mathrm{e}^{\frac{2x}{y}}y^3a_2 - \mathrm{e}^{\frac{2x}{y}}y^3b_2 + \mathrm{e}^{\frac{2x}{y}}y^3b_3 + \mathrm{e}^{\frac{2x}{y}}xyb_1 - \mathrm{e}^{\frac{2x}{y}}y^2a_1 + \mathrm{e}^{\frac{x}{y}}x^3b_2 - \mathrm{e}^{\frac{x}{y}}x^2ya_2 + \mathrm{e}^{\frac{x}{y}}x^2yb_3 + \mathrm{e}^{\frac{x}{y}}x\,y \cdots\right.}{(x-y)^2\,y}
$$

$= 0$

Setting the numerator to zero gives

$$
\begin{aligned}
&-2\,\mathrm{e}^{\frac{2x}{y}}x\,y^2b_2 + \mathrm{e}^{\frac{2x}{y}}y^3a_2 + \mathrm{e}^{\frac{2x}{y}}y^3b_2 - \mathrm{e}^{\frac{2x}{y}}y^3b_3 - \mathrm{e}^{\frac{2x}{y}}xyb_1 + \mathrm{e}^{\frac{2x}{y}}y^2a_1 \\
&- \mathrm{e}^{\frac{x}{y}}x^3b_2 + \mathrm{e}^{\frac{x}{y}}x^2ya_2 - \mathrm{e}^{\frac{x}{y}}x^2yb_3 - \mathrm{e}^{\frac{x}{y}}x\,y^2a_2 + \mathrm{e}^{\frac{x}{y}}x\,y^2a_3 + \mathrm{e}^{\frac{x}{y}}x\,y^2b_3 \\
&+ \mathrm{e}^{\frac{x}{y}}y^3a_2 - 2\,\mathrm{e}^{\frac{x}{y}}y^3a_3 - \mathrm{e}^{\frac{x}{y}}y^3b_3 - \mathrm{e}^{\frac{x}{y}}x^2b_1 + \mathrm{e}^{\frac{x}{y}}xya_1 - y^3a_3 = 0
\end{aligned} \tag{6E}
$$

Simplifying the above gives

$$
\begin{aligned}
&-2\,\mathrm{e}^{\frac{2x}{y}}x\,y^2b_2 + \mathrm{e}^{\frac{2x}{y}}y^3a_2 + \mathrm{e}^{\frac{2x}{y}}y^3b_2 - \mathrm{e}^{\frac{2x}{y}}y^3b_3 - \mathrm{e}^{\frac{2x}{y}}xyb_1 + \mathrm{e}^{\frac{2x}{y}}y^2a_1 \\
&- \mathrm{e}^{\frac{x}{y}}x^3b_2 + \mathrm{e}^{\frac{x}{y}}x^2ya_2 - \mathrm{e}^{\frac{x}{y}}x^2yb_3 - \mathrm{e}^{\frac{x}{y}}x\,y^2a_2 + \mathrm{e}^{\frac{x}{y}}x\,y^2a_3 + \mathrm{e}^{\frac{x}{y}}x\,y^2b_3 \\
&+ \mathrm{e}^{\frac{x}{y}}y^3a_2 - 2\,\mathrm{e}^{\frac{x}{y}}y^3a_3 - \mathrm{e}^{\frac{x}{y}}y^3b_3 - \mathrm{e}^{\frac{x}{y}}x^2b_1 + \mathrm{e}^{\frac{x}{y}}xya_1 - y^3a_3 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \mathrm{e}^{\frac{x}{y}}, \mathrm{e}^{\frac{2x}{y}}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, e^{\frac{x}{y}} = v_3, e^{\frac{2x}{y}} = v_4\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &v_3 v_1^2 v_2 a_2 - v_3 v_1 v_2^2 a_2 + v_3 v_2^3 a_2 + v_4 v_2^3 a_2 + v_3 v_1 v_2^2 a_3 - 2 v_3 v_2^3 a_3 \\ &- v_3 v_1^3 b_2 - 2 v_4 v_1 v_2^2 b_2 + v_4 v_2^3 b_2 - v_3 v_1^2 v_2 b_3 + v_3 v_1 v_2^2 b_3 - v_3 v_2^3 b_3 \\ &- v_4 v_2^3 b_3 + v_3 v_1 v_2 a_1 + v_4 v_2^2 a_1 - v_2^3 a_3 - v_3 v_1^2 b_1 - v_4 v_1 v_2 b_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$\begin{aligned} &-v_3 v_1^3 b_2 + (-b_3 + a_2) v_1^2 v_2 v_3 - v_3 v_1^2 b_1 + (-a_2 + a_3 + b_3) v_1 v_2^2 v_3 \\ &- 2 v_4 v_1 v_2^2 b_2 + v_3 v_1 v_2 a_1 - v_4 v_1 v_2 b_1 + (a_2 - 2a_3 - b_3) v_2^3 v_3 \\ &+ (a_2 + b_2 - b_3) v_2^3 v_4 - v_2^3 a_3 + v_4 v_2^2 a_1 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_1 &= 0 \\ -a_3 &= 0 \\ -b_1 &= 0 \\ -2b_2 &= 0 \\ -b_2 &= 0 \\ -b_3 + a_2 &= 0 \\ -a_2 + a_3 + b_3 &= 0 \\ a_2 - 2a_3 - b_3 &= 0 \\ a_2 + b_2 - b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{y\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}}{-x+y}\right)(x) \\
&= \frac{-y^2\mathrm{e}^{\frac{x}{y}} - xy}{\mathrm{e}^{\frac{x}{y}}x - y\,\mathrm{e}^{\frac{x}{y}}} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-y^2 \mathrm{e}^{\frac{x}{y}} - xy}{\mathrm{e}^{\frac{x}{y}} x - y \,\mathrm{e}^{\frac{x}{y}}}} dy
\end{aligned}$$

Which results in

$$S = \ln\left(y\,\mathrm{e}^{\frac{x}{y}} + x\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y\left(\mathrm{e}^{\frac{x}{y}} + 1\right)\mathrm{e}^{-\frac{x}{y}}}{-x + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{\mathrm{e}^{\frac{x}{y}} + 1}{y\,\mathrm{e}^{\frac{x}{y}} + x} \\
S_y &= -\frac{\mathrm{e}^{\frac{x}{y}}(x - y)}{y\left(y\,\mathrm{e}^{\frac{x}{y}} + x\right)}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln\left(\mathrm{e}^{\frac{x}{y}} y + x\right) = c_1$$

Which simplifies to

$$\ln\left(\mathrm{e}^{\frac{x}{y}} y + x\right) = c_1$$

Which gives

$$y = -\frac{x}{\mathrm{LambertW}\left(-\frac{x}{\mathrm{e}^{c_1 - x}}\right)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y\left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{e}^{-\frac{x}{y}}}{-x+y}$ 	$R = x$ $S = \ln\left(y\,\mathrm{e}^{\frac{x}{y}} + x\right)$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{\mathrm{LambertW}\left(-\frac{1}{\mathrm{e}^{c_1}-1}\right)}$$

$$c_1 = \ln\left(\mathrm{e}+1\right)$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{x}{\mathrm{LambertW}\left(-\frac{x}{-x+1+\mathrm{e}}\right)}$$

<u>Summary</u>

The solution(s) found are the following

$$y = -\frac{x}{\mathrm{LambertW}\left(-\frac{x}{-x+1+\mathrm{e}}\right)} \tag{1}$$

<u>Verification of solutions</u>

$$y = -\frac{x}{\mathrm{LambertW}\left(-\frac{x}{-x+1+\mathrm{e}}\right)}$$

Verified OK.

12.18.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\mathrm{e}^{\frac{x}{y}}\left(1-\frac{x}{y}\right)\right)\mathrm{d}y&=\left(-\mathrm{e}^{\frac{x}{y}}-1\right)\mathrm{d}x\\ \left(\mathrm{e}^{\frac{x}{y}}+1\right)\mathrm{d}x+\left(\mathrm{e}^{\frac{x}{y}}\left(1-\frac{x}{y}\right)\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= \mathrm{e}^{\frac{x}{y}} + 1 \\
N(x,y) &= \mathrm{e}^{\frac{x}{y}} \left(1 - \frac{x}{y}\right)
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\mathrm{e}^{\frac{x}{y}} + 1\right) \\
&= -\frac{x\,\mathrm{e}^{\frac{x}{y}}}{y^2}
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\mathrm{e}^{\frac{x}{y}}\left(1 - \frac{x}{y}\right)\right) \\
&= -\frac{x\,\mathrm{e}^{\frac{x}{y}}}{y^2}
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \mathrm{e}^{\frac{x}{y}} + 1\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = y\,\mathrm{e}^{\frac{x}{y}} + x + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\begin{aligned}\frac{\partial \phi}{\partial y} &= e^{\frac{x}{y}} - \frac{x\, e^{\frac{x}{y}}}{y} + f'(y) \qquad (4)\\ &= -\frac{e^{\frac{x}{y}} (x-y)}{y} + f'(y)\end{aligned}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = e^{\frac{x}{y}} \left(1 - \frac{x}{y}\right)$. Therefore equation (4) becomes

$$e^{\frac{x}{y}} \left(1 - \frac{x}{y}\right) = -\frac{e^{\frac{x}{y}} (x-y)}{y} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = y\, e^{\frac{x}{y}} + x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y\, e^{\frac{x}{y}} + x$$

The solution becomes

$$y = -\frac{x}{\text{LambertW}\left(-\frac{x}{-x+c_1}\right)}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{\text{LambertW}\left(-\frac{1}{-1+c_1}\right)}$$

$$c_1 = \mathrm{e} + 1$$

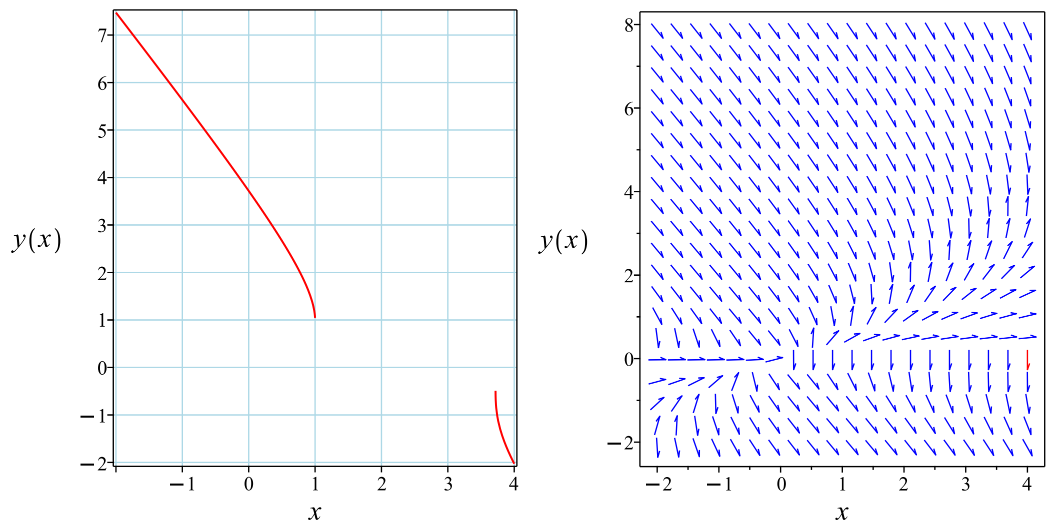
Substituting c_1 found above in the general solution gives

$$y = -\frac{x}{\operatorname{LambertW}\left(-\frac{x}{-x+1+\mathrm{e}}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{\operatorname{LambertW}\left(-\frac{x}{-x+1+\mathrm{e}}\right)} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -\frac{x}{\operatorname{LambertW}\left(-\frac{x}{-x+1+\mathrm{e}}\right)}$$

Verified OK.

12.18.5 Maple step by step solution

Let's solve

$\left[e^{\frac{x}{y}}+e^{\frac{x}{y}}\left(1-\frac{x}{y}\right) y'=-1, y(1)=1\right]$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

  $F'(x,y)=0$

  ◦ Compute derivative of lhs

  $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

  ◦ Evaluate derivatives

  $-\frac{x\,e^{\frac{x}{y}}}{y^2}=\frac{e^{\frac{x}{y}}\left(1-\frac{x}{y}\right)}{y}-\frac{e^{\frac{x}{y}}}{y}$

  ◦ Simplify

  $-\frac{x\,e^{\frac{x}{y}}}{y^2}=-\frac{x\,e^{\frac{x}{y}}}{y^2}$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int\left(e^{\frac{x}{y}}+1\right)dx+f_1(y)$

- Evaluate integral

  $F(x,y)=y\,e^{\frac{x}{y}}+x+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $e^{\frac{x}{y}}\left(1-\frac{x}{y}\right)=e^{\frac{x}{y}}-\frac{x\,e^{\frac{x}{y}}}{y}+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

$$\frac{d}{dy}f_1(y) = \mathrm{e}^{\frac{x}{y}}\left(1-\frac{x}{y}\right) - \mathrm{e}^{\frac{x}{y}} + \frac{x\,\mathrm{e}^{\frac{x}{y}}}{y}$$

- Solve for $f_1(y)$

$$f_1(y) = 0$$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$$F(x,y) = y\,\mathrm{e}^{\frac{x}{y}} + x$$

- Substitute $F(x,y)$ into the solution of the ODE

$$y\,\mathrm{e}^{\frac{x}{y}} + x = c_1$$

- Solve for y

$$y = -\frac{x}{\mathit{LambertW}\left(-\frac{x}{-x+c_1}\right)}$$

- Use initial condition $y(1) = 1$

$$1 = -\frac{1}{\mathit{LambertW}\left(-\frac{1}{-1+c_1}\right)}$$

- Solve for c_1

$$c_1 = \mathrm{e} + 1$$

- Substitute $c_1 = \mathrm{e} + 1$ into general solution and simplify

$$y = -\frac{x}{\mathit{LambertW}\left(\frac{x}{x-1-\mathrm{e}}\right)}$$

- Solution to the IVP

$$y = -\frac{x}{\mathit{LambertW}\left(\frac{x}{x-1-\mathrm{e}}\right)}$$

$$\boxed{y^2 - y'yx = -x^2}$$

12.19.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u(x)^2\,x^2 - (u'(x)\,x + u(x))\,u(x)\,x^2 = -x^2$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{1}{ux} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = \frac{1}{u}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{1}{u}}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{\frac{1}{u}}\,du &= \int \frac{1}{x}\,dx \\
\frac{u^2}{2} &= \ln\left(x\right) + c_2
\end{aligned}
$$

The solution is

$$
\frac{u(x)^2}{2} - \ln\left(x\right) - c_2 = 0
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\frac{y^2}{2x^2} - \ln\left(x\right) - c_2 = 0 \\
\frac{y^2}{2x^2} - \ln\left(x\right) - c_2 = 0
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\frac{y^2}{2x^2} - \ln\left(x\right) - c_2 = 0 \tag{1}
$$

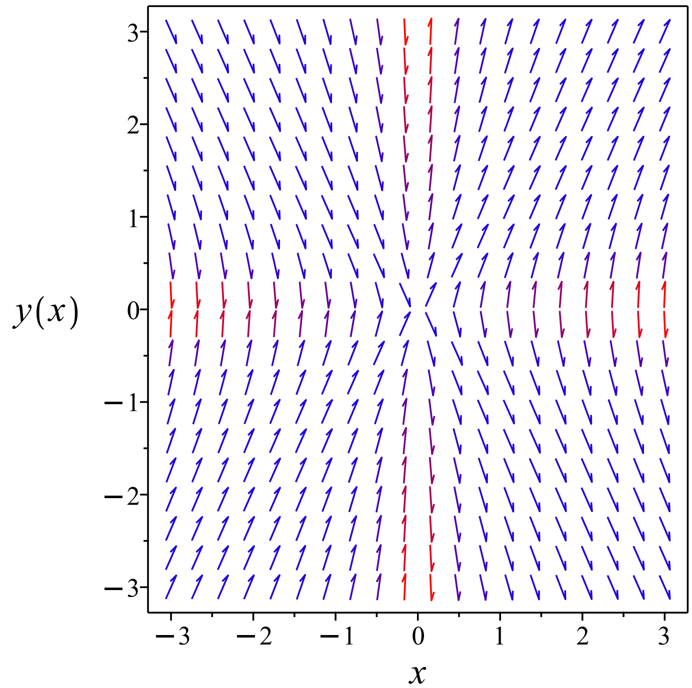

Figure 386: Slope field plot

Verification of solutions

$$\frac{y^2}{2x^2} - \ln(x) - c_2 = 0$$

Verified OK.

12.19.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2 + y^2}{yx}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 301: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{x^2}{y}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{x^2}{y}} dy
\end{aligned}$$

Which results in

$$S = \frac{y^2}{2x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x^2 + y^2}{yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{y^2}{x^3} \\
S_y &= \frac{y}{x^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x^2} = \ln(x) + c_1$$

Which simplifies to

$$\frac{y^2}{2x^2} = \ln(x) + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2+y^2}{yx}$ 	$R = x$ $S = \frac{y^2}{2x^2}$	$\frac{dS}{dR} = \frac{1}{R}$ 
Summary

The solution(s) found are the following

$$\frac{y^2}{2x^2} = \ln(x) + c_1 \tag{1}$$

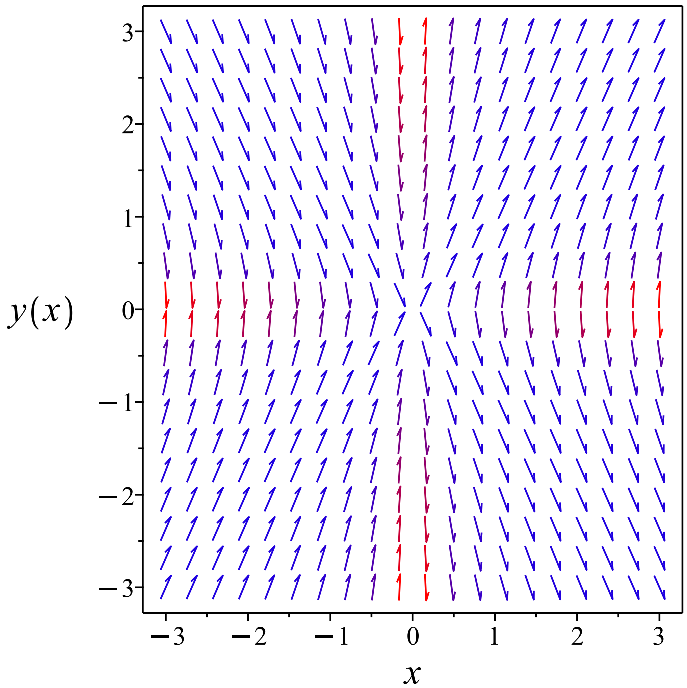

Figure 387: Slope field plot

Verification of solutions

$$\frac{y^2}{2x^2} = \ln(x) + c_1$$

Verified OK.

12.19.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 + y^2}{yx} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{x}y + x\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{1}{x} \\ f_1(x) &= x \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = \frac{y^2}{x} + x \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= \frac{w(x)}{x} + x \\ w' &= \frac{2w}{x} + 2x \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= 2x \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{2w(x)}{x} = 2x$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{2}{x}dx} \\
&= \frac{1}{x^2}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu w) &= (\mu)(2x) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{w}{x^2}\right) &= \left(\frac{1}{x^2}\right)(2x) \\
\mathrm{d}\left(\frac{w}{x^2}\right) &= \left(\frac{2}{x}\right)\,\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{w}{x^2} &= \int \frac{2}{x}\,\mathrm{d}x \\
\frac{w}{x^2} &= 2\ln(x) + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$w(x) = 2\ln(x)\,x^2 + c_1 x^2$$

which simplifies to

$$w(x) = x^2(2\ln(x) + c_1)$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = x^2(2\ln(x) + c_1)$$

Solving for y gives

$$\begin{aligned}
y(x) &= \sqrt{2\ln(x) + c_1}\,x \\
y(x) &= -\sqrt{2\ln(x) + c_1}\,x
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{2\ln(x) + c_1}\, x \tag{1}$$

$$y = -\sqrt{2\ln(x) + c_1}\, x \tag{2}$$

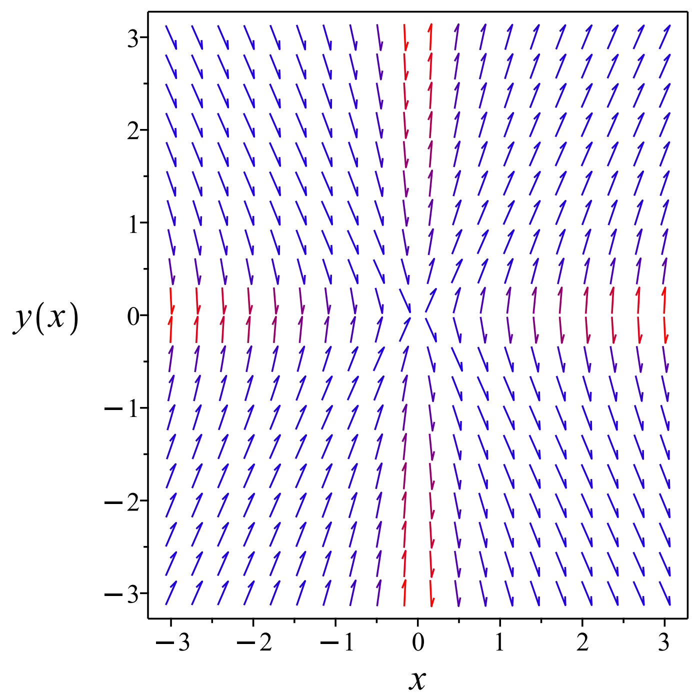

Figure 388: Slope field plot

Verification of solutions

$$y = \sqrt{2\ln(x) + c_1}\, x$$

Verified OK.

$$y = -\sqrt{2\ln(x) + c_1}\, x$$

Verified OK.

12.19.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-xy)\,\mathrm{d}y &= \left(-x^2 - y^2\right)\mathrm{d}x\\ \left(x^2 + y^2\right)\mathrm{d}x + (-xy)\,\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= x^2 + y^2\\ N(x,y) &= -xy\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^2 + y^2)\\ &= 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-xy)\\ &= -y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= -\frac{1}{xy}((2y) - (-y))\\ &= -\frac{3}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x}\\ &= e^{\int -\frac{3}{x} \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-3\ln(x)}\\ &= \frac{1}{x^3}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^3}(x^2 + y^2)\\ &= \frac{x^2 + y^2}{x^3}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{x^3}(-xy)\\ &= -\frac{y}{x^2}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(\frac{x^2+y^2}{x^3}\right) + \left(-\frac{y}{x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{x^2+y^2}{x^3}\,\mathrm{d}x\end{aligned}$$

$$\phi = -\frac{y^2}{2x^2} + \ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{y}{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y}{x^2}$. Therefore equation (4) becomes

$$-\frac{y}{x^2} = -\frac{y}{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{y^2}{2x^2} + \ln(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{y^2}{2x^2} + \ln(x)$$

Summary

The solution(s) found are the following

$$-\frac{y^2}{2x^2} + \ln(x) = c_1 \tag{1}$$

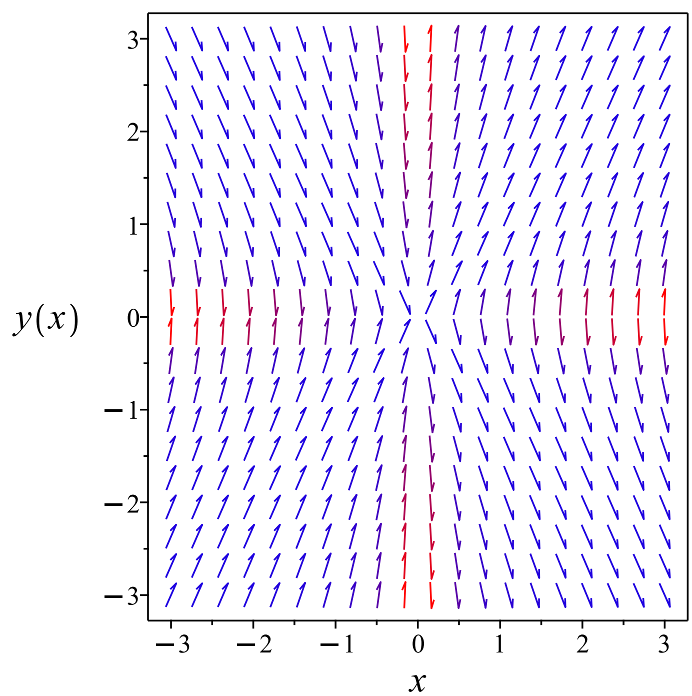

Figure 389: Slope field plot

Verification of solutions

$$-\frac{y^2}{2x^2}+\ln(x)=c_1$$

Verified OK.

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{-y+(x-y+3)\,y'=-x-2}$$

12.20.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-x+y-2}{-x+y-3} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&b_2 - \frac{(-x+y-2)(b_3-a_2)}{-x+y-3} - \frac{(-x+y-2)^2 a_3}{(-x+y-3)^2} \\
&- \left(\frac{1}{-x+y-3} - \frac{-x+y-2}{(-x+y-3)^2}\right)(xa_2 + ya_3 + a_1) \\
&- \left(-\frac{1}{-x+y-3} + \frac{-x+y-2}{(-x+y-3)^2}\right)(xb_2 + yb_3 + b_1) = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^2a_2 - x^2a_3 + x^2b_2 - x^2b_3 - 2xya_2 + 2xya_3 - 2xyb_2 + 2xyb_3 + y^2a_2 - y^2a_3 + y^2b_2 - y^2b_3 + 6xa_2 - 4xa_3}{(x-y+3)^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&x^2a_2 - x^2a_3 + x^2b_2 - x^2b_3 - 2xya_2 + 2xya_3 - 2xyb_2 + 2xyb_3 \\
&+ y^2a_2 - y^2a_3 + y^2b_2 - y^2b_3 + 6xa_2 - 4xa_3 + 5xb_2 - 5xb_3 - 5ya_2 \\
&+ 5ya_3 - 6yb_2 + 4yb_3 + a_1 + 6a_2 - 4a_3 - b_1 + 9b_2 - 6b_3 = 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&a_2v_1^2 - 2a_2v_1v_2 + a_2v_2^2 - a_3v_1^2 + 2a_3v_1v_2 - a_3v_2^2 + b_2v_1^2 - 2b_2v_1v_2 + b_2v_2^2 \\
&- b_3v_1^2 + 2b_3v_1v_2 - b_3v_2^2 + 6a_2v_1 - 5a_2v_2 - 4a_3v_1 + 5a_3v_2 + 5b_2v_1 \\
&- 6b_2v_2 - 5b_3v_1 + 4b_3v_2 + a_1 + 6a_2 - 4a_3 - b_1 + 9b_2 - 6b_3 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}&(a_2 - a_3 + b_2 - b_3)\, v_1^2 + (-2a_2 + 2a_3 - 2b_2 + 2b_3)\, v_1 v_2 \\ &+ (6a_2 - 4a_3 + 5b_2 - 5b_3)\, v_1 + (a_2 - a_3 + b_2 - b_3)\, v_2^2 \\ &+ (-5a_2 + 5a_3 - 6b_2 + 4b_3)\, v_2 + a_1 + 6a_2 - 4a_3 - b_1 + 9b_2 - 6b_3 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}-5a_2 + 5a_3 - 6b_2 + 4b_3 &= 0 \\ -2a_2 + 2a_3 - 2b_2 + 2b_3 &= 0 \\ a_2 - a_3 + b_2 - b_3 &= 0 \\ 6a_2 - 4a_3 + 5b_2 - 5b_3 &= 0 \\ a_1 + 6a_2 - 4a_3 - b_1 + 9b_2 - 6b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= -5b_2 + b_1 \\ a_2 &= -b_2 \\ a_3 &= b_2 \\ b_1 &= b_1 \\ b_2 &= b_2 \\ b_3 &= -b_2\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= 1 \\ \eta &= 1\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\, \xi \\ &= 1 - \left(-\frac{-x + y - 2}{-x + y - 3}\right)(1) \\ &= \frac{2x - 2y + 5}{x - y + 3} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{2x-2y+5}{x-y+3}} dy \end{aligned}$$

Which results in

$$S = \frac{y}{2} - \frac{\ln(-2x + 2y - 5)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{-x + y - 2}{-x + y - 3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{1}{4x - 4y + 10} \\ S_y &= \frac{x - y + 3}{2x - 2y + 5} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{R}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{2} - \frac{\ln(-2x + 2y - 5)}{4} = -\frac{x}{2} + c_1$$

Which simplifies to

$$\frac{y}{2} - \frac{\ln(-2x + 2y - 5)}{4} = -\frac{x}{2} + c_1$$

Which gives

$$y = x - \frac{\text{LambertW}\left(-\mathrm{e}^{4x+5-4c_1}\right)}{2} + \frac{5}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-x+y-2}{-x+y-3}$ 	$R = x$ $S = \frac{y}{2} - \frac{\ln(-2x + 2y -}{4}$	$\frac{dS}{dR} = -\frac{1}{2}$ 
Summary

The solution(s) found are the following

$$y = x - \frac{\text{LambertW}\left(-e^{4x+5-4c_1}\right)}{2} + \frac{5}{2} \tag{1}$$

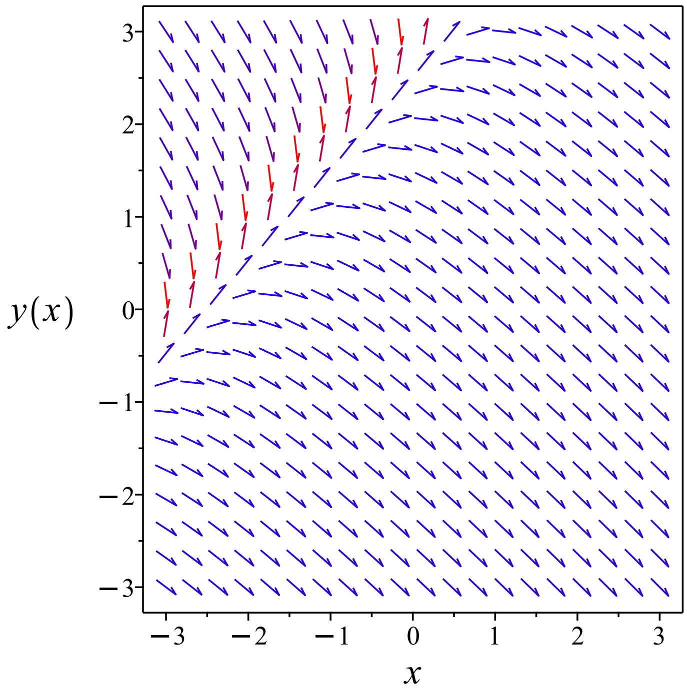

Figure 390: Slope field plot

Verification of solutions

$$y = x - \frac{\text{LambertW}\left(-\mathrm{e}^{4x+5-4c_1}\right)}{2} + \frac{5}{2}$$

Verified OK.

Problem number: 295.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati", "bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _rational, _Bernoulli]
```

$$\boxed{y^2x + y - xy' = 0}$$

12.21.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u(x)^2\,x^3 + u(x)\,x - x(u'(x)\,x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= u^2x
\end{aligned}$$

Where $f(x) = x$ and $g(u) = u^2$. Integrating both sides gives

$$\frac{1}{u^2}\,du = x\,dx$$

$$\int \frac{1}{u^2}\,du = \int x\,dx$$

$$-\frac{1}{u} = \frac{x^2}{2} + c_2$$

The solution is

$$-\frac{1}{u(x)} - \frac{x^2}{2} - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$-\frac{x}{y} - \frac{x^2}{2} - c_2 = 0$$

$$-\frac{x}{y} - \frac{x^2}{2} - c_2 = 0$$

Summary

The solution(s) found are the following

$$-\frac{x}{y} - \frac{x^2}{2} - c_2 = 0 \tag{1}$$

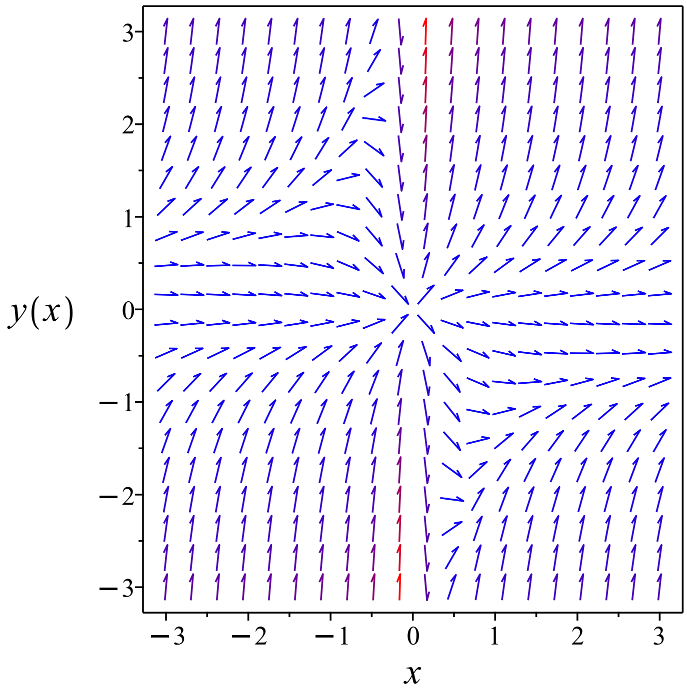

Figure 391: Slope field plot

Verification of solutions

$$-\frac{x}{y}-\frac{x^2}{2}-c_2=0$$

Verified OK.

12.21.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y'=\frac{y(xy+1)}{x}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 303: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{y^2}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{y^2}{x}} dy
\end{aligned}$$

Which results in

$$S = -\frac{x}{y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y(xy + 1)}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{1}{y} \\
S_y &= \frac{x}{y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{x}{y} = \frac{x^2}{2} + c_1$$

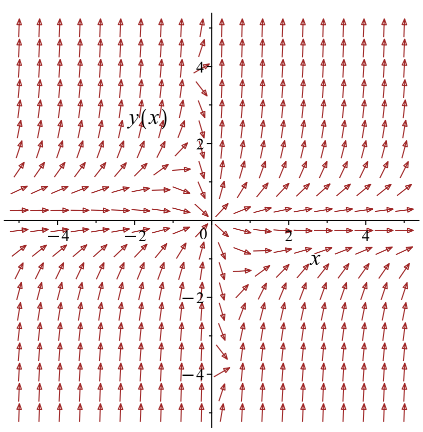
Which simplifies to

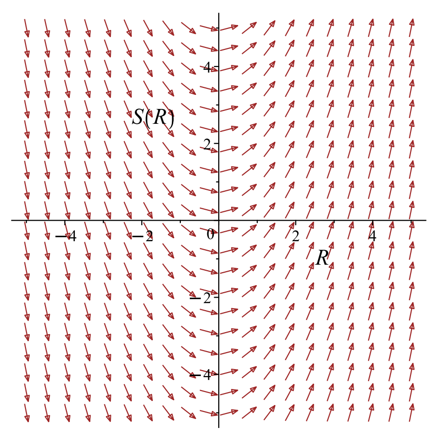
$$-\frac{x}{y} = \frac{x^2}{2} + c_1$$

Which gives

$$y = -\frac{2x}{x^2 + 2c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><td>Original ode in x, y coordinates</td><td>Canonical coordinates transformation</td><td>ODE in canonical coordinates (R, S)</td></tr>
<tr><td>$\frac{dy}{dx} = \frac{y(xy+1)}{x}$


</td><td>$R = x$
$S = -\frac{x}{y}$</td><td>$\frac{dS}{dR} = R$


</td></tr>
</table>

Summary

The solution(s) found are the following

$$y = -\frac{2x}{x^2 + 2c_1} \tag{1}$$

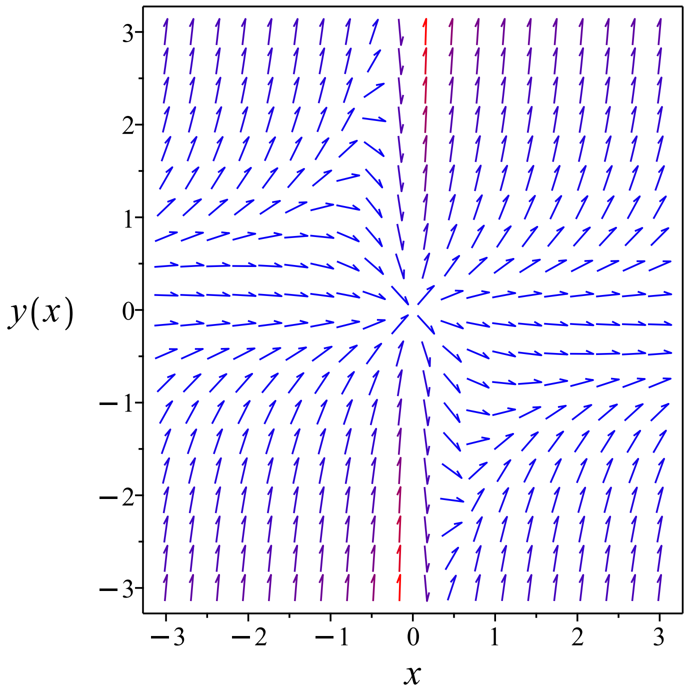


Figure 392: Slope field plot

Verification of solutions

$$y = -\frac{2x}{x^2 + 2c_1}$$

Verified OK.

12.21.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{y(xy + 1)}{x} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{x}y + y^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{1}{x} \\ f_1(x) &= 1 \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = \frac{1}{xy} + 1 \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(x) &= \frac{w(x)}{x} + 1 \\ w' &= -\frac{w}{x} - 1 \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= -1
\end{aligned}
$$

Hence the ode is

$$
w'(x) + \frac{w(x)}{x} = -1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{x} dx} \\
&= x
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu w) &= (\mu)(-1) \\
\frac{\mathrm{d}}{\mathrm{d}x}(xw) &= (x)(-1) \\
\mathrm{d}(xw) &= (-x)\, \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
xw &= \int -x \,\mathrm{d}x \\
xw &= -\frac{x^2}{2} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$
w(x) = -\frac{x}{2} + \frac{c_1}{x}
$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$
\frac{1}{y} = -\frac{x}{2} + \frac{c_1}{x}
$$

Or

$$
y = \frac{1}{-\frac{x}{2} + \frac{c_1}{x}}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \frac{1}{-\frac{x}{2} + \frac{c_1}{x}} \tag{1}
$$

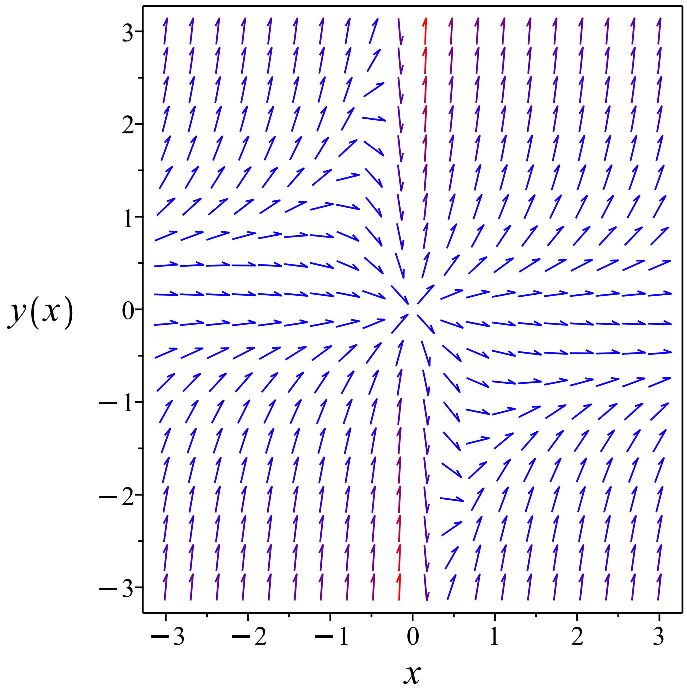

Figure 393: Slope field plot

Verification of solutions

$$y = \frac{1}{-\frac{x}{2} + \frac{c_1}{x}}$$

Verified OK.

12.21.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(-x)\,\mathrm{d}y &= \left(-x\,y^2 - y\right)\mathrm{d}x \\
\left(x\,y^2 + y\right)\mathrm{d}x + (-x)\,\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= x\,y^2 + y \\
N(x, y) &= -x
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x\,y^2 + y\right) \\
&= 2xy + 1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-x) \\
&= -1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= -\frac{1}{x}((2xy+1)-(-1)) \\ &= \frac{-2xy-2}{x} \end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= \frac{1}{x\,y^2+y}((-1)-(2xy+1)) \\ &= -\frac{2}{y} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \,\mathrm{d}y} \\ &= e^{\int -\frac{2}{y} \,\mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(y)} \\ &= \frac{1}{y^2} \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{y^2}(x\,y^2+y) \\ &= \frac{xy+1}{y} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{y^2}(-x) \\ &= -\frac{x}{y^2} \end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{xy+1}{y}\right) + \left(-\frac{x}{y^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\mathrm{d}x &= \int \frac{xy+1}{y}\,\mathrm{d}x \\
\phi &= \frac{x(xy+2)}{2y} + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\begin{aligned}
\frac{\partial \phi}{\partial y} &= \frac{x^2}{2y} - \frac{x(xy+2)}{2y^2} + f'(y) \\
&= -\frac{x}{y^2} + f'(y)
\end{aligned} \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{x}{y^2}$. Therefore equation (4) becomes

$$
-\frac{x}{y^2} = -\frac{x}{y^2} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x(xy+2)}{2y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x(xy+2)}{2y}$$

The solution becomes

$$y = \frac{2x}{-x^2 + 2c_1}$$

Summary

The solution(s) found are the following

$$y = \frac{2x}{-x^2 + 2c_1} \tag{1}$$

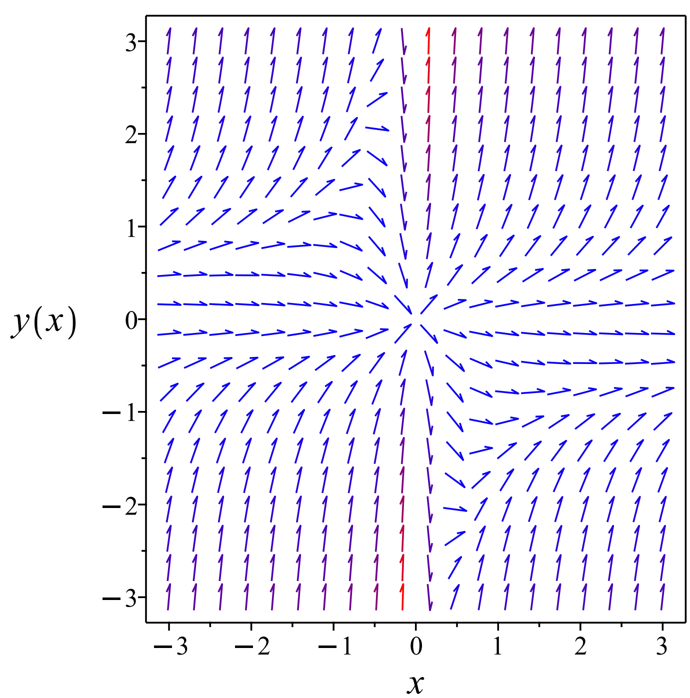

Figure 394: Slope field plot

Verification of solutions

$$y = \frac{2x}{-x^2 + 2c_1}$$

Verified OK.

12.21.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{y(xy + 1)}{x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + \frac{y}{x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = \frac{1}{x}$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= \frac{1}{x} \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) - \frac{u'(x)}{x} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_2 x^2 + c_1$$

The above shows that

$$u'(x) = 2c_2 x$$

Using the above in (1) gives the solution

$$y = -\frac{2c_2 x}{c_2 x^2 + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{2x}{x^2 + c_3}$$

Summary

The solution(s) found are the following

$$y = -\frac{2x}{x^2 + c_3} \tag{1}$$

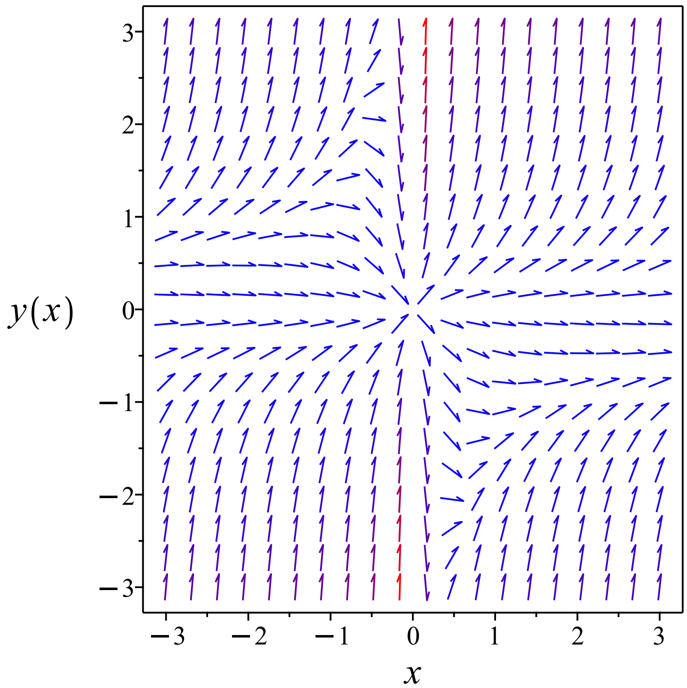

Figure 395: Slope field plot

Verification of solutions

$$y = -\frac{2x}{x^2 + c_3}$$

Verified OK.

Problem number: 296.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _rational, _Bernoulli]
```

$$\boxed{y^2 + 2yy' = -x^2 - 2x}$$

12.22.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u(x)^2\,x^2 + 2u(x)\,x(u'(x)\,x + u(x)) = -x^2 - 2x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{(x+2)\,(-u^2-1)}{2xu} \end{aligned}$$

Where $f(x) = \frac{x+2}{2x}$ and $g(u) = \frac{-u^2-1}{u}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{-u^2-1}{u}}\,du &= \frac{x+2}{2x}\,dx \\
\int \frac{1}{\frac{-u^2-1}{u}}\,du &= \int \frac{x+2}{2x}\,dx \\
-\frac{\ln\left(u^2+1\right)}{2} &= \frac{x}{2} + \ln\left(x\right) + c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
\frac{1}{\sqrt{u^2+1}} = \mathrm{e}^{\frac{x}{2}+\ln(x)+c_2}
$$

Which simplifies to

$$
\frac{1}{\sqrt{u^2+1}} = c_3 \mathrm{e}^{\frac{x}{2}+\ln(x)}
$$

The solution is

$$
\frac{1}{\sqrt{u\left(x\right)^2+1}} = c_3 \mathrm{e}^{\frac{x}{2}+\ln(x)+c_2}
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\frac{1}{\sqrt{\frac{y^2}{x^2}+1}} &= c_3 \mathrm{e}^{\frac{x}{2}+\ln(x)+c_2} \\
\frac{1}{\sqrt{\frac{x^2+y^2}{x^2}}} &= c_3 \mathrm{e}^{\frac{x}{2}+c_2} x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\frac{1}{\sqrt{\frac{x^2+y^2}{x^2}}} = c_3 \mathrm{e}^{\frac{x}{2}+c_2} x \tag{1}
$$

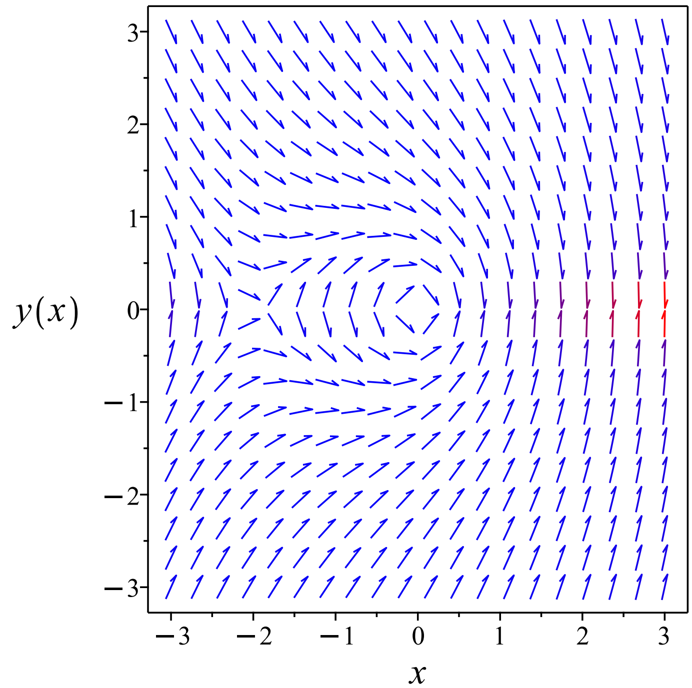

Figure 396: Slope field plot

Verification of solutions

$$\frac{1}{\sqrt{\frac{x^2+y^2}{x^2}}} = c_3 e^{\frac{x}{2}+c_2} x$$

Verified OK.

12.22.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{x^2+y^2+2x}{2y}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 305: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{e^{-x}}{y}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{e^{-x}}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{e^{x} y^{2}}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x^2 + y^2 + 2x}{2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{e^{x} y^{2}}{2} \\ S_y &= y\, e^{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{e^{x} x(x+2)}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{e^{R} R(R+2)}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{e^{R} R^{2}}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{e^{x} y^{2}}{2} = -\frac{e^{x} x^{2}}{2} + c_1$$

Which simplifies to

$$\frac{e^{x} y^{2}}{2} = -\frac{e^{x} x^{2}}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x^2+y^2+2x}{2y}$ 	$R = x$ $S = \frac{e^{x} y^{2}}{2}$	$\frac{dS}{dR} = -\frac{e^{R} R(R+2)}{2}$ 
Summary

The solution(s) found are the following

$$\frac{e^{x} y^{2}}{2} = -\frac{e^{x} x^{2}}{2} + c_1 \tag{1}$$

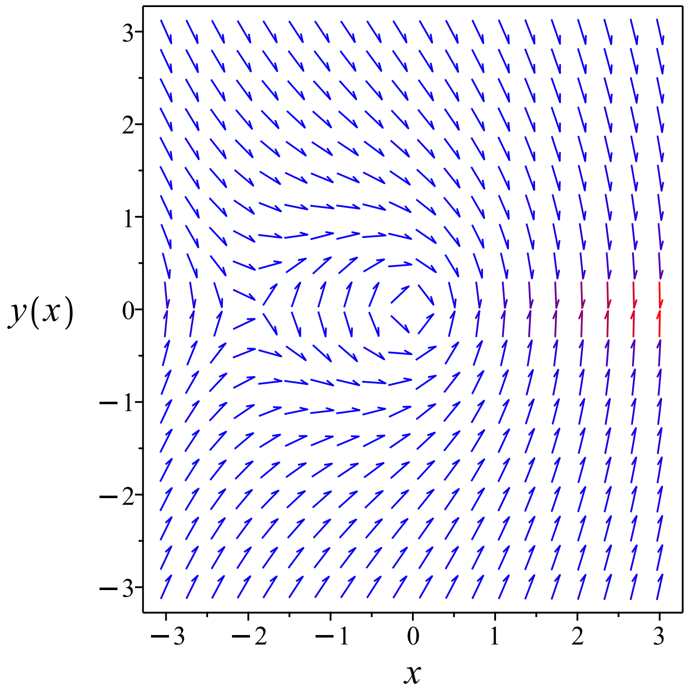

Figure 397: Slope field plot

Verification of solutions

$$\frac{e^x y^2}{2} = -\frac{e^x x^2}{2} + c_1$$

Verified OK.

12.22.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{x^2 + y^2 + 2x}{2y} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{2}y - \frac{1}{2}x^2 - x\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{1}{2} \\ f_1(x) &= -\frac{1}{2}x^2 - x \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = -\frac{y^2}{2} - \frac{1}{2}x^2 - x \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= -\frac{w(x)}{2} - \frac{x^2}{2} - x \\ w' &= -x^2 - w - 2x \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -x^2 - 2x \end{aligned}$$

Hence the ode is

$$w'(x) + w(x) = -x^2 - 2x$$

The integrating factor μ is

$$\mu = e^{\int 1dx}$$
$$= e^{x}$$

The ode becomes

$$\frac{d}{dx}(\mu w) = (\mu)\left(-x^2 - 2x\right)$$
$$\frac{d}{dx}(e^{x} w) = (e^{x})\left(-x^2 - 2x\right)$$
$$d(e^{x} w) = \left(-e^{x} x(x+2)\right)\, dx$$

Integrating gives

$$e^{x} w = \int -e^{x} x(x+2)\, dx$$
$$e^{x} w = -e^{x} x^2 + c_1$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$w(x) = -e^{-x} e^{x} x^2 + c_1 e^{-x}$$

which simplifies to

$$w(x) = -x^2 + c_1 e^{-x}$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = -x^2 + c_1 e^{-x}$$

Solving for y gives

$$y(x) = \sqrt{-x^2 + c_1 e^{-x}}$$
$$y(x) = -\sqrt{-x^2 + c_1 e^{-x}}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-x^2 + c_1 e^{-x}} \tag{1}$$
$$y = -\sqrt{-x^2 + c_1 e^{-x}} \tag{2}$$

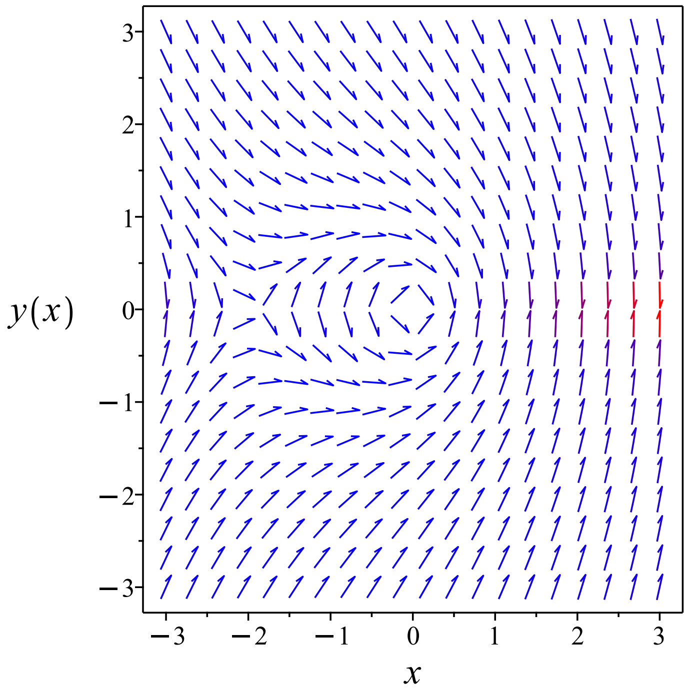

Figure 398: Slope field plot

Verification of solutions

$$y = \sqrt{-x^2 + c_1 e^{-x}}$$

Verified OK.

$$y = -\sqrt{-x^2 + c_1 e^{-x}}$$

Verified OK.

12.22.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(2y)\,\mathrm{d}y&=\left(-x^2-y^2-2x\right)\mathrm{d}x\\ \left(x^2+y^2+2x\right)\mathrm{d}x+(2y)\,\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=x^2+y^2+2x\\ N(x,y)&=2y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(x^2+y^2+2x\right)\\ &=2y\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2y) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{2y}((2y) - (0)) \\
&= 1
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int 1 \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{x} \\
&= \mathrm{e}^{x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{x}\left(x^2 + y^2 + 2x\right) \\
&= \mathrm{e}^{x}\left(x^2 + y^2 + 2x\right)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{x}(2y) \\
&= 2y\,\mathrm{e}^{x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\mathrm{e}^{x}\left(x^2 + y^2 + 2x\right)\right) + \left(2y\,\mathrm{e}^{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \mathrm{e}^{x} \left(x^2 + y^2 + 2x\right) \mathrm{d}x$$

$$\phi = \left(x^2 + y^2\right) \mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2y \, \mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2y \, \mathrm{e}^{x}$. Therefore equation (4) becomes

$$2y \, \mathrm{e}^{x} = 2y \, \mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \left(x^2 + y^2\right) \mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \left(x^2 + y^2\right) \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$\left(x^2+y^2\right) e^x = c_1 \tag{1}$$

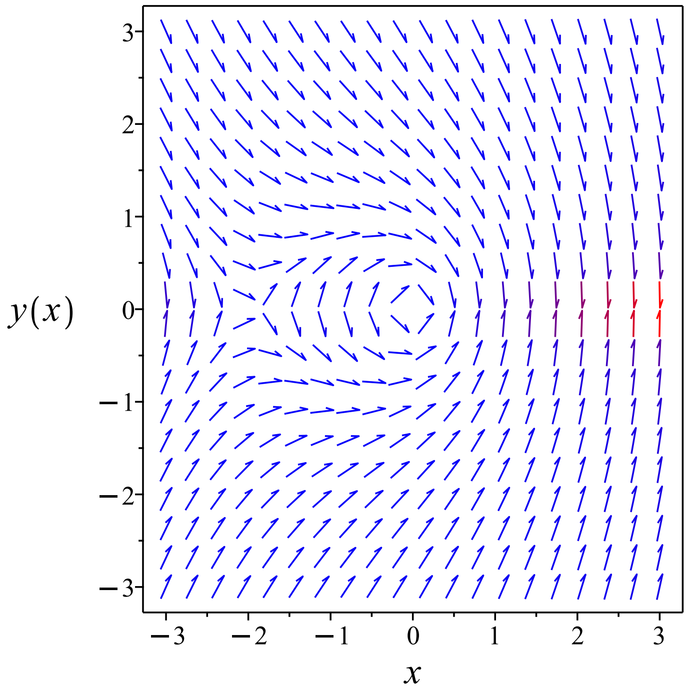

Figure 399: Slope field plot

Verification of solutions

$$\left(x^2+y^2\right) e^x = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$
\boxed{(x-1)\left(y^{2}-y+1\right)-(y-1)\left(x^{2}+x+1\right)y'=0}
$$

12.23.1 Solving as separable ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{(x-1)\left(y^{2}-y+1\right)}{(y-1)\left(x^{2}+x+1\right)}
\end{aligned}
$$

Where $f(x)=\frac{x-1}{x^{2}+x+1}$ and $g(y)=\frac{y^{2}-y+1}{y-1}$. Integrating both sides gives

$$
\frac{1}{\frac{y^{2}-y+1}{y-1}}\,dy = \frac{x-1}{x^{2}+x+1}\,dx
$$

$$
\int \frac{1}{\frac{y^{2}-y+1}{y-1}}\,dy = \int \frac{x-1}{x^{2}+x+1}\,dx
$$

$$\frac{\ln \left(y^{2}-y+1\right)}{2}-\frac{\sqrt{3}\, \arctan \left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3}=\frac{\ln \left(x^{2}+x+1\right)}{2}-\sqrt{3}\, \arctan \left(\frac{(2x+1)\sqrt{3}}{3}\right)+c_{1}$$

Which results in

12.23.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{x\,y^2 - xy - y^2 + x + y - 1}{x^2 y - x^2 + xy - x + y - 1} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 307: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{x^2+x+1}{x-1} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{x^2+x+1}{x-1}} dx
\end{aligned}
$$

Which results in

$$
S = \frac{\ln(x^2+x+1)}{2} - \sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{x\,y^2 - xy - y^2 + x + y - 1}{x^2y - x^2 + xy - x + y - 1}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{x-1}{x^2+x+1} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{y-1}{y^2-y+1} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R-1}{R^2-R+1}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{\ln(R^2-R+1)}{2} - \frac{\sqrt{3}\arctan\left(\frac{(2R-1)\sqrt{3}}{3}\right)}{3} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\ln(x^2+x+1)}{2} - \sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) = \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} + c_1
$$

Which simplifies to

$$
\frac{\ln(x^2+x+1)}{2} - \sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) = \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x\,y^2-xy-y^2+x+y-1}{x^2y-x^2+xy-x+y-1}$ 	$R = y$ $S = \frac{\ln(x^2+x+1)}{2} - \sqrt{3}$	$\frac{dS}{dR} = \frac{R-1}{R^2-R+1}$ 
Summary

The solution(s) found are the following

$$\frac{\ln(x^2+x+1)}{2} - \sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) = \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} + c_1 \tag{1}$$

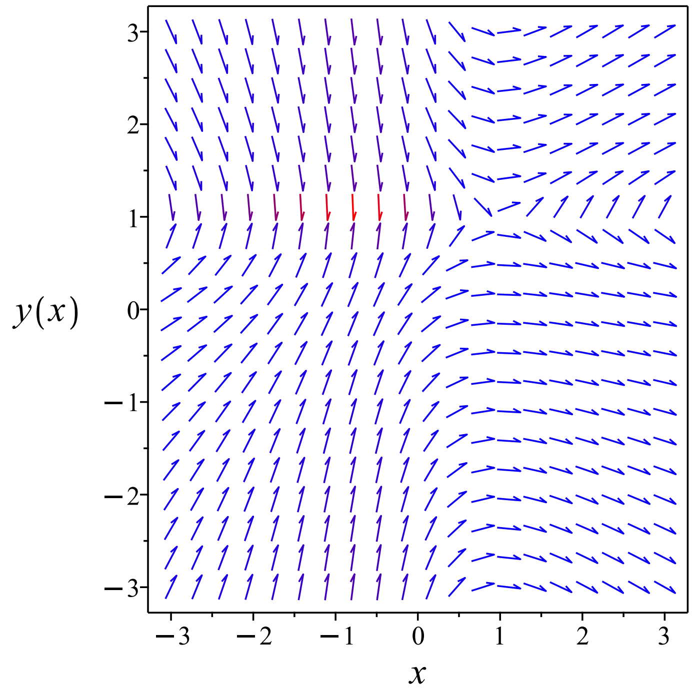

Figure 401: Slope field plot

Verification of solutions

$$\frac{\ln\left(x^2+x+1\right)}{2}-\sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)=\frac{\ln\left(y^2-y+1\right)}{2}-\frac{\sqrt{3}\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3}+c_1$$

Verified OK.

12.23.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y} \frac{d y}{d x}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \mathrm{d} x+N(x, y) \mathrm{d} y=0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(\frac{y-1}{y^2-y+1}\right) \mathrm{d} y &= \left(\frac{x-1}{x^2+x+1}\right) \mathrm{d} x \\
\left(-\frac{x-1}{x^2+x+1}\right) \mathrm{d} x+\left(\frac{y-1}{y^2-y+1}\right) \mathrm{d} y &= 0 \qquad \text{(2A)}
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= -\frac{x-1}{x^2+x+1} \\
N(x, y) &= \frac{y-1}{y^2-y+1}
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x-1}{x^2+x+1}\right) \\
&= 0
\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{y-1}{y^2-y+1}\right) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{x-1}{x^2+x+1}\,\mathrm{d}x\end{aligned}$$

$$\phi = -\frac{\ln(x^2+x+1)}{2} + \sqrt{3}\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y-1}{y^2-y+1}$. Therefore equation (4) becomes

$$\frac{y-1}{y^2-y+1} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y-1}{y^2-y+1}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{y-1}{y^2-y+1}\right) \mathrm{d}y$$

$$f(y) = \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x^2+x+1)}{2} + \sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) + \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x^2+x+1)}{2} + \sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) + \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3}$$

Summary

The solution(s) found are the following

$$-\frac{\ln(x^2+x+1)}{2} + \sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) + \frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} = c_1 \tag{1}$$

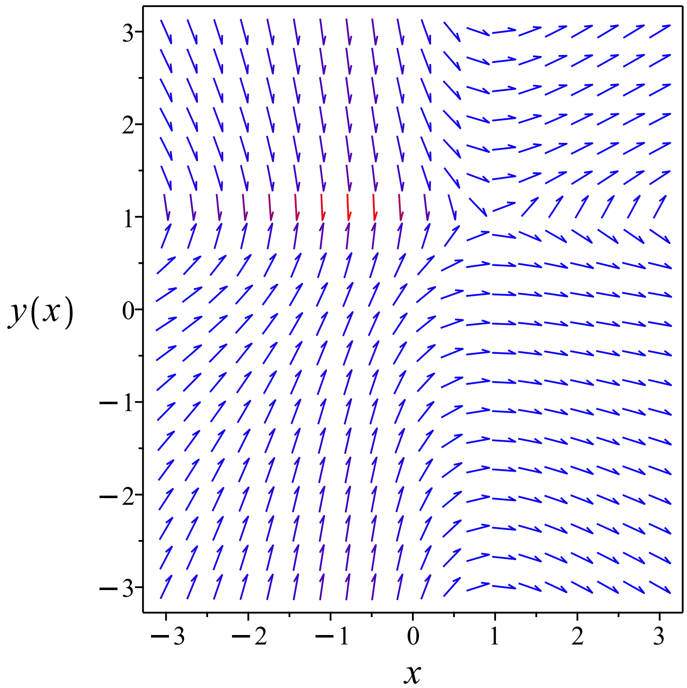

Figure 402: Slope field plot

Verification of solutions

$$-\frac{\ln\left(x^2+x+1\right)}{2}+\sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right)+\frac{\ln\left(y^2-y+1\right)}{2}-\frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3}=c_1$$

Verified OK.

12.23.4 Maple step by step solution

Let's solve

$(x-1)\left(y^2-y+1\right)-(y-1)\left(x^2+x+1\right)y'=0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(y-1)}{y^2-y+1}=\frac{x-1}{x^2+x+1}$

- Integrate both sides with respect to x

$$\int \frac{y'(y-1)}{y^2-y+1}dx = \int \frac{x-1}{x^2+x+1}dx + c_1$$

- Evaluate integral

$$\frac{\ln(y^2-y+1)}{2} - \frac{\sqrt{3}\,\arctan\left(\frac{(2y-1)\sqrt{3}}{3}\right)}{3} = \frac{\ln(x^2+x+1)}{2} - \sqrt{3}\,\arctan\left(\frac{(2x+1)\sqrt{3}}{3}\right) + c_1$$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x)*G(y),0]`]]
```

$$\boxed{(x - 2yx - y^2)\, y' + y^2 = 0}$$

12.24.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned}
y' &= \frac{y^2}{2xy + y^2 - x} \\
y' &= \omega(x, y)
\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 2 to use as anstaz gives

$$\xi = x^2 a_4 + xy a_5 + y^2 a_6 + x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x^2 b_4 + xy b_5 + y^2 b_6 + x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, b_1, b_2, b_3, b_4, b_5, b_6\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &2xb_4 + yb_5 + b_2 + \frac{y^2(-2xa_4 + xb_5 - ya_5 + 2yb_6 - a_2 + b_3)}{2xy + y^2 - x} \\ &- \frac{y^4(xa_5 + 2ya_6 + a_3)}{(2xy + y^2 - x)^2} + \frac{y^2(2y-1)\left(x^2a_4 + xya_5 + y^2a_6 + xa_2 + ya_3 + a_1\right)}{(2xy + y^2 - x)^2} \\ &- \left(\frac{2y}{2xy + y^2 - x} - \frac{y^2(2x+2y)}{(2xy + y^2 - x)^2}\right)\left(x^2b_4\right. \\ &\left. + xyb_5 + y^2b_6 + xb_2 + yb_3 + b_1\right) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{6x^3y^2b_4 - 2x^2y^3a_4 + 8x^2y^3b_4 + 4x^2y^3b_5 - 2x\,y^4a_4 - x\,y^4a_5 + 2x\,y^4b_4 + 5x\,y^4b_5 + 2x\,y^4b_6 - y^5a_5 + y^5b_5 +}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &6x^3y^2b_4 - 2x^2y^3a_4 + 8x^2y^3b_4 + 4x^2y^3b_5 - 2x\,y^4a_4 - x\,y^4a_5 + 2x\,y^4b_4 \\ &+ 5x\,y^4b_5 + 2x\,y^4b_6 - y^5a_5 + y^5b_5 + 2y^5b_6 - 6x^3yb_4 + x^2y^2a_4 \\ &+ 2x^2y^2b_2 - 4x^2y^2b_4 - 3x^2y^2b_5 + 4x\,y^3b_2 - 2x\,y^3b_5 - y^4a_2 \\ &+ y^4a_3 - y^4a_6 + y^4b_2 + y^4b_3 + 2x^3b_4 - 2x^2yb_2 + x^2yb_5 - 2x\,y^2b_1 \\ &- 2x\,y^2b_2 + x\,y^2b_3 + 2y^3a_1 - y^3a_3 + x^2b_2 + 2xyb_1 - y^2a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-2a_4v_1^2v_2^3 - 2a_4v_1v_2^4 - a_5v_1v_2^4 - a_5v_2^5 + 6b_4v_1^3v_2^2 + 8b_4v_1^2v_2^3 + 2b_4v_1v_2^4 \\
&+ 4b_5v_1^2v_2^3 + 5b_5v_1v_2^4 + b_5v_2^5 + 2b_6v_1v_2^4 + 2b_6v_2^5 - a_2v_2^4 + a_3v_2^4 \\
&+ a_4v_1^2v_2^2 - a_6v_2^4 + 2b_2v_1^2v_2^2 + 4b_2v_1v_2^3 + b_2v_2^4 + b_3v_2^4 - 6b_4v_1^3v_2 \\
&- 4b_4v_1^2v_2^2 - 3b_5v_1^2v_2^2 - 2b_5v_1v_2^3 + 2a_1v_2^3 - a_3v_2^3 - 2b_1v_1v_2^2 - 2b_2v_1^2v_2 \\
&- 2b_2v_1v_2^2 + b_3v_1v_2^2 + 2b_4v_1^3 + b_5v_1^2v_2 - a_1v_2^2 + 2b_1v_1v_2 + b_2v_1^2 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&6b_4v_1^3v_2^2 - 6b_4v_1^3v_2 + 2b_4v_1^3 + (-2a_4 + 8b_4 + 4b_5)\, v_1^2v_2^3 \\
&+ (a_4 + 2b_2 - 4b_4 - 3b_5)\, v_1^2v_2^2 + (-2b_2 + b_5)\, v_1^2v_2 + b_2v_1^2 \\
&+ (-2a_4 - a_5 + 2b_4 + 5b_5 + 2b_6)\, v_1v_2^4 + (4b_2 - 2b_5)\, v_1v_2^3 \\
&+ (-2b_1 - 2b_2 + b_3)\, v_1v_2^2 + 2b_1v_1v_2 + (-a_5 + b_5 + 2b_6)\, v_2^5 \\
&+ (-a_2 + a_3 - a_6 + b_2 + b_3)\, v_2^4 + (2a_1 - a_3)\, v_2^3 - a_1v_2^2 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
b_2 &= 0 \\
-a_1 &= 0 \\
2b_1 &= 0 \\
-6b_4 &= 0 \\
2b_4 &= 0 \\
6b_4 &= 0 \\
2a_1 - a_3 &= 0 \\
-2b_2 + b_5 &= 0 \\
4b_2 - 2b_5 &= 0 \\
-2a_4 + 8b_4 + 4b_5 &= 0 \\
-a_5 + b_5 + 2b_6 &= 0 \\
-2b_1 - 2b_2 + b_3 &= 0 \\
a_4 + 2b_2 - 4b_4 - 3b_5 &= 0 \\
-a_2 + a_3 - a_6 + b_2 + b_3 &= 0 \\
-2a_4 - a_5 + 2b_4 + 5b_5 + 2b_6 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -a_6 \\
a_3 &= 0 \\
a_4 &= 0 \\
a_5 &= 2b_6 \\
a_6 &= a_6 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 0 \\
b_4 &= 0 \\
b_5 &= 0 \\
b_6 &= b_6
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 2xy \\
\eta &= y^2
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y^2 - \left(\frac{y^2}{2xy + y^2 - x}\right)(2xy) \\
&= \frac{y^4 - x\,y^2}{2xy + y^2 - x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{y^4 - x\,y^2}{2xy + y^2 - x}} dy \end{aligned}$$

Which results in

$$S = -\frac{1}{y} - 2\ln(y) + \ln(y^2 - x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y^2}{2xy + y^2 - x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{-y^2 + x} \\ S_y &= \frac{-2xy - y^2 + x}{y^2(-y^2 + x)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{-2\ln (y)\, y + \ln (y^2 - x)\, y - 1}{y} = c_1$$

Which simplifies to

$$\frac{-2\ln (y)\, y + \ln (y^2 - x)\, y - 1}{y} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y^2}{2xy+y^2-x}$ 	$R = x$ $S = \frac{-2\ln (y)\, y + \ln (y^2 -}{y}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{-2\ln (y)\, y + \ln (y^2 - x)\, y - 1}{y} = c_1 \tag{1}$$

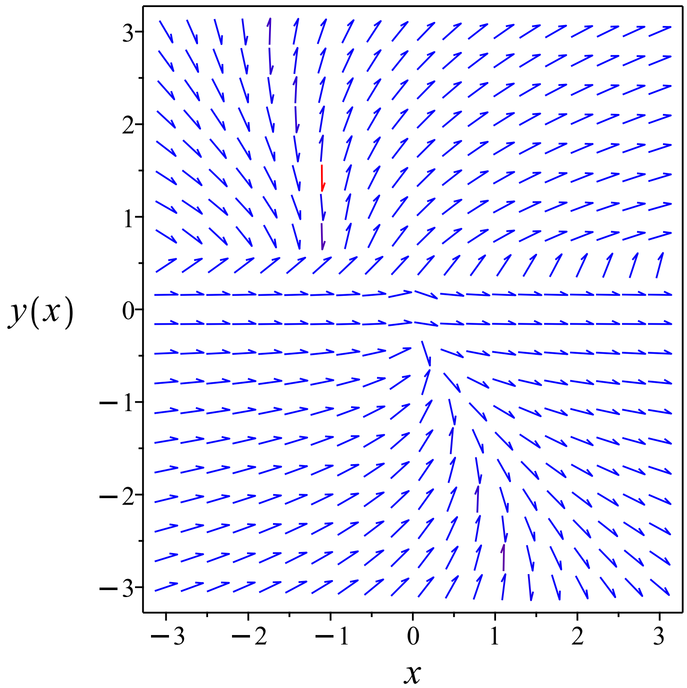

Figure 403: Slope field plot

Verification of solutions

$$\frac{-2\ln(y)\,y+\ln(y^2-x)\,y-1}{y}=c_1$$

Verified OK.

12.24.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
(-2xy - y^2 + x)\, \mathrm{d}y &= (-y^2)\, \mathrm{d}x \\
(y^2)\, \mathrm{d}x + (-2xy - y^2 + x)\, \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= y^2 \\
N(x, y) &= -2xy - y^2 + x
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y^2) \\
&= 2y
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-2xy - y^2 + x) \\
&= -2y + 1
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{-2xy - y^2 + x}((2y) - (-2y+1))\\ &= \frac{-4y+1}{2xy + y^2 - x}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\\ &= \frac{1}{y^2}((-2y+1) - (2y))\\ &= \frac{-4y+1}{y^2}\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}\mu &= e^{\int B \, \mathrm{d}y}\\ &= e^{\int \frac{-4y+1}{y^2} \, \mathrm{d}y}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-\frac{1}{y} - 4\ln(y)}\\ &= \frac{\mathrm{e}^{-\frac{1}{y}}}{y^4}\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{\mathrm{e}^{-\frac{1}{y}}}{y^4}(y^2)\\ &= \frac{\mathrm{e}^{-\frac{1}{y}}}{y^2}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{\mathrm{e}^{-\frac{1}{y}}}{y^4}\left(-2xy - y^2 + x\right) \\
&= \frac{\left(-2xy - y^2 + x\right)\mathrm{e}^{-\frac{1}{y}}}{y^4}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{\mathrm{e}^{-\frac{1}{y}}}{y^2}\right) + \left(\frac{\left(-2xy - y^2 + x\right)\mathrm{e}^{-\frac{1}{y}}}{y^4}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{\mathrm{e}^{-\frac{1}{y}}}{y^2}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{\mathrm{e}^{-\frac{1}{y}}x}{y^2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -\frac{2\,\mathrm{e}^{-\frac{1}{y}}x}{y^3} + \frac{\mathrm{e}^{-\frac{1}{y}}x}{y^4} + f'(y) \tag{4}
$$

$$
= \frac{x(-2y + 1)\,\mathrm{e}^{-\frac{1}{y}}}{y^4} + f'(y)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{(-2xy-y^2+x)\,\mathrm{e}^{-\frac{1}{y}}}{y^4}$. Therefore equation (4) becomes

$$\frac{(-2xy - y^2 + x)\,\mathrm{e}^{-\frac{1}{y}}}{y^4} = \frac{x(-2y+1)\,\mathrm{e}^{-\frac{1}{y}}}{y^4} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{\mathrm{e}^{-\frac{1}{y}}}{y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{\mathrm{e}^{-\frac{1}{y}}}{y^2}\right) \mathrm{d}y$$

$$f(y) = -\mathrm{e}^{-\frac{1}{y}} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\mathrm{e}^{-\frac{1}{y}} x}{y^2} - \mathrm{e}^{-\frac{1}{y}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\mathrm{e}^{-\frac{1}{y}} x}{y^2} - \mathrm{e}^{-\frac{1}{y}}$$

Summary

The solution(s) found are the following

$$\frac{\mathrm{e}^{-\frac{1}{y}} x}{y^2} - \mathrm{e}^{-\frac{1}{y}} = c_1 \tag{1}$$

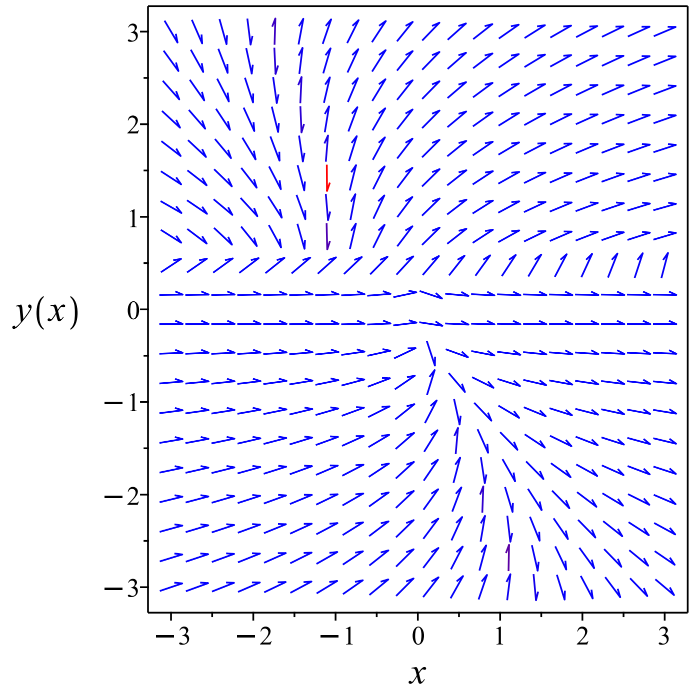

Figure 404: Slope field plot

Verification of solutions

$$\frac{e^{-\frac{1}{y}} x}{y^2} - e^{-\frac{1}{y}} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

```
[[_1st_order, `_with_symmetry_[F(x),G(y)]`], [_Abel, `2nd type
   `, `class A`]]
```

$$\boxed{\cos(x)\,y + (2y - \sin(x))\,y' = 0}$$

12.25.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2y - \sin(x))\,\mathrm{d}y &= (-y\cos(x))\,\mathrm{d}x\\ (y\cos(x))\,\mathrm{d}x + (2y - \sin(x))\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= y\cos(x)\\ N(x,y) &= 2y - \sin(x)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y\cos(x))\\ &= \cos(x)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2y - \sin(x))\\ &= -\cos(x)\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{2y - \sin(x)}((\cos(x)) - (-\cos(x))) \\ &= -\frac{2\cos(x)}{-2y + \sin(x)} \end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= \frac{\sec(x)}{y}((-\cos(x)) - (\cos(x))) \\ &= -\frac{2}{y} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \, \mathrm{d}y} \\ &= e^{\int -\frac{2}{y} \, \mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(y)} \\ &= \frac{1}{y^2} \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{y^2}(y\cos(x)) \\ &= \frac{\cos(x)}{y} \end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{y^2}(2y - \sin(x)) \\
&= \frac{2y - \sin(x)}{y^2}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{\cos(x)}{y}\right) + \left(\frac{2y - \sin(x)}{y^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \frac{\cos(x)}{y} \mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{\sin(x)}{y} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -\frac{\sin(x)}{y^2} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2y - \sin(x)}{y^2}$. Therefore equation (4) becomes

$$
\frac{2y - \sin(x)}{y^2} = -\frac{\sin(x)}{y^2} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{2}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{2}{y}\right) \mathrm{d}y$$
$$f(y) = 2\ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\sin(x)}{y} + 2\ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\sin(x)}{y} + 2\ln(y)$$

The solution becomes

$$y = \mathrm{e}^{\mathrm{LambertW}\left(-\frac{\sin(x)\mathrm{e}^{-\frac{c_1}{2}}}{2}\right)+\frac{c_1}{2}}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\mathrm{LambertW}\left(-\frac{\sin(x)\mathrm{e}^{-\frac{c_1}{2}}}{2}\right)+\frac{c_1}{2}} \tag{1}$$

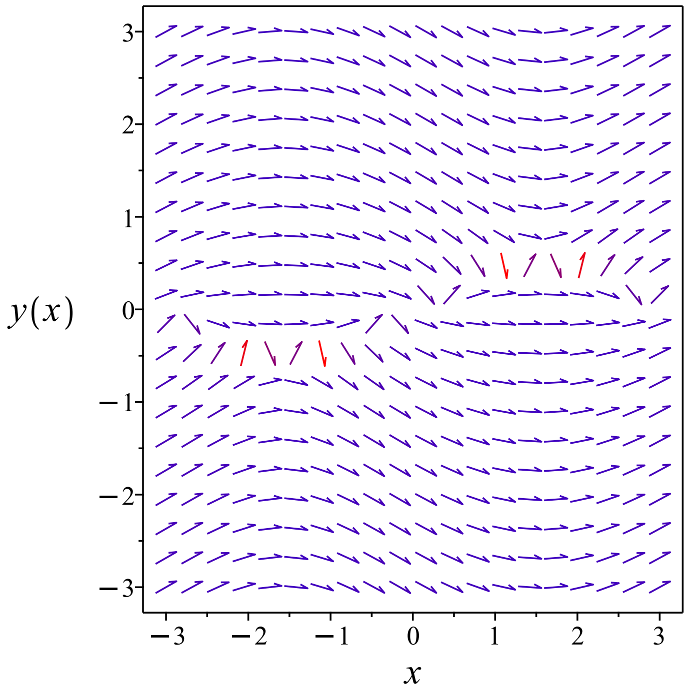

Figure 405: Slope field plot

Verification of solutions

$$y = e^{\mathrm{LambertW}\left(-\frac{\sin(x)\,e^{-\frac{c_1}{2}}}{2}\right)+\frac{c_1}{2}}$$

Verified OK.

The type(s) of ODE detected by this program : **"first order special form ID 1", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _dAlembert]
```

$$\boxed{y' - e^{x+2y} = 1}$$

12.26.1 Solving as first order special form ID 1 ode

Writing the ode as

$$y' = 1 + e^{x+2y} \tag{1}$$

And using the substitution $u = e^{-2y}$ then

$$u' = -2y' e^{-2y}$$

The above shows that

$$\begin{aligned} y' &= -\frac{u'(x) e^{2y}}{2} \\ &= -\frac{u'(x)}{2u} \end{aligned}$$

Substituting this in (1) gives

$$-\frac{u'(x)}{2u} = \frac{e^x}{u} + 1$$

The above simplifies to

$$
\begin{aligned}
-\frac{u'(x)}{2} &= e^{x}+u(x) \\
u'(x)+2u(x) &= -2\,e^{x} \qquad (2)
\end{aligned}
$$

Now ode (2) is solved for $u(x)$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
u'(x)+p(x)u(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= 2 \\
q(x) &= -2\,e^{x}
\end{aligned}
$$

Hence the ode is

$$
u'(x)+2u(x) = -2\,e^{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 2dx} \\
&= e^{2x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu u) &= (\mu)\left(-2\,e^{x}\right) \\
\frac{d}{dx}\left(e^{2x}u\right) &= \left(e^{2x}\right)\left(-2\,e^{x}\right) \\
d\left(e^{2x}u\right) &= \left(-2\,e^{3x}\right)\,dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{2x}u &= \int -2\,e^{3x}\,dx \\
e^{2x}u &= -\frac{2\,e^{3x}}{3}+c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$
u(x) = -\frac{2\,e^{-2x}e^{3x}}{3}+c_1e^{-2x}
$$

which simplifies to

$$u(x) = -\frac{(2\,\mathrm{e}^{3x} - 3c_1)\,\mathrm{e}^{-2x}}{3}$$

Substituting the solution found for $u(x)$ in $u = \mathrm{e}^{-2y}$ gives

$$\begin{aligned} y &= -\frac{\ln(u(x))}{2} \\ &= -\frac{\ln\left(-\frac{(2\,\mathrm{e}^{3x}-3c_1)\,\mathrm{e}^{-2x}}{3}\right)}{2} \\ &= \frac{\ln(3)}{2} - \frac{\ln\left((-2\,\mathrm{e}^{3x} + 3c_1)\,\mathrm{e}^{-2x}\right)}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\ln(3)}{2} - \frac{\ln\left((-2\,\mathrm{e}^{3x} + 3c_1)\,\mathrm{e}^{-2x}\right)}{2} \tag{1}$$

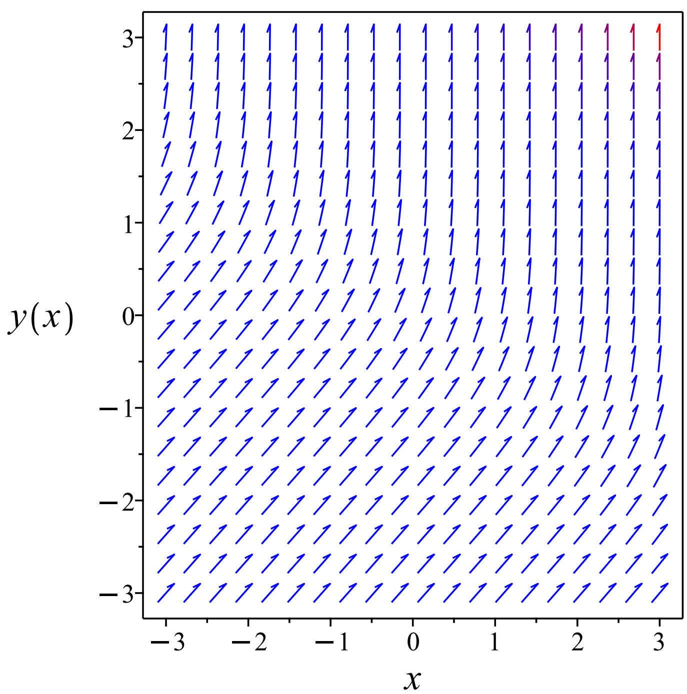

Figure 406: Slope field plot

Verification of solutions

$$y = \frac{\ln(3)}{2} - \frac{\ln\left((-2\,\mathrm{e}^{3x} + 3c_1)\,\mathrm{e}^{-2x}\right)}{2}$$

Verified OK.

12.26.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= 1 + e^{x+2y} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `first order special form ID 1`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 310: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \mathrm{e}^{-3x} \\
\eta(x,y) &= 1+\mathrm{e}^{-3x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Therefore

$$
\begin{aligned}
\frac{dy}{dx} &= \frac{\eta}{\xi} \\
&= \frac{1+\mathrm{e}^{-3x}}{\mathrm{e}^{-3x}} \\
&= 1+\mathrm{e}^{3x}
\end{aligned}
$$

This is easily solved to give

$$
y = x + \frac{\mathrm{e}^{3x}}{3} + c_1
$$

Where now the coordinate R is taken as the constant of integration. Hence

$$
R = -x - \frac{\mathrm{e}^{3x}}{3} + y
$$

And S is found from

$$
\begin{aligned}
dS &= \frac{dx}{\xi} \\
&= \frac{dx}{\mathrm{e}^{-3x}}
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
S &= \int \frac{dx}{T} \\
&= \frac{\mathrm{e}^{3x}}{3}
\end{aligned}
$$

Where the constant of integration is set to zero as we just need one solution. Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = 1 + \mathrm{e}^{x+2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= -1 - \mathrm{e}^{3x} \\ R_y &= 1 \\ S_x &= \mathrm{e}^{3x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\mathrm{e}^{3x}}{-\mathrm{e}^{3x} + \mathrm{e}^{x+2y}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{-1 + \mathrm{e}^{2R+2S(R)}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\mathrm{LambertW}\left(-\mathrm{e}^{2c_1}\mathrm{e}^{-2R}\right)}{2} - c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\mathrm{e}^{3x}}{3} = \frac{\mathrm{LambertW}\left(-\mathrm{e}^{2c_1}\mathrm{e}^{2x+\frac{2\,\mathrm{e}^{3x}}{3}-2y}\right)}{2} - c_1$$

Which simplifies to

$$\frac{\mathrm{e}^{3x}}{3}-\frac{\operatorname{LambertW}\left(-\mathrm{e}^{2c_1+2x+\frac{2\,\mathrm{e}^{3x}}{3}-2y}\right)}{2}+c_1=0$$

Which gives

$$y=c_1+x+\frac{\mathrm{e}^{3x}}{3}-\frac{\ln\left(-\frac{2\,\mathrm{e}^{\frac{2\,\mathrm{e}^{3x}}{3}+2c_1+3x}}{3}-2\,\mathrm{e}^{\frac{2\,\mathrm{e}^{3x}}{3}+2c_1}c_1\right)}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x,y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R,S)
$\frac{dy}{dx}=1+\mathrm{e}^{x+2y}$ 	$R=-x-\frac{\mathrm{e}^{3x}}{3}+y$ $S=\frac{\mathrm{e}^{3x}}{3}$	$\frac{dS}{dR}=\frac{1}{-1+\mathrm{e}^{2R+2S(R)}}$ 
Summary
The solution(s) found are the following

$$y=c_1+x+\frac{\mathrm{e}^{3x}}{3}-\frac{\ln\left(-\frac{2\,\mathrm{e}^{\frac{2\,\mathrm{e}^{3x}}{3}+2c_1+3x}}{3}-2\,\mathrm{e}^{\frac{2\,\mathrm{e}^{3x}}{3}+2c_1}c_1\right)}{2}\tag{1}$$

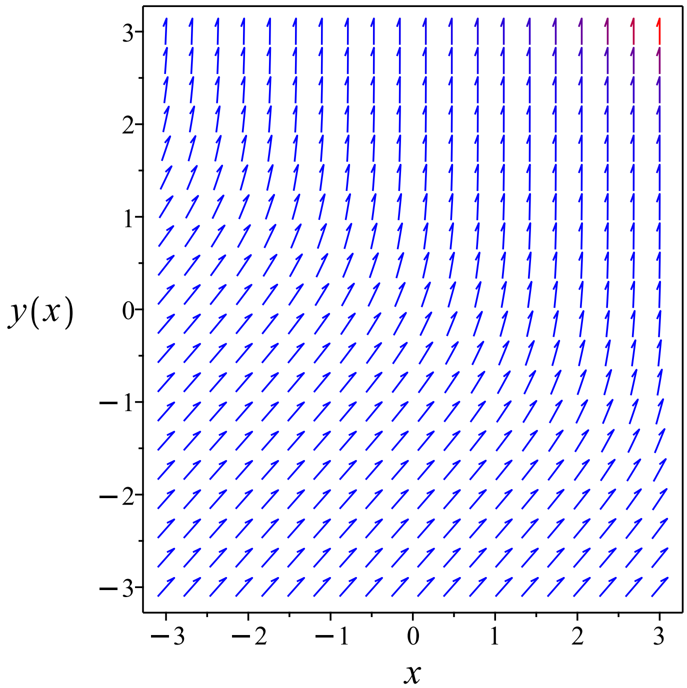

Figure 407: Slope field plot

Verification of solutions

$$y = c_1 + x + \frac{e^{3x}}{3} - \frac{\ln\left(-\frac{2\,e^{\frac{2\,e^{3x}}{3}+2c_1+3x}}{3} - 2\,e^{\frac{2\,e^{3x}}{3}+2c_1} c_1\right)}{2}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 12. Miscellaneous problems. Exercises page 93
Problem number: 301.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{4yx^3 - 2y^2x + \left(y^2 + 2yx^2 - x^4\right) y' = -2x^5}$$

12.27.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{2x(-x^4 - 2x^2y + y^2)}{-x^4 + 2x^2y + y^2} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}&b_2 + \frac{2x(-x^4 - 2x^2y + y^2)(b_3 - a_2)}{-x^4 + 2x^2y + y^2} - \frac{4x^2(-x^4 - 2x^2y + y^2)^2 a_3}{(-x^4 + 2x^2y + y^2)^2} \\ &- \left(\frac{-2x^4 - 4x^2y + 2y^2}{-x^4 + 2x^2y + y^2} + \frac{2x(-4x^3 - 4xy)}{-x^4 + 2x^2y + y^2} \right. \\ &\left. - \frac{2x(-x^4 - 2x^2y + y^2)(-4x^3 + 4xy)}{(-x^4 + 2x^2y + y^2)^2}\right)(xa_2 + ya_3 + a_1) \\ &- \left(\frac{2x(-2x^2 + 2y)}{-x^4 + 2x^2y + y^2} \right. \\ &\left. - \frac{2x(-x^4 - 2x^2y + y^2)(2x^2 + 2y)}{(-x^4 + 2x^2y + y^2)^2}\right)(xb_2 + yb_3 + b_1) = 0\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{4x^{10}a_3 + 4x^9a_2 - 2x^9b_3 + 18x^8ya_3 + 2x^8a_1 + 7x^8b_2 - 16x^7ya_2 + 8x^7yb_3 - 8x^6y^2a_3 + 8x^7b_1 - 16x^6ya_1 +}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}&-4x^{10}a_3 - 4x^9a_2 + 2x^9b_3 - 18x^8ya_3 - 2x^8a_1 - 7x^8b_2 + 16x^7ya_2 - 8x^7yb_3 \\ &+ 8x^6y^2a_3 - 8x^7b_1 + 16x^6ya_1 - 4x^6yb_2 + 24x^5y^2a_2 - 12x^5y^2b_3 + 28x^4y^3a_3 \\ &+ 12x^4y^2a_1 - 6x^4y^2b_2 + 16x^3y^3a_2 - 8x^3y^3b_3 + 12x^2y^4a_3 - 8x^3y^2b_1 \\ &+ 16x^2y^3a_1 + 4x^2y^3b_2 - 4x\,y^4a_2 + 2x\,y^4b_3 - 2y^5a_3 - 2y^4a_1 + y^4b_2 = 0\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-4a_3v_1^{10} - 4a_2v_1^9 - 18a_3v_1^8v_2 + 2b_3v_1^9 - 2a_1v_1^8 + 16a_2v_1^7v_2 + 8a_3v_1^6v_2^2 - 7b_2v_1^8 \\
&- 8b_3v_1^7v_2 + 16a_1v_1^6v_2 + 24a_2v_1^5v_2^2 + 28a_3v_1^4v_2^3 - 8b_1v_1^7 - 4b_2v_1^6v_2 - 12b_3v_1^5v_2^2 \\
&+ 12a_1v_1^4v_2^2 + 16a_2v_1^3v_2^3 + 12a_3v_1^2v_2^4 - 6b_2v_1^4v_2^2 - 8b_3v_1^3v_2^3 + 16a_1v_1^2v_2^3 \\
&- 4a_2v_1v_2^4 - 2a_3v_2^5 - 8b_1v_1^3v_2^2 + 4b_2v_1^2v_2^3 + 2b_3v_1v_2^4 - 2a_1v_2^4 + b_2v_2^4 = 0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&-4a_3v_1^{10} + (-4a_2 + 2b_3)\, v_1^9 - 18a_3v_1^8v_2 + (-2a_1 - 7b_2)\, v_1^8 + (16a_2 - 8b_3)\, v_1^7v_2 \\
&- 8b_1v_1^7 + 8a_3v_1^6v_2^2 + (16a_1 - 4b_2)\, v_1^6v_2 + (24a_2 - 12b_3)\, v_1^5v_2^2 + 28a_3v_1^4v_2^3 \\
&+ (12a_1 - 6b_2)\, v_1^4v_2^2 + (16a_2 - 8b_3)\, v_1^3v_2^3 - 8b_1v_1^3v_2^2 + 12a_3v_1^2v_2^4 \\
&+ (16a_1 + 4b_2)\, v_1^2v_2^3 + (-4a_2 + 2b_3)\, v_1v_2^4 - 2a_3v_2^5 + (-2a_1 + b_2)\, v_2^4 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-18a_3 &= 0 \\
-4a_3 &= 0 \\
-2a_3 &= 0 \\
8a_3 &= 0 \\
12a_3 &= 0 \\
28a_3 &= 0 \\
-8b_1 &= 0 \\
-2a_1 - 7b_2 &= 0 \\
-2a_1 + b_2 &= 0 \\
12a_1 - 6b_2 &= 0 \\
16a_1 - 4b_2 &= 0 \\
16a_1 + 4b_2 &= 0 \\
-4a_2 + 2b_3 &= 0 \\
16a_2 - 8b_3 &= 0 \\
24a_2 - 12b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 2a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= 2y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 2y - \left(\frac{2x(-x^4 - 2x^2y + y^2)}{-x^4 + 2x^2y + y^2}\right)(x) \\
&= \frac{-2x^6 - 2x^4y - 2x^2y^2 - 2y^3}{x^4 - 2x^2y - y^2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-2x^6 - 2x^4y - 2x^2y^2 - 2y^3}{x^4 - 2x^2y - y^2}} dy
\end{aligned}
$$

Which results in

$$S = \frac{\ln(x^4+y^2)}{2} - \frac{\ln(x^2+y)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2x(-x^4-2x^2y+y^2)}{-x^4+2x^2y+y^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{2x^3}{x^4+y^2} - \frac{x}{x^2+y} \\ S_y &= \frac{y}{x^4+y^2} - \frac{1}{2x^2+2y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y^2+x^4)}{2} - \frac{\ln(x^2+y)}{2} = c_1$$

Which simplifies to

$$\frac{\ln(y^2+x^4)}{2} - \frac{\ln(x^2+y)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2x(-x^4-2x^2y+y^2)}{-x^4+2x^2y+y^2}$ 	$R = x$ $S = \frac{\ln(x^4+y^2)}{2} - \frac{\ln(x^2}{2}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(y^2+x^4)}{2} - \frac{\ln(x^2+y)}{2} = c_1 \tag{1}$$

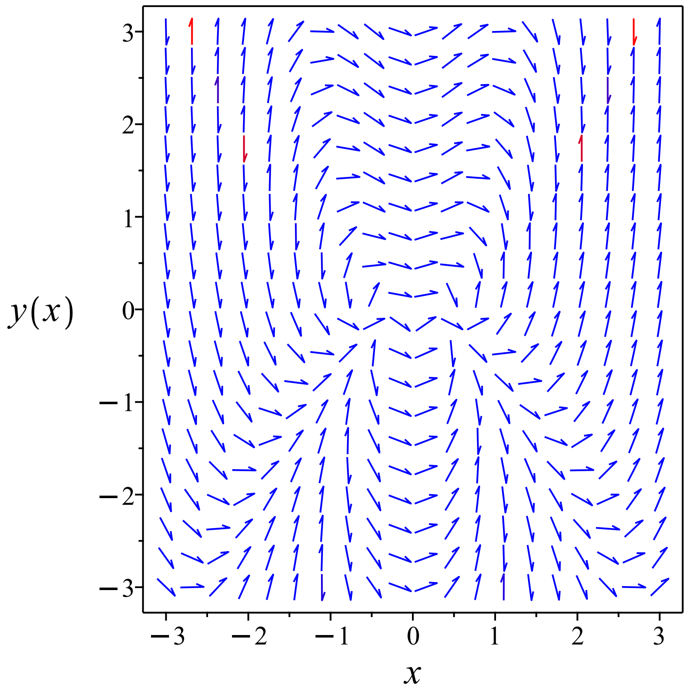

Figure 408: Slope field plot

Verification of solutions

$$\frac{\ln(y^2+x^4)}{2}-\frac{\ln(x^2+y)}{2}=c_1$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{x^2y^ny' - 2xy' + y = 0}$$

12.28.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{y}{x\,(y^nx-2)} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 - \frac{y(b_3 - a_2)}{x\,(y^n x - 2)} - \frac{y^2 a_3}{x^2\,(y^n x - 2)^2} \\ &- \left(\frac{y}{x^2\,(y^n x - 2)} + \frac{y\,y^n}{x\,(y^n x - 2)^2}\right)(x a_2 + y a_3 + a_1) \\ &- \left(-\frac{1}{x\,(y^n x - 2)} + \frac{y^n n}{(y^n x - 2)^2}\right)(x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{y^{2n} x^4 b_2 - y^n n\,x^3 b_2 - y^n n\,x^2 y b_3 - y^n n\,x^2 b_1 - 3y^n x^3 b_2 - y^n x^2 y a_2 - 2y^n x\,y^2 a_3 + y^n x^2 b_1 - 2y^n x y a_1 + 2b_2 x}{x^2\,(y^n x - 2)^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} &y^{2n} x^4 b_2 - y^n n\,x^3 b_2 - y^n n\,x^2 y b_3 - y^n n\,x^2 b_1 - 3y^n x^3 b_2 - y^n x^2 y a_2 \\ &- 2y^n x\,y^2 a_3 + y^n x^2 b_1 - 2y^n x y a_1 + 2b_2 x^2 + y^2 a_3 - 2x b_1 + 2y a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, y^n\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, y^n = v_3\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &v_3^2 v_1^4 b_2 - v_3 n v_1^3 b_2 - v_3 n v_1^2 v_2 b_3 - v_3 n v_1^2 b_1 - v_3 v_1^2 v_2 a_2 - 2v_3 v_1 v_2^2 a_3 \\ &- 3v_3 v_1^3 b_2 - 2v_3 v_1 v_2 a_1 + v_3 v_1^2 b_1 + v_2^2 a_3 + 2b_2 v_1^2 + 2v_2 a_1 - 2v_1 b_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$\begin{aligned} & v_3^2 v_1^4 b_2 + (-n b_2 - 3 b_2) v_1^3 v_3 + (-n b_3 - a_2) v_1^2 v_2 v_3 + (-n b_1 + b_1) v_1^2 v_3 \\ & + 2 b_2 v_1^2 - 2 v_3 v_1 v_2^2 a_3 - 2 v_3 v_1 v_2 a_1 - 2 v_1 b_1 + v_2^2 a_3 + 2 v_2 a_1 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_3 &= 0 \\ b_2 &= 0 \\ -2a_1 &= 0 \\ 2a_1 &= 0 \\ -2a_3 &= 0 \\ -2b_1 &= 0 \\ 2b_2 &= 0 \\ -nb_1 + b_1 &= 0 \\ -nb_2 - 3b_2 &= 0 \\ -nb_3 - a_2 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= -nb_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= -nx \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi \\ &= y - \left(-\frac{y}{x\,(y^n x - 2)}\right)(-nx) \\ &= \frac{y\,y^n x - yn - 2y}{y^n x - 2} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{y\,y^n x - yn - 2y}{y^n x - 2}} dy\end{aligned}$$

Which results in

$$S = \frac{2\ln(y)}{n+2} + \frac{\ln\left(-\mathrm{e}^{n\ln(y)} x + n + 2\right)}{n+2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y}{x\,(y^n x - 2)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{y^n}{(n+2)\,(n-y^n x+2)} \\
S_y &= \frac{-y^n x+2}{y\,(n-y^n x+2)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{(n+2)\,x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{(n+2)\,R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{\ln(R)}{n+2} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{2\ln(y)+\ln(n-y^n x+2)}{n+2} = \frac{\ln(x)}{n+2} + c_1
$$

Which simplifies to

$$
\frac{2\ln(y)+\ln(n-y^n x+2)}{n+2} = \frac{\ln(x)}{n+2} + c_1
$$

Summary

The solution(s) found are the following

$$
\frac{2\ln(y)+\ln(n-y^n x+2)}{n+2} = \frac{\ln(x)}{n+2} + c_1 \tag{1}
$$

Verification of solutions

$$
\frac{2\ln(y)+\ln(n-y^n x+2)}{n+2} = \frac{\ln(x)}{n+2} + c_1
$$

Verified OK.

$$\boxed{(3y+3x+a^2)\,y'-4y=b^2+4x}$$

12.29.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{b^2+4x+4y}{a^2+3x+3y}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{(b^2+4x+4y)(b_3-a_2)}{a^2+3x+3y} - \frac{(b^2+4x+4y)^2 a_3}{(a^2+3x+3y)^2} - \left(\frac{4}{a^2+3x+3y} - \frac{3(b^2+4x+4y)}{(a^2+3x+3y)^2}\right)(xa_2+ya_3+a_1) - \left(\frac{4}{a^2+3x+3y} - \frac{3(b^2+4x+4y)}{(a^2+3x+3y)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{a^4b_2 - a^2b^2a_2 + a^2b^2b_3 - b^4a_3 - 8a^2xa_2 + 2a^2xb_2 + 4a^2xb_3 - 4a^2ya_2 - 4a^2ya_3 + 6a^2yb_2 - 8b^2xa_3 + 3b^2xb}{}$$

$$= 0$$

Setting the numerator to zero gives

$$a^4b_2 - a^2b^2a_2 + a^2b^2b_3 - b^4a_3 - 8a^2xa_2 + 2a^2xb_2 + 4a^2xb_3 - 4a^2ya_2 - 4a^2ya_3 + 6a^2yb_2 - 8b^2xa_3 + 3b^2xb_2 + 3b^2xb_3 - 3b^2ya_2 - 5b^2ya_3 + 6b^2yb_3 - 4a^2a_1 - 4a^2b_1 + 3b^2a_1 + 3b^2b_1 - 12x^2a_2 - 16x^2a_3 + 9x^2b_2 + 12x^2b_3 - 24xya_2 - 32xya_3 + 18xyb_2 + 24xyb_3 - 12y^2a_2 - 16y^2a_3 + 9y^2b_2 + 12y^2b_3 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$a^4b_2 - a^2b^2a_2 + a^2b^2b_3 - b^4a_3 - 8a^2a_2v_1 - 4a^2a_2v_2 - 4a^2a_3v_2 + 2a^2b_2v_1 + 6a^2b_2v_2 + 4a^2b_3v_1 - 3b^2a_2v_2 - 8b^2a_3v_1 - 5b^2a_3v_2 + 3b^2b_2v_1 + 3b^2b_3v_1 + 6b^2b_3v_2 - 4a^2a_1 - 4a^2b_1 + 3b^2a_1 + 3b^2b_1 - 12a_2v_1^2 - 24a_2v_1v_2 - 12a_2v_2^2 - 16a_3v_1^2 - 32a_3v_1v_2 - 16a_3v_2^2 + 9b_2v_1^2 + 18b_2v_1v_2 + 9b_2v_2^2 + 12b_3v_1^2 + 24b_3v_1v_2 + 12b_3v_2^2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(-12a_2 - 16a_3 + 9b_2 + 12b_3) v_1^2 + (-24a_2 - 32a_3 + 18b_2 + 24b_3) v_1 v_2 \\
&+ \left(-8a^2a_2 + 2a^2b_2 + 4a^2b_3 - 8b^2a_3 + 3b^2b_2 + 3b^2b_3\right) v_1 \\
&+ (-12a_2 - 16a_3 + 9b_2 + 12b_3) v_2^2 \\
&+ \left(-4a^2a_2 - 4a^2a_3 + 6a^2b_2 - 3b^2a_2 - 5b^2a_3 + 6b^2b_3\right) v_2 + a^4b_2 \\
&- a^2b^2a_2 + a^2b^2b_3 - b^4a_3 - 4a^2a_1 - 4a^2b_1 + 3b^2a_1 + 3b^2b_1 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-24a_2 - 32a_3 + 18b_2 + 24b_3 &= 0 \\
-12a_2 - 16a_3 + 9b_2 + 12b_3 &= 0 \\
-8a^2a_2 + 2a^2b_2 + 4a^2b_3 - 8b^2a_3 + 3b^2b_2 + 3b^2b_3 &= 0 \\
-4a^2a_2 - 4a^2a_3 + 6a^2b_2 - 3b^2a_2 - 5b^2a_3 + 6b^2b_3 &= 0 \\
a^4b_2 - a^2b^2a_2 + a^2b^2b_3 - b^4a_3 - 4a^2a_1 - 4a^2b_1 + 3b^2a_1 + 3b^2b_1 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= \frac{1}{3}a^2a_3 + \frac{1}{3}b^2a_3 - b_1 \\
a_2 &= a_3 \\
a_3 &= a_3 \\
b_1 &= b_1 \\
b_2 &= \frac{4a_3}{3} \\
b_3 &= \frac{4a_3}{3}
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= -1 \\
\eta &= 1
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 1 - \left(\frac{b^2+4x+4y}{a^2+3x+3y}\right)(-1) \\
&= \frac{a^2+b^2+7x+7y}{a^2+3x+3y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{a^2+b^2+7x+7y}{a^2+3x+3y}} dy
\end{aligned}
$$

Which results in

$$
S = \frac{3y}{7} + \left(\frac{4a^2}{49} - \frac{3b^2}{49}\right) \ln\left(a^2+b^2+7x+7y\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{b^2+4x+4y}{a^2+3x+3y}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{4a^2 - 3b^2}{7a^2 + 7b^2 + 49x + 49y} \\
S_y &= \frac{a^2 + 3x + 3y}{a^2 + b^2 + 7x + 7y}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{4}{7} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{4}{7}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{4R}{7} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{3y}{7} + \frac{(4a^2 - 3b^2)\ln(a^2 + b^2 + 7x + 7y)}{49} = \frac{4x}{7} + c_1
$$

Which simplifies to

$$
\frac{3y}{7} + \frac{(4a^2 - 3b^2)\ln(a^2 + b^2 + 7x + 7y)}{49} = \frac{4x}{7} + c_1
$$

Which gives

$$
y = \frac{4\,\mathrm{LambertW}\left(\frac{3\,\mathrm{e}^{\frac{3a^2+3b^2+49c_1+49x}{4a^2-3b^2}}}{4a^2-3b^2}\right) a^2}{21} - \frac{\mathrm{LambertW}\left(\frac{3\,\mathrm{e}^{\frac{3a^2+3b^2+49c_1+49x}{4a^2-3b^2}}}{4a^2-3b^2}\right) b^2}{7} - \frac{a^2}{7} - \frac{b^2}{7} - x
$$

Summary

The solution(s) found are the following

$$
y = \frac{4\,\text{LambertW}\left(\frac{3\,\mathrm{e}^{\frac{3a^2+3b^2+49c_1+49x}{4a^2-3b^2}}}{4a^2-3b^2}\right)a^2}{21} - \frac{\text{LambertW}\left(\frac{3\,\mathrm{e}^{\frac{3a^2+3b^2+49c_1+49x}{4a^2-3b^2}}}{4a^2-3b^2}\right)b^2}{7} - \frac{a^2}{7} - \frac{b^2}{7} - x \tag{1}
$$

Verification of solutions

$$
y = \frac{4\,\text{LambertW}\left(\frac{3\,\mathrm{e}^{\frac{3a^2+3b^2+49c_1+49x}{4a^2-3b^2}}}{4a^2-3b^2}\right)a^2}{21} - \frac{\text{LambertW}\left(\frac{3\,\mathrm{e}^{\frac{3a^2+3b^2+49c_1+49x}{4a^2-3b^2}}}{4a^2-3b^2}\right)b^2}{7} - \frac{a^2}{7} - \frac{b^2}{7} - x
$$

Verified OK.

The type(s) of ODE detected by this program : **"bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Bernoulli]
```

$$\boxed{-y^2 + 2y'yx = -x}$$

12.30.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y^2 - x}{2yx}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 312: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \frac{x}{y} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2}{2x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y^2 - x}{2yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y^2}{2x^2} \\ S_y &= \frac{y}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{2x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{2R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x} = -\frac{\ln(x)}{2} + c_1$$

Which simplifies to

$$\frac{y^2}{2x} = -\frac{\ln(x)}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y^2-x}{2yx}$ 	$R = x$ $S = \frac{y^2}{2x}$	$\frac{dS}{dR} = -\frac{1}{2R}$ 
Summary

The solution(s) found are the following

$$\frac{y^2}{2x} = -\frac{\ln(x)}{2} + c_1 \tag{1}$$

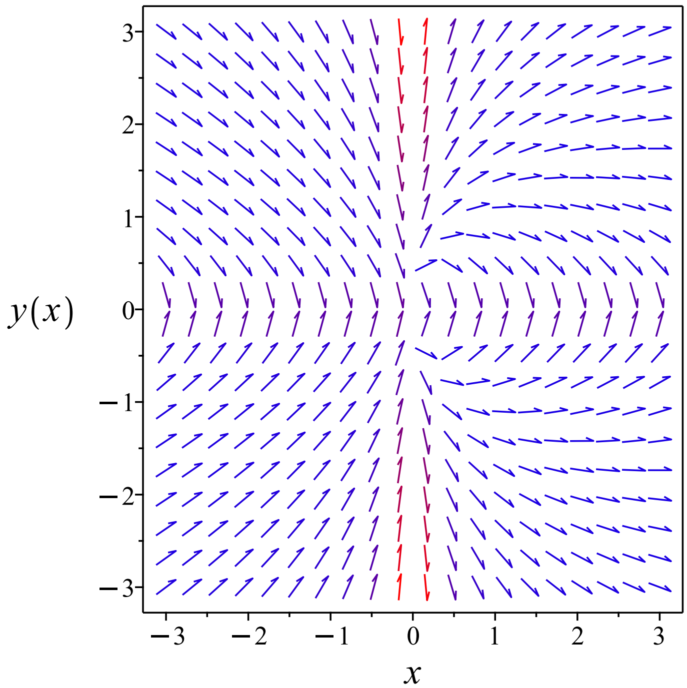

Figure 409: Slope field plot

Verification of solutions

$$\frac{y^2}{2x} = -\frac{\ln(x)}{2} + c_1$$

Verified OK.

12.30.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{y^2 - x}{2yx} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{2x}y - \frac{1}{2}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{1}{2x} \\ f_1(x) &= -\frac{1}{2} \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = \frac{y^2}{2x} - \frac{1}{2} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= \frac{w(x)}{2x} - \frac{1}{2} \\ w' &= \frac{w}{x} - 1 \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= -1 \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{w(x)}{x} = -1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)(-1) \\ \frac{d}{dx}\left(\frac{w}{x}\right) &= \left(\frac{1}{x}\right)(-1) \\ d\left(\frac{w}{x}\right) &= \left(-\frac{1}{x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x} &= \int -\frac{1}{x} dx \\ \frac{w}{x} &= -\ln(x) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$w(x) = -\ln(x)\,x + c_1 x$$

which simplifies to

$$w(x) = x(-\ln(x) + c_1)$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = x(-\ln(x) + c_1)$$

Solving for y gives

$$\begin{aligned}y(x) &= \sqrt{-x(\ln(x) - c_1)} \\ y(x) &= -\sqrt{x(-\ln(x) + c_1)}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-x(\ln(x) - c_1)} \tag{1}$$

$$y = -\sqrt{x(-\ln(x) + c_1)} \tag{2}$$

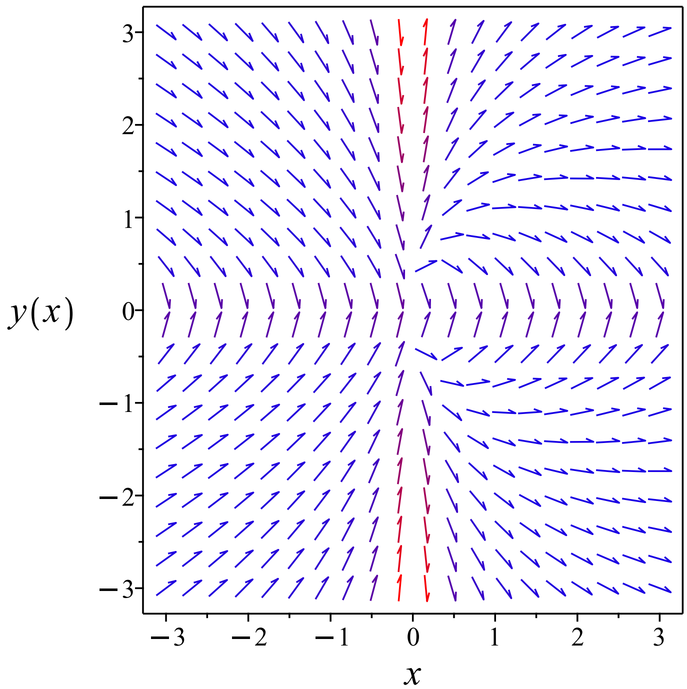

Figure 410: Slope field plot

Verification of solutions

$$y = \sqrt{-x(\ln(x) - c_1)}$$

Verified OK.

$$y = -\sqrt{x(-\ln(x) + c_1)}$$

Verified OK.

12.30.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(2xy)\,\mathrm{d}y&=\left(y^2-x\right)\mathrm{d}x\\ \left(-y^2+x\right)\mathrm{d}x+(2xy)\,\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-y^2+x\\ N(x,y)&=2xy\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y^2 + x)\\ &= -2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2xy)\\ &= 2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2xy}((-2y) - (2y))\\ &= -\frac{2}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}x}\\ &= e^{\int -\frac{2}{x} \,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(x)}\\ &= \frac{1}{x^2}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^2}(-y^2 + x)\\ &= \frac{-y^2 + x}{x^2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{x^2}(2xy)\\ &= \frac{2y}{x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(\frac{-y^2 + x}{x^2}\right) + \left(\frac{2y}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x\\ \int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\frac{-y^2 + x}{x^2}\,\mathrm{d}x\end{aligned}$$

$$\phi = \frac{y^2}{x} + \ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \frac{2y}{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \frac{2y}{x}$. Therefore equation (4) becomes

$$\frac{2y}{x} = \frac{2y}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{y^2}{x} + \ln(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{y^2}{x} + \ln(x)$$

Summary

The solution(s) found are the following

$$\frac{y^2}{x} + \ln(x) = c_1 \tag{1}$$

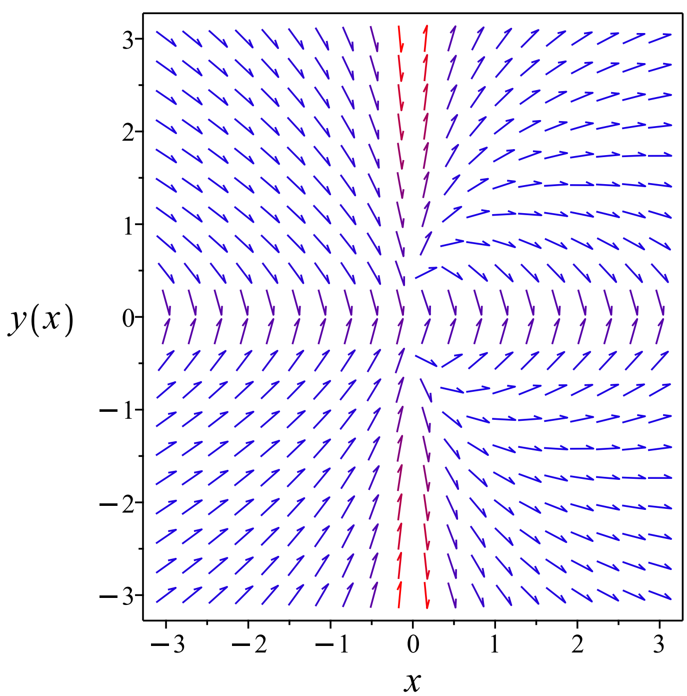

Figure 411: Slope field plot

Verification of solutions

$$\frac{y^2}{x}+\ln(x)=c_1$$

The type(s) of ODE detected by this program : **"riccati", "bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_Bernoulli]`

$$\boxed{xy' + y - y^2 \ln(x) = 0}$$

With initial conditions

$$\left[y(1) = \frac{1}{2}\right]$$

12.31.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= \frac{y(\ln(x) y - 1)}{x} \end{aligned}$$

The x domain of $f(x, y)$ when $y = \frac{1}{2}$ is

$$\{0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x, y)$ when $x = 1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = \frac{1}{2}$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y(\ln(x)\, y - 1)}{x}\right) \\
&= \frac{\ln(x)\, y - 1}{x} + \frac{\ln(x)\, y}{x}
\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = \frac{1}{2}$ is

$$\{0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = \frac{1}{2}$ is inside this domain. Therefore solution exists and is unique.

12.31.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned}
y' &= \frac{y(\ln(x)\, y - 1)}{x} \\
y' &= \omega(x, y)
\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 314: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= x\, y^2
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{x\,y^2} dy
\end{aligned}$$

Which results in

$$S = -\frac{1}{xy}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y(\ln(x)\,y - 1)}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{x^2 y} \\
S_y &= \frac{1}{x\,y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\ln(x)}{x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{\ln(R)}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{R} - \frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{xy} = -\frac{\ln(x)}{x} - \frac{1}{x} + c_1$$

Which simplifies to

$$\frac{-c_1 xy + \ln(x)\, y + y - 1}{xy} = 0$$

Which gives

$$y = \frac{1}{-c_1 x + \ln(x) + 1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y(\ln(x)y-1)}{x}$ 	$R = x$ $S = -\frac{1}{xy}$	$\frac{dS}{dR} = \frac{\ln(R)}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = -\frac{1}{-1 + c_1}$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$y = \frac{1}{x + \ln(x) + 1}$$

Summary
The solution(s) found are the following

$$y = \frac{1}{x + \ln(x) + 1} \tag{1}$$

Verification of solutions

$$y = \frac{1}{x + \ln(x) + 1}$$

Verified OK.

12.31.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{y(\ln(x)\, y-1)}{x} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{x}y + \frac{\ln(x)}{x}y^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{1}{x} \\ f_1(x) &= \frac{\ln(x)}{x} \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = -\frac{1}{xy} + \frac{\ln(x)}{x} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
-w'(x) &= -\frac{w(x)}{x} + \frac{\ln(x)}{x} \\
w' &= \frac{w}{x} - \frac{\ln(x)}{x}
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= -\frac{\ln(x)}{x}
\end{aligned}
$$

Hence the ode is

$$
w'(x) - \frac{w(x)}{x} = -\frac{\ln(x)}{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu w) &= (\mu)\left(-\frac{\ln(x)}{x}\right) \\
\frac{d}{dx}\left(\frac{w}{x}\right) &= \left(\frac{1}{x}\right)\left(-\frac{\ln(x)}{x}\right) \\
d\left(\frac{w}{x}\right) &= \left(-\frac{\ln(x)}{x^2}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{w}{x} &= \int -\frac{\ln(x)}{x^2} dx \\
\frac{w}{x} &= \frac{\ln(x)}{x} + \frac{1}{x} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$w(x) = x\left(\frac{\ln(x)}{x} + \frac{1}{x}\right) + c_1 x$$

which simplifies to

$$w(x) = c_1 x + \ln(x) + 1$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$\frac{1}{y} = c_1 x + \ln(x) + 1$$

Or

$$y = \frac{1}{c_1 x + \ln(x) + 1}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = \frac{1}{c_1 + 1}$$

$$c_1 = 1$$

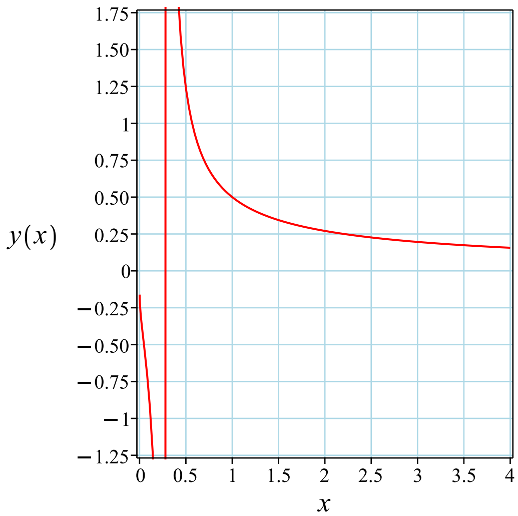
Substituting c_1 found above in the general solution gives

$$y = \frac{1}{x + \ln(x) + 1}$$

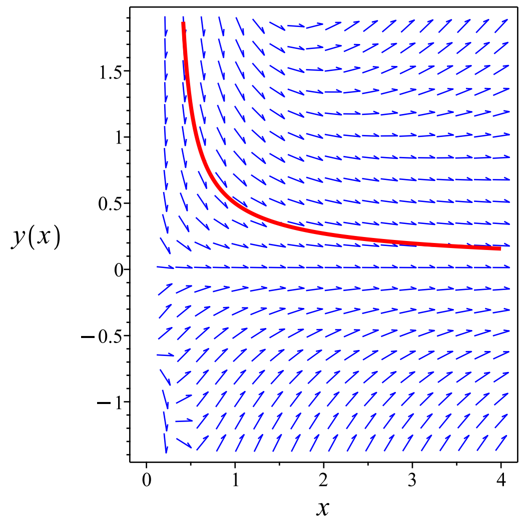
Summary

The solution(s) found are the following

$$y = \frac{1}{x + \ln(x) + 1} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{x + \ln(x) + 1}$$

Verified OK.

12.31.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y &= \left(-y + y^2\ln(x)\right)\mathrm{d}x\\ \left(-y^2\ln(x) + y\right)\mathrm{d}x + (x)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -y^2\ln(x) + y\\ N(x,y) &= x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y^2\ln(x) + y\right)\\ &= -2\ln(x)\,y + 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{x}\left(\left(-2\ln(x)\,y + 1\right) - (1)\right)\\ &= -\frac{2\ln(x)\,y}{x}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= -\frac{1}{y(\ln(x)\,y-1)}((1)-(-2\ln(x)\,y+1)) \\ &= -\frac{2\ln(x)}{\ln(x)\,y-1} \end{aligned}$$

Since B depends on x, it can not be used to obtain an integrating factor.We will now try a third method to find an integrating factor. Let

$$R = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN}$$

R is now checked to see if it is a function of only $t = xy$. Therefore

$$\begin{aligned} R &= \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN} \\ &= \frac{(1)-(-2\ln(x)\,y+1)}{x(-y^2\ln(x)+y)-y(x)} \\ &= -\frac{2}{xy} \end{aligned}$$

Replacing all powers of terms xy by t gives

$$R = -\frac{2}{t}$$

Since R depends on t only, then it can be used to find an integrating factor. Let the integrating factor be μ then

$$\begin{aligned} \mu &= e^{\int R\,\mathrm{d}t} \\ &= e^{\int \left(-\frac{2}{t}\right)\mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(t)} \\ &= \frac{1}{t^2} \end{aligned}$$

Now t is replaced back with xy giving

$$\mu = \frac{1}{x^2y^2}$$

Multiplying M and N by this integrating factor gives new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^2y^2}\left(-y^2\ln\left(x\right)+y\right) \\
&= \frac{-\ln\left(x\right)y+1}{x^2y}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^2y^2}(x) \\
&= \frac{1}{x\,y^2}
\end{aligned}
$$

A modified ODE is now obtained from the original ODE, which is exact and can solved. The modified ODE is

$$
\begin{aligned}
\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{-\ln\left(x\right)y+1}{x^2y}\right)+\left(\frac{1}{x\,y^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x \\
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\frac{-\ln\left(x\right)y+1}{x^2y}\,\mathrm{d}x \\
\phi &= \frac{\ln\left(x\right)y+y-1}{xy}+f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{\ln(x)+1}{xy} - \frac{\ln(x)\, y + y - 1}{x\, y^2} + f'(y) \tag{4}$$
$$= \frac{1}{x\, y^2} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{x\, y^2}$. Therefore equation (4) becomes

$$\frac{1}{x\, y^2} = \frac{1}{x\, y^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\ln(x)\, y + y - 1}{xy} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\ln(x)\, y + y - 1}{xy}$$

The solution becomes

$$y = \frac{1}{-c_1 x + \ln(x) + 1}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = -\frac{1}{-1 + c_1}$$

$$c_1 = -1$$

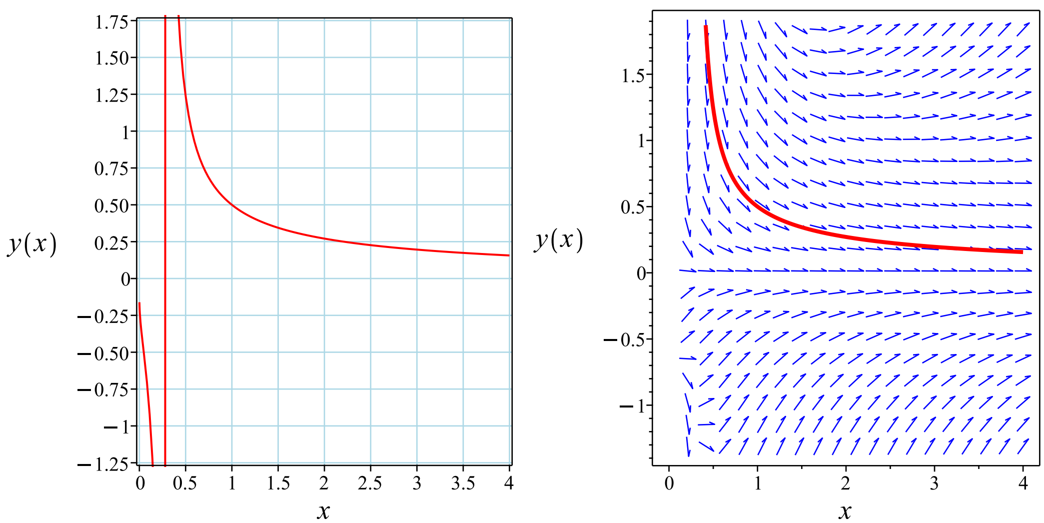
Substituting c_1 found above in the general solution gives

$$y = \frac{1}{x + \ln(x) + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{x + \ln(x) + 1} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{1}{x + \ln(x) + 1}$$

Verified OK.

12.31.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\ &= \frac{y(\ln(x)\,y-1)}{x}\end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{y^2\ln(x)}{x} - \frac{y}{x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = -\frac{1}{x}$ and $f_2(x) = \frac{\ln(x)}{x}$. Let

$$\begin{aligned}y &= \frac{-u'}{f_2 u}\\ &= \frac{-u'}{\frac{\ln(x)u}{x}}\end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned}f_2' &= -\frac{\ln(x)}{x^2} + \frac{1}{x^2}\\ f_1f_2 &= -\frac{\ln(x)}{x^2}\\ f_2^2f_0 &= 0\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\frac{\ln(x)\,u''(x)}{x} - \left(-\frac{2\ln(x)}{x^2} + \frac{1}{x^2}\right)u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \frac{-c_2\ln(x) + c_1x - c_2}{x}$$

The above shows that

$$u'(x) = \frac{c_2 \ln(x)}{x^2}$$

Using the above in (1) gives the solution

$$y = -\frac{c_2}{-c_2 \ln(x) + c_1 x - c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{1}{-c_3 x + \ln(x) + 1}$$

Initial conditions are used to solve for c_3. Substituting $x = 1$ and $y = \frac{1}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = -\frac{1}{c_3 - 1}$$

$$c_3 = -1$$

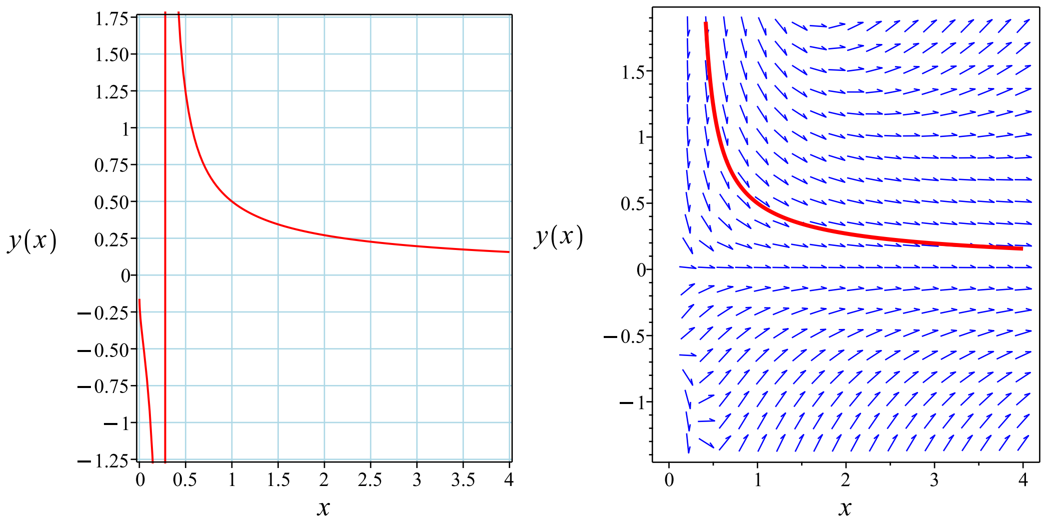
Substituting c_3 found above in the general solution gives

$$y = \frac{1}{x + \ln(x) + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{x + \ln(x) + 1} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{1}{x + \ln(x) + 1}$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$
\boxed{-\cos\left(\ln\left(y\right)\right) y' = -\sin\left(\ln\left(x\right)\right)}
$$

12.32.1 Solving as separable ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{\sin\left(\ln\left(x\right)\right)}{\cos\left(\ln\left(y\right)\right)}
\end{aligned}
$$

Where $f(x) = \sin\left(\ln\left(x\right)\right)$ and $g(y) = \frac{1}{\cos(\ln(y))}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{1}{\cos(\ln(y))}}\,dy &= \sin\left(\ln\left(x\right)\right)\,dx \\
\int \frac{1}{\frac{1}{\cos(\ln(y))}}\,dy &= \int \sin\left(\ln\left(x\right)\right)\,dx
\end{aligned}
$$

$$\frac{\cos(\ln(y))\, y}{2}+\frac{\sin(\ln(y))\, y}{2}=-\frac{\cos(\ln(x))\, x}{2}+\frac{\sin(\ln(x))\, x}{2}+c_1$$

Which results in

$$y = \mathrm{e}^{\mathrm{RootOf}\left(-2\sin(\ln(x))\sin(\_Z)\mathrm{e}^{\_Z}x+2\sin(\_Z)^2\mathrm{e}^{2\_Z}+2\sin(\_Z)\cos(\ln(x))\mathrm{e}^{\_Z}x+4c_1x\sin(\ln(x))-4\sin(\_Z)\mathrm{e}^{\_Z}c_1-4\cos(\ln(x))c_1x-x^2\sin(2\right.}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\mathrm{RootOf}\left(-2\sin(\ln(x))\sin(\_Z)\mathrm{e}^{\_Z}x+2\sin(\_Z)^2\mathrm{e}^{2\_Z}+2\sin(\_Z)\cos(\ln(x))\mathrm{e}^{\_Z}x+4c_1x\sin(\ln(x))-4\sin(\_Z)\mathrm{e}^{\_Z}c_1-4\cos(\ln(x))c_1x-x^2\sin(2\right.} \quad (1)$$

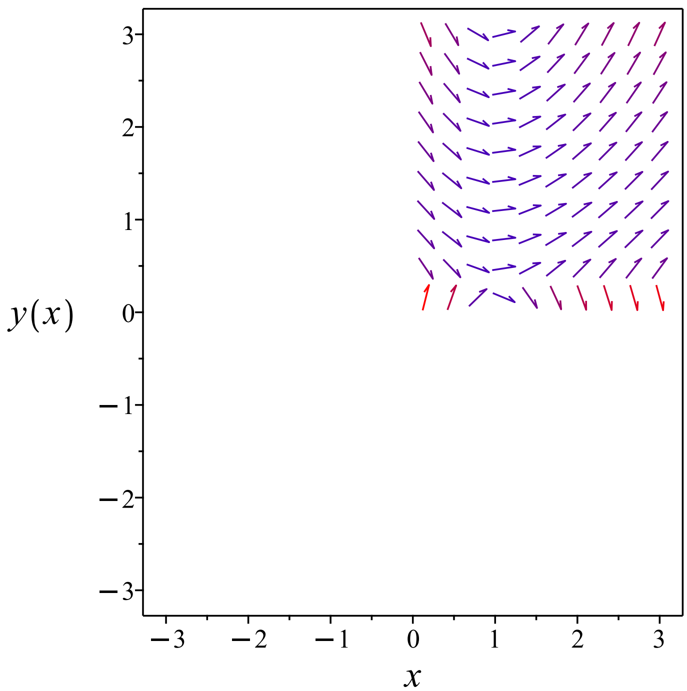

Figure 416: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{\mathrm{RootOf}\left(-2\sin(\ln(x))\sin(\_Z)\mathrm{e}^{\_Z}x+2\sin(\_Z)^2\mathrm{e}^{2\_Z}+2\sin(\_Z)\cos(\ln(x))\mathrm{e}^{\_Z}x+4c_1x\sin(\ln(x))-4\sin(\_Z)\mathrm{e}^{\_Z}c_1-4\cos(\ln(x))c_1x-x^2\sin(2\right.}$$

Warning, solution could not be verified

12.32.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{\sin(\ln(x))}{\cos(\ln(y))} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 316: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= \frac{1}{\sin\left(\ln\left(x\right)\right)} \\ \eta(x,y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{\sin(\ln(x))}} dx\end{aligned}$$

Which results in

$$S = -\frac{\cos\left(\ln\left(x\right)\right) x}{2} + \frac{\sin\left(\ln\left(x\right)\right) x}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\sin\left(\ln\left(x\right)\right)}{\cos\left(\ln\left(y\right)\right)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \sin(\ln(x)) \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \cos(\ln(y)) \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \cos(\ln(R))
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 + \frac{R(\cos(\ln(R)) + \sin(\ln(R)))}{2} \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} = c_1 + \frac{y(\cos(\ln(y)) + \sin(\ln(y)))}{2}
$$

Which simplifies to

$$
\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} = c_1 + \frac{y(\cos(\ln(y)) + \sin(\ln(y)))}{2}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\sin(\ln(x))}{\cos(\ln(y))}$ 	$R = y$ $S = \frac{x(-\cos(\ln(x)) + \text{sir}}{2}$	$\frac{dS}{dR} = \cos(\ln(R))$ 
Summary
The solution(s) found are the following

$$\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} = c_1 + \frac{y(\cos(\ln(y)) + \sin(\ln(y)))}{2} \tag{1}$$

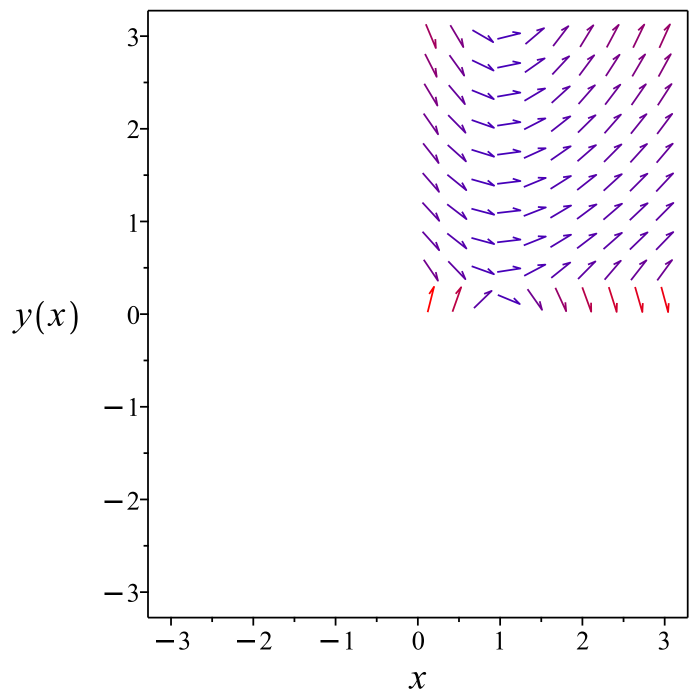

Figure 417: Slope field plot

Verification of solutions

$$\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} = c_1 + \frac{y(\cos(\ln(y)) + \sin(\ln(y)))}{2}$$

Verified OK.

12.32.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(\cos(\ln(y)))\,\mathrm{d}y = (\sin(\ln(x)))\,\mathrm{d}x$$
$$(-\sin(\ln(x)))\,\mathrm{d}x + (\cos(\ln(y)))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\sin(\ln(x))$$
$$N(x, y) = \cos(\ln(y))$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\sin(\ln(x))) \\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(\ln(y))) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$

$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int -\sin(\ln(x))\,\mathrm{d}x$$

$$\phi=-\frac{x(-\cos(\ln(x))+\sin(\ln(x)))}{2}+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=0+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=\cos(\ln(y))$. Therefore equation (4) becomes

$$\cos(\ln(y))=0+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=\cos(\ln(y))$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y=\int (\cos(\ln(y)))\,\mathrm{d}y$$

$$f(y)=\frac{\cos(\ln(y))\,y}{2}+\frac{\sin(\ln(y))\,y}{2}+c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} + \frac{\cos(\ln(y))\, y}{2} + \frac{\sin(\ln(y))\, y}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} + \frac{\cos(\ln(y))\, y}{2} + \frac{\sin(\ln(y))\, y}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} + \frac{\cos(\ln(y))\, y}{2} + \frac{\sin(\ln(y))\, y}{2} = c_1 \tag{1}$$

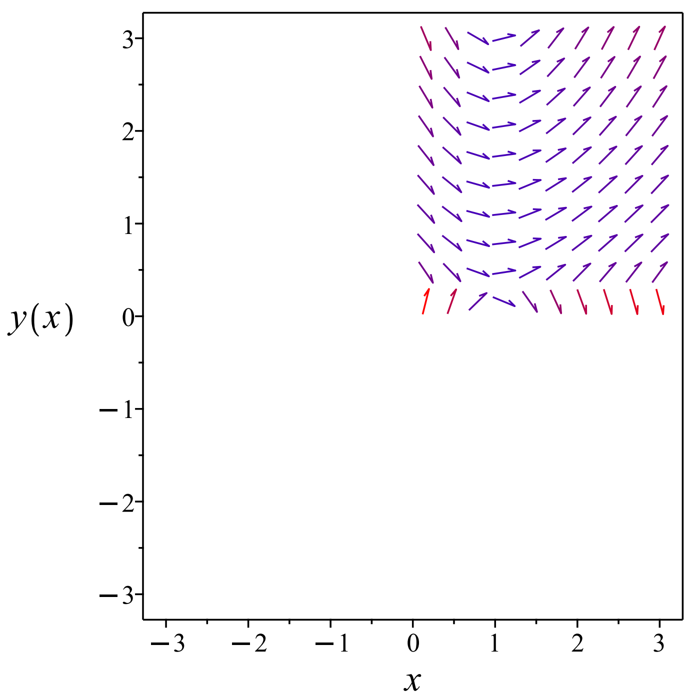

Figure 418: Slope field plot

Verification of solutions

$$-\frac{x(-\cos(\ln(x)) + \sin(\ln(x)))}{2} + \frac{\cos(\ln(y))\, y}{2} + \frac{\sin(\ln(y))\, y}{2} = c_1$$

Verified OK.

12.32.4 Maple step by step solution

Let's solve

$-\cos(\ln(y))\, y' = -\sin(\ln(x))$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int -\cos(\ln(y))\, y' dx = \int -\sin(\ln(x))\, dx + c_1$

- Evaluate integral

  $-\frac{\cos(\ln(y))y}{2} - \frac{\sin(\ln(y))y}{2} = \frac{\cos(\ln(x))x}{2} - \frac{\sin(\ln(x))x}{2} + c_1$

12.33.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\mathrm{d}y=\left(\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\right)\mathrm{d}x$$

$$\left(-\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\right)\mathrm{d}x+\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\\N(x,y)&=1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\right)\\&=\frac{-9y+3}{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,(x^2-2x+5)}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}(1)\\&=0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1\left(\left(-\frac{18y-6}{2\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,(x^2-2x+5)}\right) - (0)\right) \\ &= \frac{-9y+3}{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,(x^2-2x+5)} \end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= -\frac{1}{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}}\left((0) - \left(-\frac{18y-6}{2\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,(x^2-2x+5)}\right)\right) \\ &= \frac{-9y+3}{9y^2-6y+2} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \, \mathrm{d}y} \\ &= e^{\int \frac{-9y+3}{9y^2-6y+2} \, \mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-\frac{\ln(9y^2-6y+2)}{2}} \\ &= \frac{1}{\sqrt{9y^2-6y+2}} \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{\sqrt{9y^2-6y+2}}\left(-\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\right) \\ &= -\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}}{\sqrt{9y^2-6y+2}} \end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{\sqrt{9y^2-6y+2}}(1) \\
&= \frac{1}{\sqrt{9y^2-6y+2}}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{gathered}
\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x}=0 \\
\left(-\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}}{\sqrt{9y^2-6y+2}}\right)+\left(\frac{1}{\sqrt{9y^2-6y+2}}\right)\frac{\mathrm{d}y}{\mathrm{d}x}=0
\end{gathered}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial\phi}{\partial x}=\overline{M} \tag{1}
$$

$$
\frac{\partial\phi}{\partial y}=\overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x \\
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int-\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}}{\sqrt{9y^2-6y+2}}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi=-\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}\,\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)}{\sqrt{9y^2-6y+2}}+f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\begin{aligned}
\frac{\partial\phi}{\partial y} &= \frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}\,\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)(18y-6)}{2\left(9y^2-6y+2\right)^{\frac{3}{2}}} \\
&\quad-\frac{\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)(18y-6)}{2\sqrt{9y^2-6y+2}\,\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}}+f'(y) \\
&= 0+f'(y)
\end{aligned} \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{\sqrt{9y^2-6y+2}}$. Therefore equation (4) becomes

$$\frac{1}{\sqrt{9y^2-6y+2}} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{\sqrt{9y^2-6y+2}}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{\sqrt{9y^2-6y+2}}\right) \mathrm{d}y$$
$$f(y) = \frac{\operatorname{arcsinh}(3y-1)}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}\,\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)}{\sqrt{9y^2-6y+2}} + \frac{\operatorname{arcsinh}(3y-1)}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}\,\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)}{\sqrt{9y^2-6y+2}} + \frac{\operatorname{arcsinh}(3y-1)}{3}$$

Summary

The solution(s) found are the following

$$-\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}\,\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)}{\sqrt{9y^2-6y+2}} + \frac{\operatorname{arcsinh}(3y-1)}{3} = c_1 \tag{1}$$

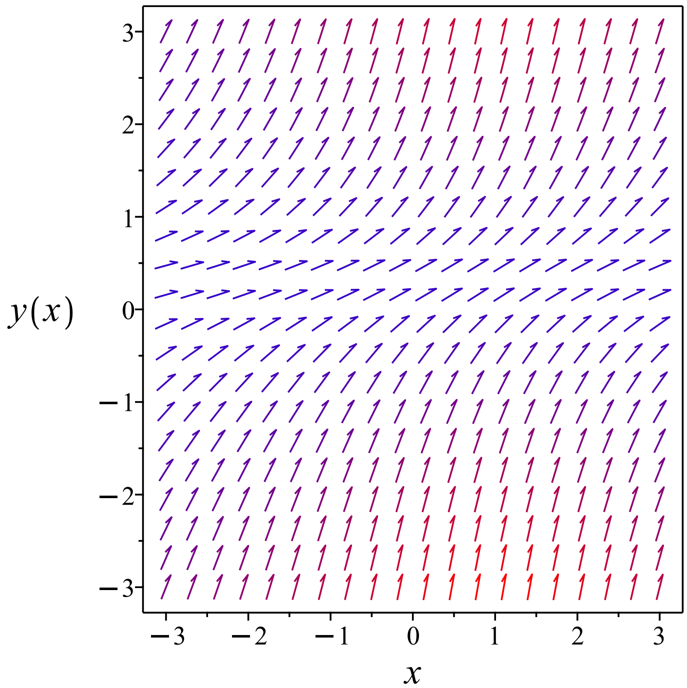

Figure 419: Slope field plot

Verification of solutions

$$-\frac{\sqrt{\frac{9y^2-6y+2}{x^2-2x+5}}\,\sqrt{x^2-2x+5}\,\operatorname{arcsinh}\left(\frac{x}{2}-\frac{1}{2}\right)}{\sqrt{9y^2-6y+2}}+\frac{\operatorname{arcsinh}\left(3y-1\right)}{3}=c_1$$

Verified OK.

Problem number: 308.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{(5x - 7y + 1)\, y' + y = 1 - x}$$

12.34.1 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{X + x_0 + Y(X) + y_0 - 1}{-5X - 5x_0 + 7Y\,(X) + 7y_0 - 1}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = \frac{1}{2}$$
$$y_0 = \frac{1}{2}$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{X + Y(X)}{-5X + 7Y\,(X)}$$

In canonical form, the ODE is

$$
\begin{aligned}
Y' &= F(X,Y) \\
&= \frac{X+Y}{-5X+7Y}
\end{aligned} \tag{1}
$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$
f(t^n X, t^n Y) = t^n f(X,Y)
$$

In this case, it can be seen that both $M = -X - Y$ and $N = 5X - 7Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$
\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u
$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$
\begin{aligned}
\frac{\mathrm{d}u}{\mathrm{d}X}X + u &= \frac{u+1}{7u-5} \\
\frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{\frac{u(X)+1}{7u(X)-5} - u(X)}{X}
\end{aligned}
$$

Or

$$
\frac{d}{dX}u(X) - \frac{\frac{u(X)+1}{7u(X)-5} - u(X)}{X} = 0
$$

Or

$$
7\left(\frac{d}{dX}u(X)\right) Xu(X) - 5\left(\frac{d}{dX}u(X)\right) X + 7u(X)^2 - 6u(X) - 1 = 0
$$

Or

$$
-1 + X(7u(X) - 5)\left(\frac{d}{dX}u(X)\right) + 7u(X)^2 - 6u(X) = 0
$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(X,u) \\
&= f(X)g(u) \\
&= -\frac{7u^2 - 6u - 1}{X(7u-5)}
\end{aligned}
$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{7u^2-6u-1}{7u-5}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{7u^2-6u-1}{7u-5}}\,du &= -\frac{1}{X}\,dX \\
\int \frac{1}{\frac{7u^2-6u-1}{7u-5}}\,du &= \int -\frac{1}{X}\,dX \\
\frac{\ln(u-1)}{4} + \frac{3\ln(7u+1)}{4} &= -\ln(X) + c_2
\end{aligned}
$$

The above can be written as

$$
\begin{aligned}
\frac{\ln(u-1) + 3\ln(7u+1)}{4} &= -\ln(X) + c_2 \\
\ln(u-1) + 3\ln(7u+1) &= (4)\left(-\ln(X) + c_2\right) \\
&= -4\ln(X) + 4c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
e^{\ln(u-1)+3\ln(7u+1)} = e^{-4\ln(X)+4c_2}
$$

Which simplifies to

$$
\begin{aligned}
(u-1)(7u+1)^3 &= \frac{4c_2}{X^4} \\
&= \frac{c_3}{X^4}
\end{aligned}
$$

Which simplifies to

$$
u(X) = \text{RootOf}\left(343\_Z^4 - 196\_Z^3 - \frac{c_3 e^{4c_2}}{X^4} - 126\_Z^2 - 20\_Z - 1\right)
$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$
Y(X) = X\,\text{RootOf}\left(343\_Z^4X^4 - 196\_Z^3X^4 - 126\_Z^2X^4 - c_3e^{4c_2} - 20\_ZX^4 - X^4\right)
$$

Using the solution for $Y(X)$

$$
Y(X) = X\,\text{RootOf}\left(343\_Z^4X^4 - 196\_Z^3X^4 - 126\_Z^2X^4 - c_3e^{4c_2} - 20\_ZX^4 - X^4\right)
$$

And replacing back terms in the above solution using

$$
\begin{aligned}
Y &= y + y_0 \\
X &= x + x_0
\end{aligned}
$$

Or

$$
\begin{aligned}
Y &= y + \frac{1}{2} \\
X &= x + \frac{1}{2}
\end{aligned}
$$

Then the solution in y becomes

$$
y - \frac{1}{2} = \left(x - \frac{1}{2}\right) \operatorname{RootOf}\left(\left(5488x^4 - 10976x^3 + 8232x^2 - 2744x + 343\right)\_Z^4 + \left(-3136x^4 + 6272x^3 - 47\right.
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y - \frac{1}{2} = \left(x - \frac{1}{2}\right) \operatorname{RootOf}\Big(&\left(5488x^4 - 10976x^3 + 8232x^2 - 2744x + 343\right)\_Z^4 \\
&+ \left(-3136x^4 + 6272x^3 - 4704x^2 + 1568x - 196\right)\_Z^3 \\
&+ \left(-2016x^4 + 4032x^3 - 3024x^2 + 1008x - 126\right)\_Z^2 \\
&+ \left(-320x^4 + 640x^3 - 480x^2 + 160x - 20\right)\_Z - 16c_3 e^{4c_2} - 16x^4 + 32x^3 \\
&- 24x^2 + 8x - 1\Big)
\end{aligned} \tag{1}
$$

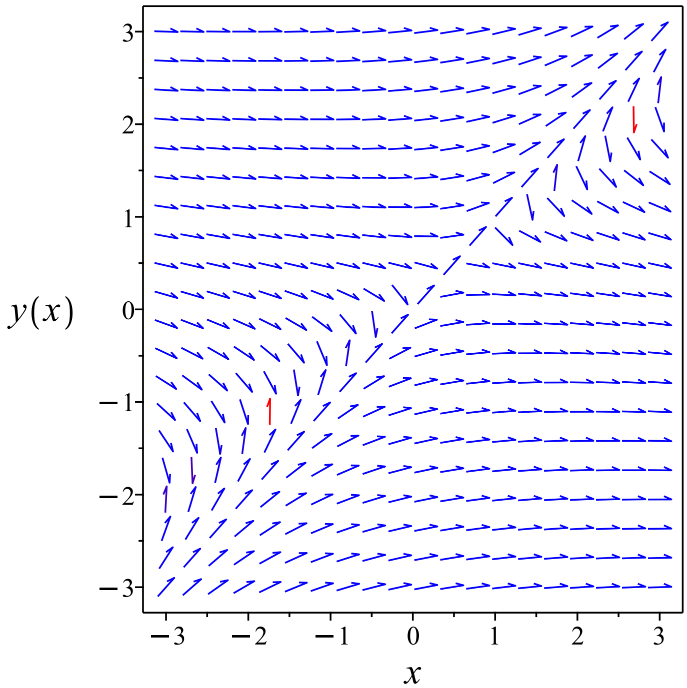

Figure 420: Slope field plot

Verification of solutions

$$y-\frac{1}{2}=\left(x-\frac{1}{2}\right)\operatorname{RootOf}\left(\left(5488x^4-10976x^3+8232x^2-2744x+343\right)\_Z^4+\left(-3136x^4+6272x^3-4704x^2+1568x-196\right)\_Z^3+\left(-2016x^4+4032x^3-3024x^2+1008x-126\right)\_Z^2+\left(-320x^4+640x^3-480x^2+160x-20\right)\_Z-16c_3e^{4c_2}-16x^4+32x^3-24x^2+8x-1\right)$$

Verified OK.

12.34.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{x+y-1}{-5x+7y-1}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&b_2 + \frac{(x+y-1)(b_3-a_2)}{-5x+7y-1} - \frac{(x+y-1)^2 a_3}{(-5x+7y-1)^2} \\
&- \left(\frac{1}{-5x+7y-1} + \frac{5x+5y-5}{(-5x+7y-1)^2}\right)(xa_2+ya_3+a_1) \\
&- \left(\frac{1}{-5x+7y-1} - \frac{7(x+y-1)}{(-5x+7y-1)^2}\right)(xb_2+yb_3+b_1) = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{5x^2a_2 - x^2a_3 + 37x^2b_2 - 5x^2b_3 - 14xya_2 - 2xya_3 - 70xyb_2 + 14xyb_3 - 7y^2a_2 - 13y^2a_3 + 49y^2b_2 + 7y^2b_3}{(5x}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&5x^2a_2 - x^2a_3 + 37x^2b_2 - 5x^2b_3 - 14xya_2 - 2xya_3 - 70xyb_2 + 14xyb_3 \\
&- 7y^2a_2 - 13y^2a_3 + 49y^2b_2 + 7y^2b_3 + 2xa_2 + 2xa_3 + 12xb_1 + 4xb_2 + 4xb_3 \\
&- 12ya_1 + 8ya_2 + 8ya_3 - 14yb_2 - 14yb_3 + 6a_1 - a_2 - a_3 - 6b_1 + b_2 + b_3 = 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&5a_2v_1^2 - 14a_2v_1v_2 - 7a_2v_2^2 - a_3v_1^2 - 2a_3v_1v_2 - 13a_3v_2^2 + 37b_2v_1^2 - 70b_2v_1v_2 \\
&+ 49b_2v_2^2 - 5b_3v_1^2 + 14b_3v_1v_2 + 7b_3v_2^2 - 12a_1v_2 + 2a_2v_1 + 8a_2v_2 + 2a_3v_1 + 8a_3v_2 \\
&+ 12b_1v_1 + 4b_2v_1 - 14b_2v_2 + 4b_3v_1 - 14b_3v_2 + 6a_1 - a_2 - a_3 - 6b_1 + b_2 + b_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&(5a_2 - a_3 + 37b_2 - 5b_3)\, v_1^2 + (-14a_2 - 2a_3 - 70b_2 + 14b_3)\, v_1v_2 \\
&+ (2a_2 + 2a_3 + 12b_1 + 4b_2 + 4b_3)\, v_1 + (-7a_2 - 13a_3 + 49b_2 + 7b_3)\, v_2^2 \\
&+ (-12a_1 + 8a_2 + 8a_3 - 14b_2 - 14b_3)\, v_2 + 6a_1 - a_2 - a_3 - 6b_1 + b_2 + b_3 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-14a_2 - 2a_3 - 70b_2 + 14b_3 &= 0 \\
-7a_2 - 13a_3 + 49b_2 + 7b_3 &= 0 \\
5a_2 - a_3 + 37b_2 - 5b_3 &= 0 \\
-12a_1 + 8a_2 + 8a_3 - 14b_2 - 14b_3 &= 0 \\
2a_2 + 2a_3 + 12b_1 + 4b_2 + 4b_3 &= 0 \\
6a_1 - a_2 - a_3 - 6b_1 + b_2 + b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= b_1 \\
a_2 &= 12b_1 + 7b_3 \\
a_3 &= -14b_1 - 7b_3 \\
b_1 &= b_1 \\
b_2 &= -2b_1 - b_3 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 7x - 7y \\
\eta &= -x + y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= -x + y - \left(\frac{x+y-1}{-5x+7y-1}\right)(7x-7y) \\
&= \frac{2x^2+12xy-14y^2-8x+8y}{5x-7y+1} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{2x^2+12xy-14y^2-8x+8y}{5x-7y+1}} dy
\end{aligned}
$$

Which results in

$$
S = \frac{3\ln(x+7y-4)}{8} + \frac{\ln(-x+y)}{8}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{x+y-1}{-5x+7y-1}
$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{x+y-1}{2\left(x+7y-4\right)\left(x-y\right)} \\
S_y &= \frac{21}{8x+56y-32} - \frac{1}{8x-8y}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{3\ln\left(x+7y-4\right)}{8} + \frac{\ln\left(-x+y\right)}{8} = c_1$$

Which simplifies to

$$\frac{3\ln\left(x+7y-4\right)}{8} + \frac{\ln\left(-x+y\right)}{8} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x+y-1}{-5x+7y-1}$ 	$R = x$ $S = \frac{3\ln(x+7y-4)}{8} + \text{l}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{3\ln(x+7y-4)}{8} + \frac{\ln(-x+y)}{8} = c_1 \tag{1}$$

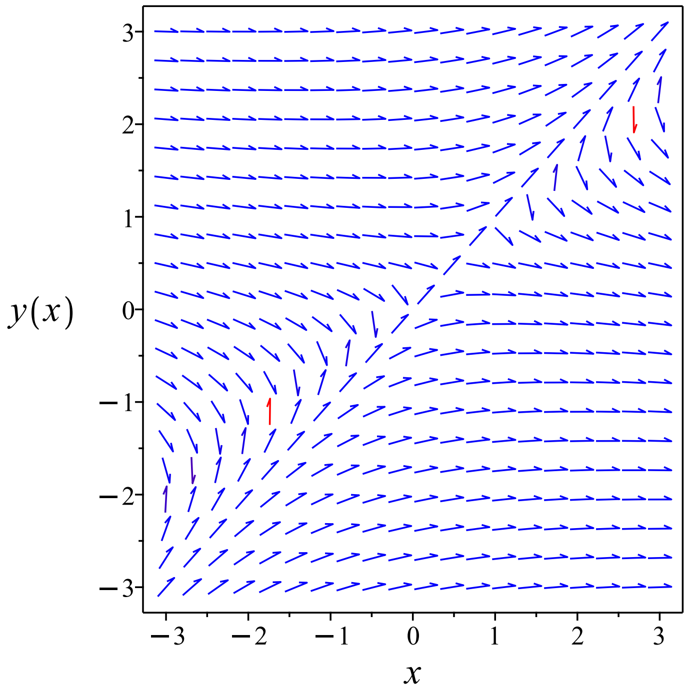

Figure 421: Slope field plot

Verification of solutions

$$\frac{3\ln\left(x+7y-4\right)}{8}+\frac{\ln\left(-x+y\right)}{8}=c_1$$

Verified OK.

12.35.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{x + y + 1}{2x + 2y - 1} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 2$ is

$$\left\{x < -\frac{3}{2} \vee -\frac{3}{2} < x\right\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x, y)$ when $x = 1$ is

$$\left\{y < -\frac{1}{2} \vee -\frac{1}{2} < y\right\}$$

And the point $y_0 = 2$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x + y + 1}{2x + 2y - 1}\right) \\ &= -\frac{1}{2x + 2y - 1} + \frac{2x + 2y + 2}{(2x + 2y - 1)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 2$ is

$$\left\{x < -\frac{3}{2} \vee -\frac{3}{2} < x\right\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\left\{y < -\frac{1}{2} \vee -\frac{1}{2} < y\right\}$$

And the point $y_0 = 2$ is inside this domain. Therefore solution exists and is unique.

12.35.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned}y' &= -\frac{x + y + 1}{2x + 2y - 1} \\ y' &= \omega(x, y)\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 - \frac{(x+y+1)(b_3-a_2)}{2x+2y-1} - \frac{(x+y+1)^2 a_3}{(2x+2y-1)^2} \\ - \left(-\frac{1}{2x+2y-1} + \frac{2x+2y+2}{(2x+2y-1)^2}\right)(xa_2+ya_3+a_1) \\ - \left(-\frac{1}{2x+2y-1} + \frac{2x+2y+2}{(2x+2y-1)^2}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{2x^2a_2 - x^2a_3 + 4x^2b_2 - 2x^2b_3 + 4xya_2 - 2xya_3 + 8xyb_2 - 4xyb_3 + 2y^2a_2 - y^2a_3 + 4y^2b_2 - 2y^2b_3 - 2xa_2}{(2x+2y-1)^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} 2x^2a_2 - x^2a_3 + 4x^2b_2 - 2x^2b_3 + 4xya_2 - 2xya_3 + 8xyb_2 - 4xyb_3 \\ + 2y^2a_2 - y^2a_3 + 4y^2b_2 - 2y^2b_3 - 2xa_2 - 2xa_3 - 7xb_2 - xb_3 \\ + ya_2 - 5ya_3 - 4yb_2 - 4yb_3 - 3a_1 - a_2 - a_3 - 3b_1 + b_2 + b_3 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} 2a_2v_1^2 + 4a_2v_1v_2 + 2a_2v_2^2 - a_3v_1^2 - 2a_3v_1v_2 - a_3v_2^2 + 4b_2v_1^2 + 8b_2v_1v_2 \\ + 4b_2v_2^2 - 2b_3v_1^2 - 4b_3v_1v_2 - 2b_3v_2^2 - 2a_2v_1 + a_2v_2 - 2a_3v_1 - 5a_3v_2 \\ - 7b_2v_1 - 4b_2v_2 - b_3v_1 - 4b_3v_2 - 3a_1 - a_2 - a_3 - 3b_1 + b_2 + b_3 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(2a_2 - a_3 + 4b_2 - 2b_3) v_1^2 + (4a_2 - 2a_3 + 8b_2 - 4b_3) v_1 v_2 \\
&+ (-2a_2 - 2a_3 - 7b_2 - b_3) v_1 + (2a_2 - a_3 + 4b_2 - 2b_3) v_2^2 \\
&+ (a_2 - 5a_3 - 4b_2 - 4b_3) v_2 - 3a_1 - a_2 - a_3 - 3b_1 + b_2 + b_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-2a_2 - 2a_3 - 7b_2 - b_3 &= 0 \\
a_2 - 5a_3 - 4b_2 - 4b_3 &= 0 \\
2a_2 - a_3 + 4b_2 - 2b_3 &= 0 \\
4a_2 - 2a_3 + 8b_2 - 4b_3 &= 0 \\
-3a_1 - a_2 - a_3 - 3b_1 + b_2 + b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 2b_2 - b_1 \\
a_2 &= -2b_2 \\
a_3 &= -2b_2 \\
b_1 &= b_1 \\
b_2 &= b_2 \\
b_3 &= b_2
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= -1 \\
\eta &= 1
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= 1 - \left(-\frac{x + y + 1}{2x + 2y - 1}\right)(-1) \\
&= \frac{x + y - 2}{2x + 2y - 1} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x+y-2}{2x+2y-1}} dy \end{aligned}$$

Which results in

$$S = 2y + 3\ln(x + y - 2)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x + y + 1}{2x + 2y - 1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{3}{x + y - 2} \\ S_y &= 2 + \frac{3}{x + y - 2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$2y + 3\ln(x + y - 2) = -x + c_1$$

Which simplifies to

$$2y + 3\ln(x + y - 2) = -x + c_1$$

Which gives

$$y = \frac{3\,\text{LambertW}\left(\frac{2\,e^{\frac{x}{3}+\frac{c_1}{3}-\frac{4}{3}}}{3}\right)}{2} - x + 2$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x+y+1}{2x+2y-1}$ 	$R = x$ $S = 2y + 3\ln(x + y - 2)$	$\frac{dS}{dR} = -1$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = \frac{3\,\text{LambertW}\left(\frac{2\,e^{-1+\frac{c_1}{3}}}{3}\right)}{2} + 1$$

$$c_1 = 5$$

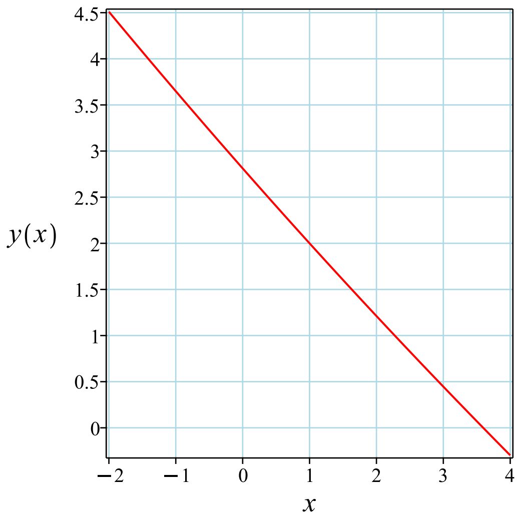
Substituting c_1 found above in the general solution gives

$$y = \frac{3\,\text{LambertW}\left(\frac{2\,e^{\frac{x}{3}+\frac{1}{3}}}{3}\right)}{2} - x + 2$$

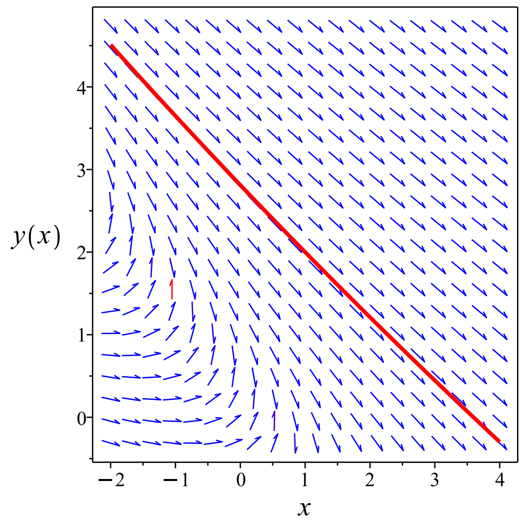
Summary

The solution(s) found are the following

$$y = \frac{3\,\text{LambertW}\left(\frac{2\,e^{\frac{x}{3}+\frac{1}{3}}}{3}\right)}{2} - x + 2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{3\,\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{x}{3}+\frac{1}{3}}}{3}\right)}{2} - x + 2$$

Verified OK.

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{y^3 + 2(x^2 - y^2x)\, y' = 0}$$

12.36.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{y^3}{2x\,(y^2 - x)} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{y^3(b_3 - a_2)}{2x\,(y^2 - x)} - \frac{y^6 a_3}{4x^2\,(y^2 - x)^2} \\ & - \left(-\frac{y^3}{2x^2\,(y^2 - x)} + \frac{y^3}{2x\,(y^2 - x)^2}\right)(x a_2 + y a_3 + a_1) \\ & - \left(\frac{3y^2}{2x\,(y^2 - x)} - \frac{y^4}{x\,(y^2 - x)^2}\right)(x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{2x^2y^4b_2 + y^6a_3 - 2x^3y^2b_2 - 2x^2y^3a_2 + 4x^2y^3b_3 - 4x\,y^4a_3 - 2x\,y^4b_1 + 2y^5a_1 + 4x^4b_2 + 6x^2y^2b_1 - 4x\,y^3a_1}{4x^2\,(-y^2 + x)^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} & 2x^2y^4b_2 + y^6a_3 - 2x^3y^2b_2 - 2x^2y^3a_2 + 4x^2y^3b_3 - 4x\,y^4a_3 \\ & - 2x\,y^4b_1 + 2y^5a_1 + 4x^4b_2 + 6x^2y^2b_1 - 4x\,y^3a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & a_3v_2^6 + 2b_2v_1^2v_2^4 + 2a_1v_2^5 - 2a_2v_1^2v_2^3 - 4a_3v_1v_2^4 - 2b_1v_1v_2^4 \\ & - 2b_2v_1^3v_2^2 + 4b_3v_1^2v_2^3 - 4a_1v_1v_2^3 + 6b_1v_1^2v_2^2 + 4b_2v_1^4 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$4b_2v_1^4 - 2b_2v_1^3v_2^2 + 2b_2v_1^2v_2^4 + (-2a_2 + 4b_3)\, v_1^2v_2^3 + 6b_1v_1^2v_2^2 + (-4a_3 - 2b_1)\, v_1v_2^4 - 4a_1v_1v_2^3 + a_3v_2^6 + 2a_1v_2^5 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
a_3 &= 0 \\
-4a_1 &= 0 \\
2a_1 &= 0 \\
6b_1 &= 0 \\
-2b_2 &= 0 \\
2b_2 &= 0 \\
4b_2 &= 0 \\
-2a_2 + 4b_3 &= 0 \\
-4a_3 - 2b_1 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= 2b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= 2x \\
\eta &= y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{y^3}{2x\,(y^2-x)}\right)(2x) \\
&= \frac{xy}{-y^2+x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{xy}{-y^2+x}} dy
\end{aligned}
$$

Which results in

$$
S = -\frac{y^2}{2x} + \ln(y)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{y^3}{2x\,(y^2-x)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{y^2}{2x^2} \\
S_y &= \frac{-y^2 + x}{xy}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{2 \ln (y)\, x - y^2}{2x} = c_1
$$

Which simplifies to

$$
\frac{2 \ln (y)\, x - y^2}{2x} = c_1
$$

Which gives

$$
y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{2c_1}}{x}\right)}{2} + c_1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y^3}{2x(y^2-x)}$ 	$R = x$ $S = \frac{2\ln(y)\,x - y^2}{2x}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{2c_1}}{x}\right)}{2}+c_1} \tag{1}$$

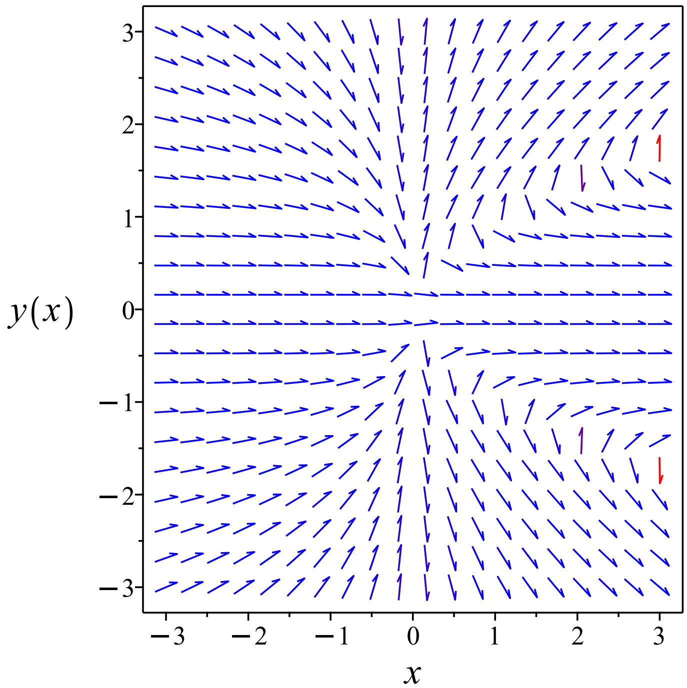

Figure 423: Slope field plot

Verification of solutions

$$y = e^{-\frac{\text{LambertW}\left(-\frac{e^{2c_1}}{x}\right)}{2}+c_1}$$

Verified OK.

12.36.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(-2x\, y^2 + 2x^2\right) \mathrm{d}y &= \left(-y^3\right) \mathrm{d}x \\
\left(y^3\right) \mathrm{d}x + \left(-2x\, y^2 + 2x^2\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= y^3 \\
N(x, y) &= -2x\, y^2 + 2x^2
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y^3\right) \\
&= 3y^2
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-2x\, y^2 + 2x^2\right) \\
&= -2y^2 + 4x
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. By inspection $\frac{1}{x^2 y}$ is an integrating factor. Therefore by multiplying $M = y^3$ and $N = 2x^2 - 2y^2 x$ by this integrating factor the ode becomes exact. The new M, N are

$$
\begin{aligned}
M &= \frac{y^2}{x^2} \\
N &= \frac{2x^2 - 2y^2 x}{x^2 y}
\end{aligned}
$$

To solve an ode of the form

$$
M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}
$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx} \phi(x, y) = 0
$$

Hence

$$
\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \frac{dy}{dx} = 0 \tag{B}
$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$\left(\frac{-2x\,y^{2}+2x^{2}}{x^{2}y}\right)\mathrm{d}y = \left(-\frac{y^{2}}{x^{2}}\right)\mathrm{d}x$$

$$\left(\frac{y^{2}}{x^{2}}\right)\mathrm{d}x + \left(\frac{-2x\,y^{2}+2x^{2}}{x^{2}y}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= \frac{y^{2}}{x^{2}}\\
N(x,y) &= \frac{-2x\,y^{2}+2x^{2}}{x^{2}y}
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y^{2}}{x^{2}}\right)\\
&= \frac{2y}{x^{2}}
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{-2x\,y^{2}+2x^{2}}{x^{2}y}\right)\\
&= \frac{2y}{x^{2}}
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{y^{2}}{x^{2}}\,\mathrm{d}x$$

$$\phi = -\frac{y^{2}}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{2y}{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-2x\,y^2+2x^2}{x^2 y}$. Therefore equation (4) becomes

$$\frac{-2x\,y^2+2x^2}{x^2 y} = -\frac{2y}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{2}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{2}{y}\right) \mathrm{d}y$$
$$f(y) = 2\ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{y^2}{x} + 2\ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{y^2}{x} + 2\ln(y)$$

The solution becomes

$$y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{c_1}}{x}\right)}{2}+\frac{c_1}{2}}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{c_1}}{x}\right)}{2}+\frac{c_1}{2}} \tag{1}$$

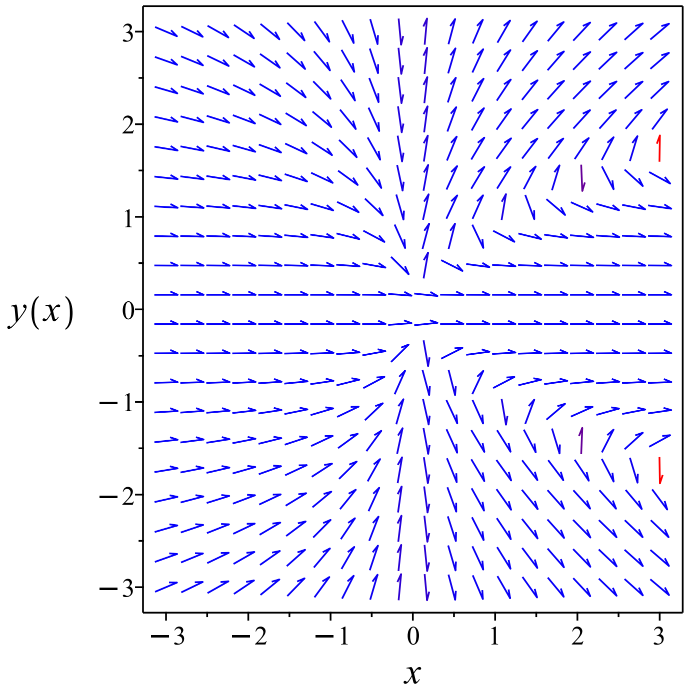

Figure 424: Slope field plot

Verification of solutions

$$y = e^{-\frac{\mathrm{LambertW}\left(-\frac{e^{c_1}}{x}\right)}{2}+\frac{c_1}{2}}$$

Verified OK.

Problem number: 311.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational]
```

$$\boxed{y' - \frac{2(y+2)^2}{(x+y-1)^2} = 0}$$

12.37.1 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{2(Y(X)+y_0+2)^2}{(X+x_0+Y(X)+y_0-1)^2}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = 3$$
$$y_0 = -2$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{2Y(X)^2}{X^2+2XY(X)+Y(X)^2}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X,Y) \\ &= \frac{2Y^2}{X^2+2XY+Y^2} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$f(t^nX, t^nY) = t^n f(X,Y)$$

In this case, it can be seen that both $M = 2Y^2$ and $N = X^2+2XY+Y^2$ are both homogeneous and of the same order $n = 2$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X}X + u &= \frac{2u^2}{(u+1)^2} \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{\frac{2u(X)^2}{(u(X)+1)^2} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{\frac{2u(X)^2}{(u(X)+1)^2} - u(X)}{X} = 0$$

Or

$$\left(\frac{d}{dX}u(X)\right)u(X)^2 X + 2\left(\frac{d}{dX}u(X)\right)u(X)\,X + u(X)^3 + \left(\frac{d}{dX}u(X)\right)X + u(X) = 0$$

Or

$$X(u(X)+1)^2\left(\frac{d}{dX}u(X)\right) + u(X)^3 + u(X) = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X,u) \\ &= f(X)g(u) \\ &= -\frac{u(u^2+1)}{X\,(u+1)^2} \end{aligned}$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u(u^2+1)}{(u+1)^2}$. Integrating both sides gives

$$\frac{1}{\frac{u(u^2+1)}{(u+1)^2}} du = -\frac{1}{X} dX$$

$$\int \frac{1}{\frac{u(u^2+1)}{(u+1)^2}} du = \int -\frac{1}{X} dX$$

$$2\arctan(u) + \ln(u) = -\ln(X) + c_2$$

The solution is

$$2\arctan(u(X)) + \ln(u(X)) + \ln(X) - c_2 = 0$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$2\arctan\left(\frac{Y(X)}{X}\right) + \ln\left(\frac{Y(X)}{X}\right) + \ln(X) - c_2 = 0$$

Using the solution for $Y(X)$

$$2\arctan\left(\frac{Y(X)}{X}\right) + \ln\left(\frac{Y(X)}{X}\right) + \ln(X) - c_2 = 0$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y - 2$$
$$X = x + 3$$

Then the solution in y becomes

$$2\arctan\left(\frac{y+2}{x-3}\right) + \ln\left(\frac{y+2}{x-3}\right) + \ln(x-3) - c_2 = 0$$

Summary

The solution(s) found are the following

$$2\arctan\left(\frac{y+2}{x-3}\right) + \ln\left(\frac{y+2}{x-3}\right) + \ln(x-3) - c_2 = 0 \tag{1}$$

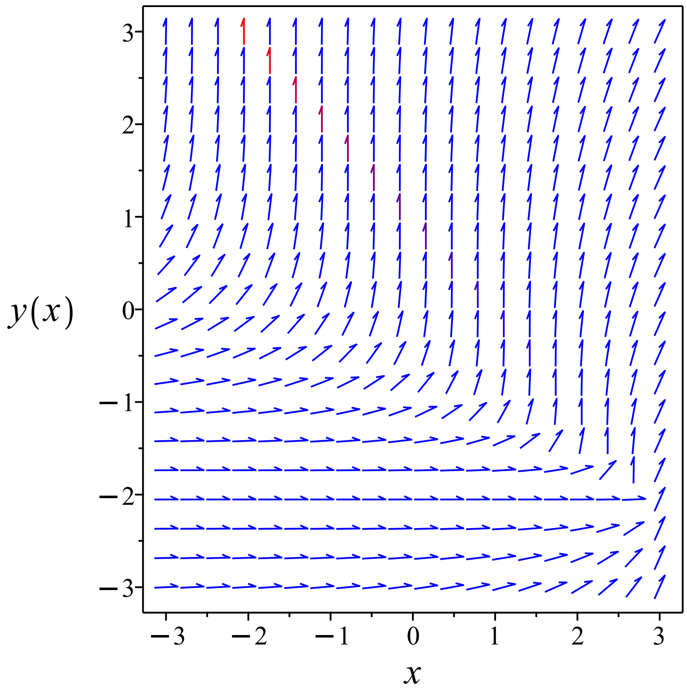

Figure 425: Slope field plot

Verification of solutions

$$2\arctan\left(\frac{y+2}{x-3}\right)+\ln\left(\frac{y+2}{x-3}\right)+\ln(x-3)-c_2=0$$

Verified OK.

12.37.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{2(y+2)^2}{(x+y-1)^2}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{2(y+2)^2 (b_3 - a_2)}{(x+y-1)^2} - \frac{4(y+2)^4 a_3}{(x+y-1)^4} + \frac{4(y+2)^2 (xa_2 + ya_3 + a_1)}{(x+y-1)^3} - \left(\frac{4y+8}{(x+y-1)^2} - \frac{4(y+2)^2}{(x+y-1)^3}\right)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^4b_2 + 2x^2y^2a_2 + 2x^2y^2b_2 - 2x^2y^2b_3 + 4x\,y^3a_3 + 4x\,y^3b_2 - 2y^4a_2 + y^4b_2 + 2y^4b_3 - 12x^3b_2 + 8x^2ya_2 - 4x^2}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&x^4b_2 + 2x^2y^2a_2 + 2x^2y^2b_2 - 2x^2y^2b_3 + 4x\,y^3a_3 + 4x\,y^3b_2 - 2y^4a_2 \\
&+ y^4b_2 + 2y^4b_3 - 12x^3b_2 + 8x^2ya_2 - 4x^2yb_1 - 4x^2yb_2 + 4x\,y^2a_1 \\
&+ 16x\,y^2a_3 - 4x\,y^2b_1 + 20x\,y^2b_3 + 4y^3a_1 - 4y^3a_2 - 20y^3a_3 - 4y^3b_2 \\
&+ 16y^3b_3 + 8x^2a_2 - 8x^2b_1 + 38x^2b_2 + 8x^2b_3 + 16xya_1 + 16xya_3 \\
&+ 8xyb_1 + 24xyb_2 + 32xyb_3 + 12y^2a_1 + 6y^2a_2 - 96y^2a_3 + 12y^2b_1 \\
&+ 6y^2b_2 + 6y^2b_3 + 16xa_1 + 32xb_1 - 28xb_2 - 16xb_3 + 8ya_2 - 144ya_3 \\
&+ 12yb_1 - 4yb_2 - 32yb_3 - 16a_1 - 8a_2 - 64a_3 - 24b_1 + b_2 + 8b_3 = 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&2a_2v_1^2v_2^2 - 2a_2v_2^4 + 4a_3v_1v_2^3 + b_2v_1^4 + 2b_2v_1^2v_2^2 + 4b_2v_1v_2^3 + b_2v_2^4 - 2b_3v_1^2v_2^2 \\
&+ 2b_3v_2^4 + 4a_1v_1v_2^2 + 4a_1v_2^3 + 8a_2v_1^2v_2 - 4a_2v_2^3 + 16a_3v_1v_2^2 - 20a_3v_2^3 \\
&- 4b_1v_1^2v_2 - 4b_1v_1v_2^2 - 12b_2v_1^3 - 4b_2v_1^2v_2 - 4b_2v_2^3 + 20b_3v_1v_2^2 + 16b_3v_2^3 \\
&+ 16a_1v_1v_2 + 12a_1v_2^2 + 8a_2v_1^2 + 6a_2v_2^2 + 16a_3v_1v_2 - 96a_3v_2^2 - 8b_1v_1^2 \\
&+ 8b_1v_1v_2 + 12b_1v_2^2 + 38b_2v_1^2 + 24b_2v_1v_2 + 6b_2v_2^2 + 8b_3v_1^2 + 32b_3v_1v_2 \\
&+ 6b_3v_2^2 + 16a_1v_1 + 8a_2v_2 - 144a_3v_2 + 32b_1v_1 + 12b_1v_2 - 28b_2v_1 \\
&- 4b_2v_2 - 16b_3v_1 - 32b_3v_2 - 16a_1 - 8a_2 - 64a_3 - 24b_1 + b_2 + 8b_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&b_2v_1^4 - 12b_2v_1^3 + (2a_2 + 2b_2 - 2b_3)\,v_1^2v_2^2 \\
&+ (8a_2 - 4b_1 - 4b_2)\,v_1^2v_2 + (8a_2 - 8b_1 + 38b_2 + 8b_3)\,v_1^2 \\
&+ (4a_3 + 4b_2)\,v_1v_2^3 + (4a_1 + 16a_3 - 4b_1 + 20b_3)\,v_1v_2^2 \\
&+ (16a_1 + 16a_3 + 8b_1 + 24b_2 + 32b_3)\,v_1v_2 + (16a_1 + 32b_1 - 28b_2 - 16b_3)\,v_1 \\
&+ (-2a_2 + b_2 + 2b_3)\,v_2^4 + (4a_1 - 4a_2 - 20a_3 - 4b_2 + 16b_3)\,v_2^3 \\
&+ (12a_1 + 6a_2 - 96a_3 + 12b_1 + 6b_2 + 6b_3)\,v_2^2 \\
&+ (8a_2 - 144a_3 + 12b_1 - 4b_2 - 32b_3)\,v_2 \\
&- 16a_1 - 8a_2 - 64a_3 - 24b_1 + b_2 + 8b_3 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
b_2 &= 0 \\
-12b_2 &= 0 \\
4a_3 + 4b_2 &= 0 \\
-2a_2 + b_2 + 2b_3 &= 0 \\
2a_2 + 2b_2 - 2b_3 &= 0 \\
8a_2 - 4b_1 - 4b_2 &= 0 \\
4a_1 + 16a_3 - 4b_1 + 20b_3 &= 0 \\
16a_1 + 32b_1 - 28b_2 - 16b_3 &= 0 \\
8a_2 - 8b_1 + 38b_2 + 8b_3 &= 0 \\
4a_1 - 4a_2 - 20a_3 - 4b_2 + 16b_3 &= 0 \\
16a_1 + 16a_3 + 8b_1 + 24b_2 + 32b_3 &= 0 \\
8a_2 - 144a_3 + 12b_1 - 4b_2 - 32b_3 &= 0 \\
-16a_1 - 8a_2 - 64a_3 - 24b_1 + b_2 + 8b_3 &= 0 \\
12a_1 + 6a_2 - 96a_3 + 12b_1 + 6b_2 + 6b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= -3b_3 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 2b_3 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x - 3 \\
\eta &= y + 2
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y + 2 - \left(\frac{2(y+2)^2}{(x+y-1)^2}\right)(x-3) \\
&= \frac{x^2y + y^3 + 2x^2 - 6xy + 6y^2 - 12x + 21y + 26}{x^2 + 2xy + y^2 - 2x - 2y + 1} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{x^2y+y^3+2x^2-6xy+6y^2-12x+21y+26}{x^2+2xy+y^2-2x-2y+1}} dy
\end{aligned}
$$

Which results in

$$
S = \ln(y+2) + 2\arctan\left(\frac{2y+4}{2x-6}\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{2(y+2)^2}{(x+y-1)^2}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{-2y - 4}{x^2 + y^2 - 6x + 4y + 13} \\
S_y &= \frac{(x + y - 1)^2}{(y + 2)(x^2 + y^2 - 6x + 4y + 13)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\ln(y + 2) + 2 \arctan\left(\frac{y + 2}{x - 3}\right) = c_1
$$

Which simplifies to

$$
\ln(y + 2) + 2 \arctan\left(\frac{y + 2}{x - 3}\right) = c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2(y+2)^2}{(x+y-1)^2}$ 	$R = x$ $S = \ln(y+2) + 2\,\mathrm{arctan}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\ln(y+2) + 2\arctan\left(\frac{y+2}{x-3}\right) = c_1 \tag{1}$$

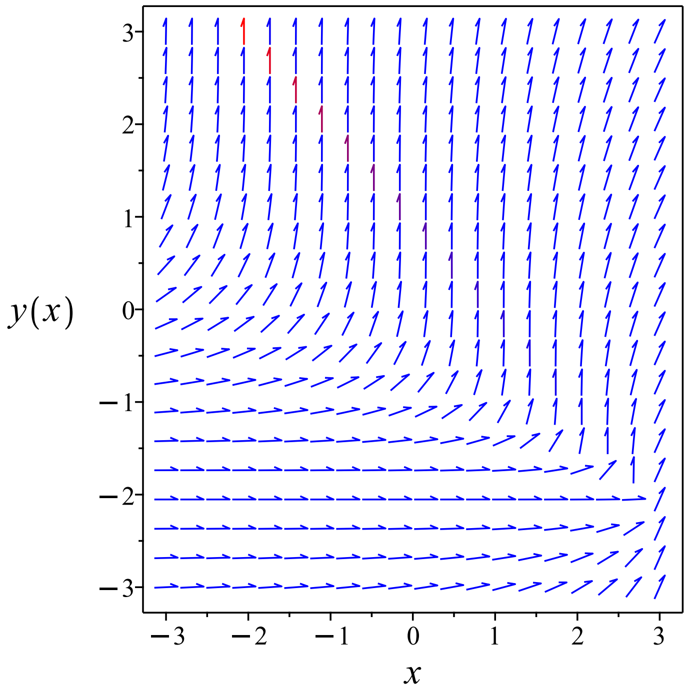

Figure 426: Slope field plot

Verification of solutions

$$\ln(y+2) + 2\arctan\left(\frac{y+2}{x-3}\right) = c_1$$

Verified OK.

Maple gives the following as the ode type

```
[[_homogeneous, `class G`]]
```

$$\boxed{4x^2y'^2 - y^2 - y^3x = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{yx+1}\, y}{2x} \tag{1}$$

$$y' = -\frac{\sqrt{yx+1}\, y}{2x} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$y' = \frac{\sqrt{xy+1}\, y}{2x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 + \frac{\sqrt{xy+1}\, y(b_3 - a_2)}{2x} - \frac{(xy+1)\, y^2 a_3}{4x^2} \\ &- \left(\frac{y^2}{4\sqrt{xy+1}\, x} - \frac{\sqrt{xy+1}\, y}{2x^2}\right)(x a_2 + y a_3 + a_1) \\ &- \left(\frac{y}{4\sqrt{xy+1}} + \frac{\sqrt{xy+1}}{2x}\right)(x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{-\sqrt{xy+1}\, x\, y^3 a_3 - 3x^3 y b_2 - x^2 y^2 a_2 - x^2 y^2 b_3 + x\, y^3 a_3 + 4 b_2 x^2 \sqrt{xy+1} - y^2 a_3 \sqrt{xy+1} - 3x^2 y b_1 + x\, y^2 a_{}}{4x^2 \sqrt{xy+1}} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-\sqrt{xy+1}\, x\, y^3 a_3 - 3x^3 y b_2 - x^2 y^2 a_2 - x^2 y^2 b_3 + x\, y^3 a_3 + 4 b_2 x^2 \sqrt{xy+1} \\ &- y^2 a_3 \sqrt{xy+1} - 3x^2 y b_1 + x\, y^2 a_1 - 2x^2 b_2 + 2y^2 a_3 - 2x b_1 + 2y a_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &-\sqrt{xy+1}\, x\, y^3 a_3 - 2(xy+1)\, x^2 b_2 + 2(xy+1)\, y^2 a_3 - x^3 y b_2 \\ &- x^2 y^2 a_2 - x^2 y^2 b_3 - x\, y^3 a_3 - 2(xy+1)\, x b_1 + 2(xy+1)\, y a_1 \\ &+ 4 b_2 x^2 \sqrt{xy+1} - y^2 a_3 \sqrt{xy+1} - x^2 y b_1 - x\, y^2 a_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$-\sqrt{xy+1}\,x\,y^{3}a_{3}-3x^{3}yb_{2}-x^{2}y^{2}a_{2}-x^{2}y^{2}b_{3}+x\,y^{3}a_{3}+4b_{2}x^{2}\sqrt{xy+1}-y^{2}a_{3}\sqrt{xy+1}-3x^{2}yb_{1}+x\,y^{2}a_{1}-2x^{2}b_{2}+2y^{2}a_{3}-2xb_{1}+2ya_{1}=0$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{xy+1}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x=v_{1}, y=v_{2}, \sqrt{xy+1}=v_{3}\right\}$$

The above PDE (6E) now becomes

$$-v_{3}v_{1}v_{2}^{3}a_{3}-v_{1}^{2}v_{2}^{2}a_{2}+v_{1}v_{2}^{3}a_{3}-3v_{1}^{3}v_{2}b_{2}-v_{1}^{2}v_{2}^{2}b_{3}+v_{1}v_{2}^{2}a_{1}-v_{2}^{2}a_{3}v_{3}-3v_{1}^{2}v_{2}b_{1}+4b_{2}v_{1}^{2}v_{3}+2v_{2}^{2}a_{3}-2v_{1}^{2}b_{2}+2v_{2}a_{1}-2v_{1}b_{1}=0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_{1}, v_{2}, v_{3}\}$$

Equation (7E) now becomes

$$-3v_{1}^{3}v_{2}b_{2}+(-a_{2}-b_{3})\,v_{1}^{2}v_{2}^{2}-3v_{1}^{2}v_{2}b_{1}+4b_{2}v_{1}^{2}v_{3}-2v_{1}^{2}b_{2}-v_{3}v_{1}v_{2}^{3}a_{3}+v_{1}v_{2}^{3}a_{3}+v_{1}v_{2}^{2}a_{1}-2v_{1}b_{1}-v_{2}^{2}a_{3}v_{3}+2v_{2}^{2}a_{3}+2v_{2}a_{1}=0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
a_1 &= 0 \\
a_3 &= 0 \\
2a_1 &= 0 \\
-a_3 &= 0 \\
2a_3 &= 0 \\
-3b_1 &= 0 \\
-2b_1 &= 0 \\
-3b_2 &= 0 \\
-2b_2 &= 0 \\
4b_2 &= 0 \\
-a_2 - b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y - \left(\frac{\sqrt{xy+1}\, y}{2x}\right)(-x) \\
&= y + \frac{y\sqrt{xy+1}}{2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{y + \frac{y\sqrt{xy+1}}{2}} dy \end{aligned}$$

Which results in

$$S = -\frac{8 \ln\left(\sqrt{xy+1}+2\right)}{3} + 2 \ln\left(\sqrt{xy+1}+1\right) + \frac{2 \ln\left(\sqrt{xy+1}-1\right)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{\sqrt{xy+1}\, y}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{2}{\left(\sqrt{xy+1}+2\right) x} \\ S_y &= \frac{2}{y\left(\sqrt{xy+1}+2\right)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{8\ln\left(\sqrt{yx+1}+2\right)}{3} + 2\ln\left(\sqrt{yx+1}+1\right) + \frac{2\ln\left(\sqrt{yx+1}-1\right)}{3} = \ln(x) + c_1$$

Which simplifies to

$$-\frac{8\ln\left(\sqrt{yx+1}+2\right)}{3} + 2\ln\left(\sqrt{yx+1}+1\right) + \frac{2\ln\left(\sqrt{yx+1}-1\right)}{3} = \ln(x) + c_1$$

Summary

The solution(s) found are the following

$$-\frac{8\ln\left(\sqrt{yx+1}+2\right)}{3} + 2\ln\left(\sqrt{yx+1}+1\right) + \frac{2\ln\left(\sqrt{yx+1}-1\right)}{3} = \ln(x) + c_1 \tag{1}$$

Verification of solutions

$$-\frac{8\ln\left(\sqrt{yx+1}+2\right)}{3} + 2\ln\left(\sqrt{yx+1}+1\right) + \frac{2\ln\left(\sqrt{yx+1}-1\right)}{3} = \ln(x) + c_1$$

Verified OK.

Solving equation (2)

Writing the ode as

$$\begin{aligned} y' &= -\frac{\sqrt{xy+1}\,y}{2x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 - \frac{\sqrt{xy+1}\, y(b_3 - a_2)}{2x} - \frac{(xy+1)\, y^2 a_3}{4x^2} \\ &- \left(-\frac{y^2}{4\sqrt{xy+1}\, x} + \frac{\sqrt{xy+1}\, y}{2x^2}\right)(x a_2 + y a_3 + a_1) \\ &- \left(-\frac{y}{4\sqrt{xy+1}} - \frac{\sqrt{xy+1}}{2x}\right)(x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{-y^3 a_3 \sqrt{xy+1}\, x + 3x^3 y b_2 + x^2 y^2 a_2 + x^2 y^2 b_3 - x\, y^3 a_3 + 4 b_2 x^2 \sqrt{xy+1} - y^2 a_3 \sqrt{xy+1} + 3x^2 y b_1 - x\, y^2 a_1}{4x^2 \sqrt{xy+1}}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-y^3 a_3 \sqrt{xy+1}\, x + 3x^3 y b_2 + x^2 y^2 a_2 + x^2 y^2 b_3 - x\, y^3 a_3 + 4 b_2 x^2 \sqrt{xy+1} \\ &- y^2 a_3 \sqrt{xy+1} + 3x^2 y b_1 - x\, y^2 a_1 + 2x^2 b_2 - 2y^2 a_3 + 2x b_1 - 2y a_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &-y^3 a_3 \sqrt{xy+1}\, x + 2(xy+1)\, x^2 b_2 - 2(xy+1)\, y^2 a_3 + x^3 y b_2 \\ &+ x^2 y^2 a_2 + x^2 y^2 b_3 + x\, y^3 a_3 + 2(xy+1)\, x b_1 - 2(xy+1)\, y a_1 \\ &+ 4 b_2 x^2 \sqrt{xy+1} - y^2 a_3 \sqrt{xy+1} + x^2 y b_1 + x\, y^2 a_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$-y^3 a_3 \sqrt{xy+1}\, x + 3x^3 y b_2 + x^2 y^2 a_2 + x^2 y^2 b_3 - x\, y^3 a_3 + 4 b_2 x^2 \sqrt{xy+1} - y^2 a_3 \sqrt{xy+1} + 3x^2 y b_1 - x\, y^2 a_1 + 2x^2 b_2 - 2y^2 a_3 + 2x b_1 - 2y a_1 = 0$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{xy+1}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{xy+1} = v_3\right\}$$

The above PDE (6E) now becomes

$$-v_2^3 a_3 v_3 v_1 + v_1^2 v_2^2 a_2 - v_1 v_2^3 a_3 + 3v_1^3 v_2 b_2 + v_1^2 v_2^2 b_3 - v_1 v_2^2 a_1 - v_2^2 a_3 v_3 + 3v_1^2 v_2 b_1 + 4 b_2 v_1^2 v_3 - 2v_2^2 a_3 + 2v_1^2 b_2 - 2v_2 a_1 + 2v_1 b_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$3v_1^3 v_2 b_2 + (a_2 + b_3)\, v_1^2 v_2^2 + 3v_1^2 v_2 b_1 + 4 b_2 v_1^2 v_3 + 2v_1^2 b_2 - v_2^3 a_3 v_3 v_1 - v_1 v_2^3 a_3 - v_1 v_2^2 a_1 + 2v_1 b_1 - v_2^2 a_3 v_3 - 2v_2^2 a_3 - 2v_2 a_1 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-2a_1 &= 0\\
-a_1 &= 0\\
-2a_3 &= 0\\
-a_3 &= 0\\
2b_1 &= 0\\
3b_1 &= 0\\
2b_2 &= 0\\
3b_2 &= 0\\
4b_2 &= 0\\
a_2 + b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{\sqrt{xy+1}\,y}{2x}\right)(-x) \\
&= y - \frac{y\sqrt{xy+1}}{2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{y - \frac{y\sqrt{xy+1}}{2}} dy
\end{aligned}
$$

Which results in

$$S = \frac{2\ln\left(\sqrt{xy+1}+1\right)}{3} + 2\ln\left(\sqrt{xy+1}-1\right) - \frac{8\ln\left(\sqrt{xy+1}-2\right)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{\sqrt{xy+1}\,y}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2}{\left(\sqrt{xy+1}-2\right)x} \\ S_y &= -\frac{2}{y\left(\sqrt{xy+1}-2\right)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{2\ln\left(\sqrt{yx+1}+1\right)}{3} + 2\ln\left(\sqrt{yx+1}-1\right) - \frac{8\ln\left(\sqrt{yx+1}-2\right)}{3} = \ln(x) + c_1$$

Which simplifies to

$$\frac{2\ln\left(\sqrt{yx+1}+1\right)}{3}+2\ln\left(\sqrt{yx+1}-1\right)-\frac{8\ln\left(\sqrt{yx+1}-2\right)}{3}=\ln\left(x\right)+c_1$$

Summary

The solution(s) found are the following

$$\frac{2\ln\left(\sqrt{yx+1}+1\right)}{3}+2\ln\left(\sqrt{yx+1}-1\right)-\frac{8\ln\left(\sqrt{yx+1}-2\right)}{3}=\ln\left(x\right)+c_1 \quad (1)$$

Verification of solutions

$$\frac{2\ln\left(\sqrt{yx+1}+1\right)}{3}+2\ln\left(\sqrt{yx+1}-1\right)-\frac{8\ln\left(\sqrt{yx+1}-2\right)}{3}=\ln\left(x\right)+c_1$$

Verified OK.

Problem number: 313.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[_rational, _dAlembert]
```

$$\boxed{y' + xy'^2 - y = 0}$$

12.39.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$x\,p^2 + p - y = 0$$

Solving for y from the above results in

$$y = x\,p^2 + p \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = p^2$$
$$g = p$$

Hence (2) becomes

$$-p^2 + p = (2xp + 1)\, p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p^2 + p = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 1$$

Substituting these in (1A) gives

$$y = 0$$
$$y = 1 + x$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{-p(x)^2 + p(x)}{2p(x)\, x + 1} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{2x(p)\, p + 1}{-p^2 + p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p - 1}$$
$$q(p) = -\frac{1}{p\,(p - 1)}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2x(p)}{p-1} = -\frac{1}{p\,(p-1)}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int \frac{2}{p-1}dp}\\ &= (p-1)^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-\frac{1}{p\,(p-1)}\right)\\ \frac{\mathrm{d}}{\mathrm{d}p}\left((p-1)^2\,x\right) &= \left((p-1)^2\right)\left(-\frac{1}{p\,(p-1)}\right)\\ \mathrm{d}\left((p-1)^2\,x\right) &= \left(\frac{-p+1}{p}\right)\,\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}(p-1)^2\,x &= \int \frac{-p+1}{p}\,\mathrm{d}p\\ (p-1)^2\,x &= -p + \ln(p) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = (p-1)^2$ results in

$$x(p) = \frac{-p+\ln(p)}{(p-1)^2} + \frac{c_1}{(p-1)^2}$$

which simplifies to

$$x(p) = \frac{-p+\ln(p)+c_1}{(p-1)^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$\begin{aligned}p &= \frac{-1+\sqrt{1+4yx}}{2x}\\ p &= -\frac{1+\sqrt{1+4yx}}{2x}\end{aligned}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{2\left(2\ln \left(2\right) x -2 \ln \left(\frac{-1+\sqrt{1+4yx}}{x}\right) x -2 c_1 x +\sqrt{1+4yx}-1\right) x}{\left(-1+\sqrt{1+4yx}-2x \right)^{2}}$$

$$x = \frac{4 x^{2} \ln \left(\frac{-1-\sqrt{1+4yx}}{x}\right)+2 \left(2 c_1 x -2 \ln \left(2\right) x +\sqrt{1+4yx}+1\right) x}{\left(1+\sqrt{1+4yx}+2x \right)^{2}}$$

Summary

The solution(s) found are the following

$$y = 0 \tag{1}$$

$$y = 1+x \tag{2}$$

$$x = -\frac{2\left(2\ln \left(2\right) x -2 \ln \left(\frac{-1+\sqrt{1+4yx}}{x}\right) x -2 c_1 x +\sqrt{1+4yx}-1\right) x}{\left(-1+\sqrt{1+4yx}-2x \right)^{2}} \tag{3}$$

$$x = \frac{4 x^{2} \ln \left(\frac{-1-\sqrt{1+4yx}}{x}\right)+2 \left(2 c_1 x -2 \ln \left(2\right) x +\sqrt{1+4yx}+1\right) x}{\left(1+\sqrt{1+4yx}+2x \right)^{2}} \tag{4}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$y = 1+x$$

Verified OK.

$$x = -\frac{2\left(2\ln \left(2\right) x -2 \ln \left(\frac{-1+\sqrt{1+4yx}}{x}\right) x -2 c_1 x +\sqrt{1+4yx}-1\right) x}{\left(-1+\sqrt{1+4yx}-2x \right)^{2}}$$

Verified OK.

$$x = \frac{4 x^{2} \ln \left(\frac{-1-\sqrt{1+4yx}}{x}\right)+2 \left(2 c_1 x -2 \ln \left(2\right) x +\sqrt{1+4yx}+1\right) x}{\left(1+\sqrt{1+4yx}+2x \right)^{2}}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = 2\cos(x) + 2\sin(x)}$$

13.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 2\cos(x) + 2\sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\cos(x) + 2\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\sin(x), \cos(x)\, x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \sin(x) + A_2 \cos(x)\, x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \cos(x) - 2A_2 \sin(x) = 2\cos(x) + 2\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x\sin(x) - \cos(x)\, x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + (x \sin(x) - \cos(x) x)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + x \sin(x) - \cos(x) x \tag{1}$$

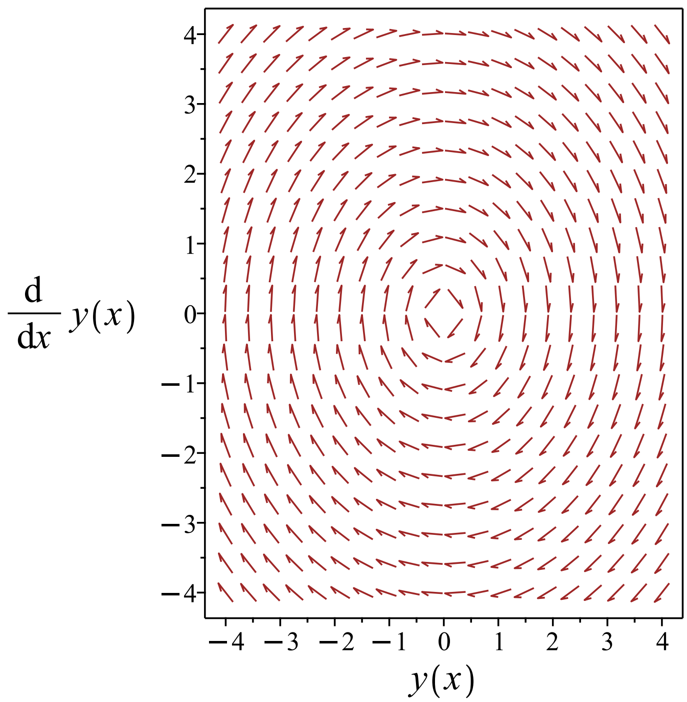

Figure 427: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + x \sin(x) - \cos(x) x$$

Verified OK.

13.1.2 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{aligned}
y'' + y &= 0 \qquad (1)\\
Ay'' + By' + Cy &= 0 \qquad (2)
\end{aligned}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1\\
B &= 0 \qquad (3)\\
C &= 1
\end{aligned}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \qquad (4)
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \qquad (5)\\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{1} \qquad (6)
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1\\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \qquad (7)
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 319: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B=0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B=0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\
&= \cos(x)(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \cos(x) + c_2 \sin(x)
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\cos(x) + 2\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\sin(x), \cos(x)x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\sin(x) + A_2\cos(x)x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1\cos(x) - 2A_2\sin(x) = 2\cos(x) + 2\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x\sin(x) - \cos(x)x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(x) + c_2\sin(x)) + (x\sin(x) - \cos(x)x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + x \sin(x) - \cos(x) x \tag{1}$$

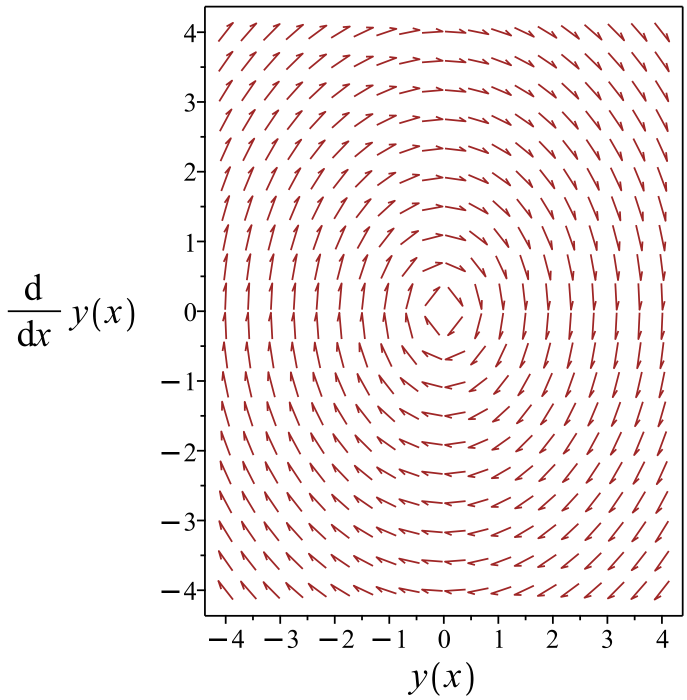

Figure 428: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + x \sin(x) - \cos(x) x$$

Verified OK.

13.1.3 Maple step by step solution

Let's solve

$y'' + y = 2\cos(x) + 2\sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\cos(x) + 2\sin(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int (1 - \cos(2x) + \sin(2x)) dx\right) + \sin(x) \left(\int (1 + \sin(2x) + \cos(2x)) dx\right)$

  ◦ Compute integrals

    $y_p(x) = \frac{(-2x+1)\cos(x)}{2} + \frac{(2x+1)\sin(x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + \frac{(-2x+1)\cos(x)}{2} + \frac{(2x+1)\sin(x)}{2}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 13. Basic concepts and definitions. Exercises page 98
Problem number: 319.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

```
[[_3rd_order, _quadrature]]
```

$$\boxed{xy''' = 2}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$xv''(x) = 0$$

Integrating twice gives the solution

$$v(x) = c_1 x + c_2$$

But since $y' = v(x)$ then we now need to solve the ode $y' = c_1 x + c_2$. Integrating both sides gives

$$\begin{aligned} y &= \int c_1 x + c_2 \, \mathrm{d}x \\ &= \frac{1}{2} c_1 x^2 + c_2 x + c_3 \end{aligned}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$xy''' = 0$$

Let the particular solution be

$$y_p = U_1 y_1 + U_2 y_2 + U_3 y_3$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i} \int \frac{F(x) W_i(x)}{a W(x)} \, dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 \\ y_1' & y_2' & y_3' \\ y_1'' & y_2'' & y_3'' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} 1 & x & x^2 \\ 0 & 1 & 2x \\ 0 & 0 & 2 \end{bmatrix}$$
$$|W| = 2$$

The determinant simplifies to

$$|W| = 2$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} x & x^2 \\ 1 & 2x \end{bmatrix}$$
$$= x^2$$

$$
\begin{aligned}
W_2(x) &= \det \begin{bmatrix} 1 & x^2 \\ 0 & 2x \end{bmatrix} \\
&= 2x
\end{aligned}
$$

$$
\begin{aligned}
W_3(x) &= \det \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix} \\
&= 1
\end{aligned}
$$

Now we are ready to evaluate each $U_i(x)$.

$$
\begin{aligned}
U_1 &= (-1)^{3-1} \int \frac{F(x)W_1(x)}{aW(x)} \, dx \\
&= (-1)^2 \int \frac{(2)\left(x^2\right)}{(x)\,(2)} \, dx \\
&= \int \frac{2x^2}{2x} \, dx \\
&= \int (x) \; dx \\
&= \frac{x^2}{2}
\end{aligned}
$$

$$
\begin{aligned}
U_2 &= (-1)^{3-2} \int \frac{F(x)W_2(x)}{aW(x)} \, dx \\
&= (-1)^1 \int \frac{(2)\,(2x)}{(x)\,(2)} \, dx \\
&= -\int \frac{4x}{2x} \, dx \\
&= -\int (2) \; dx \\
&= -2x
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{3-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{(2)\,(1)}{(x)\,(2)}\,dx \\
&= \int \frac{2}{2x}\,dx \\
&= \int \left(\frac{1}{x}\right) dx \\
&= \ln(x)
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1 y_1 + U_2 y_2 + U_3 y_3
$$

Hence

$$
\begin{aligned}
y_p = &\left(\frac{x^2}{2}\right) \\
&+ (-2x)\,(x) \\
&+ (\ln(x))\,(x^2)
\end{aligned}
$$

Therefore the particular solution is

$$
y_p = x^2 \left(-\frac{3}{2} + \ln(x)\right)
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \Big(y \\
&= \frac{1}{2} c_1 x^2 + c_2 x + c_3\Big) + \left(x^2\left(-\frac{3}{2} + \ln(x)\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 x^2}{2} + c_2 x + c_3 + x^2\left(-\frac{3}{2} + \ln(x)\right) \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 x^2}{2} + c_2 x + c_3 + x^2\left(-\frac{3}{2} + \ln(x)\right)
$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 13. Basic concepts and definitions. Exercises page 98
Problem number: 320.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_xy]]
```

$$\boxed{y'' - y'^2 = 0}$$

13.3.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p^2} dp = x + c_1$$
$$-\frac{1}{p} = x + c_1$$

Solving for p gives these solutions

$$p_1 = -\frac{1}{x + c_1}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{1}{x + c_1}$$

Integrating both sides gives

$$y = \int -\frac{1}{x + c_1} \, \mathrm{d}x$$
$$= -\ln(x + c_1) + c_2$$

Summary

The solution(s) found are the following

$$y = -\ln(x + c_1) + c_2 \tag{1}$$

Verification of solutions

$$y = -\ln(x + c_1) + c_2$$

Verified OK.

13.3.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$y'' = \frac{dp}{dx}$$
$$= \frac{dy}{dx} \frac{dp}{dy}$$
$$= p \frac{dp}{dy}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right)-p(y)^{2}=0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\begin{aligned}\int \frac{1}{p}dp &= y+c_1\\ \ln(p) &= y+c_1\\ p &= e^{y+c_1}\\ p &= c_1 e^{y}\end{aligned}$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$y'=c_1 e^{y}$$

Integrating both sides gives

$$\begin{aligned}\int \frac{e^{-y}}{c_1}dy &= x+c_2\\ -\frac{e^{-y}}{c_1} &= x+c_2\end{aligned}$$

Solving for y gives these solutions

$$y_1=\ln\left(-\frac{1}{(x+c_2)\,c_1}\right)$$

Summary

The solution(s) found are the following

$$y=\ln\left(-\frac{1}{(x+c_2)\,c_1}\right)\tag{1}$$

Verification of solutions

$$y=\ln\left(-\frac{1}{(x+c_2)\,c_1}\right)$$

Verified OK.

13.3.3 Maple step by step solution

Let's solve

$y'' - y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) - u(x)^2 = 0$

- Separate variables

  $\frac{u'(x)}{u(x)^2} = 1$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)^2} dx = \int 1 dx + c_1$

- Evaluate integral

  $-\frac{1}{u(x)} = x + c_1$

- Solve for $u(x)$

  $u(x) = -\frac{1}{x+c_1}$

- Solve 1st ODE for $u(x)$

  $u(x) = -\frac{1}{x+c_1}$

- Make substitution $u = y'$

  $y' = -\frac{1}{x+c_1}$

- Integrate both sides to solve for y

  $\int y' dx = \int -\frac{1}{x+c_1} dx + c_2$

- Compute integrals

  $y = -\ln(x + c_1) + c_2$

Section: Chapter 2 (Higher order ODE's). Section 13. Basic concepts and definitions. Exercises page 98
Problem number: 321.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{(x-1)\,y''=1}$$

Simplyfing the ode gives

$$y''=\frac{1}{x-1}$$

13.4.1 Solving as second order ode quadrature ode

Integrating once gives

$$y' = \ln(x-1) + c_1$$

Integrating again gives

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2$$

Summary

The solution(s) found are the following

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2 \tag{1}$$

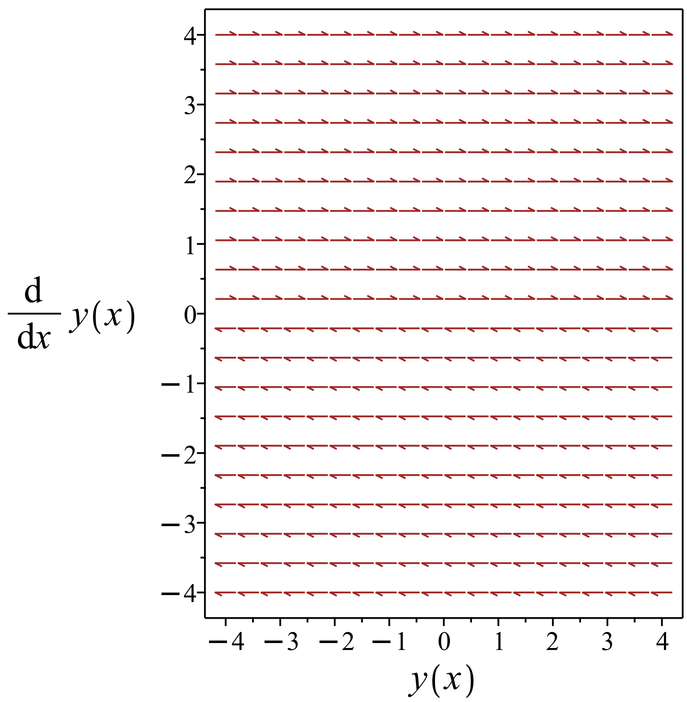

Figure 429: Slope field plot

Verification of solutions

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2$$

Verified OK.

13.4.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = \frac{1}{x-1}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)} \\
&= 0
\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= 1 \\ y_2 &= x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x}{x-1}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{x-1} dx$$

Hence

$$u_1 = -x - \ln(x-1)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1}{x-1}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x-1} dx$$

Hence

$$u_2 = \ln(x-1)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x - \ln(x-1) + \ln(x-1)\, x$$

Which simplifies to

$$y_p(x) = \ln(x-1)\,(x-1) - x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + (\ln(x-1)\,(x-1) - x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 x + c_1 + \ln(x-1)(x-1) - x \tag{1}$$

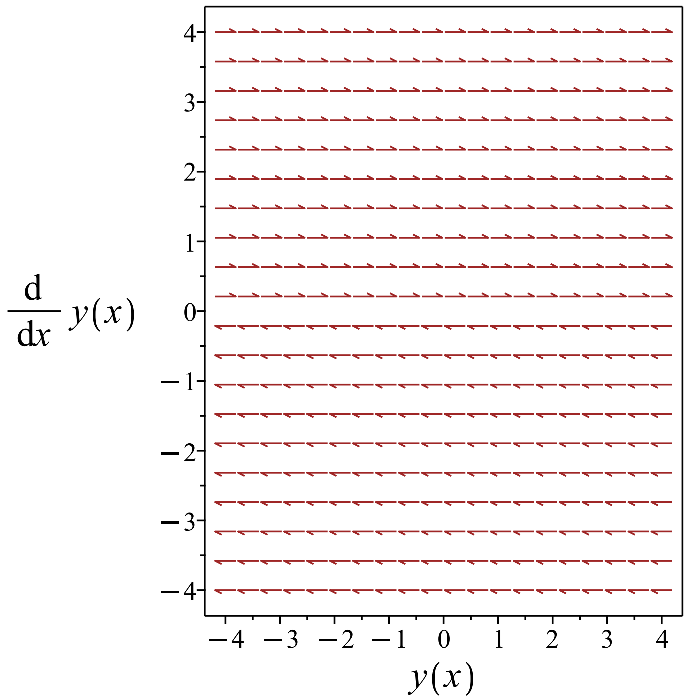

Figure 430: Slope field plot

Verification of solutions

$$y = c_2 x + c_1 + \ln(x-1)(x-1) - x$$

Verified OK.

13.4.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int y'' dx = \int \frac{1}{x-1} dx$$
$$y' = \ln(x-1) + c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int \ln(x-1) + c_1 \, \mathrm{d}x \\ &= \ln(x-1)(x-1) - x + 1 + c_1 x + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2 \tag{1}$$

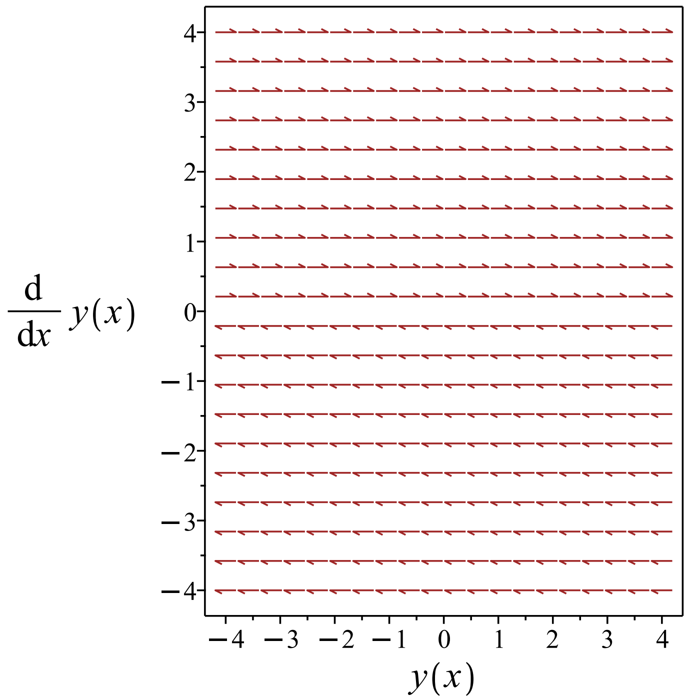

Figure 431: Slope field plot

Verification of solutions

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2$$

Verified OK.

13.4.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \frac{1}{x-1} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(x) &= \int \frac{1}{x-1}\, dx \\ &= \ln(x-1) + c_1 \end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \ln(x-1) + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \ln(x-1) + c_1\, dx \\ &= \ln(x-1)(x-1) - x + 1 + c_1 x + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2 \tag{1}$$

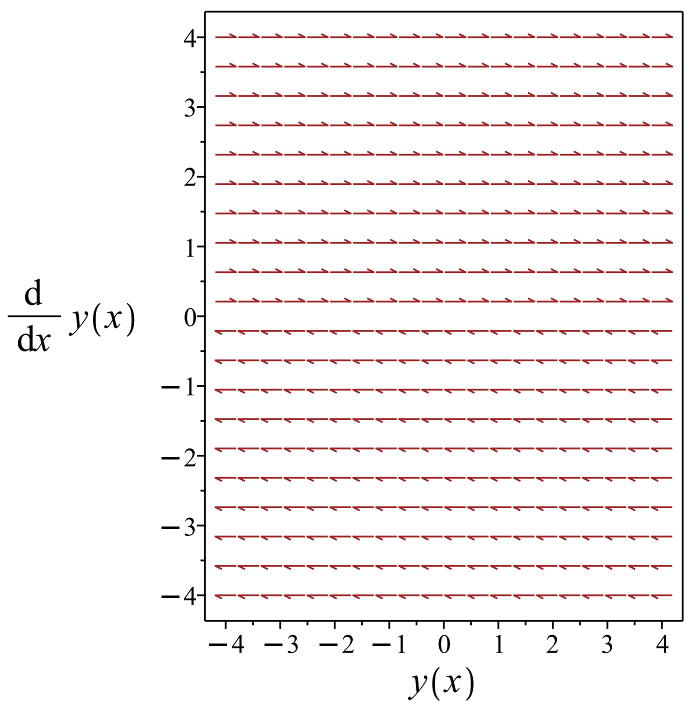

Figure 432: Slope field plot

Verification of solutions

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2$$

Verified OK.

13.4.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 322: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B=0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= 1
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B=0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= 1 \int \frac{1}{1}\, dx \\
&= 1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2 x + c_1
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x}{x-1}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{x-1} dx$$

Hence

$$u_1 = -x - \ln(x-1)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1}{x-1}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x-1} dx$$

Hence

$$u_2 = \ln(x-1)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x - \ln(x-1) + \ln(x-1)\, x$$

Which simplifies to

$$y_p(x) = \ln(x-1)(x-1) - x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + (\ln(x-1)(x-1) - x) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2x + c_1 + \ln(x-1)(x-1) - x \tag{1}$$

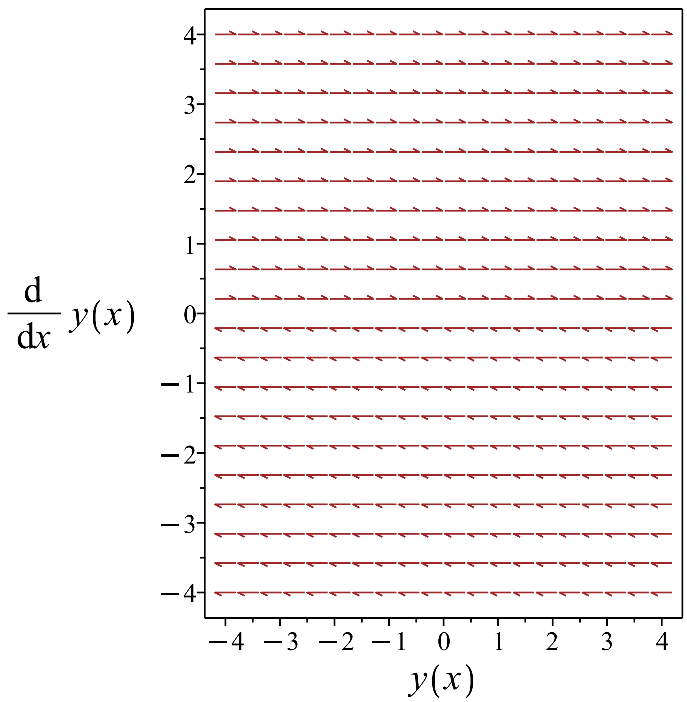

Figure 433: Slope field plot

Verification of solutions

$$y = c_2x + c_1 + \ln(x-1)(x-1) - x$$

Verified OK.

13.4.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$
\begin{aligned}
p(x) &= 1 \\
q(x) &= 0 \\
r(x) &= 0 \\
s(x) &= \frac{1}{x-1}
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0-(0)+(0) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\,y' + (q(x)-p'(x))\,y)' = s(x)
$$

Integrating gives

$$
p(x)\,y' + (q(x)-p'(x))\,y = \int s(x)\;dx
$$

Substituting the above values for p, q, r, s gives

$$
y' = \int \frac{1}{x-1}\,dx
$$

We now have a first order ode to solve which is

$$
y' = \ln(x-1) + c_1
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \ln(x-1) + c_1 \,\mathrm{d}x \\
&= \ln(x-1)\,(x-1) - x + 1 + c_1 x + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \ln(x-1)\,(x-1) - x + 1 + c_1 x + c_2 \tag{1}
$$

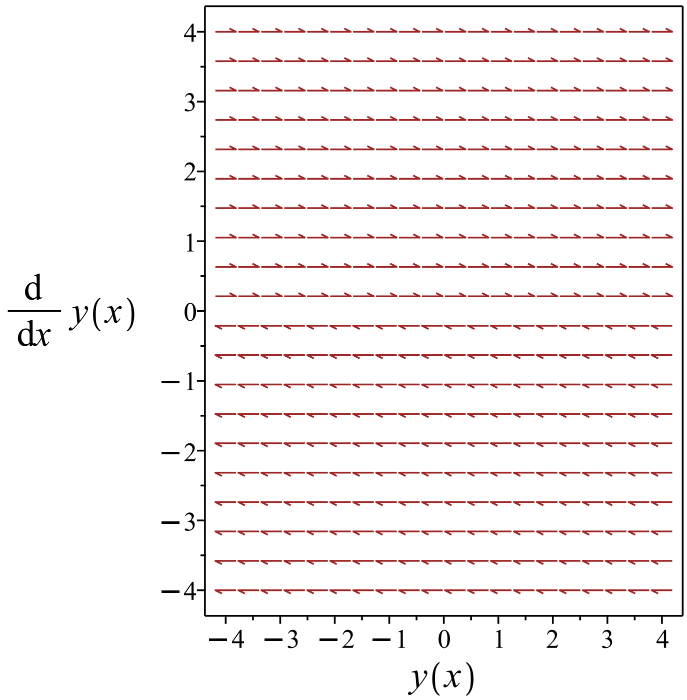

Figure 434: Slope field plot

Verification of solutions

$$y = \ln(x-1)(x-1) - x + 1 + c_1 x + c_2$$

Verified OK.

13.4.7 Maple step by step solution

Let's solve

$y'' = \frac{1}{x-1}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm \left(\sqrt{0}\right)}{2}$

- Roots of the characteristic polynomial

$r = 0$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))}dx\right), f(x) = \frac{1}{x-1}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\left(\int \frac{x}{x-1}dx\right) + x\left(\int \frac{1}{x-1}dx\right)$

  - Compute integrals

    $y_p(x) = \ln(x-1)(x-1) - x$

- Substitute particular solution into general solution to ODE

  $y = c_2 x + c_1 + \ln(x-1)(x-1) - x$

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y'^4 = 1}$$

Solving the given ode for y' results in 4 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = 1 \tag{1}$$
$$y' = -1 \tag{2}$$
$$y' = i \tag{3}$$
$$y' = -i \tag{4}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int 1 \, \mathrm{d}x \\ &= x + c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x + c_1 \tag{1}$$

Verification of solutions

$$y = x + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int -1 \,\mathrm{d}x \\ &= -x + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -x + c_2 \tag{1}$$

Verification of solutions

$$y = -x + c_2$$

Verified OK.

Solving equation (3)

Integrating both sides gives

$$\begin{aligned} y &= \int i \,\mathrm{d}x \\ &= ix + c_3 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = ix + c_3 \tag{1}$$

Verification of solutions

$$y = ix + c_3$$

Verified OK.

Solving equation (4)

Integrating both sides gives

$$y = \int -i \, \mathrm{d}x$$
$$= -ix + c_4$$

Summary
The solution(s) found are the following

$$y = -ix + c_4 \tag{1}$$

Verification of solutions

$$y = -ix + c_4$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y = 0}$$

13.6.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) \tag{1}$$

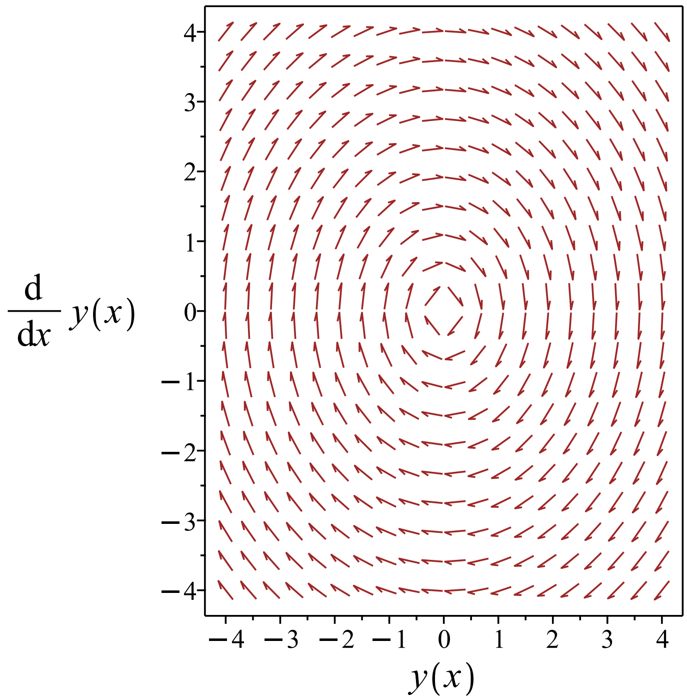

Figure 435: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Verified OK.

13.6.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + yy')\, dx = 0$$

$$\frac{y'^2}{2} + \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-y^2 + 2c_1} \tag{1}$$

$$y' = -\sqrt{-y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-y^2+2c_1}}dy = \int dx$$
$$\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x+c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-y^2+2c_1}}dy = \int dx$$
$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = c_3+x$$

Summary

The solution(s) found are the following

$$\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x+c_2 \tag{1}$$
$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = c_3+x \tag{2}$$

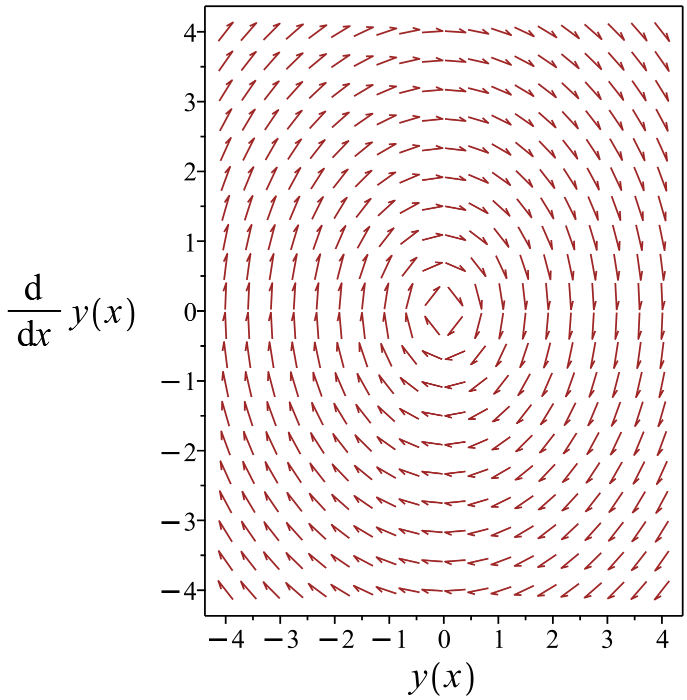

Figure 436: Slope field plot

<u>Verification of solutions</u>

$$\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = x + c_2$$

Verified OK.

$$-\arctan\left(\frac{y}{\sqrt{-y^2+2c_1}}\right) = c_3 + x$$

Verified OK.

13.6.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= 1
\end{aligned}
\tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 325: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x)(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)(\tan(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) \tag{1}$$

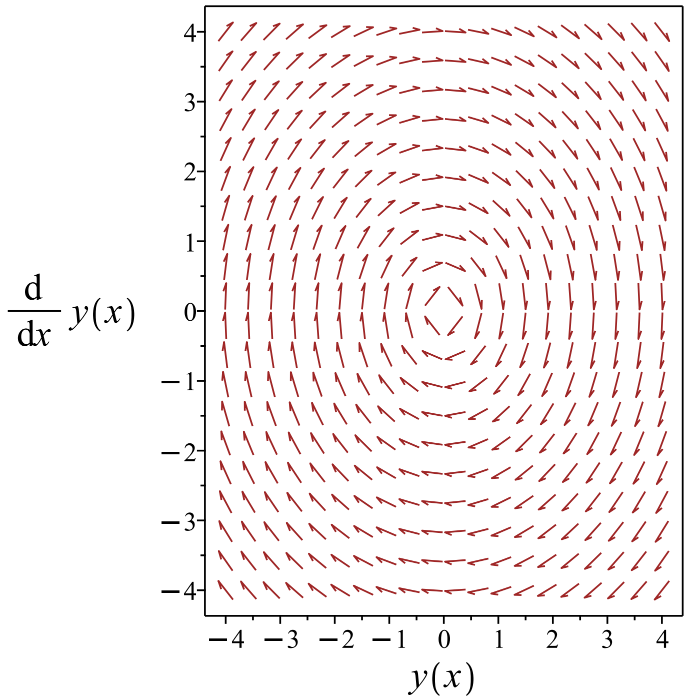

Figure 437: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Verified OK.

13.6.4 Maple step by step solution

Let's solve

$y'' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \cos(x) + c_2 \sin(x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 3y' + 2y = 2}$$

13.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda \, \mathrm{e}^{\lambda x} + 2 \, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(2)} \\ &= \frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{3}{2} + \frac{1}{2}$$

$$\lambda_2 = \frac{3}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 2$$

$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$y = c_1 e^{(2)x} + c_2 e^{(1)x}$$

Or

$$y = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 = 2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2 e^x\right) + (1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^x + 1 \tag{1}$$

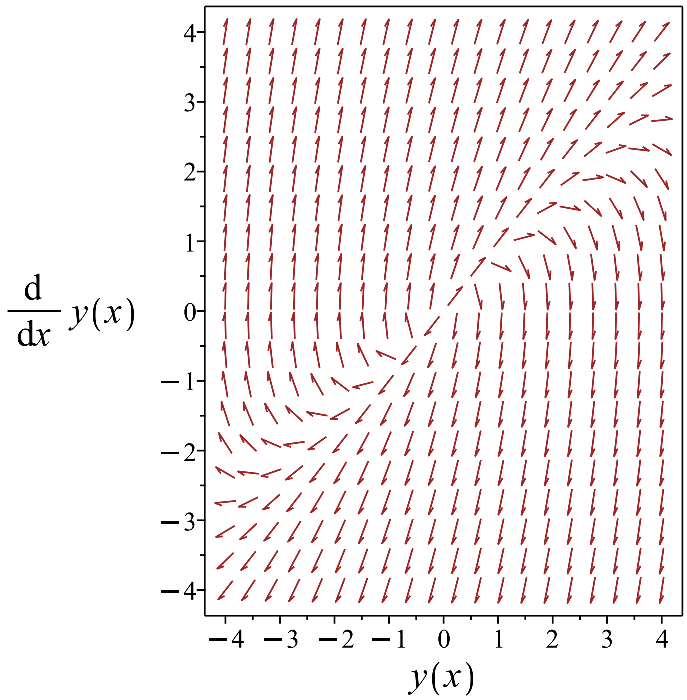

Figure 438: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{x} + 1$$

Verified OK.

13.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 327: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\
&= z_1 e^{\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(\mathrm{e}^x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x c_1 + c_2 \mathrm{e}^{2x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
1
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\mathrm{e}^x, \mathrm{e}^{2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
2A_1 = 2
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + c_2 e^{2x}\right) + (1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x c_1 + c_2 e^{2x} + 1 \tag{1}$$

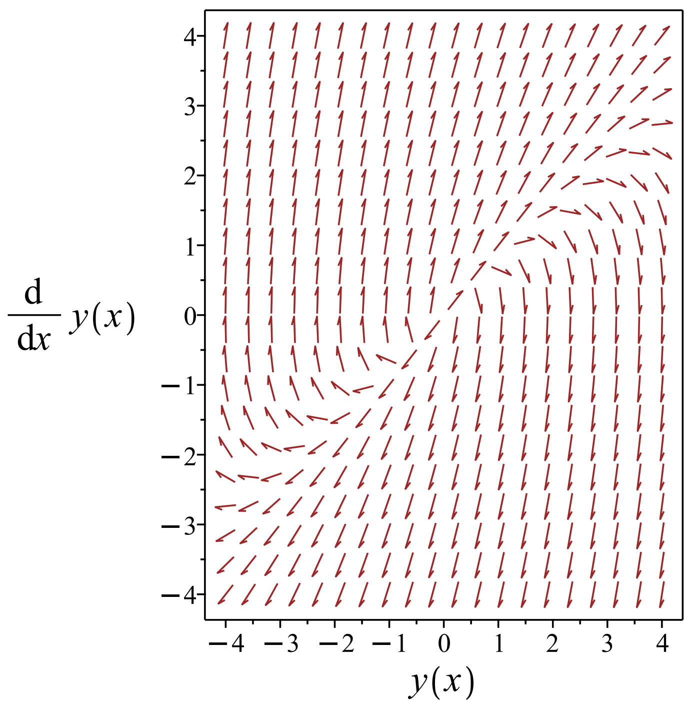

Figure 439: Slope field plot

Verification of solutions

$$y = e^x c_1 + c_2 e^{2x} + 1$$

Verified OK.

13.7.3 Maple step by step solution

Let's solve

$y'' - 3y' + 2y = 2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + c_2 e^{2x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{2x} \\ e^x & 2\,e^{2x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{3x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -2\,e^x\left(\int e^{-x} dx\right) + 2\,e^{2x}\left(\int e^{-2x} dx\right)$

- Compute integrals

  $y_p(x) = 1$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + c_2 e^{2x} + 1$

Section: Chapter 2 (Higher order ODE's). Section 13. Basic concepts and definitions. Exercises page 98
Problem number: 325.
ODE order: 2.
ODE degree: 2.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - \left(1 + {y'}^2\right)^{\frac{3}{2}} = 0}$$

13.8.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \left(1 + p(x)^2\right)^{\frac{3}{2}} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{(p^2+1)^{\frac{3}{2}}} dp = \int dx$$
$$\frac{p(x)}{\sqrt{1+p(x)^2}} = x + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{y'}{\sqrt{1+y'^2}} = x + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int c_1\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}} + x\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}\,\mathrm{d}x \\ &= \sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}\,(c_1+x+1)\,(c_1+x-1)+c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}\,(c_1+x+1)\,(c_1+x-1)+c_2 \tag{1}$$

Verification of solutions

$$y = \sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}\,(c_1+x+1)\,(c_1+x-1)+c_2$$

Verified OK.

13.8.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y)\left(\frac{d}{dy}p(y)\right) = \left(1+p(y)^2\right)^{\frac{3}{2}}
$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{p}{(p^2+1)^{\frac{3}{2}}}dp &= \int dy \\
-\frac{1}{\sqrt{1+p\left(y\right)^2}} &= y+c_1
\end{aligned}
$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$
-\frac{1}{\sqrt{1+y'^2}} = y+c_1
$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$
y' = \frac{\sqrt{-y^2-2yc_1-c_1^2+1}}{y+c_1} \tag{1}
$$

$$
y' = -\frac{\sqrt{-y^2-2yc_1-c_1^2+1}}{y+c_1} \tag{2}
$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$
\begin{aligned}
\int \frac{y+c_1}{\sqrt{-c_1^2-2c_1y-y^2+1}}dy &= \int dx \\
\frac{(y+c_1+1)\,(y+c_1-1)}{\sqrt{-y^2-2yc_1-c_1^2+1}} &= x+c_2
\end{aligned}
$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{y+c_1}{\sqrt{-c_1^2-2c_1y-y^2+1}}dy = \int dx$$
$$-\frac{(y+c_1+1)(y+c_1-1)}{\sqrt{-y^2-2yc_1-c_1^2+1}} = c_3+x$$

Summary

The solution(s) found are the following

$$\frac{(y+c_1+1)(y+c_1-1)}{\sqrt{-y^2-2yc_1-c_1^2+1}} = x+c_2 \tag{1}$$
$$-\frac{(y+c_1+1)(y+c_1-1)}{\sqrt{-y^2-2yc_1-c_1^2+1}} = c_3+x \tag{2}$$

Verification of solutions

$$\frac{(y+c_1+1)(y+c_1-1)}{\sqrt{-y^2-2yc_1-c_1^2+1}} = x+c_2$$

Verified OK.

$$-\frac{(y+c_1+1)(y+c_1-1)}{\sqrt{-y^2-2yc_1-c_1^2+1}} = c_3+x$$

Verified OK.

13.8.3 Maple step by step solution

Let's solve

$y'' = \left(1+y'^2\right)^{\frac{3}{2}}$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) = \left(1+u(x)^2\right)^{\frac{3}{2}}$

- Separate variables

$$\frac{u'(x)}{\left(1+u(x)^2\right)^{\frac{3}{2}}} = 1$$

- Integrate both sides with respect to x

$$\int \frac{u'(x)}{\left(1+u(x)^2\right)^{\frac{3}{2}}} dx = \int 1dx + c_1$$

- Evaluate integral

$$\frac{u(x)}{\sqrt{1+u(x)^2}} = x + c_1$$

- Solve for $u(x)$

$$u(x) = c_1\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}} + x\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}$$

- Solve 1st ODE for $u(x)$

$$u(x) = c_1\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}} + x\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}$$

- Make substitution $u = y'$

$$y' = c_1\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}} + x\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}$$

- Integrate both sides to solve for y

$$\int y'dx = \int \left(c_1\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}} + x\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}\right) dx + c_2$$

- Compute integrals

$$y = \sqrt{-\frac{1}{c_1^2+2c_1x+x^2-1}}\,(c_1+x+1)\,(c_1+x-1) + c_2$$

Section: Chapter 2 (Higher order ODE's). Section 13. Basic concepts and definitions. Exercises page 98
Problem number: 326.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear], [
   _2nd_order, _reducible, _mu_x_y1], [_2nd_order, _reducible,
   _mu_xy]]
```

$$\boxed{{y'}^2+yy''=1}$$

13.9.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left({y'}^2+yy''\right) dx = \int 1 dx$$
$$yy' = x + c_1$$

Which is now solved for y. In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x+c_1}{y} \end{aligned}$$

Where $f(x) = x + c_1$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{1}{y}}\, dy &= x + c_1\, dx \\ \int \frac{1}{\frac{1}{y}}\, dy &= \int x + c_1\, dx \\ \frac{y^2}{2} &= \frac{1}{2}x^2 + c_1 x + c_2 \end{aligned}$$

The solution is

$$\frac{y^2}{2} - \frac{x^2}{2} - c_1 x - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{y^2}{2} - \frac{x^2}{2} - c_1 x - c_2 = 0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2} - \frac{x^2}{2} - c_1 x - c_2 = 0$$

Verified OK.

13.9.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y)^2 + yp(y)\left(\frac{d}{dy}p(y)\right) = 1
$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(y,p) \\
&= f(y)g(p) \\
&= -\frac{p^2-1}{yp}
\end{aligned}
$$

Where $f(y) = -\frac{1}{y}$ and $g(p) = \frac{p^2-1}{p}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{p^2-1}{p}}\,dp &= -\frac{1}{y}\,dy \\
\int \frac{1}{\frac{p^2-1}{p}}\,dp &= \int -\frac{1}{y}\,dy \\
\frac{\ln(p-1)}{2} + \frac{\ln(p+1)}{2} &= -\ln(y) + c_1
\end{aligned}
$$

The above can be written as

$$
\begin{aligned}
\left(\frac{1}{2}\right)(\ln(p-1) + \ln(p+1)) &= -\ln(y) + 2c_1 \\
\ln(p-1) + \ln(p+1) &= (2)(-\ln(y) + 2c_1) \\
&= -2\ln(y) + 4c_1
\end{aligned}
$$

Raising both side to exponential gives

$$
e^{\ln(p-1)+\ln(p+1)} = e^{-2\ln(y)+2c_1}
$$

Which simplifies to

$$
\begin{aligned}
p^2 - 1 &= \frac{2c_1}{y^2} \\
&= \frac{c_2}{y^2}
\end{aligned}
$$

The solution is

$$
p(y)^2 - 1 = \frac{c_2}{y^2}
$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
y'^2 - 1 = \frac{c_2}{y^2}
$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$
y' = \frac{\sqrt{y^2 + c_2}}{y} \tag{1}
$$

$$
y' = -\frac{\sqrt{y^2 + c_2}}{y} \tag{2}
$$

Now each one of the above ODE is solved.

<u>Solving equation (1)</u>

Integrating both sides gives

$$
\begin{aligned}
\int \frac{y}{\sqrt{y^2 + c_2}} dy &= \int dx \\
\sqrt{y^2 + c_2} &= c_3 + x
\end{aligned}
$$

<u>Solving equation (2)</u>

Integrating both sides gives

$$
\begin{aligned}
\int -\frac{y}{\sqrt{y^2 + c_2}} dy &= \int dx \\
-\sqrt{y^2 + c_2} &= x + c_4
\end{aligned}
$$

Summary
The solution(s) found are the following

$$\sqrt{y^2+c_2} = c_3 + x \tag{1}$$
$$-\sqrt{y^2+c_2} = x + c_4 \tag{2}$$

Verification of solutions

$$\sqrt{y^2+c_2} = c_3 + x$$

Verified OK.

$$-\sqrt{y^2+c_2} = x + c_4$$

Verified OK.

13.9.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'^2 + yy'' = 1$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y'^2 + yy''\right) dx = \int 1dx$$
$$yy' = x + c_1$$

Which is now solved for y. In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x+c_1}{y} \end{aligned}$$

Where $f(x) = x + c_1$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\, dy = x + c_1\, dx$$
$$\int \frac{1}{\frac{1}{y}}\, dy = \int x + c_1\, dx$$
$$\frac{y^2}{2} = \frac{1}{2}x^2 + c_1 x + c_2$$

The solution is

$$\frac{y^2}{2} - \frac{x^2}{2} - c_1 x - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{y^2}{2} - \frac{x^2}{2} - c_1 x - c_2 = 0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2} - \frac{x^2}{2} - c_1 x - c_2 = 0$$

Verified OK.

13.9.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\begin{aligned}\frac{\partial a_2}{\partial y} &= \frac{\partial a_1}{\partial y'}\\ \frac{\partial a_2}{\partial x} &= \frac{\partial a_0}{\partial y'}\\ \frac{\partial a_1}{\partial x} &= \frac{\partial a_0}{\partial y}\end{aligned}$$

Looking at the the ode given we see that

$$\begin{aligned}a_2 &= y\\ a_1 &= y'\\ a_0 &= -1\end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\begin{aligned}\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx &= c_1\\ \int y\, dy' + \int y'\, dy + \int -1\, dx &= c_1\end{aligned}$$

Which results in

$$2yy' - x = c_1$$

Which is now solved In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{\frac{x}{2}+\frac{c_1}{2}}{y} \end{aligned}$$

Where $f(x)=\frac{x}{2}+\frac{c_1}{2}$ and $g(y)=\frac{1}{y}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{1}{y}}\,dy &= \frac{x}{2}+\frac{c_1}{2}\,dx \\ \int \frac{1}{\frac{1}{y}}\,dy &= \int \frac{x}{2}+\frac{c_1}{2}\,dx \\ \frac{y^2}{2} &= \frac{1}{4}x^2+\frac{1}{2}c_1x+c_2 \end{aligned}$$

The solution is

$$\frac{y^2}{2}-\frac{x^2}{4}-\frac{c_1x}{2}-c_2=0$$

Summary

The solution(s) found are the following

$$\frac{y^2}{2}-\frac{x^2}{4}-\frac{c_1x}{2}-c_2=0 \tag{1}$$

Verification of solutions

$$\frac{y^2}{2}-\frac{x^2}{4}-\frac{c_1x}{2}-c_2=0$$

Warning, solution could not be verified

13.9.5 Maple step by step solution

Let's solve

$y'^2 + yy'' = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y), y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $u(y)^2 + yu(y)\left(\frac{d}{dy}u(y)\right) = 1$

- Separate variables

  $\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{-u(y)^2+1} = \frac{1}{y}$

- Integrate both sides with respect to y

  $\int \frac{\left(\frac{d}{dy}u(y)\right)u(y)}{-u(y)^2+1}dy = \int \frac{1}{y}dy + c_1$

- Evaluate integral

  $-\frac{\ln(u(y)-1)}{2} - \frac{\ln(u(y)+1)}{2} = \ln(y) + c_1$

- Solve for $u(y)$

  $\left\{u(y) = \frac{y\,e^{c_1}\left(y\,e^{c_1}-\sqrt{(e^{c_1})^2y^2+1}\right)+1}{y\,e^{c_1}\left(y\,e^{c_1}-\sqrt{(e^{c_1})^2y^2+1}\right)}, u(y) = \frac{y\,e^{c_1}\left(y\,e^{c_1}+\sqrt{(e^{c_1})^2y^2+1}\right)+1}{y\,e^{c_1}\left(y\,e^{c_1}+\sqrt{(e^{c_1})^2y^2+1}\right)}\right\}$

- Solve 1st ODE for $u(y)$

  $u(y) = \frac{y\,e^{c_1}\left(y\,e^{c_1}-\sqrt{(e^{c_1})^2y^2+1}\right)+1}{y\,e^{c_1}\left(y\,e^{c_1}-\sqrt{(e^{c_1})^2y^2+1}\right)}$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}-\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}-\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}$$

- Separate variables

$$\frac{y' y\left(y\,\mathrm{e}^{c_1}-\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}-\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1} = \frac{1}{\mathrm{e}^{c_1}}$$

- Integrate both sides with respect to x

$$\int \frac{y' y\left(y\,\mathrm{e}^{c_1}-\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}-\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1}dx = \int \frac{1}{\mathrm{e}^{c_1}}dx + c_2$$

- Evaluate integral

$$-\frac{\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}}{(\mathrm{e}^{c_1})^2} = \frac{x}{\mathrm{e}^{c_1}} + c_2$$

- Solve for y

$$\left\{y = \frac{\sqrt{-1+(\mathrm{e}^{c_1})^4 c_2^2+2(\mathrm{e}^{c_1})^3 c_2 x+(\mathrm{e}^{c_1})^2 x^2}}{\mathrm{e}^{c_1}}, y = -\frac{\sqrt{-1+(\mathrm{e}^{c_1})^4 c_2^2+2(\mathrm{e}^{c_1})^3 c_2 x+(\mathrm{e}^{c_1})^2 x^2}}{\mathrm{e}^{c_1}}\right\}$$

- Solve 2nd ODE for $u(y)$

$$u(y) = \frac{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}$$

- Separate variables

$$\frac{y' y\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1} = \frac{1}{\mathrm{e}^{c_1}}$$

- Integrate both sides with respect to x

$$\int \frac{y' y\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)}{y\,\mathrm{e}^{c_1}\left(y\,\mathrm{e}^{c_1}+\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}\right)+1}dx = \int \frac{1}{\mathrm{e}^{c_1}}dx + c_2$$

- Evaluate integral

$$\frac{\sqrt{(\mathrm{e}^{c_1})^2 y^2+1}}{(\mathrm{e}^{c_1})^2} = \frac{x}{\mathrm{e}^{c_1}} + c_2$$

- Solve for y

$$\left\{y=\frac{\sqrt{-1+(\mathrm{e}^{c_1})^4c_2^2+2(\mathrm{e}^{c_1})^3c_2x+(\mathrm{e}^{c_1})^2x^2}}{\mathrm{e}^{c_1}}, y=-\frac{\sqrt{-1+(\mathrm{e}^{c_1})^4c_2^2+2(\mathrm{e}^{c_1})^3c_2x+(\mathrm{e}^{c_1})^2x^2}}{\mathrm{e}^{c_1}}\right\}$$

Problem number: 327.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _quadrature]]
```

$$\boxed{y'''' = x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' = 0$$

The characteristic equation is

$$\lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_4x^3 + c_3x^2 + c_2x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$
$$y_4 = x^3$$

Now the particular solution to the given ODE is found

$$y'''' = x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, x^3\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2, x^3\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3, x^4\}]$$

Since x^3 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4, x^5\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2x^5 + A_1x^4$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$120xA_2 + 24A_1 = x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{120}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^5}{120}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_4x^3 + c_3x^2 + c_2x + c_1\right) + \left(\frac{x^5}{120}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_4x^3 + c_3x^2 + c_2x + c_1 + \frac{1}{120}x^5 \tag{1}$$

Verification of solutions

$$y = c_4x^3 + c_3x^2 + c_2x + c_1 + \frac{1}{120}x^5$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _quadrature]]
```

$$\boxed{y''' = x + \cos(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' = 0$$

The characteristic equation is

$$\lambda^3 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_3x^2 + c_2x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$

Now the particular solution to the given ODE is found

$$y''' = x + \cos(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}, \{\cos(x), \sin(x)\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2, x^3\}, \{\cos(x), \sin(x)\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3, x^4\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^4 + A_1 x^3 + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$24A_2 x + 6A_1 + A_3 \sin(x) - A_4 \cos(x) = x + \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{24}, A_3 = 0, A_4 = -1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^4}{24} - \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_3 x^2 + c_2 x + c_1) + \left(\frac{x^4}{24} - \sin(x)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_3 x^2 + c_2 x + c_1 + \frac{x^4}{24} - \sin(x) \tag{1}$$

Verification of solutions

$$y = c_3 x^2 + c_2 x + c_1 + \frac{x^4}{24} - \sin(x)$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 329.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{y''(x+2)^5 = 1}$$

With initial conditions

$$\left[y(-1) = \frac{1}{12}, y'(-1) = -\frac{1}{4}\right]$$

Simplyfing the ode gives

$$y'' = \frac{1}{(x+2)^5}$$

14.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 0 \\ F &= \frac{1}{(x+2)^5} \end{aligned}$$

Hence the ode is

$$y'' = \frac{1}{(x+2)^5}$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = -1$ is inside this domain. The domain of $F = \frac{1}{(x+2)^5}$ is

$$\{x < -2 \lor -2 < x\}$$

And the point $x_0 = -1$ is also inside this domain. Hence solution exists and is unique.

14.3.2 Solving as second order ode quadrature ode

Integrating once gives

$$y' = -\frac{1}{4(x+2)^4} + c_1$$

Integrating again gives

$$y = \frac{1}{12(x+2)^3} + c_1 x + c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{1}{12(x+2)^3} + c_1 x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{12}$ and $x = -1$ in the above gives

$$\frac{1}{12} = -c_1 + c_2 + \frac{1}{12} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{1}{4 (x+2)^4} + c_1$$

substituting $y' = -\frac{1}{4}$ and $x = -1$ in the above gives

$$-\frac{1}{4} = c_1 - \frac{1}{4} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

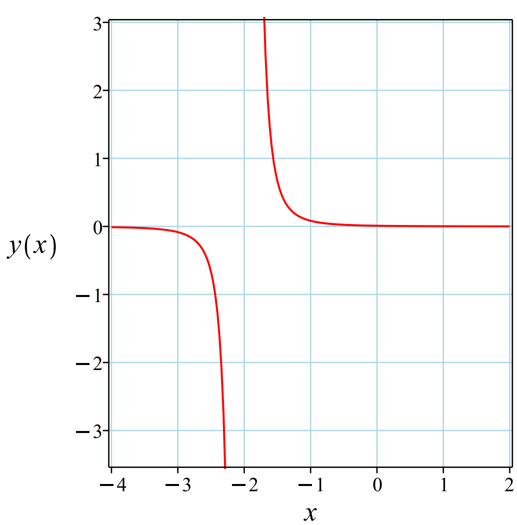
Substituting these values back in above solution results in

$$y = \frac{1}{12 (x+2)^3}$$

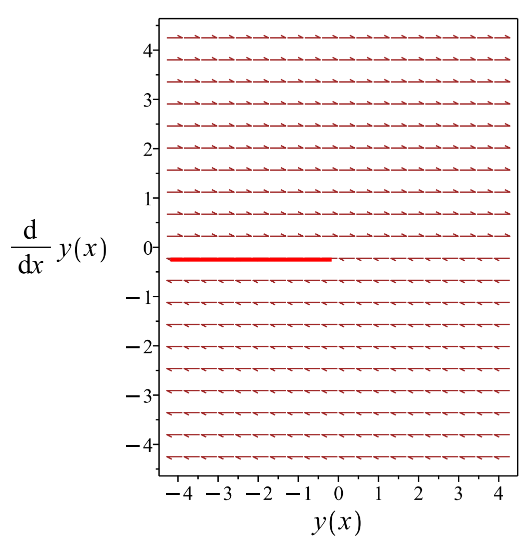
Summary

The solution(s) found are the following

$$y = \frac{1}{12 (x+2)^3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{12 (x+2)^3}$$

Verified OK.

14.3.3 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = \frac{1}{(x+2)^5}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)} \\ &= 0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x}{(x+2)^5}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{(x+2)^5} dx$$

Hence

$$u_1 = \frac{1}{3(x+2)^3} - \frac{1}{2(x+2)^4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1}{(x+2)^5}}{1} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{(x+2)^5} dx$$

Hence

$$u_2 = -\frac{1}{4(x+2)^4}$$

Which simplifies to

$$u_1 = \frac{2x+1}{6(x+2)^4}$$

$$u_2 = -\frac{1}{4(x+2)^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2x+1}{6\left(x+2\right)^4} - \frac{x}{4\left(x+2\right)^4}$$

Which simplifies to

$$y_p(x) = \frac{1}{12\left(x+2\right)^3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(\frac{1}{12\left(x+2\right)^3}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 + \frac{1}{12\left(x+2\right)^3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{12}$ and $x = -1$ in the above gives

$$\frac{1}{12} = c_1 - c_2 + \frac{1}{12} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 - \frac{1}{4\left(x+2\right)^4}$$

substituting $y' = -\frac{1}{4}$ and $x = -1$ in the above gives

$$-\frac{1}{4} = c_2 - \frac{1}{4} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 0 \\ c_2 &= 0 \end{aligned}$$

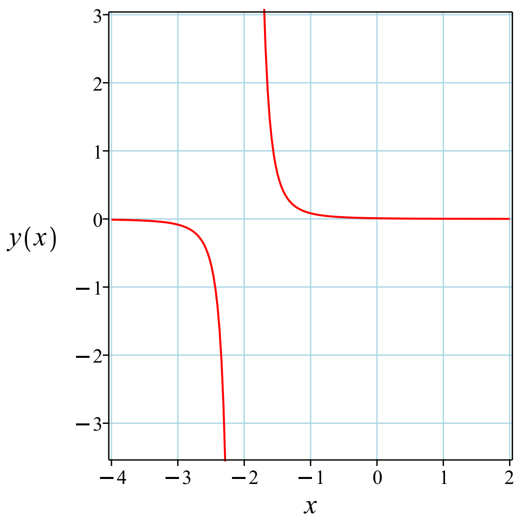
Substituting these values back in above solution results in

$$y = \frac{1}{12 (x+2)^3}$$

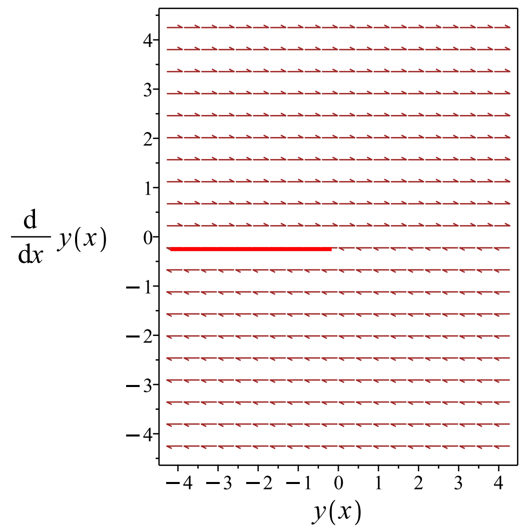
Summary

The solution(s) found are the following

$$y = \frac{1}{12 (x+2)^3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{12 (x+2)^3}$$

Verified OK.

14.3.4 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int y'' dx = \int \frac{1}{(x+2)^5} dx$$

$$y' = -\frac{1}{4 (x+2)^4} + c_1$$

Which is now solved for y. Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{4c_1x^4 + 32c_1x^3 + 96c_1x^2 + 128c_1x + 64c_1 - 1}{4(x+2)^4} dx \\
&= \frac{1}{12(x+2)^3} + c_1x + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{1}{12(x+2)^3} + c_1x + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{12}$ and $x = -1$ in the above gives

$$
\frac{1}{12} = -c_1 + c_2 + \frac{1}{12} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\frac{1}{4(x+2)^4} + c_1
$$

substituting $y' = -\frac{1}{4}$ and $x = -1$ in the above gives

$$
-\frac{1}{4} = c_1 - \frac{1}{4} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= 0
\end{aligned}
$$

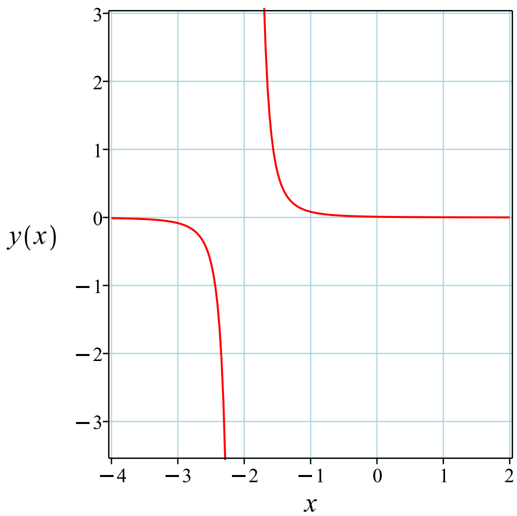
Substituting these values back in above solution results in

$$
y = \frac{1}{12(x+2)^3}
$$

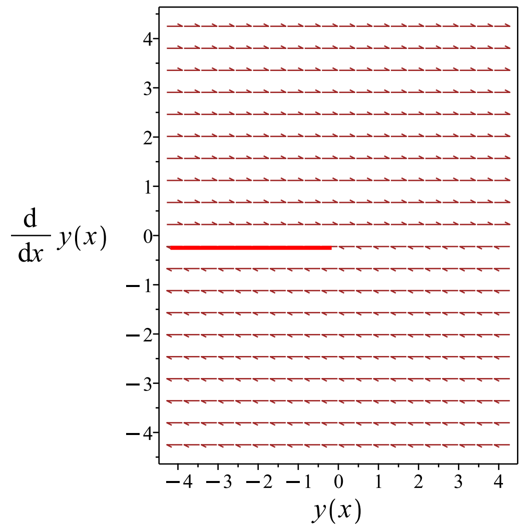
Summary

The solution(s) found are the following

$$
y = \frac{1}{12(x+2)^3} \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{12 (x+2)^3}$$

Verified OK.

14.3.5 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \frac{1}{(x+2)^5} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(x) &= \int \frac{1}{(x+2)^5} \, dx \\ &= -\frac{1}{4 (x+2)^4} + c_1 \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = -1$ and $p = -\frac{1}{4}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{1}{4} = c_1 - \frac{1}{4}$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$p(x) = -\frac{1}{4(x+2)^4}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{1}{4(x+2)^4}$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{1}{4(x+2)^4} \,\mathrm{d}x \\ &= \frac{1}{12(x+2)^3} + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = -1$ and $y = \frac{1}{12}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{12} = c_2 + \frac{1}{12}$$

$$c_2 = 0$$

Substituting c_2 found above in the general solution gives

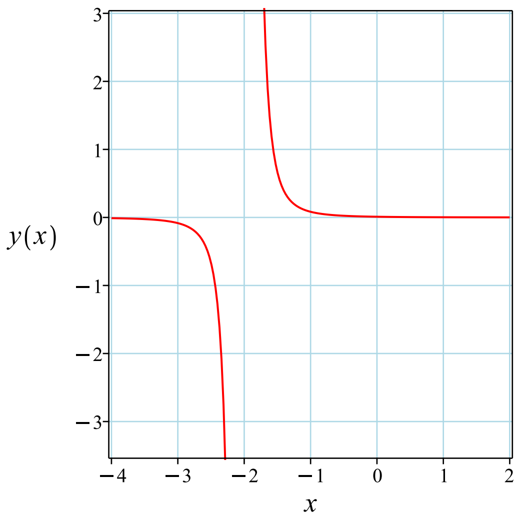
$$y = \frac{1}{12(x+2)^3}$$

Initial conditions are used to solve for the constants of integration.

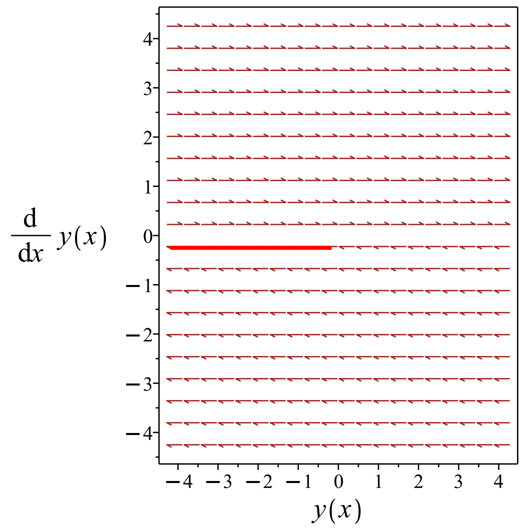
Summary

The solution(s) found are the following

$$y = \frac{1}{12(x+2)^3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{12\left(x+2\right)^{3}}$$

Verified OK.

14.3.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 331: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= 1
\end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= 1 \int \frac{1}{1}\, dx \\
&= 1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2 x + c_1
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x}{(x+2)^5}}{1} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{(x+2)^5} dx$$

Hence

$$u_1 = \frac{1}{3(x+2)^3} - \frac{1}{2(x+2)^4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{1}{(x+2)^5}}{1} \, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{(x+2)^5} dx$$

Hence

$$u_2 = -\frac{1}{4(x+2)^4}$$

Which simplifies to

$$u_1 = \frac{2x+1}{6(x+2)^4}$$

$$u_2 = -\frac{1}{4(x+2)^4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2x+1}{6(x+2)^4} - \frac{x}{4(x+2)^4}$$

Which simplifies to

$$y_p(x) = \frac{1}{12(x+2)^3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(\frac{1}{12(x+2)^3}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 + \frac{1}{12(x+2)^3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{12}$ and $x = -1$ in the above gives

$$\frac{1}{12} = c_1 - c_2 + \frac{1}{12} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 - \frac{1}{4\left(x+2\right)^4}$$

substituting $y' = -\frac{1}{4}$ and $x = -1$ in the above gives

$$-\frac{1}{4} = c_2 - \frac{1}{4} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

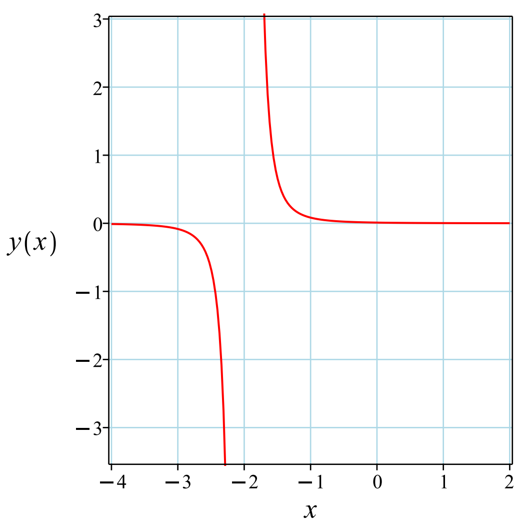
$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

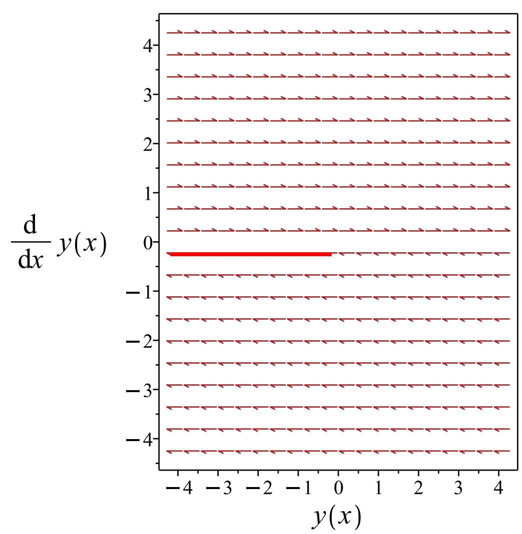
$$y = \frac{1}{12\left(x+2\right)^3}$$

Summary
The solution(s) found are the following

$$y = \frac{1}{12\left(x+2\right)^3} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{1}{12\left(x+2\right)^3}$$

Verified OK.

14.3.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x) &= 1\\ q(x) &= 0\\ r(x) &= 0\\ s(x) &= \frac{1}{(x+2)^5}\end{aligned}$$

Hence

$$\begin{aligned}p''(x) &= 0\\ q'(x) &= 0\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$y' = \int \frac{1}{(x+2)^5}\,dx$$

We now have a first order ode to solve which is

$$y' = -\frac{1}{4\,(x+2)^4} + c_1$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{4c_1x^4 + 32c_1x^3 + 96c_1x^2 + 128c_1x + 64c_1 - 1}{4\left(x+2\right)^4} \mathrm{d}x \\
&= \frac{1}{12\left(x+2\right)^3} + c_1x + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{1}{12\left(x+2\right)^3} + c_1x + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{1}{12}$ and $x = -1$ in the above gives

$$
\frac{1}{12} = -c_1 + c_2 + \frac{1}{12} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\frac{1}{4\left(x+2\right)^4} + c_1
$$

substituting $y' = -\frac{1}{4}$ and $x = -1$ in the above gives

$$
-\frac{1}{4} = c_1 - \frac{1}{4} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{1}{12\left(x+2\right)^3}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \frac{1}{12\left(x+2\right)^3} \tag{1}
$$

14.3.8 Maple step by step solution

Let's solve

$$\left[y'' = \frac{1}{(x+2)^5}, y(-1) = \frac{1}{12}, y'\Big|_{\{x=-1\}} = -\frac{1}{4}\right]$$

- Highest derivative means the order of the ODE is 2

  y''
- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$
- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$
- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{1}{(x+2)^5}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\left(\int \frac{x}{(x+2)^5} dx\right) + x\left(\int \frac{1}{(x+2)^5} dx\right)$

  ◦ Compute integrals

  $y_p(x) = \frac{1}{12(x+2)^3}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x + c_1 + \frac{1}{12(x+2)^3}$

☐ Check validity of solution $y = c_2 x + c_1 + \frac{1}{12(x+2)^3}$

  ◦ Use initial condition $y(-1) = \frac{1}{12}$

  $\frac{1}{12} = c_1 - c_2 + \frac{1}{12}$

  ◦ Compute derivative of the solution

  $y' = c_2 - \frac{1}{4(x+2)^4}$

- Use the initial condition $y'\Big|_{\{x=-1\}} = -\frac{1}{4}$

  $-\frac{1}{4} = c_2 - \frac{1}{4}$
- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = 0\}$
- Substitute constant values into general solution and simplify

  $y = \frac{1}{12(x+2)^3}$

- Solution to the IVP

  $y = \frac{1}{12(x+2)^3}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{y'' = e^{x} x}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

14.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 0 \\ F &= e^x x \end{aligned}$$

Hence the ode is

$$y'' = e^x x$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $F = e^x x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

14.4.2 Solving as second order ode quadrature ode

Integrating once gives

$$y' = (x - 1) e^x + c_1$$

Integrating again gives

$$y = (x - 2) e^x + c_1 x + c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (x - 2) e^x + c_1 x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -2 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x} + (x-2)\,e^{x} + c_1$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -1 + c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = e^{x}x - 2\,e^{x} + 2 + x$$

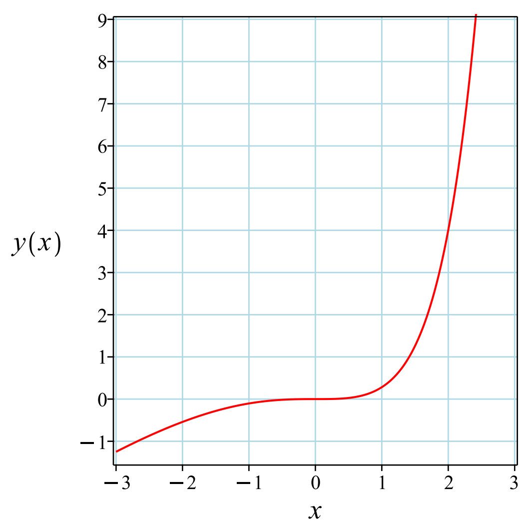
Which simplifies to

$$y = (x-2)\,e^{x} + x + 2$$

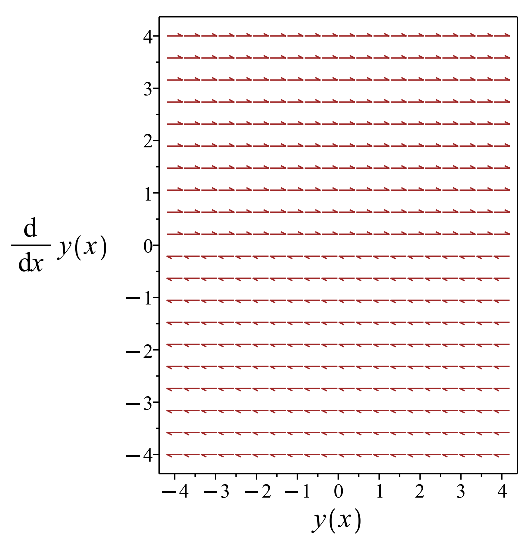
Summary

The solution(s) found are the following

$$y = (x-2)\,e^{x} + x + 2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (x-2)\,e^{x} + x + 2$$

Verified OK.

14.4.3 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = e^x x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)} \\ &= 0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 x + c_1$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x x + A_2 e^x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^x x + 2A_1 e^x + A_2 e^x = e^x x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^x x - 2\, e^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + (e^x x - 2\, e^x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 + e^x x - 2\, e^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -2 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 + e^x x - e^x$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = e^x x - 2e^x + 2 + x$$

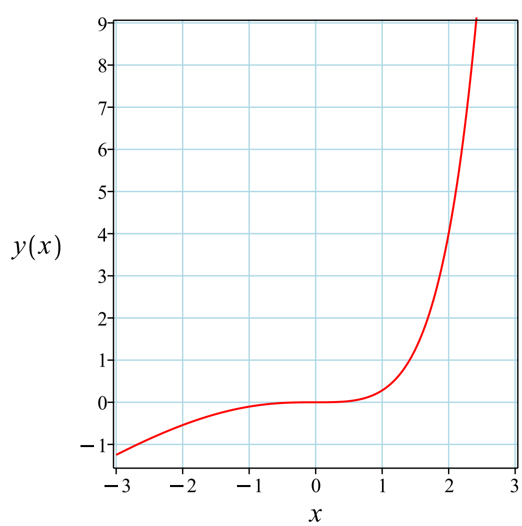
Which simplifies to

$$y = (x - 2)e^x + x + 2$$

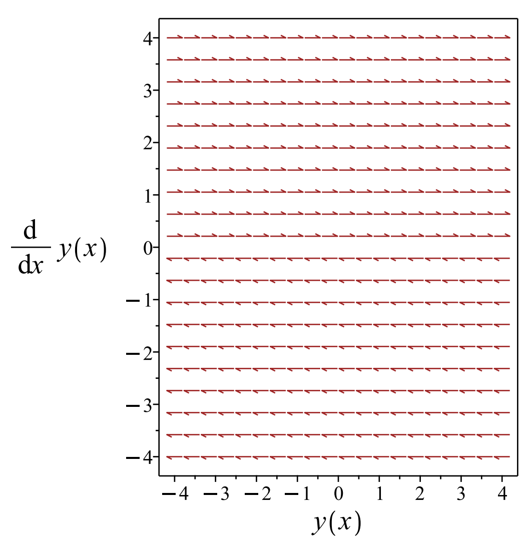
Summary

The solution(s) found are the following

$$y = (x - 2)e^x + x + 2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (x - 2)\,e^{x} + x + 2$$

Verified OK.

14.4.4 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int y'' dx = \int e^{x} x dx$$
$$y' = (x - 1)\,e^{x} + c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int e^{x} x - e^{x} + c_1 \, \mathrm{d}x \\ &= c_1 x + e^{x} x - 2\,e^{x} + c_2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x + e^{x} x - 2\,e^{x} + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -2 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x} x - e^{x} + c_1$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -1 + c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = e^x x - 2e^x + 2 + x$$

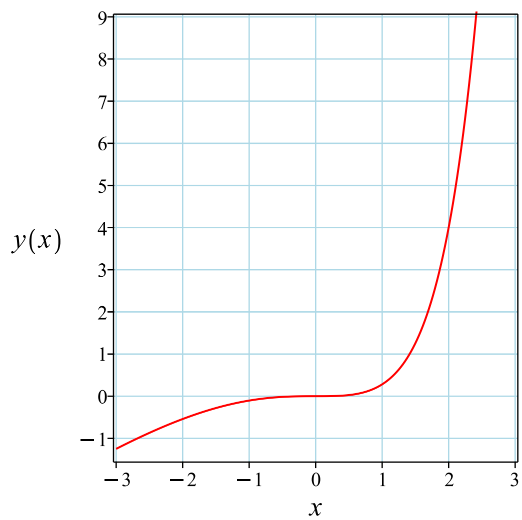
Which simplifies to

$$y = (x - 2)e^x + x + 2$$

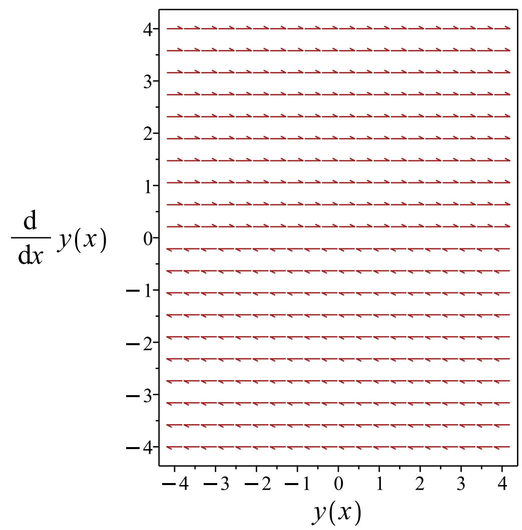
Summary

The solution(s) found are the following

$$y = (x - 2)e^x + x + 2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (x - 2)e^x + x + 2$$

Verified OK.

14.4.5 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - e^x x = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(x) &= \int e^x x \, dx \\ &= (x-1) e^x + c_1 \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $p = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -1 + c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$p(x) = e^x x - e^x + 1$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^x x - e^x + 1$$

Integrating both sides gives

$$\begin{aligned} y &= \int e^x x - e^x + 1 \, dx \\ &= e^x x - 2 e^x + c_2 + x \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -2 + c_2$$

$$c_2 = 2$$

Substituting c_2 found above in the general solution gives

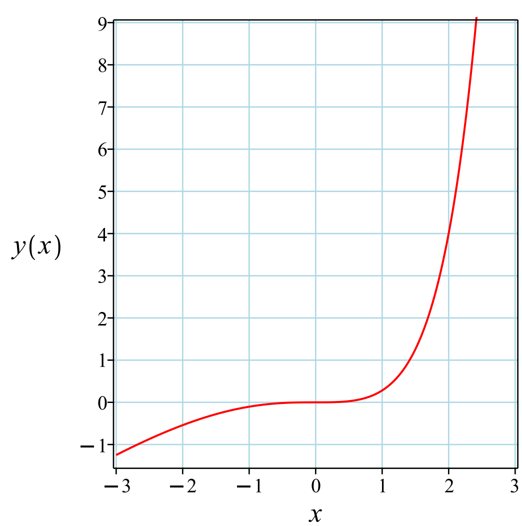
$$y = e^x x - 2e^x + 2 + x$$

Initial conditions are used to solve for the constants of integration.

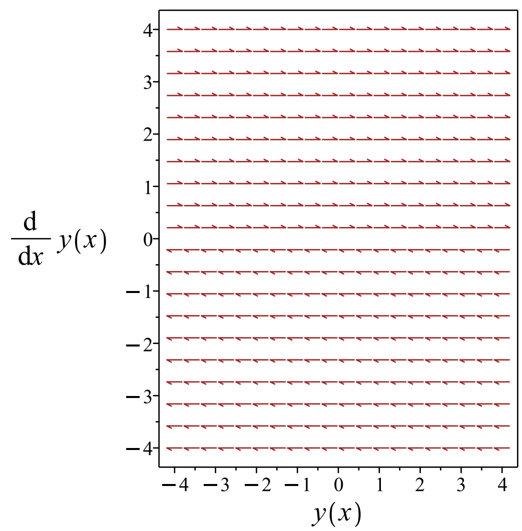
Summary

The solution(s) found are the following

$$y = e^x x - 2e^x + 2 + x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^x x - 2e^x + 2 + x$$

Verified OK.

14.4.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= 0
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{0}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 0 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 333: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= 1
\end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= 1 \int \frac{1}{1}\,dx \\
&= 1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(x))
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_2 x + c_1$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}x, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} x + A_2 e^{x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{x} x + 2A_1 e^{x} + A_2 e^{x} = e^{x} x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = e^{x} x - 2\,e^{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + (e^{x} x - 2\,e^{x}) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 + e^{x} x - 2\,e^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -2 + c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 + e^x x - e^x$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = e^x x - 2e^x + 2 + x$$

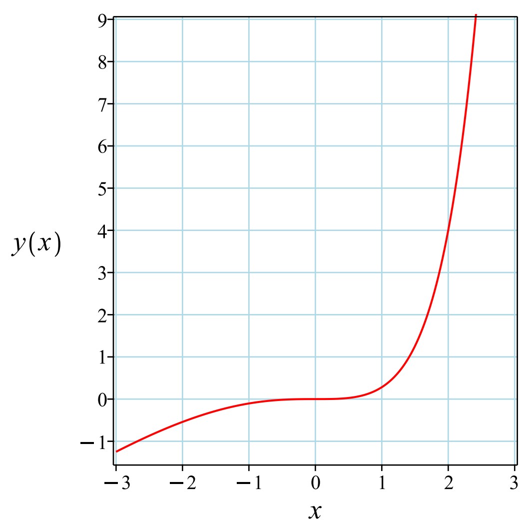
Which simplifies to

$$y = (x - 2)e^x + x + 2$$

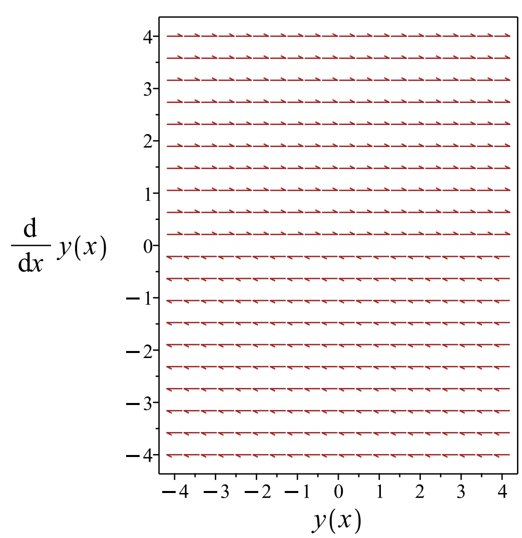
Summary

The solution(s) found are the following

$$y = (x - 2)e^x + x + 2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (x - 2)e^x + x + 2$$

Verified OK.

14.4.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ r(x) &= 0 \\ s(x) &= \mathrm{e}^{x} x \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + \left(q(x) - p'(x)\right) y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + \left(q(x) - p'(x)\right) y = \int s(x)\; dx$$

Substituting the above values for p, q, r, s gives

$$y' = \int \mathrm{e}^{x} x \, dx$$

We now have a first order ode to solve which is

$$y' = (x - 1)\, \mathrm{e}^{x} + c_1$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int e^x x - e^x + c_1 \, dx \\
&= c_1 x + e^x x - 2 e^x + c_2
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 x + e^x x - 2 e^x + c_2 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = -2 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = e^x x - e^x + c_1
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = -1 + c_1 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= 2
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = e^x x - 2 e^x + 2 + x
$$

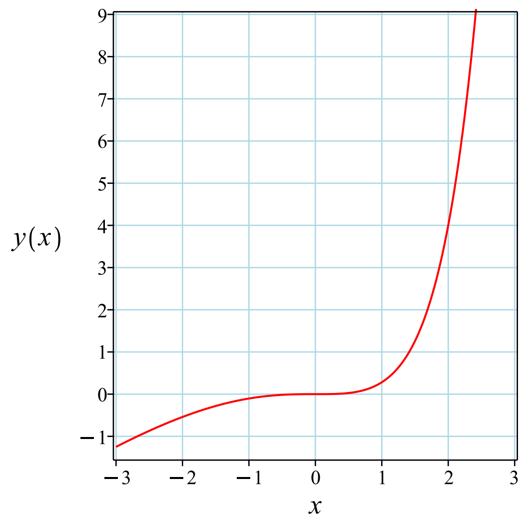
Which simplifies to

$$
y = (x - 2) e^x + x + 2
$$

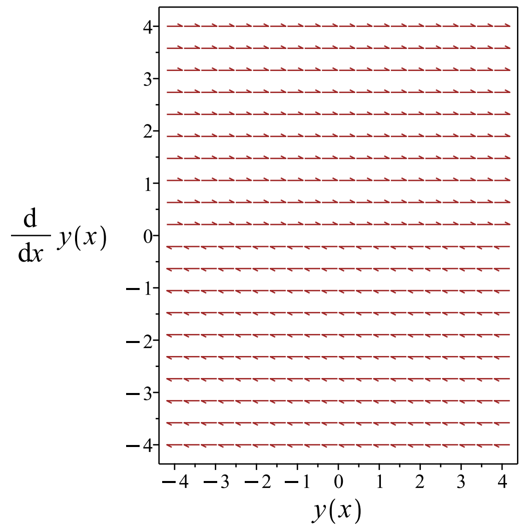
Summary

The solution(s) found are the following

$$
y = (x - 2) e^x + x + 2 \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = (x-2)\,\mathrm{e}^{x} + x + 2$$

Verified OK.

14.4.8 Maple step by step solution

Let's solve

$$\left[y'' = \mathrm{e}^{x} x, y(0) = 0, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the homogeneous ODE

$y_1(x) = 1$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 x + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^x x\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\left(\int e^x x^2 dx\right) + x\left(\int e^x x dx\right)$

  ◦ Compute integrals

  $y_p(x) = (x-2)\, e^x$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 x + (x-2)\, e^x$

□ Check validity of solution $y = c_1 + c_2 x + (x-2)\, e^x$

  ◦ Use initial condition $y(0) = 0$

  $0 = -2 + c_1$

  ◦ Compute derivative of the solution

  $y' = c_2 + e^x + (x-2)\, e^x$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = -1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 2, c_2 = 1\}$

- Substitute constant values into general solution and simplify

  $y = (x - 2)\,\mathrm{e}^{x} + x + 2$

- Solution to the IVP

  $y = (x - 2)\,\mathrm{e}^{x} + x + 2$

Problem number: 331.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second__order__integrable__as__is", "second__order__ode__missing__y", "second__order__ode__quadrature", "second__order__linear__constant__coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{y'' = 2\ln(x)\, x}$$

14.5.1 Solving as second order ode quadrature ode

Integrating once gives

$$y' = \ln(x)\, x^2 - \frac{x^2}{2} + c_1$$

Integrating again gives

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2$$

Summary

The solution(s) found are the following

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln (x)}{3} + c_1 x + c_2 \tag{1}$$

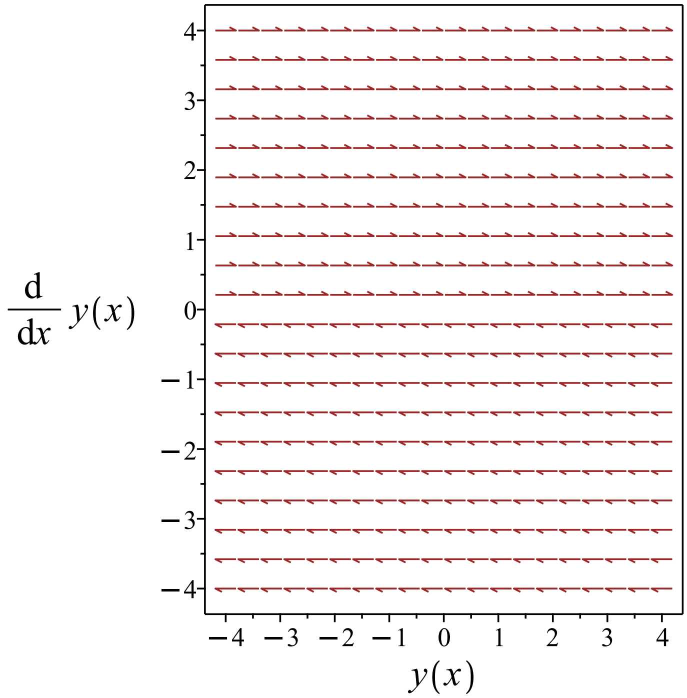

Figure 452: Slope field plot

Verification of solutions

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln (x)}{3} + c_1 x + c_2$$

Verified OK.

14.5.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = 2\ln (x)\, x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=0, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) thro927ughout by $e^{\lambda x}$ gives

$$\lambda^2=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=0, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{0}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{(0)^2-(4)(1)(0)}\\&=0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2}=0$. Therefore the solution is

$$y=c_1 1+c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h=c_2 x+c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1 y_1+u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\ln(x)\, x^2}{1}\, dx$$

Which simplifies to

$$u_1 = -\int 2 \ln(x)\, x^2 dx$$

Hence

$$u_1 = -\frac{2x^3 \ln(x)}{3} + \frac{2x^3}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2 \ln(x)\, x}{1}\, dx$$

Which simplifies to

$$u_2 = \int 2 \ln(x)\, x dx$$

Hence

$$u_2 = \ln(x)\, x^2 - \frac{x^2}{2}$$

Which simplifies to

$$u_1 = -\frac{2x^3(-1 + 3\ln(x))}{9}$$
$$u_2 = x^2\left(-\frac{1}{2} + \ln(x)\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{2x^3(-1 + 3\ln(x))}{9} + x^3\left(-\frac{1}{2} + \ln(x)\right)$$

Which simplifies to

$$y_p(x) = \frac{x^3(-5 + 6\ln(x))}{18}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(\frac{x^3(-5 + 6\ln(x))}{18}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 x + c_1 + \frac{x^3(-5 + 6 \ln(x))}{18} \tag{1}$$

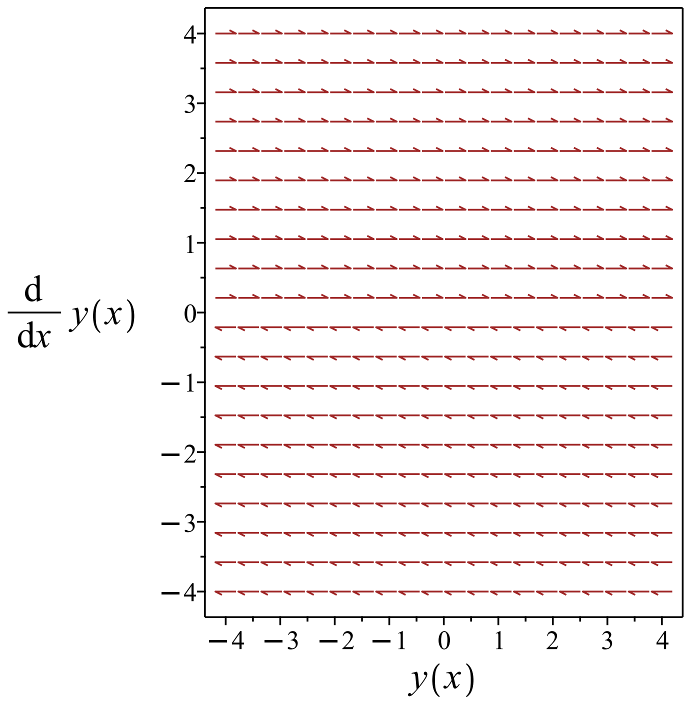

Figure 453: Slope field plot

Verification of solutions

$$y = c_2 x + c_1 + \frac{x^3(-5 + 6 \ln(x))}{18}$$

Verified OK.

14.5.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int y'' dx = \int 2 \ln(x) x dx$$

$$y' = \ln(x) x^2 - \frac{x^2}{2} + c_1$$

Which is now solved for y. Integrating both sides gives

$$y = \int -\frac{x^2}{2} + \ln(x)\, x^2 + c_1 \,\mathrm{d}x$$
$$= -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2$$

Summary

The solution(s) found are the following

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2 \tag{1}$$

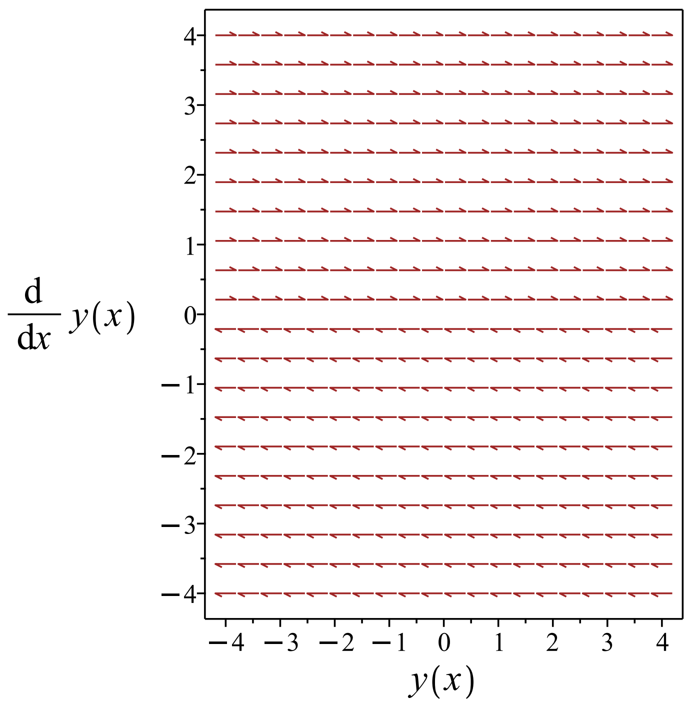

Figure 454: Slope field plot

Verification of solutions

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2$$

Verified OK.

14.5.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 2\ln(x)\, x = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(x) &= \int 2\ln(x)\, x \, \mathrm{d}x \\ &= -\frac{x^2}{2} + \ln(x)\, x^2 + c_1 \end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{x^2}{2} + \ln(x)\, x^2 + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{x^2}{2} + \ln(x)\, x^2 + c_1 \, \mathrm{d}x \\ &= -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2 \tag{1}$$

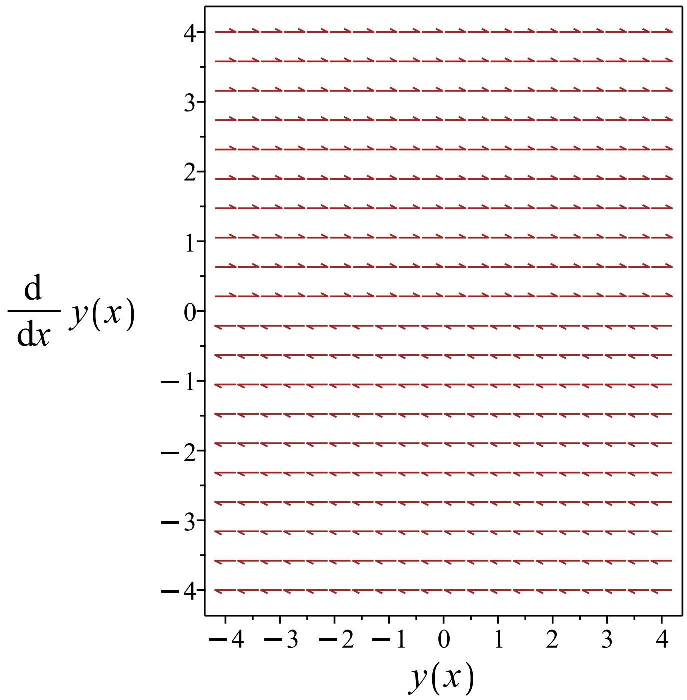

Figure 455: Slope field plot

Verification of solutions

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2$$

Verified OK.

14.5.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 335: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= 1 \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= 1 \int \frac{1}{1}\,dx \\ &= 1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(1) + c_2(1(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2x + c_1
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\ln(x)\,x^2}{1}\,dx$$

Which simplifies to

$$u_1 = -\int 2\ln(x)\,x^2 dx$$

Hence

$$u_1 = -\frac{2x^3\ln(x)}{3} + \frac{2x^3}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\ln(x)\,x}{1}\,dx$$

Which simplifies to

$$u_2 = \int 2\ln(x)\,x dx$$

Hence

$$u_2 = \ln(x)\, x^2 - \frac{x^2}{2}$$

Which simplifies to

$$\begin{aligned} u_1 &= -\frac{2x^3(-1+3\ln(x))}{9} \\ u_2 &= x^2\left(-\frac{1}{2}+\ln(x)\right) \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{2x^3(-1+3\ln(x))}{9} + x^3\left(-\frac{1}{2}+\ln(x)\right)$$

Which simplifies to

$$y_p(x) = \frac{x^3(-5+6\ln(x))}{18}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2x + c_1) + \left(\frac{x^3(-5+6\ln(x))}{18}\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_2x + c_1 + \frac{x^3(-5+6\ln(x))}{18} \tag{1}$$

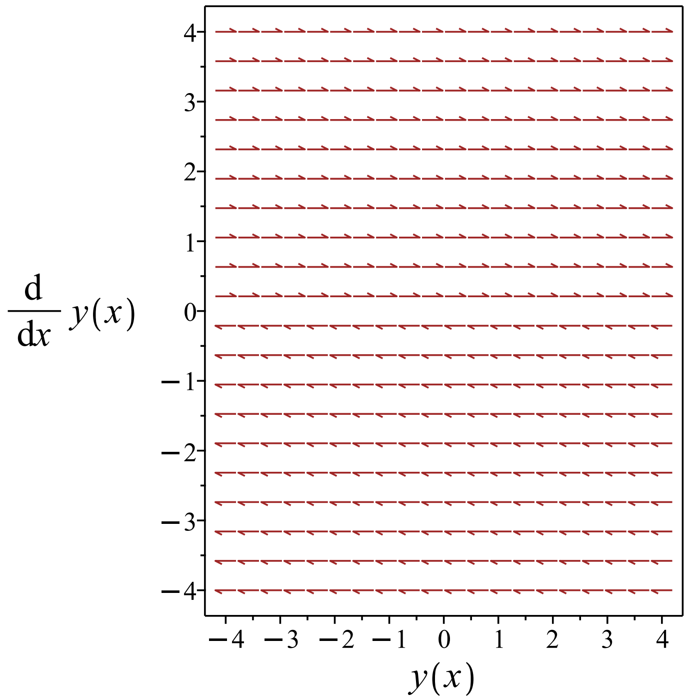

Figure 456: Slope field plot

Verification of solutions

$$y = c_2x + c_1 + \frac{x^3(-5 + 6\ln(x))}{18}$$

Verified OK.

14.5.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1\\
q(x) &= 0\\
r(x) &= 0\\
s(x) &= 2\ln(x)\,x
\end{aligned}$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0-(0)+(0)=0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\,y' + (q(x)-p'(x))\,y)' = s(x)
$$

Integrating gives

$$
p(x)\,y' + (q(x)-p'(x))\,y = \int s(x)\;dx
$$

Substituting the above values for p, q, r, s gives

$$
y' = \int 2\ln(x)\,x\,dx
$$

We now have a first order ode to solve which is

$$
y' = -\frac{x^2}{2} + \ln(x)\,x^2 + c_1
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int -\frac{x^2}{2} + \ln(x)\,x^2 + c_1\;\mathrm{d}x \\
&= -\frac{5x^3}{18} + \frac{x^3\ln(x)}{3} + c_1x + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{5x^3}{18} + \frac{x^3\ln(x)}{3} + c_1x + c_2 \tag{1}
$$

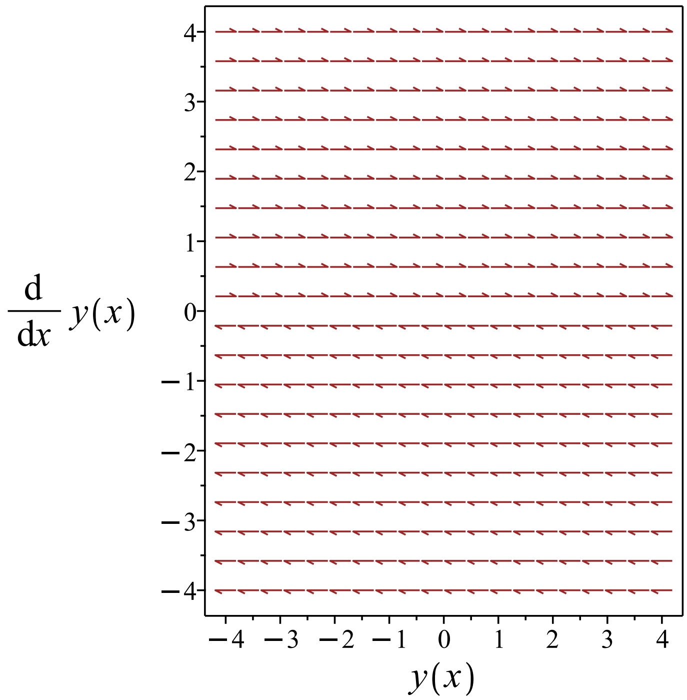

Figure 457: Slope field plot

Verification of solutions

$$y = -\frac{5x^3}{18} + \frac{x^3 \ln(x)}{3} + c_1 x + c_2$$

Verified OK.

14.5.7 Maple step by step solution

Let's solve

$y'' = 2\ln(x)\, x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm \left(\sqrt{0}\right)}{2}$

- Roots of the characteristic polynomial

$r = 0$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2\ln(x)\, x\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -2\left(\int \ln(x)\, x^2 dx\right) + 2x\left(\int \ln(x)\, x dx\right)$

  - Compute integrals

    $y_p(x) = \frac{x^3(-5+6\ln(x))}{18}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x + c_1 + \frac{x^3(-5+6\ln(x))}{18}$

Problem number: 332.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' - y' = 0}$$

14.6.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' - y')\,dx = 0$$

$$xy' - 2y = c_1$$

Which is now solved for y. In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{2y + c_1}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = 2y + c_1$. Integrating both sides gives

$$\begin{aligned} \frac{1}{2y + c_1}\,dy &= \frac{1}{x}\,dx \\ \int \frac{1}{2y + c_1}\,dy &= \int \frac{1}{x}\,dx \\ \frac{\ln(2y + c_1)}{2} &= \ln(x) + c_2 \end{aligned}$$

Raising both side to exponential gives

$$\sqrt{2y + c_1} = \mathrm{e}^{\ln(x) + c_2}$$

Which simplifies to

$$\sqrt{2y + c_1} = c_3 x$$

Summary

The solution(s) found are the following

$$y = \frac{c_3^2 \mathrm{e}^{2c_2} x^2}{2} - \frac{c_1}{2} \tag{1}$$

Verification of solutions

$$y = \frac{c_3^2 \mathrm{e}^{2c_2} x^2}{2} - \frac{c_1}{2}$$

Verified OK.

14.6.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x)\, x - p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= \frac{p}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned} \frac{1}{p}\, dp &= \frac{1}{x}\, dx \\ \int \frac{1}{p}\, dp &= \int \frac{1}{x}\, dx \\ \ln(p) &= \ln(x) + c_1 \\ p &= \mathrm{e}^{\ln(x)+c_1} \\ &= c_1 x \end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_1 x$$

Integrating both sides gives

$$\begin{aligned} y &= \int c_1 x \, \mathrm{d}x \\ &= \frac{c_1 x^2}{2} + c_2 \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{c_1 x^2}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^2}{2} + c_2$$

Verified OK.

14.6.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x \\ B &= -1 \\ C &= 0 \\ F &= 0 \end{aligned}$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (x)(0) + (-1)(0) + (0)(-1) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-xv'' + (1)v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-xu'(x) + u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u}{x}
\end{aligned}
$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= \frac{1}{x}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{1}{x}\, dx \\
\ln(u) &= \ln(x) + c_1 \\
u &= \mathrm{e}^{\ln(x)+c_1} \\
&= c_1 x
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1 x
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 x \,\mathrm{d}x \\
&= \frac{c_1 x^2}{2} + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (-1)\left(\frac{c_1 x^2}{2} + c_2\right) \\
&= -\frac{c_1 x^2}{2} - c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{c_1 x^2}{2} - c_2 \tag{1}
$$

Verification of solutions

$$
y = -\frac{c_1 x^2}{2} - c_2
$$

Verified OK.

14.6.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$
xy'' - y' = 0
$$

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int (xy'' - y')\,dx &= 0 \\
xy' - 2y &= c_1
\end{aligned}
$$

Which is now solved for y. In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x, y) \\
&= f(x)g(y) \\
&= \frac{2y + c_1}{x}
\end{aligned}
$$

Where $f(x) = \frac{1}{x}$ and $g(y) = 2y + c_1$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{2y + c_1} \, dy &= \frac{1}{x} \, dx \\
\int \frac{1}{2y + c_1} \, dy &= \int \frac{1}{x} \, dx \\
\frac{\ln (2y + c_1)}{2} &= \ln (x) + c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
\sqrt{2y + c_1} = e^{\ln(x) + c_2}
$$

Which simplifies to

$$
\sqrt{2y + c_1} = c_3 x
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_3^2 e^{2c_2} x^2}{2} - \frac{c_1}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_3^2 e^{2c_2} x^2}{2} - \frac{c_1}{2}
$$

Verified OK.

14.6.5 Solving using Kovacic algorithm

Writing the ode as

$$
xy'' - y' = 0 \tag{1}
$$
$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x \\
B &= -1 \\
C &= 0
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 337: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^{-} &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + (-)\,(0) \\
&= -\frac{1}{2x} \\
&= -\frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{1}{2x} dx} \\
&= \frac{1}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{x}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 + \frac{c_2 x^2}{2} \tag{1}
$$

Verification of solutions

$$
y = c_1 + \frac{c_2 x^2}{2}
$$

Verified OK.

14.6.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x \\ q(x) &= -1 \\ r(x) &= 0 \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$xy' - 2y = c_1$$

We now have a first order ode to solve which is

$$xy' - 2y = c_1$$

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{2y+c_1}{x}
\end{aligned}
$$

Where $f(x)=\frac{1}{x}$ and $g(y)=2y+c_1$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{2y+c_1}\,dy &= \frac{1}{x}\,dx \\
\int \frac{1}{2y+c_1}\,dy &= \int \frac{1}{x}\,dx \\
\frac{\ln(2y+c_1)}{2} &= \ln(x)+c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
\sqrt{2y+c_1} = \mathrm{e}^{\ln(x)+c_2}
$$

Which simplifies to

$$
\sqrt{2y+c_1} = c_3 x
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_3^2\mathrm{e}^{2c_2}x^2}{2} - \frac{c_1}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_3^2\mathrm{e}^{2c_2}x^2}{2} - \frac{c_1}{2}
$$

Verified OK.

14.6.7 Maple step by step solution

Let's solve

$y''x - y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} = 0$

- Multiply by denominators of the ODE

  $y''x - y' = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x - \frac{\frac{d}{dt}y(t)}{x} = 0$

- Simplify

  $\frac{\frac{d^2}{dt^2}y(t) - 2\frac{d}{dt}y(t)}{x} = 0$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t) = 2\frac{d}{dt}y(t)$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) - 2\frac{d}{dt}y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 2r = 0$

- Factor the characteristic polynomial

  $r(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (0, 2)$

- 1st solution of the ODE

  $y_1(t) = 1$

- 2nd solution of the ODE

  $y_2(t) = e^{2t}$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 + c_2 e^{2t}$

- Change variables back using $t = \ln(x)$

  $y = c_2 x^2 + c_1$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 333.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_y]]`

$$\boxed{xy'' + y' = 0}$$

14.7.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + y')\, dx = 0$$
$$xy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int \frac{c_1}{x}\, \mathrm{d}x \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

14.7.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x)\, x + p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= -\frac{p}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\, dp &= -\frac{1}{x}\, dx \\
\int \frac{1}{p}\, dp &= \int -\frac{1}{x}\, dx \\
\ln(p) &= -\ln(x) + c_1 \\
p &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{c_1}{x}$$

Integrating both sides gives

$$\begin{aligned}
y &= \int \frac{c_1}{x}\, \mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

14.7.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x \\
B &= 1 \\
C &= 0 \\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (x)\,(0) + (1)\,(0) + (0)\,(1) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
xv'' + (1)\,v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
xu'(x) + u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\
\ln(u) &= -\ln(x) + c_1 \\
u &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= \frac{c_1}{x}
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{c_1}{x}\,\mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y(x) &= Bv \\
&= (1)\,(c_1 \ln(x) + c_2) \\
&= c_1 \ln(x) + c_2
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

14.7.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' + y' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + y')\, dx = 0$$
$$xy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$y = \int \frac{c_1}{x}\, \mathrm{d}x$$
$$= c_1 \ln(x) + c_2$$

Summary
The solution(s) found are the following

$$y = c_1 \ln(x) + c_2 \tag{1}$$

Verification of solutions

$$y = c_1 \ln(x) + c_2$$

Verified OK.

14.7.5 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$A = x$$
$$B = 1 \tag{3}$$
$$C = 0$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 339: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{1}{x}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2(1(\ln(x)))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2 \ln(x) \tag{1}$$

Verification of solutions

$$y = c_1 + c_2 \ln(x)$$

Verified OK.

14.7.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x \\
q(x) &= 1 \\
r(x) &= 0 \\
s(x) &= 0
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0 - (0) + (0) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)
$$

Integrating gives

$$
p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx
$$

Substituting the above values for p, q, r, s gives

$$
xy' = c_1
$$

We now have a first order ode to solve which is

$$
xy' = c_1
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{c_1}{x}\, \mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \ln(x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = c_1 \ln(x) + c_2
$$

Verified OK.

14.7.7 Maple step by step solution

Let's solve

$y''x + y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} = 0$

- Multiply by denominators of the ODE

  $y''x + y' = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right)x + \frac{\frac{d}{dt}y(t)}{x} = 0$

- Simplify

  $\frac{\frac{d^2}{dt^2}y(t)}{x} = 0$

- Isolate 2nd derivative

$\frac{d^2}{dt^2}y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{0})}{2}$

- Roots of the characteristic polynomial

  $r = 0$

- 1st solution of the ODE

  $y_1(t) = 1$

- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t$

- General solution of the ODE

  $y(t) = c_1y_1(t) + c_2y_2(t)$

- Substitute in solutions

  $y(t) = c_2t + c_1$

- Change variables back using $t = \ln(x)$

  $y = c_1 + c_2 \ln(x)$

Problem number: 334.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second__order__ode__missing__y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' - (2x^2 + 1)\, y' = 0}$$

14.8.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x)\, x + (-2x^2 - 1)\, p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= \frac{p(2x^2+1)}{x} \end{aligned}$$

Where $f(x) = \frac{2x^2+1}{x}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned} \frac{1}{p}\, dp &= \frac{2x^2+1}{x}\, dx \\ \int \frac{1}{p}\, dp &= \int \frac{2x^2+1}{x}\, dx \\ \ln(p) &= x^2 + \ln(x) + c_1 \\ p &= e^{x^2+\ln(x)+c_1} \\ &= c_1 e^{x^2+\ln(x)} \end{aligned}$$

Which simplifies to

$$p(x) = c_1 x\, e^{x^2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_1 x\, e^{x^2}$$

Integrating both sides gives

$$\begin{aligned} y &= \int c_1 x\, e^{x^2}\, dx \\ &= \frac{c_1 e^{x^2}}{2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 e^{x^2}}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 e^{x^2}}{2} + c_2$$

Verified OK.

14.8.2 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + (-2x^2 - 1)\, y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -2x^2 - 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^4 + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x^4 + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^4 + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 341: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 4 \\
&= -2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$
L = [1, 2]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = x^2 + \frac{3}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx x + \frac{3}{8x^3} - \frac{9}{128x^7} + \frac{27}{1024x^{11}} - \frac{405}{32768x^{15}} + \frac{1701}{262144x^{19}} - \frac{15309}{4194304x^{23}} + \frac{72171}{33554432x^{27}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{4x^4+3}{4x^2} \\
&= Q + \frac{R}{4x^2} \\
&= (x^2) + \left(\frac{3}{4x^2}\right) \\
&= x^2 + \frac{3}{4x^2}
\end{aligned}$$

We see that the coefficient of the term x in the quotient is 0. Now b can be found.

$$\begin{aligned}
b &= (0) - (0) \\
&= 0
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= x \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{1} - 1\right) &&= -\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{1} - 1\right) &&= -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x^4+3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	x	$-\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)\,(x) \\ &= -\frac{1}{2x} - x \\ &= -\frac{1}{2x} - x \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2x} - x\right)(0) + \left(\left(\frac{1}{2x^2} - 1\right) + \left(-\frac{1}{2x} - x\right)^2 - \left(\frac{4x^4+3}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\,dx} \\ &= e^{\int \left(-\frac{1}{2x} - x\right)dx} \\ &= \frac{e^{-\frac{x^2}{2}}}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-1}{x}\,dx} \\
&= z_1 e^{\frac{x^2}{2}+\frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\,\mathrm{e}^{\frac{x^2}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-1}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x^2+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{x^2}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{\mathrm{e}^{x^2}}{2}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + \frac{c_2 \mathrm{e}^{x^2}}{2} \tag{1}
$$

Verification of solutions

$$y = c_1 + \frac{c_2 \mathrm{e}^{x^2}}{2}$$

Verified OK.

14.8.3 Maple step by step solution

Let's solve

$y''x + (-2x^2 - 1) y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(2x^2+1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(2x^2+1)y'}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{2x^2+1}{x}, P_3(x) = 0\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (-2x^2 - 1) y' = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- Rewrite ODE with series expansions
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$
  - Shift index using $k->k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-2+r)\, x^{-1+r} + a_1(1+r)\,(-1+r)\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)\,(k+r-1) - 2a_{k-1}(k+r-\right.$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$
- Each term must be 0

  $a_1(1+r)\,(-1+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\,(a_{k+1}(k+1+r) - 2a_{k-1}) = 0$
- Shift index using $k->k+1$

  $(k+r)\,(a_{k+2}(k+2+r) - 2a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{2a_k}{k+2+r}$
- Recursion relation for $r = 0$

  $a_{k+2} = \frac{2a_k}{k+2}$
- Solution for $r = 0$

$$\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=\frac{2a_k}{k+2}, -a_1=0\right]$$

- Recursion relation for $r=2$

$a_{k+2}=\frac{2a_k}{k+4}$

- Solution for $r=2$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2}=\frac{2a_k}{k+4}, 3a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2}=\frac{2a_k}{k+2}, -a_1=0, b_{k+2}=\frac{2b_k}{k+4}, 3b_1=0\right]$$

Problem number: 335.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' - y' = x^2}$$

14.9.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' - y')\, dx = \int x^2 dx$$
$$xy' - 2y = \frac{x^3}{3} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{x^3 + 3c_1}{3x}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{x^3 + 3c_1}{3x}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{2}{x}dx}$$
$$= \frac{1}{x^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^3 + 3c_1}{3x}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^2}\right) = \left(\frac{1}{x^2}\right)\left(\frac{x^3 + 3c_1}{3x}\right)$$
$$d\left(\frac{y}{x^2}\right) = \left(\frac{x^3 + 3c_1}{3x^3}\right) dx$$

Integrating gives

$$\frac{y}{x^2} = \int \frac{x^3 + 3c_1}{3x^3} dx$$
$$\frac{y}{x^2} = \frac{x}{3} - \frac{c_1}{2x^2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2 \left(\frac{x}{3} - \frac{c_1}{2x^2}\right) + c_2 x^2$$

which simplifies to

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2$$

Summary

The solution(s) found are the following

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2 \tag{1}$$

Verification of solutions

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2$$

Verified OK.

14.9.2 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x)\, x - p(x) - x^2 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = x$$

Hence the ode is

$$p'(x) - \frac{p(x)}{x} = x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)(x) \\ \frac{d}{dx}\left(\frac{p}{x}\right) &= \left(\frac{1}{x}\right)(x) \\ d\left(\frac{p}{x}\right) &= dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{p}{x} &= \int dx \\ \frac{p}{x} &= x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$p(x) = c_1 x + x^2$$

which simplifies to

$$p(x) = x(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = x(x + c_1)$$

Integrating both sides gives

$$\begin{aligned}y &= \int x(x + c_1)\, dx \\ &= \frac{1}{3}x^3 + \frac{1}{2}c_1 x^2 + c_2\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{1}{3}x^3 + \frac{1}{2}c_1x^2 + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{1}{3}x^3 + \frac{1}{2}c_1x^2 + c_2$$

Verified OK.

14.9.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + (2AB' + B^2)\, v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + (2AB' + B^2)\, v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + (2AB' + B^2)\, u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x \\
B &= -1 \\
C &= 0 \\
F &= x^2
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (x)\,(0) + (-1)\,(0) + (0)\,(-1) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-xv'' + (1)\,v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-xu'(x) + u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= \frac{u}{x}
\end{aligned}
$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{1}{x}\,dx \\
\ln(u) &= \ln(x) + c_1 \\
u &= e^{\ln(x)+c_1} \\
&= c_1 x
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1 x
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}v(x) &= \int c_1 x \, \mathrm{d}x\\ &= \frac{c_1 x^2}{2} + c_2\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}y_h(x) &= Bv\\ &= (-1)\left(\frac{c_1 x^2}{2} + c_2\right)\\ &= -\frac{c_1 x^2}{2} - c_2\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= -1\\ y_2 &= x^2\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} -1 & x^2 \\ \frac{d}{dx}(-1) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} -1 & x^2 \\ 0 & 2x \end{vmatrix}$$

Therefore

$$W = (-1)(2x) - (x^2)(0)$$

Which simplifies to

$$W = -2x$$

Which simplifies to

$$W = -2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^4}{-2x^2}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^2}{2} dx$$

Hence

$$u_1 = \frac{x^3}{6}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-x^2}{-2x^2}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{2} dx$$

Hence

$$u_2 = \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^3}{3}$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= \left(-\frac{c_1 x^2}{2} - c_2\right) + \left(\frac{x^3}{3}\right) \\ &= -\frac{1}{2}c_1 x^2 - c_2 + \frac{1}{3}x^3 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{2}c_1 x^2 - c_2 + \frac{1}{3}x^3 \tag{1}$$

Verification of solutions

$$y = -\frac{1}{2}c_1 x^2 - c_2 + \frac{1}{3}x^3$$

Verified OK.

14.9.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' - y' = x^2$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned} \int (xy'' - y')\, dx &= \int x^2 dx \\ xy' - 2y &= \frac{x^3}{3} + c_1 \end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{x^3 + 3c_1}{3x}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{x^3 + 3c_1}{3x}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{2}{x} dx}$$
$$= \frac{1}{x^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^3 + 3c_1}{3x}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^2}\right) = \left(\frac{1}{x^2}\right)\left(\frac{x^3 + 3c_1}{3x}\right)$$
$$d\left(\frac{y}{x^2}\right) = \left(\frac{x^3 + 3c_1}{3x^3}\right) dx$$

Integrating gives

$$\frac{y}{x^2} = \int \frac{x^3 + 3c_1}{3x^3} dx$$
$$\frac{y}{x^2} = \frac{x}{3} - \frac{c_1}{2x^2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(\frac{x}{3} - \frac{c_1}{2x^2}\right) + c_2 x^2$$

which simplifies to

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2$$

Summary

The solution(s) found are the following

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2 \tag{1}$$

Verification of solutions

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2$$

Verified OK.

14.9.5 Solving using Kovacic algorithm

Writing the ode as

$$xy'' - y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 343: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{3}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{3}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_{\infty} \\ &= -\frac{1}{2x} + (-)\,(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{2x} dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{x}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{x}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
xy'' - y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 x^2}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \frac{x^2}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{x^2}{2} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{x^2}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{x^2}{2} \\ 0 & x \end{vmatrix}$$

Therefore

$$W = (1)(x) - \left(\frac{x^2}{2}\right)(0)$$

Which simplifies to

$$W = x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^4}{2}}{x^2} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{x^2}{2} dx$$

Hence

$$u_1 = -\frac{x^3}{6}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2}{x^2} \, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 x^2}{2}\right) + \left(\frac{x^3}{3}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 + \frac{1}{2} c_2 x^2 + \frac{1}{3} x^3 \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 + \frac{1}{2} c_2 x^2 + \frac{1}{3} x^3$$

Verified OK.

14.9.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x) y'' + q(x) y' + r(x) y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x \\ q(x) &= -1 \\ r(x) &= 0 \\ s(x) &= x^2 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$xy' - 2y = \int x^2\,dx$$

We now have a first order ode to solve which is

$$xy' - 2y = \frac{x^3}{3} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{x^3 + 3c_1}{3x} \end{aligned}$$

Hence the ode is

$$y' - \frac{2y}{x} = \frac{x^3 + 3c_1}{3x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{x^3 + 3c_1}{3x}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(\frac{x^3 + 3c_1}{3x}\right) \\ \mathrm{d}\left(\frac{y}{x^2}\right) &= \left(\frac{x^3 + 3c_1}{3x^3}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\frac{y}{x^2} = \int \frac{x^3 + 3c_1}{3x^3}\,\mathrm{d}x$$
$$\frac{y}{x^2} = \frac{x}{3} - \frac{c_1}{2x^2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = x^2\left(\frac{x}{3} - \frac{c_1}{2x^2}\right) + c_2 x^2$$

which simplifies to

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2$$

Summary

The solution(s) found are the following

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2 \tag{1}$$

Verification of solutions

$$y = \frac{1}{3}x^3 - \frac{1}{2}c_1 + c_2 x^2$$

Verified OK.

14.9.7 Maple step by step solution

Let's solve

$y''x - y' = x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x)\,x - u(x) = x^2$

- Isolate the derivative

  $u'(x) = \frac{u(x)}{x} + x$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $u'(x) - \frac{u(x)}{x} = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(u'(x)-\frac{u(x)}{x}\right)=\mu(x)\,x$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

  $\mu(x)\left(u'(x)-\frac{u(x)}{x}\right)=\mu'(x)\,u(x)+\mu(x)\,u'(x)$
- Isolate $\mu'(x)$

  $\mu'(x)=-\frac{\mu(x)}{x}$
- Solve to find the integrating factor

  $\mu(x)=\frac{1}{x}$
- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,u(x))\right)dx=\int\mu(x)\,xdx+c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,u(x)=\int\mu(x)\,xdx+c_1$
- Solve for $u(x)$

  $u(x)=\frac{\int\mu(x)xdx+c_1}{\mu(x)}$
- Substitute $\mu(x)=\frac{1}{x}$

  $u(x)=x\left(\int 1dx+c_1\right)$
- Evaluate the integrals on the rhs

  $u(x)=x(x+c_1)$
- Solve 1st ODE for $u(x)$

  $u(x)=x(x+c_1)$
- Make substitution $u=y'$

  $y'=x(x+c_1)$
- Integrate both sides to solve for y

  $\int y'dx=\int x(x+c_1)\,dx+c_2$
- Compute integrals

  $y=\frac{1}{3}x^3+\frac{1}{2}c_1x^2+c_2$

Problem number: 336.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{x \ln(x) y'' - y' = 0}$$

14.10.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$x \ln(x) p'(x) - p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(x,p) \\
&= f(x)g(p) \\
&= \frac{p}{x\ln(x)}
\end{aligned}
$$

Where $f(x)=\frac{1}{x\ln(x)}$ and $g(p)=p$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{p}\,dp &= \frac{1}{x\ln(x)}\,dx \\
\int \frac{1}{p}\,dp &= \int \frac{1}{x\ln(x)}\,dx \\
\ln(p) &= \ln(\ln(x)) + c_1 \\
p &= e^{\ln(\ln(x))+c_1} \\
&= c_1\ln(x)
\end{aligned}
$$

Since $p=y'$ then the new first order ode to solve is

$$
y' = c_1\ln(x)
$$

Integrating both sides gives

$$
\begin{aligned}
y &= \int c_1\ln(x)\,\mathrm{d}x \\
&= c_1(\ln(x)\,x - x) + c_2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1(\ln(x)\,x - x) + c_2 \tag{1}
$$

Verification of solutions

$$
y = c_1(\ln(x)\,x - x) + c_2
$$

Verified OK.

14.10.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= \ln(x)\, x \\ B &= -1 \\ C &= 0 \\ F &= 0 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= (\ln(x)\, x)\,(0) + (-1)\,(0) + (0)\,(-1) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-\ln(x)\,xv'' + (1)\,v' = 0$$

Now by applying $v' = u$ the above becomes

$$-\ln(x)\,xu'(x) + u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u}{x\ln(x)} \end{aligned}$$

Where $f(x) = \frac{1}{x\ln(x)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= \frac{1}{x\ln(x)}\,dx \\ \int \frac{1}{u}\,du &= \int \frac{1}{x\ln(x)}\,dx \\ \ln(u) &= \ln(\ln(x)) + c_1 \\ u &= e^{\ln(\ln(x))+c_1} \\ &= c_1\ln(x) \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= c_1\ln(x) \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int c_1\ln(x)\,\mathrm{d}x \\ &= c_1(\ln(x)\,x - x) + c_2 \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (-1)\,(c_1(\ln(x)\,x - x) + c_2) \\ &= -xc_1\ln(x) + c_1x - c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -x c_1 \ln(x) + c_1 x - c_2 \tag{1}$$

Verification of solutions

$$y = -x c_1 \ln(x) + c_1 x - c_2$$

Verified OK.

14.10.3 Maple step by step solution

Let's solve

$x \ln(x) y'' - y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $x \ln(x) u'(x) - u(x) = 0$

- Separate variables

  $\frac{u'(x)}{u(x)} = \frac{1}{x \ln(x)}$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)} dx = \int \frac{1}{x \ln(x)} dx + c_1$

- Evaluate integral

  $\ln(u(x)) = \ln(\ln(x)) + c_1$

- Solve for $u(x)$

  $u(x) = e^{c_1} \ln(x)$

- Solve 1st ODE for $u(x)$

  $u(x) = e^{c_1} \ln(x)$

- Make substitution $u = y'$

  $y' = e^{c_1} \ln(x)$

- Integrate both sides to solve for y

  $\int y' dx = \int e^{c_1} \ln(x) dx + c_2$

- Compute integrals

$$y = e^{c_1}(\ln(x)\, x - x) + c_2$$

Problem number: 337.
ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"separable"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{yx - y' \ln\left(\frac{y'}{x}\right) = 0}$$

14.11.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{yx}{\operatorname{LambertW}(y)} \end{aligned}$$

Where $f(x) = x$ and $g(y) = \frac{y}{\operatorname{LambertW}(y)}$. Integrating both sides gives

$$\frac{1}{\frac{y}{\operatorname{LambertW}(y)}}\, dy = x\, dx$$

$$\int \frac{1}{\frac{y}{\operatorname{LambertW}(y)}}\, dy = \int x\, dx$$

$$\frac{\operatorname{LambertW}(y)^2}{2} + \operatorname{LambertW}(y) = \frac{x^2}{2} + c_1$$

Which results in

$$y = \left(-1+\sqrt{x^2+2c_1+1}\right) \mathrm{e}^{-1+\sqrt{x^2+2c_1+1}}$$

$$y = \left(-1-\sqrt{x^2+2c_1+1}\right) \mathrm{e}^{-1-\sqrt{x^2+2c_1+1}}$$

Summary

The solution(s) found are the following

$$y = \left(-1+\sqrt{x^2+2c_1+1}\right) \mathrm{e}^{-1+\sqrt{x^2+2c_1+1}} \tag{1}$$

$$y = \left(-1-\sqrt{x^2+2c_1+1}\right) \mathrm{e}^{-1-\sqrt{x^2+2c_1+1}} \tag{2}$$

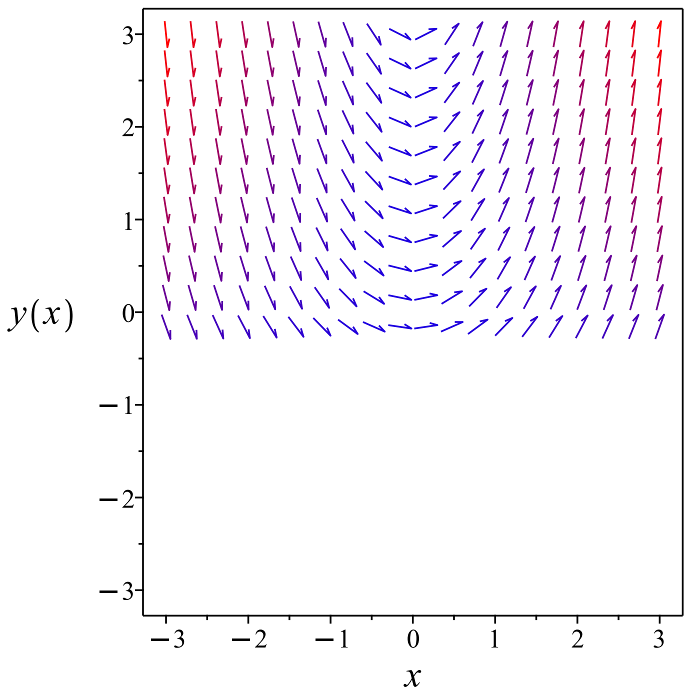

Figure 458: Slope field plot

Verification of solutions

$$y = \left(-1+\sqrt{x^2+2c_1+1}\right) \mathrm{e}^{-1+\sqrt{x^2+2c_1+1}}$$

Verified OK.

$$y = \left(-1-\sqrt{x^2+2c_1+1}\right) \mathrm{e}^{-1-\sqrt{x^2+2c_1+1}}$$

Verified OK.

14.11.2 Maple step by step solution

Let's solve

$yx - y' \ln\left(\frac{y'}{x}\right) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y' \mathit{LambertW}(y)}{y} = x$

- Integrate both sides with respect to x

  $\int \frac{y' \mathit{LambertW}(y)}{y} dx = \int x dx + c_1$

- Evaluate integral

  $\frac{\mathit{LambertW}(y)^2}{2} + \mathit{LambertW}(y) = \frac{x^2}{2} + c_1$

- Solve for y

  $\left\{y = \left(-1 - \sqrt{x^2 + 2c_1 + 1}\right) \mathrm{e}^{-1-\sqrt{x^2+2c_1+1}}, y = \left(-1 + \sqrt{x^2 + 2c_1 + 1}\right) \mathrm{e}^{-1+\sqrt{x^2+2c_1+1}}\right\}$

Problem number: 338.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y], [_2nd_order, _reducible, _mu_poly_yn
    ]]
```

$$\boxed{2y'' - \frac{y'}{x} - \frac{x^2}{y'} = 0}$$

With initial conditions

$$\left[y(1) = \frac{\sqrt{2}}{5}, y'(1) = \frac{\sqrt{2}}{2}\right]$$

14.12.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$2p'(x)\,xp(x) - x^3 - p(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode. Writing the ode as

$$p'(x) = \frac{x^3 + p^2}{2xp}$$
$$p'(x) = \omega(x, p)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_p - \xi_x) - \omega^2 \xi_p - \omega_x \xi - \omega_p \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 347: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,p) &= 0\\ \eta(x,p) &= \frac{x}{p}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,p) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dp}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial p}\right) S(x,p) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\frac{x}{p}} dy\end{aligned}$$

Which results in

$$S = \frac{p^2}{2x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,p)S_p}{R_x + \omega(x,p)R_p} \tag{2}$$

Where in the above R_x, R_p, S_x, S_p are all partial derivatives and $\omega(x,p)$ is the right hand side of the original ode given by

$$\omega(x,p) = \frac{x^3 + p^2}{2xp}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_p &= 0 \\
S_x &= -\frac{p^2}{2x^2} \\
S_p &= \frac{p}{x}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{x}{2} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, p in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R}{2}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{R^2}{4} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, p coordinates. This results in

$$
\frac{p(x)^2}{2x} = \frac{x^2}{4} + c_1
$$

Which simplifies to

$$
\frac{p(x)^2}{2x} = \frac{x^2}{4} + c_1
$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $p = \frac{\sqrt{2}}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$
\frac{1}{4} = \frac{1}{4} + c_1
$$

$$
c_1 = 0
$$

Substituting c_1 found above in the general solution gives

$$\frac{p^2}{2x} = \frac{x^2}{4}$$

The above simplifies to

$$-x^3 + 2p^2 = 0$$

Solving for $p(x)$ from the above gives

$$p(x) = \frac{\sqrt{2}\, x^{\frac{3}{2}}}{2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{\sqrt{2}\, x^{\frac{3}{2}}}{2}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\sqrt{2}\, x^{\frac{3}{2}}}{2}\, \mathrm{d}x \\ &= \frac{x^{\frac{5}{2}}\sqrt{2}}{5} + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = \frac{\sqrt{2}}{5}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\sqrt{2}}{5} = \frac{\sqrt{2}}{5} + c_2$$

$$c_2 = 0$$

Substituting c_2 found above in the general solution gives

$$y = \frac{x^{\frac{5}{2}}\sqrt{2}}{5}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = \frac{x^{\frac{5}{2}}\sqrt{2}}{5} \tag{1}$$

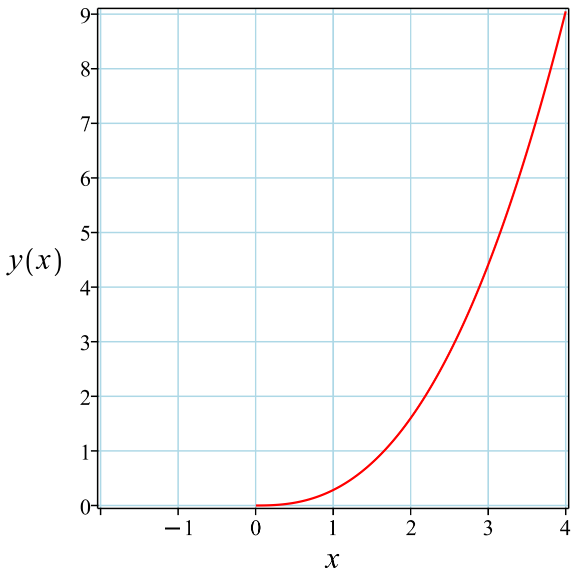

Figure 459: Solution plot

Verification of solutions

$$y = \frac{x^{\frac{5}{2}}\sqrt{2}}{5}$$

Verified OK.

Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 340.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{xy''' - y'' = 0}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$xv''(x) - v'(x) = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (xv''(x) - v'(x))\,dx = 0$$
$$v'(x)\,x - 2v(x) = c_1$$

Which is now solved for $v(x)$. In canonical form the ODE is

$$\begin{aligned} v' &= F(x,v) \\ &= f(x)g(v) \\ &= \frac{2v + c_1}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(v) = 2v + c_1$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{2v + c_1}\, dv &= \frac{1}{x}\, dx \\
\int \frac{1}{2v + c_1}\, dv &= \int \frac{1}{x}\, dx \\
\frac{\ln(2v + c_1)}{2} &= \ln(x) + c_2
\end{aligned}$$

Raising both side to exponential gives

$$\sqrt{2v + c_1} = \mathrm{e}^{\ln(x) + c_2}$$

Which simplifies to

$$\sqrt{2v + c_1} = c_3 x$$

But since $y' = v(x)$ then we now need to solve the ode $y' = \frac{c_3^2 \mathrm{e}^{2c_2} x^2}{2} - \frac{c_1}{2}$. Integrating both sides gives

$$\begin{aligned}
y &= \int \frac{c_3^2 \mathrm{e}^{2c_2} x^2}{2} - \frac{c_1}{2}\, \mathrm{d}x \\
&= \frac{c_3^2 \mathrm{e}^{2c_2} x^3}{6} - \frac{c_1 x}{2} + c_4
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_3^2 \mathrm{e}^{2c_2} x^3}{6} - \frac{c_1 x}{2} + c_4 \tag{1}$$

Verification of solutions

$$y = \frac{c_3^2 \mathrm{e}^{2c_2} x^3}{6} - \frac{c_1 x}{2} + c_4$$

Verified OK.

14.14.1 Maple step by step solution

Let's solve

$xy''' - y'' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = \frac{y''}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' - \frac{y''}{x} = 0$

- Multiply by denominators of the ODE

  $xy''' - y'' = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3}y(t)\right)t'(x)^3 + 3t'(x)\,t''(x)\left(\frac{d^2}{dt^2}y(t)\right) + t'''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

$$x\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) - \frac{\frac{d^2}{dt^2}y(t)}{x^2} + \frac{\frac{d}{dt}y(t)}{x^2} = 0$$

- Simplify

$$\frac{\frac{d^3}{dt^3}y(t) - 4\frac{d^2}{dt^2}y(t) + 3\frac{d}{dt}y(t)}{x^2} = 0$$

- Isolate 3rd derivative

$$\frac{d^3}{dt^3}y(t) = 4\frac{d^2}{dt^2}y(t) - 3\frac{d}{dt}y(t)$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^3}{dt^3}y(t) - 4\frac{d^2}{dt^2}y(t) + 3\frac{d}{dt}y(t) = 0$$

☐ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(t)$

    $y_1(t) = y(t)$

  - Define new variable $y_2(t)$

    $y_2(t) = \frac{d}{dt}y(t)$

  - Define new variable $y_3(t)$

    $y_3(t) = \frac{d^2}{dt^2}y(t)$

  - Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

    $\frac{d}{dt}y_3(t) = 4y_3(t) - 3y_2(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = 4y_3(t) - 3y_2(t)\right]$

- Define vector

$$\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -3 & 4 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -3 & 4 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c}\frac{1}{9}\\ \frac{1}{3}\\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = e^{3t} \cdot \left[\begin{array}{c}\frac{1}{9}\\ \frac{1}{3}\\ 1\end{array}\right]$$

- General solution to the system of ODEs

$$\overrightarrow{y} = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3$$

- Substitute solutions into the general solution

$$\overrightarrow{y} = c_2 e^t \cdot \left[\begin{array}{c}1\\ 1\\ 1\end{array}\right] + c_3 e^{3t} \cdot \left[\begin{array}{c}\frac{1}{9}\\ \frac{1}{3}\\ 1\end{array}\right] + \left[\begin{array}{c}c_1\\ 0\\ 0\end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y(t) = c_2 e^t + \frac{c_3 e^{3t}}{9} + c_1$$

- Change variables back using $t = \ln(x)$

$$y = c_2 x + \frac{1}{9} c_3 x^3 + c_1$$

Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 341.
ODE order: 2.
ODE degree: 2.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - \sqrt{1 + y'^2} = 0}$$

14.15.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \sqrt{1 + p(x)^2} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{\sqrt{p^2+1}}dp = x + c_1$$
$$\operatorname{arcsinh}(p) = x + c_1$$

Solving for p gives these solutions

$$p_1 = \sinh(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \sinh(x + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \sinh(x + c_1)\,\mathrm{d}x \\ &= \cosh(x + c_1) + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \cosh(x + c_1) + c_2 \tag{1}$$

Verification of solutions

$$y = \cosh(x + c_1) + c_2$$

Verified OK.

14.15.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) = \sqrt{1+p(y)^2}$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int \frac{p}{\sqrt{p^2+1}}dp = \int dy$$
$$\sqrt{1+p(y)^2} = y + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\sqrt{1+y'^2} = y + c_1$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^2+2yc_1+c_1^2-1} \tag{1}$$
$$y' = -\sqrt{y^2+2yc_1+c_1^2-1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{c_1^2+2c_1y+y^2-1}}dy = \int dx$$
$$\ln\left(y+c_1+\sqrt{c_1^2+2c_1y+y^2-1}\right) = x + c_2$$

Raising both side to exponential gives

$$y+c_1+\sqrt{c_1^2+2c_1y+y^2-1} = \mathrm{e}^{x+c_2}$$

Which simplifies to

$$y+c_1+\sqrt{(c_1+y+1)(c_1+y-1)} = \mathrm{e}^{x}c_3$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{c_1^2+2c_1y+y^2-1}}dy = \int dx$$

$$-\ln\left(y+c_1+\sqrt{c_1^2+2c_1y+y^2-1}\right) = x+c_4$$

Raising both side to exponential gives

$$\frac{1}{y+c_1+\sqrt{c_1^2+2c_1y+y^2-1}} = \mathrm{e}^{x+c_4}$$

Which simplifies to

$$\frac{1}{y+c_1+\sqrt{(c_1+y+1)(c_1+y-1)}} = c_5\mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \frac{(\mathrm{e}^{2x}c_3^2-2\,\mathrm{e}^{x}c_1c_3+1)\,\mathrm{e}^{-x}}{2c_3} \tag{1}$$

$$y = -\frac{(-c_5^2\mathrm{e}^{2x}+2c_1c_5\mathrm{e}^{x}-1)\,\mathrm{e}^{-x}}{2c_5} \tag{2}$$

Verification of solutions

$$y = \frac{(\mathrm{e}^{2x}c_3^2-2\,\mathrm{e}^{x}c_1c_3+1)\,\mathrm{e}^{-x}}{2c_3}$$

Verified OK.

$$y = -\frac{(-c_5^2\mathrm{e}^{2x}+2c_1c_5\mathrm{e}^{x}-1)\,\mathrm{e}^{-x}}{2c_5}$$

Verified OK.

14.15.3 Maple step by step solution

Let's solve

$y'' = \sqrt{1+y'^2}$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

$$u'(x) = \sqrt{1 + u(x)^2}$$

- Separate variables

$$\frac{u'(x)}{\sqrt{1+u(x)^2}} = 1$$

- Integrate both sides with respect to x

$$\int \frac{u'(x)}{\sqrt{1+u(x)^2}}dx = \int 1dx + c_1$$

- Evaluate integral

$$\operatorname{arcsinh}(u(x)) = x + c_1$$

- Solve for $u(x)$

$$u(x) = \sinh(x + c_1)$$

- Solve 1st ODE for $u(x)$

$$u(x) = \sinh(x + c_1)$$

- Make substitution $u = y'$

$$y' = \sinh(x + c_1)$$

- Integrate both sides to solve for y

$$\int y'dx = \int \sinh(x + c_1)\, dx + c_2$$

- Compute integrals

$$y = \cosh(x + c_1) + c_2$$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_xy]]
```

$$\boxed{y'' - {y'}^2 = 0}$$

14.16.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p^2} dp = x + c_1$$
$$-\frac{1}{p} = x + c_1$$

Solving for p gives these solutions

$$p_1 = -\frac{1}{x + c_1}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{1}{x + c_1}$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{1}{x + c_1} \, \mathrm{d}x \\ &= -\ln(x + c_1) + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\ln(x + c_1) + c_2 \tag{1}$$

Verification of solutions

$$y = -\ln(x + c_1) + c_2$$

Verified OK.

14.16.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx} \frac{dp}{dy} \\ &= p \frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right)-p(y)^2=0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\begin{aligned}\int \frac{1}{p}dp &= y+c_1\\ \ln(p) &= y+c_1\\ p &= e^{y+c_1}\\ p &= c_1 e^{y}\end{aligned}$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$y'=c_1 e^{y}$$

Integrating both sides gives

$$\begin{aligned}\int \frac{e^{-y}}{c_1}dy &= x+c_2\\ -\frac{e^{-y}}{c_1} &= x+c_2\end{aligned}$$

Solving for y gives these solutions

$$y_1=\ln\left(-\frac{1}{(x+c_2)\,c_1}\right)$$

Summary

The solution(s) found are the following

$$y=\ln\left(-\frac{1}{(x+c_2)\,c_1}\right) \tag{1}$$

Verification of solutions

$$y=\ln\left(-\frac{1}{(x+c_2)\,c_1}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second__order__ode__missing__x", "second__order__ode__missing__y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - \sqrt{-y'^2 + 1} = 0}$$

14.17.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \sqrt{-p(x)^2 + 1} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{\sqrt{-p^2+1}}dp = x + c_1$$
$$\arcsin(p) = x + c_1$$

Solving for p gives these solutions

$$p_1 = \sin(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \sin(x + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \sin(x + c_1)\,\mathrm{d}x \\ &= -\cos(x + c_1) + c_2 \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\cos(x + c_1) + c_2 \tag{1}$$

<u>Verification of solutions</u>

$$y = -\cos(x + c_1) + c_2$$

Verified OK.

14.17.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) = \sqrt{-p(y)^2+1}$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int \frac{p}{\sqrt{-p^2+1}}dp = \int dy$$

$$\frac{(p(y)-1)(p(y)+1)}{\sqrt{-p(y)^2+1}} = y + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{(y'-1)(y'+1)}{\sqrt{-y'^2+1}} = y + c_1$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-y^2 - 2yc_1 - c_1^2 + 1} \tag{1}$$

$$y' = -\sqrt{-y^2 - 2yc_1 - c_1^2 + 1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-c_1^2 - 2c_1y - y^2 + 1}}dy = x + c_2$$

$$\arcsin(y + c_1) = x + c_2$$

Solving for y gives these solutions

$$y_1 = -c_1 + \sin(x + c_2)$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-c_1^2 - 2c_1y - y^2 + 1}}dy = c_3 + x$$

$$-\arcsin(y + c_1) = c_3 + x$$

Solving for y gives these solutions

$$y_1 = -c_1 - \sin(c_3 + x)$$

Summary

The solution(s) found are the following

$$y = -c_1 + \sin(x + c_2) \tag{1}$$

$$y = -c_1 - \sin(c_3 + x) \tag{2}$$

Verification of solutions

$$y = -c_1 + \sin(x + c_2)$$

Verified OK.

$$y = -c_1 - \sin(c_3 + x)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{y'' - y'^2 = 1}$$

14.18.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 1 - p(x)^2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p^2+1} dp = x + c_1$$
$$\arctan(p) = x + c_1$$

Solving for p gives these solutions

$$p_1 = \tan(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \tan(x + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \tan(x + c_1) \,\mathrm{d}x \\ &= \frac{\ln\left(1 + \tan(x + c_1)^2\right)}{2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\ln\left(1 + \tan(x + c_1)^2\right)}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{\ln\left(1 + \tan(x + c_1)^2\right)}{2} + c_2$$

Verified OK.

14.18.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) - p(y)^2 = 1$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int \frac{p}{p^2+1}dp = \int dy$$
$$\frac{\ln(p^2+1)}{2} = y + c_1$$

Raising both side to exponential gives

$$\sqrt{p^2+1} = e^{y+c_1}$$

Which simplifies to

$$\sqrt{p^2+1} = c_2 e^{y}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \operatorname{RootOf}\left(\_Z^2 - c_2^2 e^{2y} + 1\right)$$

Integrating both sides gives

$$\int \frac{1}{\operatorname{RootOf}\left(\_Z^2 - c_2^2 e^{2y} + 1\right)}dy = \int dx$$
$$\int^y \frac{1}{\operatorname{RootOf}\left(\_Z^2 - c_2^2 e^{2\_a} + 1\right)}d\_a = c_3 + x$$

Summary

The solution(s) found are the following

$$\int^y \frac{1}{\operatorname{RootOf}\left(\_Z^2 - c_2^2 e^{2\_a} + 1\right)}d\_a = c_3 + x \tag{1}$$

Verification of solutions

$$\int^y \frac{1}{\operatorname{RootOf}\left(\_Z^2 - c_2^2 e^{2\_a} + 1\right)}d\_a = c_3 + x$$

Verified OK.

14.18.3 Maple step by step solution

Let's solve

$y'' - y'^2 = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) - u(x)^2 = 1$

ODE order: 2.
ODE degree: 2.

The type(s) of ODE detected by this program : **"second__order__ode__missing__x", "second__order__ode__missing__y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - \sqrt{y' + 1} = 0}$$

14.19.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \sqrt{p(x) + 1} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{\sqrt{p+1}} dp = \int dx$$

$$2\sqrt{p(x) + 1} = x + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$2\sqrt{y' + 1} = x + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{1}{4}c_1^2 + \frac{1}{2}c_1 x + \frac{1}{4}x^2 - 1 \, \mathrm{d}x \\ &= \frac{x^3}{12} + \frac{c_1 x^2}{4} + \frac{(c_1 + 2)(c_1 - 2)x}{4} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x^3}{12} + \frac{c_1 x^2}{4} + \frac{(c_1 + 2)(c_1 - 2)x}{4} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{x^3}{12} + \frac{c_1 x^2}{4} + \frac{(c_1 + 2)(c_1 - 2)x}{4} + c_2$$

Verified OK.

14.19.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) = \sqrt{p(y) + 1}$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\int \frac{p}{\sqrt{p+1}}dp = \int dy$$

$$\frac{2\sqrt{p(y)+1}\,(p(y)-2)}{3} = y + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{2\sqrt{y'+1}\,(y'-2)}{3} = y + c_1$$

Solving the given ode for y' results in 3 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \left(\frac{\left(6y+6c_1+2\sqrt{-16+9y^2+18yc_1+9c_1^2}\right)^{\frac{1}{3}}}{2} + \frac{2}{\left(6y+6c_1+2\sqrt{-16+9y^2+18yc_1+9c_1^2}\right)^{\frac{1}{3}}}\right)^2 - 1 \tag{1}$$

$$y' = \left(-\frac{\left(6y+6c_1+2\sqrt{-16+9y^2+18yc_1+9c_1^2}\right)^{\frac{1}{3}}}{4} - \frac{1}{\left(6y+6c_1+2\sqrt{-16+9y^2+18yc_1+9c_1^2}\right)^{\frac{1}{3}}} + \frac{i\sqrt{}}{} \tag{2}$$

$$y' = \left(-\frac{\left(6y+6c_1+2\sqrt{-16+9y^2+18yc_1+9c_1^2}\right)^{\frac{1}{3}}}{4} - \frac{1}{\left(6y+6c_1+2\sqrt{-16+9y^2+18yc_1+9c_1^2}\right)^{\frac{1}{3}}} - \frac{i\sqrt{}}{} \tag{3}$$

Now each one of the above ODE is solved.

<u>Solving equation (1)</u>

Integrating both sides gives

$$\int \frac{4\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{2}{3}}}{\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{4}{3}}+4\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{2}{3}}+16}dy$$
$$=\int dx$$

$$4\left(\int^{y}\frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}+4\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}\right.$$
$$=x+c_2$$

Solving equation (2)

Integrating both sides gives

$$\int$$

$$-\frac{8\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{2}{3}}}{i\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{4}{3}}\sqrt{3}+\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{4}{3}}-16i\sqrt{3}-}$$
$$=\int dx$$

$$-8\left(\int^{y}\frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+}\right.}{i\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}\sqrt{3}+\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-\right.}\right.$$
$$=c_3+x$$

Solving equation (3)

Integrating both sides gives

$$\int\frac{8\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{2}{3}}}{i\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{4}{3}}\sqrt{3}-\left(6y+6c_1+2\sqrt{9c_1^2+18c_1y+9y^2-16}\right)^{\frac{4}{3}}-16i\sqrt{3}-}$$
$$=\int dx$$

$$8\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}{i\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}\sqrt{3}-\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}}\right.$$

$$= x+c_4$$

Summary

The solution(s) found are the following

$$4\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}+4\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}\right. \quad (1)$$

$$= x+c_2$$

$$-8\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}{i\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}\sqrt{3}+\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}}\right. \quad (2)$$

$$= c_3+x$$

$$8\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}{i\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}\sqrt{3}-\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}}\right. \quad (3)$$

$$= x+c_4$$

Verification of solutions

$$4\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}}{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}+4\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{2}{3}}\right.$$
$$= x + c_2$$

Verified OK.

$$-8\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+\right.}{i\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}\sqrt{3}+\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-\right.}\right.$$
$$= c_3 + x$$

Verified OK.

$$8\left(\int^{y} \frac{\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9\right.}{i\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-16}\right)^{\frac{4}{3}}\sqrt{3}-\left(6\_a+6c_1+2\sqrt{9\_a^2+18\_ac_1+9c_1^2-1\right.}\right.$$
$$= x + c_4$$

Verified OK.

14.19.3 Maple step by step solution

Let's solve

$y'' = \sqrt{y'+1}$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) = \sqrt{u(x)+1}$

- Separate variables

  $\frac{u'(x)}{\sqrt{u(x)+1}} = 1$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{\sqrt{u(x)+1}}dx = \int 1dx + c_1$

- Evaluate integral

$2\sqrt{u(x)+1} = x + c_1$

- Solve for $u(x)$

  $u(x) = \frac{1}{4}c_1^2 + \frac{1}{2}c_1 x + \frac{1}{4}x^2 - 1$

- Solve 1st ODE for $u(x)$

  $u(x) = \frac{1}{4}c_1^2 + \frac{1}{2}c_1 x + \frac{1}{4}x^2 - 1$

- Make substitution $u = y'$

  $y' = \frac{1}{4}c_1^2 + \frac{1}{2}c_1 x + \frac{1}{4}x^2 - 1$

- Integrate both sides to solve for y

  $\int y' dx = \int \left(\frac{1}{4}c_1^2 + \frac{1}{2}c_1 x + \frac{1}{4}x^2 - 1\right) dx + c_2$

- Compute integrals

  $y = \frac{x^3}{12} + \frac{c_1 x^2}{4} + \frac{(c_1+2)(c_1-2)x}{4} + c_2$

Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 346.
ODE order: 2.
ODE degree: 0.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y' \ln(y') = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

14.20.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x) \ln(p(x)) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p \ln(p)} dp = \int dx$$
$$\ln(\ln(p)) = x + c_1$$

Raising both side to exponential gives

$$\ln(p) = e^{x+c_1}$$

Which simplifies to

$$\ln(p) = c_2 e^x$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = e^{c_2}$$

$$c_2 = 0$$

Substituting c_2 found above in the general solution gives

$$p(x) = 1$$

Since $p = y'$ then the new first order ode to solve is

$$y' = 1$$

Integrating both sides gives

$$y = \int 1 \, dx$$
$$= c_3 + x$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_3$$

$$c_3 = 0$$

Substituting c_3 found above in the general solution gives

$$y = x$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = x \tag{1}$$

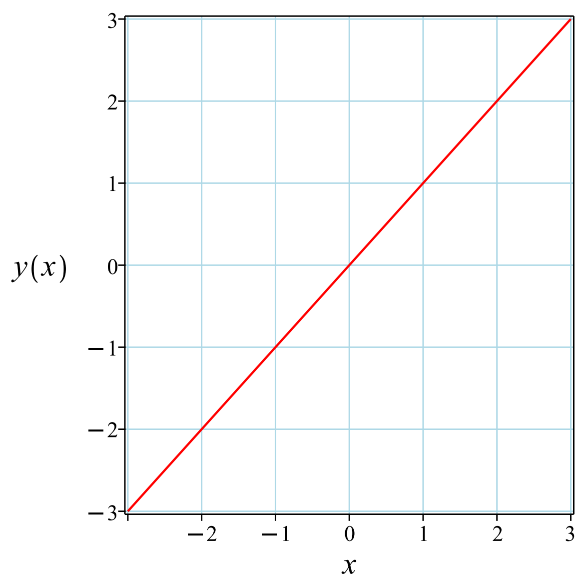

Figure 460: Solution plot

Verification of solutions

$$y = x$$

Verified OK.

14.20.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y)\left(\frac{d}{dy}p(y)\right) - p(y)\ln\left(p(y)\right) = 0
$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{\ln\left(p\right)}dp &= \int dy \\
-\operatorname{expIntegral}_1\left(-\ln\left(p\right)\right) &= y + c_1
\end{aligned}
$$

Raising both side to exponential gives

$$
e^{-\operatorname{expIntegral}_1(-\ln(p))} = e^{y+c_1}
$$

Which simplifies to

$$
e^{-\operatorname{expIntegral}_1(-\ln(p))} = c_2 e^{y}
$$

Unable to solve for constant of integration due to RootOf in solution.

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
y' = e^{\operatorname{RootOf}(\operatorname{expIntegral}_1(-\_Z)+\ln(c_2)+y)}
$$

Integrating both sides gives

$$
\begin{aligned}
\int e^{-\operatorname{RootOf}(\operatorname{expIntegral}_1(-\_Z)+\ln(c_2)+y)}dy &= \int dx \\
\int^{y} e^{-\operatorname{RootOf}(\operatorname{expIntegral}_1(-\_Z)+\ln(c_2)+\_a)}d\_a &= c_3 + x
\end{aligned}
$$

Unable to solve for constant of integration due to RootOf in solution.

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$\int^{y} \mathrm{e}^{-\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(-\_Z)+\ln(c_2)+\_a\right)}d\_a = c_3 + x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$\int^{0} \mathrm{e}^{-\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(-\_Z)+\ln(c_2)+\_a\right)}d\_a = c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \mathrm{e}^{\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(-\_Z)+\ln(c_2)+\operatorname{RootOf}\left(-\left(\int^{\_Z} \mathrm{e}^{-\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(-\_Z)+\ln(c_2)+\_a\right)}d\_a\right)+c_3+x\right)\right)}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \mathrm{e}^{\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(-\_Z)+\ln(c_2)+\operatorname{RootOf}\left(-\left(\int^{\_Z} \mathrm{e}^{\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(\_Z)+\ln(c_2)+\_a\right)}d\_a\right)+c_3+x\right)\Big|_{\left\{\int^{\_Z} \mathrm{e}^{\operatorname{RootOf}\left(\operatorname{expIntegral}_{1}(\_Z)+\right.}\right.}\right.} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_2, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

<u>Verification of solutions</u> N/A

14.20.3 Maple step by step solution

Let's solve

$$\left[y'' - y' \ln(y') = 0, y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) - u(x)\ln(u(x)) = 0$

- Separate variables

  $\frac{u'(x)}{u(x)\ln(u(x))} = 1$

- Integrate both sides with respect to x

$\int \frac{u'(x)}{u(x)\ln(u(x))}dx = \int 1dx + c_1$

- Evaluate integral

  $\ln(\ln(u(x))) = x + c_1$

- Solve for $u(x)$

  $u(x) = e^{e^{x+c_1}}$

- Solve 1st ODE for $u(x)$

  $u(x) = e^{e^{x+c_1}}$

- Make substitution $u = y'$

  $y' = e^{e^{x+c_1}}$

- Integrate both sides to solve for y

  $\int y'dx = \int e^{e^{x+c_1}}dx + c_2$

- Compute integrals

  $y = -\mathrm{Ei}_1(-e^{x+c_1}) + c_2$

☐ Check validity of solution $y = -\mathrm{Ei}_1(-e^{x+c_1}) + c_2$

  - Use initial condition $y(0) = 0$

    $0 = -\mathrm{Ei}_1(-e^{c_1}) + c_2$

  - Compute derivative of the solution

    $y' = e^{e^{x+c_1}}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 1$

    $1 = e^{e^{c_1}}$

  - Solve for c_1 and c_2
  - The solution does not satisfy the initial conditions

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y' = -2}$$

With initial conditions

$$[y(0) = 0, y'(0) = -2]$$

14.21.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ F &= -2 \end{aligned}$$

Hence the ode is

$$y'' + y' = -2$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $F = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

14.21.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = -2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \lambda \, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{1^2 - (4)(1)(0)} \\ &= -\frac{1}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + \frac{1}{2} \\ \lambda_2 &= -\frac{1}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 0 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(0)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 + c_2 \mathrm{e}^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 \mathrm{e}^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = -2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + c_2 e^{-x}) + (-2x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 + c_2 e^{-x} - 2x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_2 e^{-x} - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -c_2 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

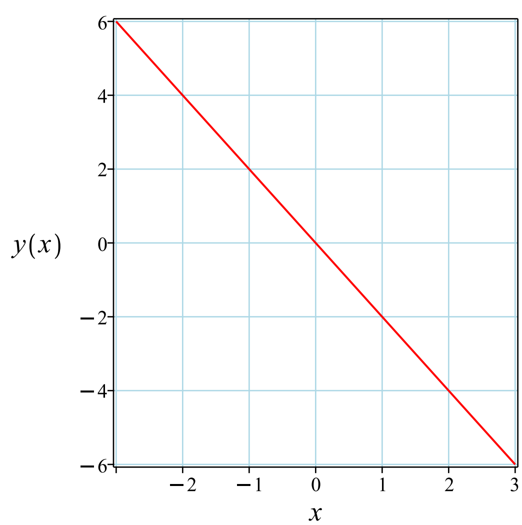
Substituting these values back in above solution results in

$$y = -2x$$

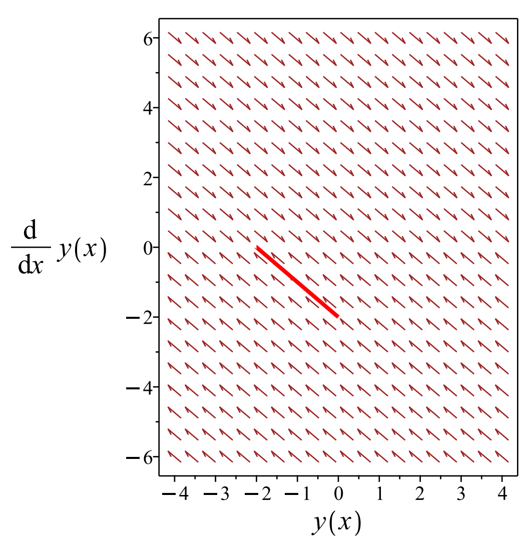
Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -2x$$

Verified OK.

14.21.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}\int (y'' + y')\, dx &= \int (-2)\, dx \\ y' + y &= -2x + c_1\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 1 \\ q(x) &= -2x + c_1\end{aligned}$$

Hence the ode is

$$y' + y = -2x + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1 dx} \\ &= e^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(-2x + c_1) \\ \frac{d}{dx}(y\, e^{x}) &= (e^{x})(-2x + c_1) \\ d(y\, e^{x}) &= ((-2x + c_1)\, e^{x})\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}y\, e^{x} &= \int (-2x + c_1)\, e^{x}\, dx \\ y\, e^{x} &= -e^{x}(2x - c_1 - 2) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = -e^{-x} e^x (2x - c_1 - 2) + c_2 e^{-x}$$

which simplifies to

$$y = -2x + c_1 + 2 + c_2 e^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -2x + c_1 + 2 + c_2 e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 2 + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_2 e^{-x} - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -c_2 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 0$$

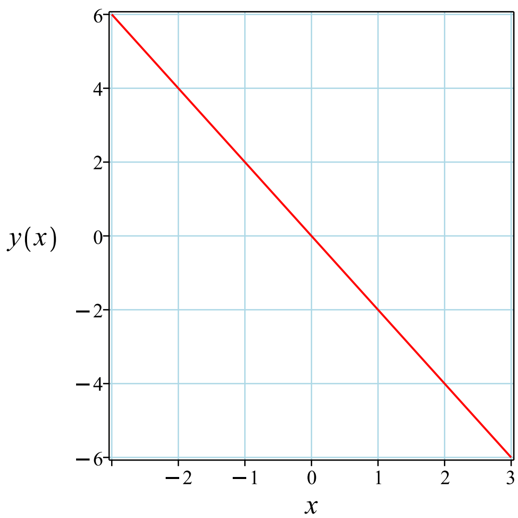
Substituting these values back in above solution results in

$$y = -2x$$

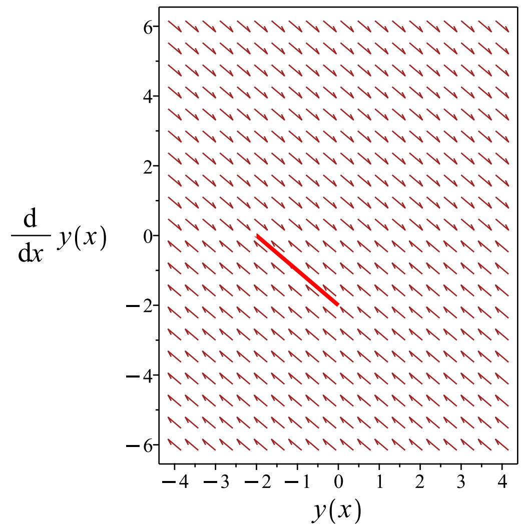
Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -2x$$

Verified OK.

14.21.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + p(x) + 2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{-p-2} dp = \int dx$$
$$-\ln(-p-2) = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{-p-2} = e^{x+c_1}$$

Which simplifies to

$$\frac{1}{-p-2} = c_2 e^x$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $p = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-2 = \frac{-1-2c_2}{c_2}$$

Unable to solve for constant of integration. Since $\lim_{c_1\to\infty}$ gives $p = -\frac{e^{-x}}{c_2} - 2 = p = -2$ and this result satisfies the given initial condition. Since $p = y'$ then the new first order ode to solve is

$$y' = -2$$

Integrating both sides gives

$$\begin{aligned}y &= \int -2 \, dx \\ &= -2x + c_3\end{aligned}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_3$$

$$c_3 = 0$$

Substituting c_3 found above in the general solution gives

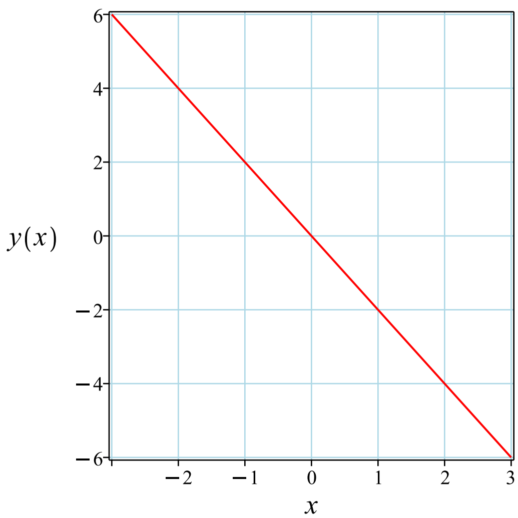
$$y = -2x$$

Initial conditions are used to solve for the constants of integration.

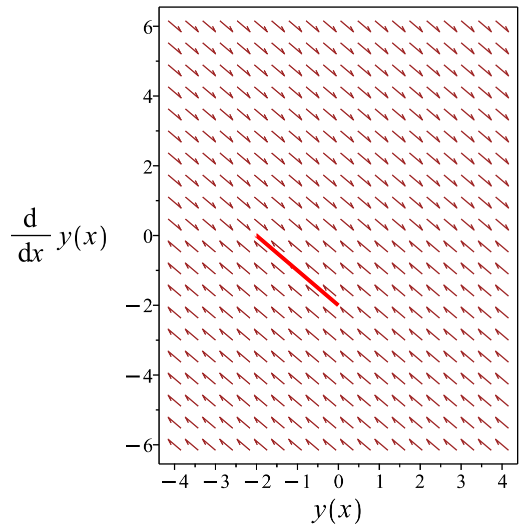
Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -2x$$

Verified OK.

14.21.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + y' = -2$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + y')\, dx = \int (-2)\, dx$$

$$y' + y = -2x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = -2x + c_1$$

Hence the ode is

$$y' + y = -2x + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1 dx} \\ &= e^x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(-2x + c_1) \\ \frac{d}{dx}(y\, e^x) &= (e^x)(-2x + c_1) \\ d(y\, e^x) &= ((-2x + c_1)\, e^x)\; dx\end{aligned}$$

Integrating gives

$$\begin{aligned}y\, e^x &= \int (-2x + c_1)\, e^x\, dx \\ y\, e^x &= -e^x(2x - c_1 - 2) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = -e^{-x} e^x(2x - c_1 - 2) + c_2 e^{-x}$$

which simplifies to

$$y = -2x + c_1 + 2 + c_2 e^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -2x + c_1 + 2 + c_2 e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 2 + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_2 e^{-x} - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -c_2 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

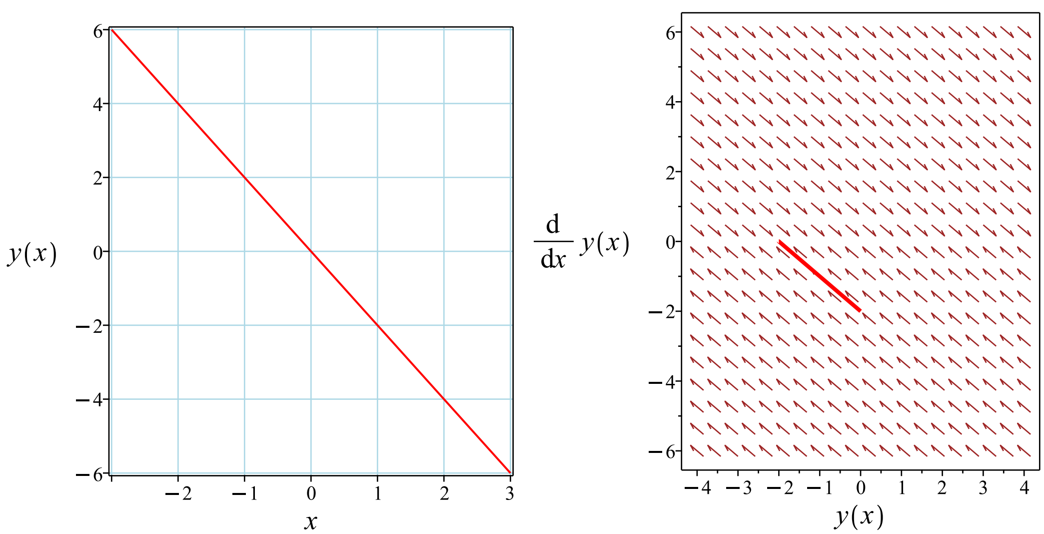
$$c_1 = -2$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -2x$$

Summary
The solution(s) found are the following

$$y = -2x \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -2x$$

Verified OK.

14.21.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 356: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx}
\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{-\frac{x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\, dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} (\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = -2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2\right) + (-2x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 - 2x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -c_1 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

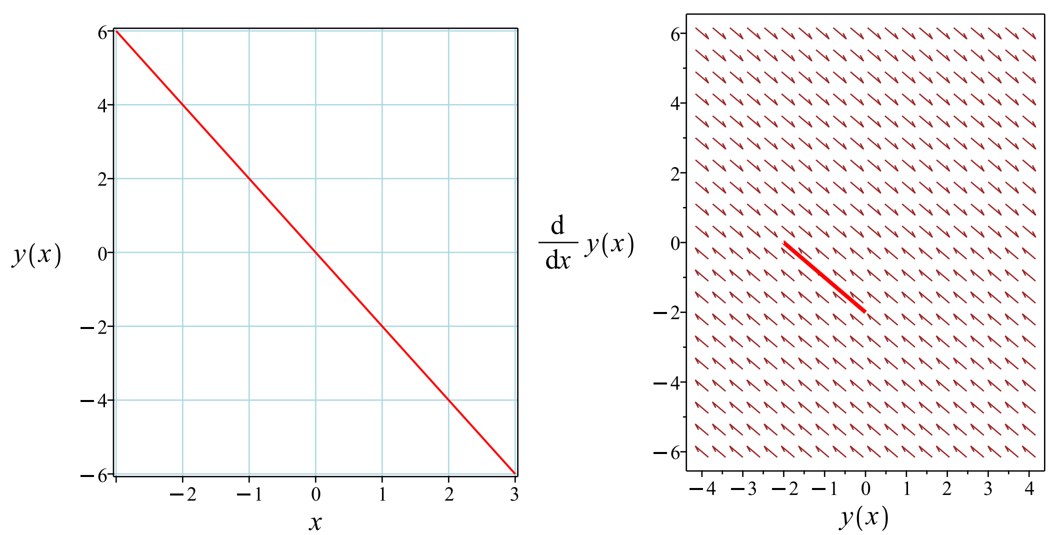
Substituting these values back in above solution results in

$$y = -2x$$

Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -2x$$

Verified OK.

14.21.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 1 \\ r(x) &= 0 \\ s(x) &= -2 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' + y = \int -2\, dx$$

We now have a first order ode to solve which is

$$y' + y = -2x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -2x + c_1 \end{aligned}$$

Hence the ode is

$$y' + y = -2x + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 1 dx} \\ &= e^{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)(-2x + c_1) \\ \frac{d}{dx}(y\,e^{x}) &= (e^{x})(-2x + c_1) \\ d(y\,e^{x}) &= ((-2x + c_1)\,e^{x})\,dx \end{aligned}$$

Integrating gives

$$\begin{aligned} y\,e^{x} &= \int (-2x + c_1)\,e^{x}\,dx \\ y\,e^{x} &= -e^{x}(2x - c_1 - 2) + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = -e^{-x}e^{x}(2x - c_1 - 2) + c_2e^{-x}$$

which simplifies to

$$y = -2x + c_1 + 2 + c_2e^{-x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -2x + c_1 + 2 + c_2 e^{-x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 2 + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_2 e^{-x} - 2$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -c_2 - 2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = 0$$

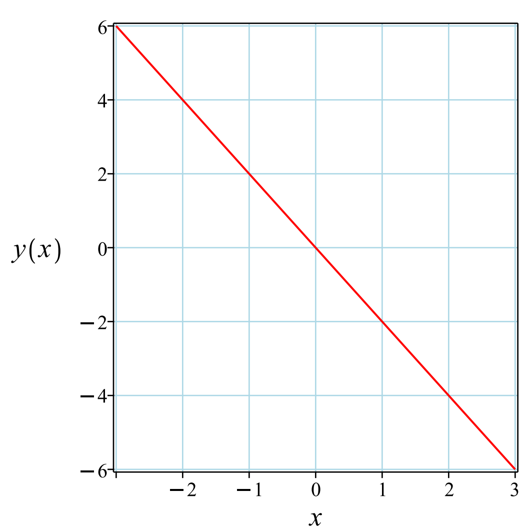
Substituting these values back in above solution results in

$$y = -2x$$

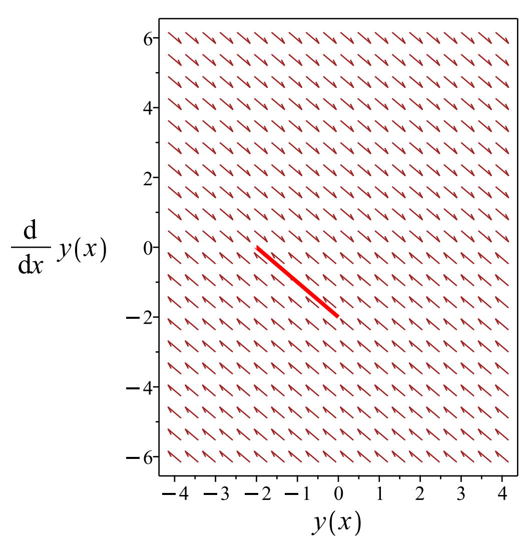
Summary

The solution(s) found are the following

$$y = -2x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -2x$$

Verified OK.

14.21.8 Maple step by step solution

Let's solve

$\left[y'' + y' = -2, y(0) = 0, y'\Big|_{\{x=0\}} = -2\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -2\right]$

  ◦ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & 1 \\ -e^{-x} & 0 \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = 2\,e^{-x}\left(\int e^{x} dx\right) - 2\left(\int 1 dx\right)$
- Compute integrals

  $y_p(x) = -2x + 2$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 - 2x + 2$

☐ Check validity of solution $y = c_1 e^{-x} + c_2 - 2x + 2$

- Use initial condition $y(0) = 0$

  $0 = 2 + c_1 + c_2$
- Compute derivative of the solution

  $y' = -c_1 e^{-x} - 2$
- Use the initial condition $y'\Big|_{\{x=0\}} = -2$

  $-2 = -c_1 - 2$
- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = -2\}$
- Substitute constant values into general solution and simplify

  $y = -2x$

- Solution to the IVP

  $y = -2x$

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y", "second_order_nonlinear_solved_by_mainardi_lioville_method"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], _Liouville, [_2nd_order, _reducible,
    _mu_xy]]
```

$$\boxed{y'' - y'(y' + 1) = 0}$$

14.22.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + (-p(x) - 1)\, p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{p\,(p+1)} dp = \int dx$$
$$-\ln\left(p+1\right)+\ln\left(p\right) = x+c_1$$

Raising both side to exponential gives

$$\mathrm{e}^{-\ln(p+1)+\ln(p)} = \mathrm{e}^{x+c_1}$$

Which simplifies to

$$\frac{p}{p+1} = c_2\mathrm{e}^{x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{c_2\mathrm{e}^{x}}{-1+c_2\mathrm{e}^{x}}$$

Integrating both sides gives

$$y = \int -\frac{c_2\mathrm{e}^{x}}{-1+c_2\mathrm{e}^{x}}\,\mathrm{d}x$$
$$= -\ln\left(-1+c_2\mathrm{e}^{x}\right)+c_3$$

Summary
The solution(s) found are the following

$$y = -\ln\left(-1+c_2\mathrm{e}^{x}\right)+c_3 \tag{1}$$

Verification of solutions

$$y = -\ln\left(-1+c_2\mathrm{e}^{x}\right)+c_3$$

Verified OK.

14.22.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y)\left(\frac{d}{dy}p(y)\right)+(-p(y)-1)\,p(y)=0
$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{p+1}dp &= \int dy \\
\ln(p+1) &= y+c_1
\end{aligned}
$$

Raising both side to exponential gives

$$
p+1 = \mathrm{e}^{y+c_1}
$$

Which simplifies to

$$
p+1 = c_2\mathrm{e}^{y}
$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$
y' = c_2\mathrm{e}^{y}-1
$$

Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{c_2\mathrm{e}^{y}-1}dy &= \int dx \\
\ln(c_2\mathrm{e}^{y}-1)-\ln(\mathrm{e}^{y}) &= c_3+x
\end{aligned}
$$

Raising both side to exponential gives

$$
\mathrm{e}^{\ln(c_2\mathrm{e}^{y}-1)-\ln(\mathrm{e}^{y})} = \mathrm{e}^{c_3+x}
$$

Which simplifies to

$$
c_2-\mathrm{e}^{-y} = c_4\mathrm{e}^{x}
$$

Summary
The solution(s) found are the following

$$y = -\ln\left(-c_4 e^x + c_2\right) \tag{1}$$

Verification of solutions

$$y = -\ln\left(-c_4 e^x + c_2\right)$$

Verified OK.

14.22.3 Solving as second order nonlinear solved by mainardi lioville method ode

The ode has the Liouville form given by

$$y'' + f(x)y' + g(y)y'^2 = 0 \tag{1A}$$

Where in this problem

$$f(x) = -1$$
$$g(y) = -1$$

Dividing through by y' then Eq (1A) becomes

$$\frac{y''}{y'} + f + gy' = 0 \tag{2A}$$

But the first term in Eq (2A) can be written as

$$\frac{y''}{y'} = \frac{d}{dx}\ln\left(y'\right) \tag{3A}$$

And the last term in Eq (2A) can be written as

$$\begin{aligned} g\frac{dy}{dx} &= \left(\frac{d}{dy}\int g dy\right)\frac{dy}{dx} \\ &= \frac{d}{dx}\int g dy \end{aligned} \tag{4A}$$

Substituting (3A,4A) back into (2A) gives

$$\frac{d}{dx}\ln\left(y'\right) + \frac{d}{dx}\int g dy = -f \tag{5A}$$

Integrating the above w.r.t. x gives

$$\ln\left(y'\right) + \int g dy = -\int f dx + c_1$$

Where c_1 is arbitrary constant. Taking the exponential of the above gives

$$y' = c_2 e^{\int -g dy} e^{\int -f dx} \tag{6A}$$

Where c_2 is a new arbitrary constant. But since $g = -1$ and $f = -1$, then

$$\begin{aligned}\int -g dy &= \int 1 dy \\ &= y \\ \int -f dx &= \int 1 dx \\ &= x\end{aligned}$$

Substituting the above into Eq(6A) gives

$$y' = c_2 e^y e^x$$

Which is now solved as first order separable ode. In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y) \\ &= f(x) g(y) \\ &= c_2 e^y e^x\end{aligned}$$

Where $f(x) = c_2 e^x$ and $g(y) = e^y$. Integrating both sides gives

$$\begin{aligned}\frac{1}{e^y} dy &= c_2 e^x dx \\ \int \frac{1}{e^y} dy &= \int c_2 e^x dx \\ -e^{-y} &= c_2 e^x + c_3\end{aligned}$$

The solution is

$$-e^{-y} - c_2 e^x - c_3 = 0$$

Summary

The solution(s) found are the following

$$-e^{-y} - c_2 e^x - c_3 = 0 \tag{1}$$

Verification of solutions

$$-e^{-y} - c_2 e^x - c_3 = 0$$

Verified OK.

14.22.4 Maple step by step solution

Let's solve

$y'' + (-y' - 1)\, y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) + (-u(x) - 1)\, u(x) = 0$

- Separate variables

  $\frac{u'(x)}{(-u(x)-1)u(x)} = -1$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{(-u(x)-1)u(x)} dx = \int (-1)\, dx + c_1$

- Evaluate integral

  $\ln (u(x) + 1) - \ln (u(x)) = -x + c_1$

- Solve for $u(x)$

  $u(x) = \frac{1}{\mathrm{e}^{-x+c_1}-1}$

- Solve 1st ODE for $u(x)$

  $u(x) = \frac{1}{\mathrm{e}^{-x+c_1}-1}$

- Make substitution $u = y'$

  $y' = \frac{1}{\mathrm{e}^{-x+c_1}-1}$

- Integrate both sides to solve for y

  $\int y' dx = \int \frac{1}{\mathrm{e}^{-x+c_1}-1} dx + c_2$

- Compute integrals

  $y = \ln (\mathrm{e}^{-x+c_1}) - \ln (\mathrm{e}^{-x+c_1} - 1) + c_2$

Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 349.
ODE order: 2.
ODE degree: 2.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{3y'' - \left(1+{y'}^2\right)^{\frac{3}{2}} = 0}$$

14.23.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$3p'(x) - \left(1+p(x)^2\right)^{\frac{3}{2}} = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{3}{(p^2+1)^{\frac{3}{2}}} dp = \int dx$$

$$\frac{3p(x)}{\sqrt{1+p(x)^2}} = x + c_1$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{3y'}{\sqrt{1+y'^2}} = x + c_1$$

Integrating both sides gives

$$\begin{aligned} y &= \int \sqrt{-\frac{1}{c_1^2+2c_1x+x^2-9}}\,(x+c_1)\,\mathrm{d}x \\ &= (c_1+x+3)(c_1+x-3)\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-9}} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = (c_1+x+3)(c_1+x-3)\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-9}} + c_2 \tag{1}$$

Verification of solutions

$$y = (c_1+x+3)(c_1+x-3)\sqrt{-\frac{1}{c_1^2+2c_1x+x^2-9}} + c_2$$

Verified OK.

14.23.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
3p(y)\left(\frac{d}{dy}p(y)\right) = \left(1+p(y)^2\right)^{\frac{3}{2}}
$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{3p}{(p^2+1)^{\frac{3}{2}}}dp &= \int dy \\
-\frac{3}{\sqrt{1+p(y)^2}} &= y+c_1
\end{aligned}
$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$
-\frac{3}{\sqrt{1+y'^2}} = y+c_1
$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$
y' = \frac{\sqrt{-y^2-2yc_1-c_1^2+9}}{y+c_1} \tag{1}
$$

$$
y' = -\frac{\sqrt{-y^2-2yc_1-c_1^2+9}}{y+c_1} \tag{2}
$$

Now each one of the above ODE is solved.

<u>Solving equation (1)</u>

Integrating both sides gives

$$
\begin{aligned}
\int \frac{y+c_1}{\sqrt{-c_1^2-2c_1y-y^2+9}}dy &= \int dx \\
\frac{(y+c_1+3)(y+c_1-3)}{\sqrt{-y^2-2yc_1-c_1^2+9}} &= x+c_2
\end{aligned}
$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{y+c_1}{\sqrt{-c_1^2-2c_1y-y^2+9}}dy = \int dx$$
$$-\frac{(y+c_1+3)\,(y+c_1-3)}{\sqrt{-y^2-2yc_1-c_1^2+9}} = c_3+x$$

Summary

The solution(s) found are the following

$$\frac{(y+c_1+3)\,(y+c_1-3)}{\sqrt{-y^2-2yc_1-c_1^2+9}} = x+c_2 \tag{1}$$
$$-\frac{(y+c_1+3)\,(y+c_1-3)}{\sqrt{-y^2-2yc_1-c_1^2+9}} = c_3+x \tag{2}$$

Verification of solutions

$$\frac{(y+c_1+3)\,(y+c_1-3)}{\sqrt{-y^2-2yc_1-c_1^2+9}} = x+c_2$$

Verified OK.

$$-\frac{(y+c_1+3)\,(y+c_1-3)}{\sqrt{-y^2-2yc_1-c_1^2+9}} = c_3+x$$

Verified OK.

14.23.3 Maple step by step solution

Let's solve

$3y'' = \left(1+y'^2\right)^{\frac{3}{2}}$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $3u'(x) = \left(1+u(x)^2\right)^{\frac{3}{2}}$

- Separate variables

$$\frac{u'(x)}{\left(1+u(x)^2\right)^{\frac{3}{2}}} = \frac{1}{3}$$

- Integrate both sides with respect to x

$$\int \frac{u'(x)}{\left(1+u(x)^2\right)^{\frac{3}{2}}} dx = \int \frac{1}{3} dx + c_1$$

- Evaluate integral

$$\frac{u(x)}{\sqrt{1+u(x)^2}} = \frac{x}{3} + c_1$$

- Solve for $u(x)$

$$u(x) = \sqrt{-\frac{1}{9c_1^2+6c_1x+x^2-9}}\,(x+3c_1)$$

- Solve 1st ODE for $u(x)$

$$u(x) = \sqrt{-\frac{1}{9c_1^2+6c_1x+x^2-9}}\,(x+3c_1)$$

- Make substitution $u = y'$

$$y' = \sqrt{-\frac{1}{9c_1^2+6c_1x+x^2-9}}\,(x+3c_1)$$

- Integrate both sides to solve for y

$$\int y' dx = \int \sqrt{-\frac{1}{9c_1^2+6c_1x+x^2-9}}\,(x+3c_1)\,dx + c_2$$

- Compute integrals

$$y = (3c_1+x+3)\,(3c_1+x-3)\sqrt{-\frac{1}{9c_1^2+6c_1x+x^2-9}} + c_2$$

    _mu_x_y1], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{yy'' - y'^2 = 0}$$

14.25.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right)-p(y)^2=0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}p' &= F(y,p)\\ &= f(y)g(p)\\ &= \frac{p}{y}\end{aligned}$$

Where $f(y)=\frac{1}{y}$ and $g(p)=p$. Integrating both sides gives

$$\begin{aligned}\frac{1}{p}\,dp &= \frac{1}{y}\,dy\\ \int \frac{1}{p}\,dp &= \int \frac{1}{y}\,dy\\ \ln(p) &= \ln(y)+c_1\\ p &= e^{\ln(y)+c_1}\\ &= c_1 y\end{aligned}$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$y' = yc_1$$

Integrating both sides gives

$$\begin{aligned}\int \frac{1}{c_1 y}dy &= \int dx\\ \frac{\ln(y)}{c_1} &= x+c_2\end{aligned}$$

Raising both side to exponential gives

$$e^{\frac{\ln(y)}{c_1}} = e^{x+c_2}$$

Which simplifies to

$$y^{\frac{1}{c_1}} = e^x c_3$$

Summary

The solution(s) found are the following

$$y = (e^x c_3)^{c_1} \tag{1}$$

Verification of solutions

$$y = (e^x c_3)^{c_1}$$

Verified OK.

14.25.2 Maple step by step solution

Let's solve

$yy'' - y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y' \left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y) \left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y) \left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $yu(y) \left(\frac{d}{dy}u(y)\right) - u(y)^2 = 0$

- Separate variables

  $\frac{\frac{d}{dy}u(y)}{u(y)} = \frac{1}{y}$

- Integrate both sides with respect to y

  $\int \frac{\frac{d}{dy}u(y)}{u(y)}dy = \int \frac{1}{y}dy + c_1$

- Evaluate integral

  $\ln(u(y)) = \ln(y) + c_1$

- Solve for $u(y)$

  $u(y) = y\,\mathrm{e}^{c_1}$

- Solve 1st ODE for $u(y)$

  $u(y) = y\,\mathrm{e}^{c_1}$

- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = y\,\mathrm{e}^{c_1}$

- Separate variables

  $\frac{y'}{y} = e^{c_1}$
- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int e^{c_1} dx + c_2$
- Evaluate integral

  $\ln(y) = e^{c_1} x + c_2$
- Solve for y

  $y = e^{e^{c_1} x + c_2}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 352.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
  _Lagerstrom, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
   _reducible, _mu_xy]]
```

$$\boxed{y'' - 2yy' = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 1]$$

14.26.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 2yy')\,dx = 0$$
$$-y^2 + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{y^2 + c_1} dy = x + c_2$$
$$\frac{\arctan\left(\frac{y}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = \tan\left(c_2\sqrt{c_1}\right)\sqrt{c_1} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\left(1 + \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)^2\right)$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \sec\left(c_2\sqrt{c_1}\right)^2 c_1 \tag{2A}$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

14.26.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) - 2yp(y) = 0$$

Which is now solved as first order ode for $p(y)$. Integrating both sides gives

$$\begin{aligned} p(y) &= \int 2y \,\mathrm{d}y \\ &= y^2 + c_1 \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $y = 1$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1 + 1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$p(y) = y^2$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = y^2$$

Integrating both sides gives

$$\int \frac{1}{y^2} dy = x + c_2$$

$$-\frac{1}{y} = x + c_2$$

Solving for y gives these solutions

$$y_1 = -\frac{1}{x + c_2}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -\frac{1}{c_2}$$

$$c_2 = -1$$

Substituting c_2 found above in the general solution gives

$$y = -\frac{1}{x - 1}$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = -\frac{1}{x - 1} \tag{1}$$

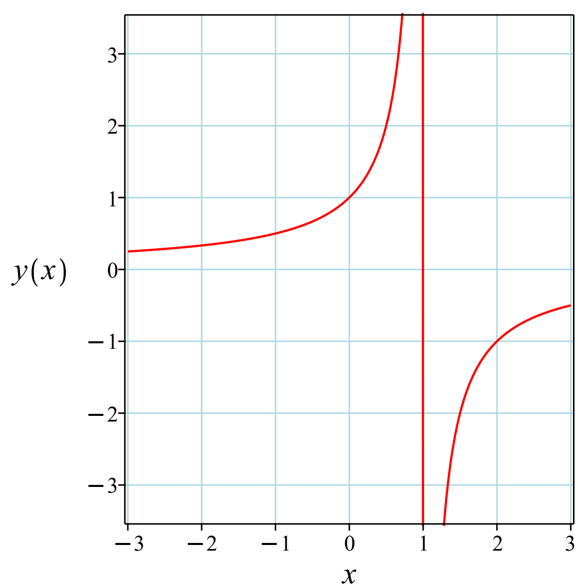

Figure 467: Solution plot

Verification of solutions

$$y = -\frac{1}{x-1}$$

Verified OK.

14.26.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 2yy' = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 2yy')\, dx = 0$$
$$-y^2 + y' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{1}{y^2 + c_1} dy = x + c_2$$
$$\frac{\arctan\left(\frac{y}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = \tan\left(c_2\sqrt{c_1}\right)\sqrt{c_1} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\left(1 + \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)^2\right)$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \sec\left(c_2\sqrt{c_1}\right)^2 c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

14.26.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\begin{aligned}\frac{\partial a_2}{\partial y} &= \frac{\partial a_1}{\partial y'}\\ \frac{\partial a_2}{\partial x} &= \frac{\partial a_0}{\partial y'}\\ \frac{\partial a_1}{\partial x} &= \frac{\partial a_0}{\partial y}\end{aligned}$$

Looking at the the ode given we see that

$$\begin{aligned}a_2 &= 1\\ a_1 &= -2y\\ a_0 &= 0\end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\begin{aligned}\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx &= c_1\\ \int 1\, dy' + \int -2y\, dy + \int 0\, dx &= c_1\end{aligned}$$

Which results in

$$-y^2 + y' = c_1$$

Which is now solved Integrating both sides gives

$$\begin{aligned}\int \frac{1}{y^2 + c_1} dy &= x + c_2\\ \frac{\arctan\left(\frac{y}{\sqrt{c_1}}\right)}{\sqrt{c_1}} &= x + c_2\end{aligned}$$

Solving for y gives these solutions

$$y_1 = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = \tan\left(c_2\sqrt{c_1}\right)\sqrt{c_1} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1\left(1 + \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)^2\right)$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \sec\left(c_2\sqrt{c_1}\right)^2 c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

14.26.5 Maple step by step solution

Let's solve

$\left[y'' - 2yy' = 0, y(0) = 1, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$
- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$
- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $u(y)\left(\frac{d}{dy}u(y)\right) - 2yu(y) = 0$
- Separate variables

  $\frac{d}{dy}u(y) = 2y$
- Integrate both sides with respect to y

  $\int \left(\frac{d}{dy}u(y)\right) dy = \int 2y dy + c_1$
- Evaluate integral

  $u(y) = y^2 + c_1$
- Solve for $u(y)$

  $u(y) = y^2 + c_1$
- Solve 1st ODE for $u(y)$

  $u(y) = y^2 + c_1$
- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = y^2 + c_1$
- Separate variables

  $\frac{y'}{y^2+c_1} = 1$
- Integrate both sides with respect to x

  $\int \frac{y'}{y^2+c_1} dx = \int 1 dx + c_2$
- Evaluate integral

  $\frac{\arctan\left(\frac{y}{\sqrt{c_1}}\right)}{\sqrt{c_1}} = x + c_2$
- Solve for y

  $y = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1}$

☐ Check validity of solution $y = \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)\sqrt{c_1}$

- Use initial condition $y(0) = 1$

  $$1 = \tan\left(c_2\sqrt{c_1}\right)\sqrt{c_1}$$

- Compute derivative of the solution

  $$y' = c_1\left(1 + \tan\left(c_2\sqrt{c_1} + x\sqrt{c_1}\right)^2\right)$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

  $$1 = c_1\left(1 + \tan\left(c_2\sqrt{c_1}\right)^2\right)$$

- Solve for c_1 and c_2
- The solution does not satisfy the initial conditions

Problem number: 353.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{3y'y'' - 2y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 1]$$

14.27.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$3p(y)^2 \left(\frac{d}{dy}p(y)\right) - 2y = 0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(y,p) \\ &= f(y)g(p) \\ &= \frac{2y}{3p^2} \end{aligned}$$

Where $f(y) = \frac{2y}{3}$ and $g(p) = \frac{1}{p^2}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{1}{p^2}}\,dp &= \frac{2y}{3}\,dy \\ \int \frac{1}{\frac{1}{p^2}}\,dp &= \int \frac{2y}{3}\,dy \\ \frac{p^3}{3} &= \frac{y^2}{3} + c_1 \end{aligned}$$

The solution is

$$\frac{p(y)^3}{3} - \frac{y^2}{3} - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $y = 1$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-c_1 = 0$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{p^3}{3} - \frac{y^2}{3} = 0$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{y'^3}{3} - \frac{y^2}{3} = 0$$

Solving the given ode for y' results in 3 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = y^{\frac{2}{3}} \tag{1}$$

$$y' = -\frac{y^{\frac{2}{3}}}{2} + \frac{i\sqrt{3}\, y^{\frac{2}{3}}}{2} \tag{2}$$

$$y' = -\frac{y^{\frac{2}{3}}}{2} - \frac{i\sqrt{3}\, y^{\frac{2}{3}}}{2} \tag{3}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{y^{\frac{2}{3}}} dy = \int dx$$

$$3y^{\frac{1}{3}} = x + c_2$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$3 = c_2$$

$$c_2 = 3$$

Substituting c_2 found above in the general solution gives

$$3y^{\frac{1}{3}} = x + 3$$

Solving for y from the above gives

$$y = \frac{(x + 3)^3}{27}$$

Solving equation (2)

Integrating both sides gives

$$\int \frac{1}{-\frac{y^{\frac{2}{3}}}{2} + \frac{i\sqrt{3}\, y^{\frac{2}{3}}}{2}} dy = \int dx$$

$$\frac{6y^{\frac{1}{3}}}{i\sqrt{3} - 1} = c_3 + x$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{6}{i\sqrt{3}-1} = c_3$$

$$c_3 = \frac{6}{i\sqrt{3}-1}$$

Substituting c_3 found above in the general solution gives

$$\frac{6y^{\frac{1}{3}}}{i\sqrt{3}-1} = \frac{i\sqrt{3}\,x - x + 6}{i\sqrt{3}-1}$$

The above simplifies to

$$-i\sqrt{3}\,x + 6y^{\frac{1}{3}} + x - 6 = 0$$

Solving for y from the above gives

$$y = -\frac{i(x-3)\,x\sqrt{3}}{6} + \frac{x^3}{27} - \frac{x^2}{6} - \frac{x}{2} + 1$$

Solving equation (3)

Integrating both sides gives

$$\int \frac{1}{-\frac{y^{\frac{2}{3}}}{2} - \frac{i\sqrt{3}\,y^{\frac{2}{3}}}{2}}dy = \int dx$$

$$-\frac{6y^{\frac{1}{3}}}{1+i\sqrt{3}} = x + c_4$$

Initial conditions are used to solve for c_4. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{6}{1+i\sqrt{3}} = c_4$$

$$c_4 = -\frac{6}{1+i\sqrt{3}}$$

Substituting c_4 found above in the general solution gives

$$-\frac{6y^{\frac{1}{3}}}{1+i\sqrt{3}} = \frac{i\sqrt{3}\,x + x - 6}{1+i\sqrt{3}}$$

The above simplifies to

$$-i\sqrt{3}\,x - 6y^{\frac{1}{3}} - x + 6 = 0$$

Solving for y from the above gives

$$y = \frac{i(x-3)\,x\sqrt{3}}{6} + \frac{x^3}{27} - \frac{x^2}{6} - \frac{x}{2} + 1$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = \frac{(x+3)^3}{27} \tag{1}$$

$$y = -\frac{i(x-3)\,x\sqrt{3}}{6} + \frac{x^3}{27} - \frac{x^2}{6} - \frac{x}{2} + 1 \tag{2}$$

$$y = \frac{i(x-3)\,x\sqrt{3}}{6} + \frac{x^3}{27} - \frac{x^2}{6} - \frac{x}{2} + 1 \tag{3}$$

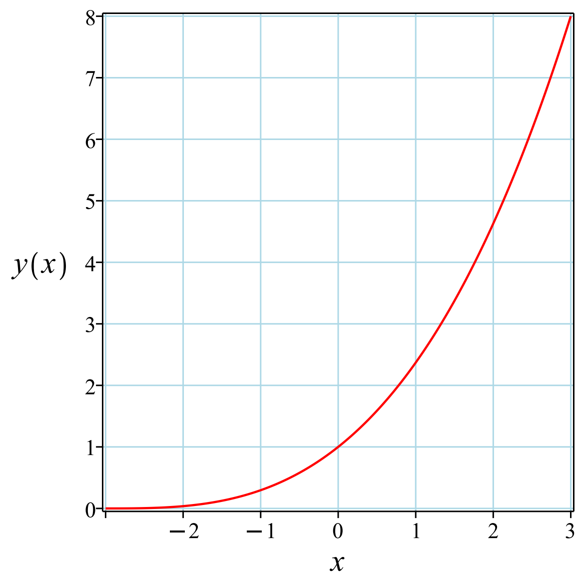

Figure 468: Solution plot

Verification of solutions

$$y = \frac{(x+3)^3}{27}$$

Verified OK.

$$y = -\frac{i(x-3)\,x\sqrt{3}}{6} + \frac{x^3}{27} - \frac{x^2}{6} - \frac{x}{2} + 1$$

Warning, solution could not be verified

$$y = \frac{i(x-3)\,x\sqrt{3}}{6} + \frac{x^3}{27} - \frac{x^2}{6} - \frac{x}{2} + 1$$

Warning, solution could not be verified

Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 354.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{2y'' - 3y^2 = 0}$$

With initial conditions

$$[y(-2) = 1, y'(-2) = -1]$$

14.28.1 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$2y'y'' - 3y'y^2 = 0$$

Integrating the above w.r.t x gives

$$\int (2y'y'' - 3y'y^2)\, dx = 0$$
$$y'^2 - y^3 = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^3 + c_1} \tag{1}$$

$$y' = -\sqrt{y^3 + c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{y^3 + c_1}} dy = \int dx$$
$$\int^y \frac{1}{\sqrt{\_a^3 + c_1}} d\_a = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{y^3 + c_1}} dy = \int dx$$
$$\int^y -\frac{1}{\sqrt{\_a^3 + c_1}} d\_a = c_3 + x$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\int^y \frac{1}{\sqrt{\_a^3 + c_1}} d\_a = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = -2$ in the above gives

$$\int^1 \frac{1}{\sqrt{\_a^3 + c_1}} d\_a = -2 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \sqrt{\operatorname{RootOf}\left(-\left(\int^{\_Z} \frac{1}{\sqrt{\_a^3 + c_1}} d\_a\right) + x + c_2\right)^3 + c_1}$$

substituting $y' = -1$ and $x = -2$ in the above gives

$$-1 = \sqrt{\operatorname{RootOf}\left(-\left(\int^{\_Z} \frac{1}{\sqrt{\_a^3 + c_1}} d\_a\right) - 2 + c_2\right)^3 + c_1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Looking at the Second solution

$$\int^{y} -\frac{1}{\sqrt{\_a^3 + c_1}} d\_a = c_3 + x \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = -2$ in the above gives

$$-\left(\int^{1} \frac{1}{\sqrt{\_a^3 + c_1}} d\_a\right) = c_3 - 2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\sqrt{\operatorname{RootOf}\left(-\left(\int^{\_Z} -\frac{1}{\sqrt{\_a^3 + c_1}} d\_a\right) + c_3 + x\right)^3 + c_1}$$

substituting $y' = -1$ and $x = -2$ in the above gives

$$-1 = -\sqrt{\operatorname{RootOf}\left(\int^{\_Z} \frac{1}{\sqrt{\_a^3 + c_1}} d\_a + c_3 - 2\right)^3 + c_1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

14.28.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
2p(y)\left(\frac{d}{dy}p(y)\right) - 3y^2 = 0
$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(y, p) \\
&= f(y)g(p) \\
&= \frac{3y^2}{2p}
\end{aligned}
$$

Where $f(y) = \frac{3y^2}{2}$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{1}{p}}\,dp &= \frac{3y^2}{2}\,dy \\
\int \frac{1}{\frac{1}{p}}\,dp &= \int \frac{3y^2}{2}\,dy \\
\frac{p^2}{2} &= \frac{y^3}{2} + c_1
\end{aligned}
$$

The solution is

$$
\frac{p(y)^2}{2} - \frac{y^3}{2} - c_1 = 0
$$

Initial conditions are used to solve for c_1. Substituting $y = 1$ and $p = -1$ in the above solution gives an equation to solve for the constant of integration.

$$
-c_1 = 0
$$

$$
c_1 = 0
$$

Substituting c_1 found above in the general solution gives

$$\frac{p^2}{2} - \frac{y^3}{2} = 0$$

Solving for $p(y)$ from the above gives

$$p(y) = -y^{\frac{3}{2}}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = -y^{\frac{3}{2}}$$

Integrating both sides gives

$$\int -\frac{1}{y^{\frac{3}{2}}} dy = \int dx$$

$$\frac{2}{\sqrt{y}} = x + c_2$$

Initial conditions are used to solve for c_2. Substituting $x = -2$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$2 = -2 + c_2$$

$$c_2 = 4$$

Substituting c_2 found above in the general solution gives

$$\frac{2}{\sqrt{y}} = x + 4$$

The above simplifies to

$$-x\sqrt{y} - 4\sqrt{y} + 2 = 0$$

Solving for y from the above gives

$$y = \frac{4}{(x + 4)^2}$$

Initial conditions are used to solve for the constants of integration.

Summary
The solution(s) found are the following

$$y = \frac{4}{(x+4)^2} \tag{1}$$

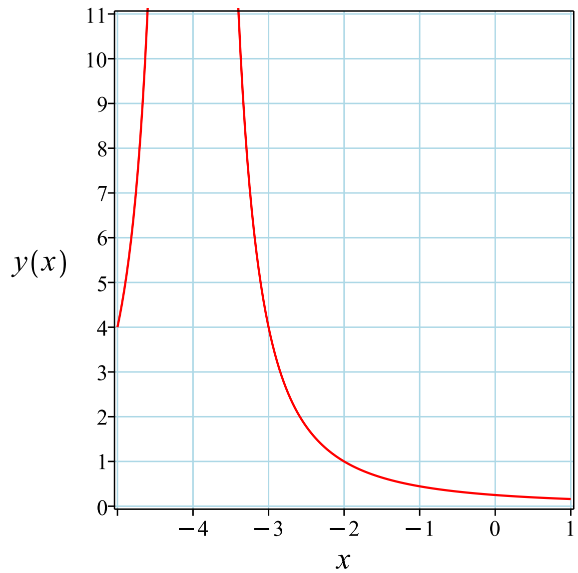

Figure 469: Solution plot

Verification of solutions

$$y = \frac{4}{(x+4)^2}$$

Verified OK.

14.28.3 Maple step by step solution

Let's solve

$$\left[2y'' - 3y^2 = 0, y(-2) = 1, y'\Big|_{\{x=-2\}} = -1\right]$$

- Highest derivative means the order of the ODE is 2

  y''
- Define new dependent variable u

  $u(x) = y'$
- Compute y''

$$u'(x) = y''$$

- Use chain rule on the lhs

$$y'\left(\frac{d}{dy}u(y)\right) = y''$$

- Substitute in the definition of u

$$u(y)\left(\frac{d}{dy}u(y)\right) = y''$$

- Make substitutions $y' = u(y), y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$$2u(y)\left(\frac{d}{dy}u(y)\right) - 3y^2 = 0$$

- Integrate both sides with respect to y

$$\int \left(2u(y)\left(\frac{d}{dy}u(y)\right) - 3y^2\right) dy = \int 0dy + c_1$$

- Evaluate integral

$$-y^3 + u(y)^2 = c_1$$

- Solve for $u(y)$

$$\left\{u(y) = \sqrt{y^3 + c_1}, u(y) = -\sqrt{y^3 + c_1}\right\}$$

- Solve 1st ODE for $u(y)$

$$u(y) = \sqrt{y^3 + c_1}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \sqrt{y^3 + c_1}$$

- Separate variables

$$\frac{y'}{\sqrt{y^3+c_1}} = 1$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{y^3+c_1}}dx = \int 1dx + c_2$$

- Evaluate integral

$$\frac{-\frac{2\mathrm{I}}{3}\sqrt{3}\,(-c_1)^{\frac{1}{3}}\sqrt{\frac{\mathrm{I}\left(y+\frac{(-c_1)^{\frac{1}{3}}}{2}-\frac{\mathrm{I}\sqrt{3}\,(-c_1)^{\frac{1}{3}}}{2}\right)\sqrt{3}}{(-c_1)^{\frac{1}{3}}}}\sqrt{\frac{y-(-c_1)^{\frac{1}{3}}}{-\frac{3(-c_1)^{\frac{1}{3}}}{2}+\frac{\mathrm{I}\sqrt{3}\,(-c_1)^{\frac{1}{3}}}{2}}}\sqrt{\frac{-\mathrm{I}\left(y+\frac{(-c_1)^{\frac{1}{3}}}{2}+\frac{\mathrm{I}\sqrt{3}\,(-c_1)^{\frac{1}{3}}}{2}\right)\sqrt{3}}{(-c_1)^{\frac{1}{3}}}}\,\mathit{EllipticF}\left(\frac{\sqrt{3}\sqrt{\frac{\mathrm{I}\left(y-\right.}{}}}{}\right.}{\sqrt{y^3+c_1}}$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 355.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_integrable_as_is", "second_order_ode_missing_x", "exact nonlinear second order ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _exact, _nonlinear],
   _Liouville, [_2nd_order, _reducible, _mu_x_y1], [_2nd_order,
   _reducible, _mu_xy]]
```

$$\boxed{yy'' + {y'}^2 = 0}$$

14.29.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(yy'' + {y'}^2\right) dx = 0$$
$$yy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{y}{c_1} dy = x + c_2$$
$$\frac{y^2}{2c_1} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \sqrt{2c_1c_2 + 2c_1x}$$
$$y_2 = -\sqrt{2c_1c_2 + 2c_1x}$$

Summary
The solution(s) found are the following

$$y = \sqrt{2c_1c_2 + 2c_1x} \tag{1}$$
$$y = -\sqrt{2c_1c_2 + 2c_1x} \tag{2}$$

Verification of solutions

$$y = \sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

$$y = -\sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

14.29.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$y'' = \frac{dp}{dx}$$
$$= \frac{dy}{dx}\frac{dp}{dy}$$
$$= p\frac{dp}{dy}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right) + p(y)^2 = 0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}
p' &= F(y,p) \\
&= f(y)g(p) \\
&= -\frac{p}{y}
\end{aligned}$$

Where $f(y) = -\frac{1}{y}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\,dp &= -\frac{1}{y}\,dy \\
\int \frac{1}{p}\,dp &= \int -\frac{1}{y}\,dy \\
\ln(p) &= -\ln(y) + c_1 \\
p &= e^{-\ln(y)+c_1} \\
&= \frac{c_1}{y}
\end{aligned}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{c_1}{y}$$

Integrating both sides gives

$$\begin{aligned}
\int \frac{y}{c_1} dy &= x + c_2 \\
\frac{y^2}{2c_1} &= x + c_2
\end{aligned}$$

Solving for y gives these solutions

$$\begin{aligned}
y_1 &= \sqrt{2c_1c_2 + 2c_1x} \\
y_2 &= -\sqrt{2c_1c_2 + 2c_1x}
\end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \sqrt{2c_1c_2 + 2c_1x} \tag{1}$$
$$y = -\sqrt{2c_1c_2 + 2c_1x} \tag{2}$$

Verification of solutions

$$y = \sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

$$y = -\sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

14.29.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$yy'' + y'^2 = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(yy'' + y'^2\right) dx = 0$$
$$yy' = c_1$$

Which is now solved for y. Integrating both sides gives

$$\int \frac{y}{c_1} dy = x + c_2$$
$$\frac{y^2}{2c_1} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \sqrt{2c_1c_2 + 2c_1x}$$
$$y_2 = -\sqrt{2c_1c_2 + 2c_1x}$$

Summary

The solution(s) found are the following

$$y = \sqrt{2c_1c_2 + 2c_1x} \tag{1}$$
$$y = -\sqrt{2c_1c_2 + 2c_1x} \tag{2}$$

Verification of solutions

$$y = \sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

$$y = -\sqrt{2c_1c_2 + 2c_1x}$$

Verified OK.

14.29.4 Solving as exact nonlinear second order ode ode

An exact non-linear second order ode has the form

$$a_2(x, y, y')\, y'' + a_1(x, y, y')\, y' + a_0(x, y, y') = 0$$

Where the following conditions are satisfied

$$\begin{aligned}
\frac{\partial a_2}{\partial y} &= \frac{\partial a_1}{\partial y'} \\
\frac{\partial a_2}{\partial x} &= \frac{\partial a_0}{\partial y'} \\
\frac{\partial a_1}{\partial x} &= \frac{\partial a_0}{\partial y}
\end{aligned}$$

Looking at the the ode given we see that

$$\begin{aligned}
a_2 &= y \\
a_1 &= y' \\
a_0 &= 0
\end{aligned}$$

Applying the conditions to the above shows this is a nonlinear exact second order ode. Therefore it can be reduced to first order ode given by

$$\begin{aligned}
\int a_2\, dy' + \int a_1\, dy + \int a_0\, dx &= c_1 \\
\int y\, dy' + \int y'\, dy + \int 0\, dx &= c_1
\end{aligned}$$

Which results in

$$2yy' = c_1$$

Which is now solved Integrating both sides gives

$$\begin{aligned}
\int \frac{2y}{c_1} dy &= x + c_2 \\
\frac{y^2}{c_1} &= x + c_2
\end{aligned}$$

Solving for y gives these solutions

$$\begin{aligned}
y_1 &= \sqrt{c_1 c_2 + c_1 x} \\
y_2 &= -\sqrt{c_1 c_2 + c_1 x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{c_1 c_2 + c_1 x} \tag{1}$$
$$y = -\sqrt{c_1 c_2 + c_1 x} \tag{2}$$

Verification of solutions

$$y = \sqrt{c_1 c_2 + c_1 x}$$

Verified OK.

$$y = -\sqrt{c_1 c_2 + c_1 x}$$

Verified OK.

14.29.5 Maple step by step solution

Let's solve

$y y'' + y'^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y' \left(\frac{d}{dy} u(y)\right) = y''$

- Substitute in the definition of u

  $u(y) \left(\frac{d}{dy} u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y) \left(\frac{d}{dy} u(y)\right)$ to reduce order of ODE

  $y u(y) \left(\frac{d}{dy} u(y)\right) + u(y)^2 = 0$

- Separate variables

  $\frac{\frac{d}{dy} u(y)}{u(y)} = -\frac{1}{y}$

- Integrate both sides with respect to y

$\int \frac{\frac{d}{dy}u(y)}{u(y)}dy = \int -\frac{1}{y}dy + c_1$

- Evaluate integral

  $\ln(u(y)) = -\ln(y) + c_1$

- Solve for $u(y)$

  $u(y) = \frac{e^{c_1}}{y}$

- Solve 1st ODE for $u(y)$

  $u(y) = \frac{e^{c_1}}{y}$

- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = \frac{e^{c_1}}{y}$

- Separate variables

  $yy' = e^{c_1}$

- Integrate both sides with respect to x

  $\int yy'dx = \int e^{c_1}dx + c_2$

- Evaluate integral

  $\frac{y^2}{2} = e^{c_1}x + c_2$

- Solve for y

  $\{y = \sqrt{2\,e^{c_1}x + 2c_2}, y = -\sqrt{2\,e^{c_1}x + 2c_2}\}$

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1],
   [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{yy'' - y' - {y'}^2 = 0}$$

14.30.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right)+(-p(y)-1)\,p(y)=0$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}p' &= F(y,p)\\ &= f(y)g(p)\\ &= \frac{p+1}{y}\end{aligned}$$

Where $f(y)=\frac{1}{y}$ and $g(p)=p+1$. Integrating both sides gives

$$\begin{aligned}\frac{1}{p+1}\,dp &= \frac{1}{y}\,dy\\ \int\frac{1}{p+1}\,dp &= \int\frac{1}{y}\,dy\\ \ln(p+1) &= \ln(y)+c_1\end{aligned}$$

Raising both side to exponential gives

$$p+1=\mathrm{e}^{\ln(y)+c_1}$$

Which simplifies to

$$p+1=c_2y$$

Which simplifies to

$$p(y)=c_2y\,\mathrm{e}^{c_1}-1$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$y'=c_2y\,\mathrm{e}^{c_1}-1$$

Integrating both sides gives

$$\begin{aligned}\int\frac{1}{c_2y\,\mathrm{e}^{c_1}-1}dy &= \int dx\\ \frac{\ln(c_2y\,\mathrm{e}^{c_1}-1)\,\mathrm{e}^{-c_1}}{c_2} &= c_3+x\end{aligned}$$

Raising both side to exponential gives

$$e^{\frac{\ln(c_2 y\,e^{c_1}-1)e^{-c_1}}{c_2}} = e^{c_3+x}$$

Which simplifies to

$$(c_2 y\,e^{c_1}-1)^{\frac{e^{-c_1}}{c_2}} = c_4 e^{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\left((c_4 e^{x})^{c_2 e^{c_1}}+1\right)e^{-c_1}}{c_2} \tag{1}$$

Verification of solutions

$$y = \frac{\left((c_4 e^{x})^{c_2 e^{c_1}}+1\right)e^{-c_1}}{c_2}$$

Verified OK.

14.30.2 Maple step by step solution

Let's solve

$yy''+(-y'-1)\,y'=0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x)=y'$

- Compute y''

  $u'(x)=y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right)=y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right)=y''$

- Make substitutions $y'=u(y)\,,y''=u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$$yu(y)\left(\frac{d}{dy}u(y)\right)+(-u(y)-1)\,u(y)=0$$

- Separate variables

$$\frac{\frac{d}{dy}u(y)}{-u(y)-1}=-\frac{1}{y}$$

- Integrate both sides with respect to y

$$\int\frac{\frac{d}{dy}u(y)}{-u(y)-1}dy=\int-\frac{1}{y}dy+c_1$$

- Evaluate integral

$$-\ln\left(-u(y)-1\right)=-\ln\left(y\right)+c_1$$

- Solve for $u(y)$

$$u(y)=-\frac{\mathrm{e}^{c_1}+y}{\mathrm{e}^{c_1}}$$

Problem number: 357.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{yy'' - y'^2 = 1}$$

14.31.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$yp(y)\left(\frac{d}{dy}p(y)\right) - p(y)^2 = 1$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}p' &= F(y,p)\\ &= f(y)g(p)\\ &= \frac{p^2+1}{yp}\end{aligned}$$

Where $f(y)=\frac{1}{y}$ and $g(p)=\frac{p^2+1}{p}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{p^2+1}{p}}\,dp &= \frac{1}{y}\,dy\\ \int \frac{1}{\frac{p^2+1}{p}}\,dp &= \int \frac{1}{y}\,dy\\ \frac{\ln(p^2+1)}{2} &= \ln(y)+c_1\end{aligned}$$

Raising both side to exponential gives

$$\sqrt{p^2+1} = \mathrm{e}^{\ln(y)+c_1}$$

Which simplifies to

$$\sqrt{p^2+1} = c_2 y$$

Which simplifies to

$$\sqrt{p(y)^2+1} = c_2 y\,\mathrm{e}^{c_1}$$

The solution is

$$\sqrt{p(y)^2+1} = c_2 y\,\mathrm{e}^{c_1}$$

For solution (1) found earlier, since $p=y'$ then we now have a new first order ode to solve which is

$$\sqrt{1+y'^2} = c_2 y\,\mathrm{e}^{c_1}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-1+c_2^2y^2\mathrm{e}^{2c_1}} \tag{1}$$

$$y' = -\sqrt{-1+c_2^2y^2\mathrm{e}^{2c_1}} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}} dy = \int dx$$

$$\frac{\ln\left(\frac{c_2^2 \mathrm{e}^{2c_1} y}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + \sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}\right)}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} = c_3 + x$$

Raising both side to exponential gives

$$\mathrm{e}^{\frac{\ln\left(\frac{c_2^2 \mathrm{e}^{2c_1} y}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + \sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}\right)}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}}} = \mathrm{e}^{c_3 + x}$$

Which simplifies to

$$\left(\frac{c_2^2 \mathrm{e}^{2c_1} y + \sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}\, \sqrt{c_2^2 \mathrm{e}^{2c_1}}}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}}\right)^{\frac{1}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}}} = c_4 \mathrm{e}^{x}$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}} dy = \int dx$$

$$-\frac{\ln\left(\frac{c_2^2 \mathrm{e}^{2c_1} y}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + \sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}\right)}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} = x + c_5$$

Raising both side to exponential gives

$$\mathrm{e}^{-\frac{\ln\left(\frac{c_2^2 \mathrm{e}^{2c_1} y}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + \sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}\right)}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}}} = \mathrm{e}^{x + c_5}$$

Which simplifies to

$$\left(\frac{c_2^2 \mathrm{e}^{2c_1} y + \sqrt{-1+c_2^2 y^2 \mathrm{e}^{2c_1}}\, \sqrt{c_2^2 \mathrm{e}^{2c_1}}}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}}\right)^{-\frac{1}{\sqrt{c_2^2 \mathrm{e}^{2c_1}}}} = c_6 \mathrm{e}^{x}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{c_2^2 \mathrm{e}^{2c_1}}\, \mathrm{e}^{-2c_1} \left((c_4 \mathrm{e}^x)^{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + (c_4 \mathrm{e}^x)^{-\sqrt{c_2^2 \mathrm{e}^{2c_1}}} \right)}{2c_2^2} \tag{1}$$

$$y = \frac{\sqrt{c_2^2 \mathrm{e}^{2c_1}}\, \mathrm{e}^{-2c_1} \left((c_6 \mathrm{e}^x)^{-\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + (c_6 \mathrm{e}^x)^{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} \right)}{2c_2^2} \tag{2}$$

Verification of solutions

$$y = \frac{\sqrt{c_2^2 \mathrm{e}^{2c_1}}\, \mathrm{e}^{-2c_1} \left((c_4 \mathrm{e}^x)^{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + (c_4 \mathrm{e}^x)^{-\sqrt{c_2^2 \mathrm{e}^{2c_1}}} \right)}{2c_2^2}$$

Verified OK.

$$y = \frac{\sqrt{c_2^2 \mathrm{e}^{2c_1}}\, \mathrm{e}^{-2c_1} \left((c_6 \mathrm{e}^x)^{-\sqrt{c_2^2 \mathrm{e}^{2c_1}}} + (c_6 \mathrm{e}^x)^{\sqrt{c_2^2 \mathrm{e}^{2c_1}}} \right)}{2c_2^2}$$

Verified OK.

14.31.2 Maple step by step solution

Let's solve

$yy'' - y'^2 = 1$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y' \left(\frac{d}{dy} u(y) \right) = y''$

- Substitute in the definition of u

  $u(y) \left(\frac{d}{dy} u(y) \right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y) \left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$$y u(y) \left(\frac{d}{dy}u(y)\right) - u(y)^2 = 1$$

- Separate variables

$$\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{u(y)^2+1} = \frac{1}{y}$$

- Integrate both sides with respect to y

$$\int \frac{\left(\frac{d}{dy}u(y)\right)u(y)}{u(y)^2+1}dy = \int \frac{1}{y}dy + c_1$$

- Evaluate integral

$$\frac{\ln\left(u(y)^2+1\right)}{2} = \ln(y) + c_1$$

- Solve for $u(y)$

$$\left\{u(y) = \sqrt{\left(e^{c_1}\right)^2 y^2 - 1}, u(y) = -\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}\right\}$$

- Solve 1st ODE for $u(y)$

$$u(y) = \sqrt{\left(e^{c_1}\right)^2 y^2 - 1}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \sqrt{\left(e^{c_1}\right)^2 y^2 - 1}$$

- Separate variables

$$\frac{y'}{\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}} = 1$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}}dx = \int 1dx + c_2$$

- Evaluate integral

$$\frac{\ln\left(\frac{\left(e^{c_1}\right)^2 y}{\sqrt{\left(e^{c_1}\right)^2}} + \sqrt{\left(e^{c_1}\right)^2 y^2 - 1}\right)}{\sqrt{\left(e^{c_1}\right)^2}} = x + c_2$$

- Solve for y

$$y = \frac{\sqrt{\left(e^{c_1}\right)^2}\left(\left(e^{c_2\sqrt{\left(e^{c_1}\right)^2}+x\sqrt{\left(e^{c_1}\right)^2}}\right)^2 + 1\right)}{2\,e^{c_2\sqrt{\left(e^{c_1}\right)^2}+x\sqrt{\left(e^{c_1}\right)^2}}\left(e^{c_1}\right)^2}$$

- Solve 2nd ODE for $u(y)$

$$u(y) = -\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = -\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}$$

- Separate variables

$$\frac{y'}{\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}} = -1$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{\left(e^{c_1}\right)^2 y^2 - 1}} dx = \int (-1)\, dx + c_2$$

- Evaluate integral

$$\frac{\ln\left(\frac{\left(e^{c_1}\right)^2 y}{\sqrt{\left(e^{c_1}\right)^2}} + \sqrt{\left(e^{c_1}\right)^2 y^2 - 1}\right)}{\sqrt{\left(e^{c_1}\right)^2}} = -x + c_2$$

- Solve for y

$$y = \frac{\sqrt{\left(e^{c_1}\right)^2}\left(\left(e^{c_2 \sqrt{\left(e^{c_1}\right)^2} - x\sqrt{\left(e^{c_1}\right)^2}}\right)^2 + 1\right)}{2\, e^{c_2 \sqrt{\left(e^{c_1}\right)^2} - x\sqrt{\left(e^{c_1}\right)^2}} \left(e^{c_1}\right)^2}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{2yy'' - {y'}^2 = 1}$$

14.32.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$2yp(y)\left(\frac{d}{dy}p(y)\right) - p(y)^2 = 1$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned}
p' &= F(y,p) \\
&= f(y)g(p) \\
&= \frac{p^2+1}{2yp}
\end{aligned}$$

Where $f(y) = \frac{1}{2y}$ and $g(p) = \frac{p^2+1}{p}$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{\frac{p^2+1}{p}}\, dp &= \frac{1}{2y}\, dy \\
\int \frac{1}{\frac{p^2+1}{p}}\, dp &= \int \frac{1}{2y}\, dy \\
\frac{\ln(p^2+1)}{2} &= \frac{\ln(y)}{2} + c_1
\end{aligned}$$

Raising both side to exponential gives

$$\sqrt{p^2+1} = e^{\frac{\ln(y)}{2}+c_1}$$

Which simplifies to

$$\sqrt{p^2+1} = c_2\sqrt{y}$$

Which simplifies to

$$\sqrt{p(y)^2+1} = c_2\sqrt{y}\, e^{c_1}$$

The solution is

$$\sqrt{p(y)^2+1} = c_2\sqrt{y}\, e^{c_1}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\sqrt{1+y'^2} = c_2\sqrt{y}\, e^{c_1}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-1 + c_2^2 e^{2c_1} y} \tag{1}$$

$$y' = -\sqrt{-1 + c_2^2 e^{2c_1} y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-1+c_2^2 \mathrm{e}^{2c_1} y}} dy = \int dx$$

$$\frac{2\sqrt{-1+c_2^2 \mathrm{e}^{2c_1} y}\, \mathrm{e}^{-2c_1}}{c_2^2} = c_3 + x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-1+c_2^2 \mathrm{e}^{2c_1} y}} dy = \int dx$$

$$-\frac{2\sqrt{-1+c_2^2 \mathrm{e}^{2c_1} y}\, \mathrm{e}^{-2c_1}}{c_2^2} = x + c_4$$

Summary

The solution(s) found are the following

$$y = \frac{(c_3^2 \mathrm{e}^{4c_1} c_2^4 + 2c_3 \mathrm{e}^{4c_1} c_2^4 x + x^2 \mathrm{e}^{4c_1} c_2^4 + 4)\, \mathrm{e}^{-2c_1}}{4c_2^2} \tag{1}$$

$$y = \frac{(c_4^2 \mathrm{e}^{4c_1} c_2^4 + 2c_4 \mathrm{e}^{4c_1} c_2^4 x + x^2 \mathrm{e}^{4c_1} c_2^4 + 4)\, \mathrm{e}^{-2c_1}}{4c_2^2} \tag{2}$$

Verification of solutions

$$y = \frac{(c_3^2 \mathrm{e}^{4c_1} c_2^4 + 2c_3 \mathrm{e}^{4c_1} c_2^4 x + x^2 \mathrm{e}^{4c_1} c_2^4 + 4)\, \mathrm{e}^{-2c_1}}{4c_2^2}$$

Verified OK.

$$y = \frac{(c_4^2 \mathrm{e}^{4c_1} c_2^4 + 2c_4 \mathrm{e}^{4c_1} c_2^4 x + x^2 \mathrm{e}^{4c_1} c_2^4 + 4)\, \mathrm{e}^{-2c_1}}{4c_2^2}$$

Verified OK.

14.32.2 Maple step by step solution

Let's solve

$2yy'' - y'^2 = 1$

- Highest derivative means the order of the ODE is 2

  y''
- Define new dependent variable u

  $u(x) = y'$
- Compute y''

  $u'(x) = y''$
- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$
- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$
- Make substitutions $y' = u(y), y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $2yu(y)\left(\frac{d}{dy}u(y)\right) - u(y)^2 = 1$
- Separate variables

  $\frac{\left(\frac{d}{dy}u(y)\right)u(y)}{u(y)^2+1} = \frac{1}{2y}$
- Integrate both sides with respect to y

  $\int \frac{\left(\frac{d}{dy}u(y)\right)u(y)}{u(y)^2+1}dy = \int \frac{1}{2y}dy + c_1$
- Evaluate integral

  $\frac{\ln\left(u(y)^2+1\right)}{2} = \frac{\ln(y)}{2} + c_1$
- Solve for $u(y)$

  $\left\{u(y) = \frac{\sqrt{-e^{-2c_1}\left(e^{-2c_1}-y\right)}}{e^{-2c_1}}, u(y) = -\frac{\sqrt{-e^{-2c_1}\left(e^{-2c_1}-y\right)}}{e^{-2c_1}}\right\}$
- Solve 1st ODE for $u(y)$

  $u(y) = \frac{\sqrt{-e^{-2c_1}\left(e^{-2c_1}-y\right)}}{e^{-2c_1}}$
- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}}{\mathrm{e}^{-2c_1}}$$

- Separate variables

$$\frac{y'}{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}} = \frac{1}{\mathrm{e}^{-2c_1}}$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}}dx = \int \frac{1}{\mathrm{e}^{-2c_1}}dx + c_2$$

- Evaluate integral

$$\frac{2\sqrt{\mathrm{e}^{-2c_1}y-\left(\mathrm{e}^{-2c_1}\right)^2}}{\mathrm{e}^{-2c_1}} = \frac{x}{\mathrm{e}^{-2c_1}} + c_2$$

- Solve for y

$$y = \frac{c_2^2\left(\mathrm{e}^{-2c_1}\right)^2+2c_2\mathrm{e}^{-2c_1}x+4\left(\mathrm{e}^{-2c_1}\right)^2+x^2}{4\,\mathrm{e}^{-2c_1}}$$

- Solve 2nd ODE for $u(y)$

$$u(y) = -\frac{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}}{\mathrm{e}^{-2c_1}}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = -\frac{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}}{\mathrm{e}^{-2c_1}}$$

- Separate variables

$$\frac{y'}{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}} = -\frac{1}{\mathrm{e}^{-2c_1}}$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{-\mathrm{e}^{-2c_1}\left(\mathrm{e}^{-2c_1}-y\right)}}dx = \int -\frac{1}{\mathrm{e}^{-2c_1}}dx + c_2$$

- Evaluate integral

$$\frac{2\sqrt{\mathrm{e}^{-2c_1}y-\left(\mathrm{e}^{-2c_1}\right)^2}}{\mathrm{e}^{-2c_1}} = -\frac{x}{\mathrm{e}^{-2c_1}} + c_2$$

- Solve for y

$$y = \frac{c_2^2\left(\mathrm{e}^{-2c_1}\right)^2-2c_2\mathrm{e}^{-2c_1}x+4\left(\mathrm{e}^{-2c_1}\right)^2+x^2}{4\,\mathrm{e}^{-2c_1}}$$

Problem number: 359.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{y^3 y'' = -1}$$

With initial conditions

$$[y(1) = 1, y'(1) = 0]$$

14.33.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$y^3 p(y) \left(\frac{d}{dy} p(y)\right) = -1$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(y, p) \\ &= f(y) g(p) \\ &= -\frac{1}{y^3 p} \end{aligned}$$

Where $f(y) = -\frac{1}{y^3}$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$\frac{1}{\frac{1}{p}}\, dp = -\frac{1}{y^3}\, dy$$

$$\int \frac{1}{\frac{1}{p}}\, dp = \int -\frac{1}{y^3}\, dy$$

$$\frac{p^2}{2} = \frac{1}{2y^2} + c_1$$

The solution is

$$\frac{p(y)^2}{2} - \frac{1}{2y^2} - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $y = 1$ and $p = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-c_1 - \frac{1}{2} = 0$$

$$c_1 = -\frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{p^2 y^2 + y^2 - 1}{2y^2} = 0$$

The above simplifies to

$$p^2 y^2 + y^2 - 1 = 0$$

Solving for $p(y)$ from the above gives

$$p(y) = \frac{\sqrt{-y^2+1}}{y}$$
$$p(y) = -\frac{\sqrt{-y^2+1}}{y}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = \frac{\sqrt{-y^2+1}}{y}$$

Integrating both sides gives

$$\int \frac{y}{\sqrt{-y^2+1}} dy = \int dx$$
$$\frac{(y-1)(y+1)}{\sqrt{-y^2+1}} = x + c_2$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 1 + c_2$$

$$c_2 = -1$$

Substituting c_2 found above in the general solution gives

$$\frac{(y-1)(y+1)}{\sqrt{-y^2+1}} = x - 1$$

The above simplifies to

$$-x\sqrt{-y^2+1} + y^2 + \sqrt{-y^2+1} - 1 = 0$$

For solution (2) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = -\frac{\sqrt{-y^2+1}}{y}$$

Integrating both sides gives

$$\int -\frac{y}{\sqrt{-y^2+1}}dy = \int dx$$
$$-\frac{(y-1)(y+1)}{\sqrt{-y^2+1}} = c_3 + x$$

Initial conditions are used to solve for c_3. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_3 + 1$$

$$c_3 = -1$$

Substituting c_3 found above in the general solution gives

$$-\frac{(y-1)(y+1)}{\sqrt{-y^2+1}} = x - 1$$

The above simplifies to

$$-x\sqrt{-y^2+1} - y^2 + \sqrt{-y^2+1} + 1 = 0$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$-x\sqrt{-y^2+1} + y^2 + \sqrt{-y^2+1} - 1 = 0 \tag{1}$$
$$-x\sqrt{-y^2+1} - y^2 + \sqrt{-y^2+1} + 1 = 0 \tag{2}$$

Verification of solutions

$$-x\sqrt{-y^2+1} + y^2 + \sqrt{-y^2+1} - 1 = 0$$

Verified OK.

$$-x\sqrt{-y^2+1} - y^2 + \sqrt{-y^2+1} + 1 = 0$$

Verified OK.

14.33.2 Maple step by step solution

Let's solve

$$\left[y^3 y'' = -1, y(1) = 1, y'\Big|_{\{x=1\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

$$y''$$

- Define new dependent variable u

$$u(x) = y'$$

- Compute y''

$$u'(x) = y''$$

- Use chain rule on the lhs

$$y'\left(\frac{d}{dy}u(y)\right) = y''$$

- Substitute in the definition of u

$$u(y)\left(\frac{d}{dy}u(y)\right) = y''$$

- Make substitutions $y' = u(y), y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$$y^3 u(y)\left(\frac{d}{dy}u(y)\right) = -1$$

- Separate variables

$$u(y)\left(\frac{d}{dy}u(y)\right) = -\frac{1}{y^3}$$

- Integrate both sides with respect to y

$$\int u(y)\left(\frac{d}{dy}u(y)\right)dy = \int -\frac{1}{y^3}dy + c_1$$

- Evaluate integral

$$\frac{u(y)^2}{2} = \frac{1}{2y^2} + c_1$$

- Solve for $u(y)$

$$\left\{u(y) = \frac{\sqrt{2c_1 y^2+1}}{y}, u(y) = -\frac{\sqrt{2c_1 y^2+1}}{y}\right\}$$

- Solve 1st ODE for $u(y)$

$$u(y) = \frac{\sqrt{2c_1 y^2+1}}{y}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = \frac{\sqrt{2y^2c_1+1}}{y}$$

- Separate variables

$$\frac{y'y}{\sqrt{2y^2c_1+1}} = 1$$

- Integrate both sides with respect to x

$$\int \frac{y'y}{\sqrt{2y^2c_1+1}}dx = \int 1dx + c_2$$

- Evaluate integral

$$\frac{\sqrt{2y^2c_1+1}}{2c_1} = x + c_2$$

- Solve for y

$$\left\{y = -\frac{\sqrt{2}\,\sqrt{c_1\left(4c_1^2c_2^2+8c_1^2c_2x+4c_1^2x^2-1\right)}}{2c_1}, y = \frac{\sqrt{2}\,\sqrt{c_1\left(4c_1^2c_2^2+8c_1^2c_2x+4c_1^2x^2-1\right)}}{2c_1}\right\}$$

- Solve 2nd ODE for $u(y)$

$$u(y) = -\frac{\sqrt{2c_1y^2+1}}{y}$$

- Revert to original variables with substitution $u(y) = y', y = y$

$$y' = -\frac{\sqrt{2y^2c_1+1}}{y}$$

- Separate variables

$$\frac{y'y}{\sqrt{2y^2c_1+1}} = -1$$

- Integrate both sides with respect to x

$$\int \frac{y'y}{\sqrt{2y^2c_1+1}}dx = \int (-1)\,dx + c_2$$

- Evaluate integral

$$\frac{\sqrt{2y^2c_1+1}}{2c_1} = -x + c_2$$

- Solve for y

$$\left\{y = -\frac{\sqrt{2}\,\sqrt{c_1\left(4c_1^2c_2^2-8c_1^2c_2x+4c_1^2x^2-1\right)}}{2c_1}, y = \frac{\sqrt{2}\,\sqrt{c_1\left(4c_1^2c_2^2-8c_1^2c_2x+4c_1^2x^2-1\right)}}{2c_1}\right\}$$

□ Check validity of solution $y = -\frac{\sqrt{2}\,\sqrt{c_1\left(4c_1^2c_2^2-8c_1^2c_2x+4c_1^2x^2-1\right)}}{2c_1}$

  - Use initial condition $y(1) = 1$

$$1 = -\frac{\sqrt{2}\,\sqrt{c_1\left(4c_1^2c_2^2-8c_1^2c_2+4c_1^2-1\right)}}{2c_1}$$

  - Compute derivative of the solution

$$y' = -\frac{\sqrt{2}\,(-8c_1^2c_2+8c_1^2x)}{4\sqrt{c_1\,(4c_1^2c_2^2-8c_1^2c_2x+4c_1^2x^2-1)}}$$

- Use the initial condition $y'\Big|_{\{x=1\}} = 0$

$$0 = -\frac{\sqrt{2}\,(-8c_1^2c_2+8c_1^2)}{4\sqrt{c_1\,(4c_1^2c_2^2-8c_1^2c_2+4c_1^2-1)}}$$

- Solve for c_1 and c_2

$$\left\{c_1 = -\frac{1}{2}, c_2 = 1\right\}$$

- Substitute constant values into general solution and simplify

$$y = \sqrt{-x\,(x-2)}$$

☐ Check validity of solution $y = \frac{\sqrt{2}\,\sqrt{c_1\,(4c_1^2c_2^2-8c_1^2c_2x+4c_1^2x^2-1)}}{2c_1}$

- Use initial condition $y(1) = 1$

$$1 = \frac{\sqrt{2}\,\sqrt{c_1\,(4c_1^2c_2^2-8c_1^2c_2+4c_1^2-1)}}{2c_1}$$

- Compute derivative of the solution

$$y' = \frac{\sqrt{2}\,(-8c_1^2c_2+8c_1^2x)}{4\sqrt{c_1\,(4c_1^2c_2^2-8c_1^2c_2x+4c_1^2x^2-1)}}$$

- Use the initial condition $y'\Big|_{\{x=1\}} = 0$

$$0 = \frac{\sqrt{2}\,(-8c_1^2c_2+8c_1^2)}{4\sqrt{c_1\,(4c_1^2c_2^2-8c_1^2c_2+4c_1^2-1)}}$$

- Solve for c_1 and c_2
- The solution does not satisfy the initial conditions

☐ Check validity of solution $y = -\frac{\sqrt{2}\,\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2x+4c_1^2x^2-1)}}{2c_1}$

- Use initial condition $y(1) = 1$

$$1 = -\frac{\sqrt{2}\,\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2+4c_1^2-1)}}{2c_1}$$

- Compute derivative of the solution

$$y' = -\frac{\sqrt{2}\,(8c_1^2c_2+8c_1^2x)}{4\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2x+4c_1^2x^2-1)}}$$

- Use the initial condition $y'\Big|_{\{x=1\}} = 0$

$$0 = -\frac{\sqrt{2}\,(8c_1^2c_2+8c_1^2)}{4\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2+4c_1^2-1)}}$$

- Solve for c_1 and c_2

  $\left\{c_1 = -\frac{1}{2}, c_2 = -1\right\}$

- Substitute constant values into general solution and simplify

  $y = \sqrt{-x\,(x-2)}$

☐ Check validity of solution $y = \frac{\sqrt{2}\,\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2x+4c_1^2x^2-1)}}{2c_1}$

- Use initial condition $y(1) = 1$

  $1 = \frac{\sqrt{2}\,\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2+4c_1^2-1)}}{2c_1}$

- Compute derivative of the solution

  $y' = \frac{\sqrt{2}\,(8c_1^2c_2+8c_1^2x)}{4\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2x+4c_1^2x^2-1)}}$

- Use the initial condition $y'\Big|_{\{x=1\}} = 0$

  $0 = \frac{\sqrt{2}\,(8c_1^2c_2+8c_1^2)}{4\sqrt{c_1\,(4c_1^2c_2^2+8c_1^2c_2+4c_1^2-1)}}$

- Solve for c_1 and c_2
- The solution does not satisfy the initial conditions

• Solution to the IVP

  $y = \sqrt{-x\,(x-2)}$

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order,
   _with_potential_symmetries], [_2nd_order, _reducible, _mu_xy
   ]]
```

$$\boxed{yy'' - y'^2 - y'y^2 = 0}$$

14.34.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$y p(y) \left(\frac{d}{dy}p(y)\right) + \left(-p(y) - y^2\right) p(y) = 0$$

Which is now solved as first order ode for $p(y)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dy}p(y) + p(y)p(y) = q(y)$$

Where here

$$p(y) = -\frac{1}{y}$$
$$q(y) = y$$

Hence the ode is

$$\frac{d}{dy}p(y) - \frac{p(y)}{y} = y$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{y}dy}$$
$$= \frac{1}{y}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}y}(\mu p) = (\mu)(y)$$
$$\frac{\mathrm{d}}{\mathrm{d}y}\left(\frac{p}{y}\right) = \left(\frac{1}{y}\right)(y)$$
$$\mathrm{d}\left(\frac{p}{y}\right) = \mathrm{d}y$$

Integrating gives

$$\frac{p}{y} = \int \mathrm{d}y$$
$$\frac{p}{y} = y + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{y}$ results in

$$p(y) = c_1 y + y^2$$

which simplifies to

$$p(y) = y(y + c_1)$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = y(y + c_1)$$

Integrating both sides gives

$$\int \frac{1}{y\left(y + c_1\right)} dy = \int dx$$
$$-\frac{\ln\left(y + c_1\right)}{c_1} + \frac{\ln\left(y\right)}{c_1} = x + c_2$$

The above can be written as

$$\left(-\frac{1}{c_1}\right)\left(\ln\left(y + c_1\right) - \ln\left(y\right)\right) = x + c_2$$
$$\ln\left(y + c_1\right) - \ln\left(y\right) = \left(-c_1\right)\left(x + c_2\right)$$
$$= -\left(x + c_2\right) c_1$$

Raising both side to exponential gives

$$e^{\ln(y+c_1)-\ln(y)} = -c_1 c_2 e^{-c_1 x}$$

Which simplifies to

$$\frac{y + c_1}{y} = c_3 e^{-c_1 x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{-1 + c_3 e^{-c_1 x}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{-1 + c_3 e^{-c_1 x}}$$

Verified OK.

14.34.2 Maple step by step solution

Let's solve

$yy'' + (-y' - y^2)\, y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

  $u(y)\left(\frac{d}{dy}u(y)\right) = y''$

- Make substitutions $y' = u(y)\,, y'' = u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

  $yu(y)\left(\frac{d}{dy}u(y)\right) + (-u(y) - y^2)\, u(y) = 0$

- Isolate the derivative

  $\frac{d}{dy}u(y) = \frac{u(y)}{y} + y$

- Group terms with $u(y)$ on the lhs of the ODE and the rest on the rhs of the ODE

  $\frac{d}{dy}u(y) - \frac{u(y)}{y} = y$

- The ODE is linear; multiply by an integrating factor $\mu(y)$

  $\mu(y)\left(\frac{d}{dy}u(y) - \frac{u(y)}{y}\right) = \mu(y)\, y$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dy}(\mu(y)\, u(y))$

  $\mu(y)\left(\frac{d}{dy}u(y) - \frac{u(y)}{y}\right) = \left(\frac{d}{dy}\mu(y)\right) u(y) + \mu(y)\left(\frac{d}{dy}u(y)\right)$

- Isolate $\frac{d}{dy}\mu(y)$

  $\frac{d}{dy}\mu(y) = -\frac{\mu(y)}{y}$

- Solve to find the integrating factor

  $\mu(y) = \frac{1}{y}$

- Integrate both sides with respect to y

  $\int \left(\frac{d}{dy}(\mu(y)\, u(y))\right) dy = \int \mu(y)\, y dy + c_1$

- Evaluate the integral on the lhs

  $\mu(y)\, u(y) = \int \mu(y)\, y dy + c_1$

- Solve for $u(y)$

  $u(y) = \frac{\int \mu(y) y dy + c_1}{\mu(y)}$

- Substitute $\mu(y) = \frac{1}{y}$

  $u(y) = y\left(\int 1 dy + c_1\right)$

- Evaluate the integrals on the rhs

  $u(y) = y(y + c_1)$

- Solve 1st ODE for $u(y)$

  $u(y) = y(y + c_1)$

- Revert to original variables with substitution $u(y) = y', y = y$

  $y' = y(y + c_1)$

- Separate variables

  $\frac{y'}{y(y+c_1)} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y(y+c_1)} dx = \int 1 dx + c_2$

- Evaluate integral

  $-\frac{\ln(y+c_1)}{c_1} + \frac{\ln(y)}{c_1} = x + c_2$

- Solve for y

  $y = -\frac{c_1 \mathrm{e}^{c_2 c_1 + c_1 x}}{-1 + \mathrm{e}^{c_2 c_1 + c_1 x}}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 14. Differential equations admitting of depression of their order. Exercises page 107
Problem number: 361.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{y'' - e^{2y} = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

14.35.1 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - y'e^{2y} = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - y'e^{2y})\, dx = 0$$
$$\frac{y'^2}{2} - \frac{e^{2y}}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{e^{2y} + 2c_1} \tag{1}$$

$$y' = -\sqrt{e^{2y} + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{e^{2y} + 2c_1}} dy = \int dx$$

$$-\frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{e^{2y}+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)}{2\sqrt{c_1}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{e^{2y} + 2c_1}} dy = \int dx$$

$$\frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{e^{2y}+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)}{2\sqrt{c_1}} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$-\frac{\sqrt{2}\, \operatorname{arctanh}\left(\frac{\sqrt{e^{2y}+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)}{2\sqrt{c_1}} = x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$-\frac{\operatorname{arctanh}\left(\frac{\sqrt{1+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)\sqrt{2}}{2\sqrt{c_1}} = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2\tanh\left(\sqrt{c_1}\,(x + c_2)\,\sqrt{2}\right) c_1^{\frac{3}{2}} \sqrt{2}\left(1 - \tanh\left(\sqrt{c_1}\,(x + c_2)\,\sqrt{2}\right)^2\right)}{2\tanh\left(\sqrt{c_1}\,(x + c_2)\,\sqrt{2}\right)^2 c_1 - 2c_1}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \frac{\left(-\mathrm{e}^{2c_2\sqrt{c_1}\,\sqrt{2}} + 1\right)\sqrt{c_1}\,\sqrt{2}}{\mathrm{e}^{2c_2\sqrt{c_1}\,\sqrt{2}} + 1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. There is no solution for the constants of integrations. This solution is removed.

Looking at the Second solution

$$\frac{\sqrt{2}\,\operatorname{arctanh}\left(\frac{\sqrt{\mathrm{e}^{2y}+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)}{2\sqrt{c_1}} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$\frac{\operatorname{arctanh}\left(\frac{\sqrt{1+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)\sqrt{2}}{2\sqrt{c_1}} = c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2\tanh\left(\sqrt{c_1}\,(x + c_3)\,\sqrt{2}\right)c_1^{\frac{3}{2}}\sqrt{2}\left(1 - \tanh\left(\sqrt{c_1}\,(x + c_3)\,\sqrt{2}\right)^2\right)}{2\tanh\left(\sqrt{c_1}\,\,(x + c_3)\,\sqrt{2}\right)^2 c_1 - 2c_1}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = \frac{\left(-\mathrm{e}^{2c_3\sqrt{c_1}\,\sqrt{2}} + 1\right)\sqrt{c_1}\,\sqrt{2}}{\mathrm{e}^{2c_3\sqrt{c_1}\,\sqrt{2}} + 1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Verification of solutions N/A

14.35.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$
\begin{aligned}
y'' &= \frac{dp}{dx} \\
&= \frac{dy}{dx}\frac{dp}{dy} \\
&= p\frac{dp}{dy}
\end{aligned}
$$

Hence the ode becomes

$$
p(y) \left(\frac{d}{dy}p(y)\right) = e^{2y}
$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$
\begin{aligned}
p' &= F(y, p) \\
&= f(y)g(p) \\
&= \frac{e^{2y}}{p}
\end{aligned}
$$

Where $f(y) = e^{2y}$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$
\frac{1}{\frac{1}{p}}\, dp = e^{2y}\, dy
$$

$$
\int \frac{1}{\frac{1}{p}}\, dp = \int e^{2y}\, dy
$$

$$
\frac{p^2}{2} = \frac{e^{2y}}{2} + c_1
$$

The solution is

$$
\frac{p(y)^2}{2} - \frac{e^{2y}}{2} - c_1 = 0
$$

Initial conditions are used to solve for c_1. Substituting $y = 0$ and $p = 1$ in the above solution gives an equation to solve for the constant of integration.

$$
-c_1 = 0
$$

$$
c_1 = 0
$$

Substituting c_1 found above in the general solution gives

$$\frac{p^2}{2} - \frac{e^{2y}}{2} = 0$$

Solving for $p(y)$ from the above gives

$$p(y) = e^y$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$y' = e^y$$

Integrating both sides gives

$$\int e^{-y} dy = x + c_2$$
$$-e^{-y} = x + c_2$$

Solving for y gives these solutions

$$y_1 = \ln\left(-\frac{1}{x + c_2}\right)$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \ln\left(-\frac{1}{c_2}\right)$$

$$c_2 = -1$$

Substituting c_2 found above in the general solution gives

$$y = \ln\left(-\frac{1}{x - 1}\right)$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$y = \ln\left(-\frac{1}{x - 1}\right) \tag{1}$$

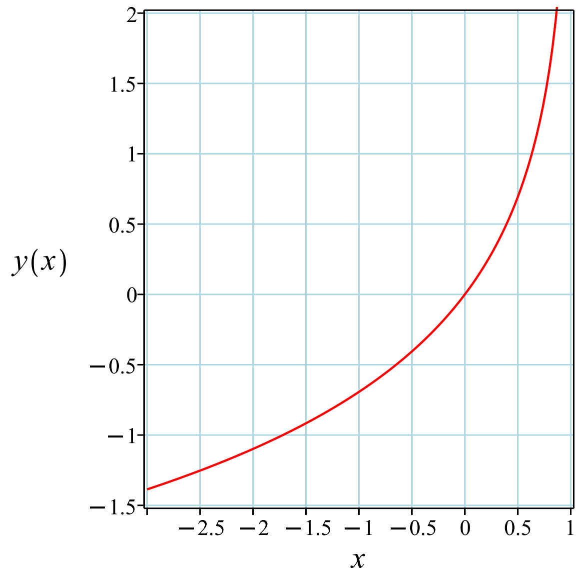

Figure 470: Solution plot

Verification of solutions

$$y = \ln\left(-\frac{1}{x-1}\right)$$

Verified OK.

14.35.3 Maple step by step solution

Let's solve

$$\left[y'' = e^{2y}, y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Define new dependent variable u

  $u(x) = y'$

- Compute y''

  $u'(x) = y''$

- Use chain rule on the lhs

  $y'\left(\frac{d}{dy}u(y)\right) = y''$

- Substitute in the definition of u

$u(y)\left(\frac{d}{dy}u(y)\right)=y''$

- Make substitutions $y'=u(y)\,,y''=u(y)\left(\frac{d}{dy}u(y)\right)$ to reduce order of ODE

$u(y)\left(\frac{d}{dy}u(y)\right)=\mathrm{e}^{2y}$

- Integrate both sides with respect to y

$\int u(y)\left(\frac{d}{dy}u(y)\right)dy=\int \mathrm{e}^{2y}dy+c_1$

- Evaluate integral

$\frac{u(y)^2}{2}=\frac{\mathrm{e}^{2y}}{2}+c_1$

- Solve for $u(y)$

$\left\{u(y)=\sqrt{\mathrm{e}^{2y}+2c_1},u(y)=-\sqrt{\mathrm{e}^{2y}+2c_1}\right\}$

- Solve 1st ODE for $u(y)$

$u(y)=\sqrt{\mathrm{e}^{2y}+2c_1}$

- Revert to original variables with substitution $u(y)=y',y=y$

$y'=\sqrt{\mathrm{e}^{2y}+2c_1}$

- Separate variables

$\frac{y'}{\sqrt{\mathrm{e}^{2y}+2c_1}}=1$

- Integrate both sides with respect to x

$\int \frac{y'}{\sqrt{\mathrm{e}^{2y}+2c_1}}dx=\int 1dx+c_2$

- Evaluate integral

$-\frac{\sqrt{2}\,\mathrm{arctanh}\left(\frac{\sqrt{\mathrm{e}^{2y}+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)}{2\sqrt{c_1}}=x+c_2$

- Solve for y

$y=\frac{\ln\left(2\tanh\left(\sqrt{c_1}\,(x+c_2)\sqrt{2}\right)^2c_1-2c_1\right)}{2}$

- Solve 2nd ODE for $u(y)$

$u(y)=-\sqrt{\mathrm{e}^{2y}+2c_1}$

- Revert to original variables with substitution $u(y)=y',y=y$

$y'=-\sqrt{\mathrm{e}^{2y}+2c_1}$

- Separate variables

$$\frac{y'}{\sqrt{e^{2y}+2c_1}} = -1$$

- Integrate both sides with respect to x

$$\int \frac{y'}{\sqrt{e^{2y}+2c_1}}dx = \int (-1)\, dx + c_2$$

- Evaluate integral

$$-\frac{\sqrt{2}\,\mathrm{arctanh}\left(\frac{\sqrt{e^{2y}+2c_1}\,\sqrt{2}}{2\sqrt{c_1}}\right)}{2\sqrt{c_1}} = -x + c_2$$

- Solve for y

$$y = \frac{\ln\left(2\tanh\left(\sqrt{c_1}\,(-x+c_2)\sqrt{2}\right)^2 c_1 - 2c_1\right)}{2}$$

□ Check validity of solution $y = \frac{\ln\left(2\tanh\left(\sqrt{c_1}\,(-x+c_2)\sqrt{2}\right)^2 c_1 - 2c_1\right)}{2}$

- ○ Use initial condition $y(0) = 0$

$$0 = \frac{\ln\left(2\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)^2 c_1 - 2c_1\right)}{2}$$

- ○ Compute derivative of the solution

$$y' = -\frac{2\tanh\left(\sqrt{c_1}\,(-x+c_2)\sqrt{2}\right)c_1^{\frac{3}{2}}\sqrt{2}\left(1-\tanh\left(\sqrt{c_1}\,(-x+c_2)\sqrt{2}\right)^2\right)}{2\tanh\left(\sqrt{c_1}\,(-x+c_2)\sqrt{2}\right)^2 c_1 - 2c_1}$$

- ○ Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$$1 = -\frac{2\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)c_1^{\frac{3}{2}}\sqrt{2}\left(1-\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)^2\right)}{2\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)^2 c_1 - 2c_1}$$

- ○ Solve for c_1 and c_2
- ○ The solution does not satisfy the initial conditions

□ Check validity of solution $y = \frac{\ln\left(2\tanh\left(\sqrt{c_1}\,(x+c_2)\sqrt{2}\right)^2 c_1 - 2c_1\right)}{2}$

- ○ Use initial condition $y(0) = 0$

$$0 = \frac{\ln\left(2\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)^2 c_1 - 2c_1\right)}{2}$$

- ○ Compute derivative of the solution

$$y' = \frac{2\tanh\left(\sqrt{c_1}\,(x+c_2)\sqrt{2}\right)c_1^{\frac{3}{2}}\sqrt{2}\left(1-\tanh\left(\sqrt{c_1}\,(x+c_2)\sqrt{2}\right)^2\right)}{2\tanh\left(\sqrt{c_1}\,(x+c_2)\sqrt{2}\right)^2 c_1 - 2c_1}$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

$$1 = \frac{2\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)c_1^{\frac{3}{2}}\sqrt{2}\,\left(1-\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)^2\right)}{2\tanh\left(c_2\sqrt{c_1}\,\sqrt{2}\right)^2 c_1-2c_1}$$

- Solve for c_1 and c_2
- The solution does not satisfy the initial conditions

Problem number: 362.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_xy]]
```

$$\boxed{2yy'' - 3{y'}^2 - 4y^2 = 0}$$

14.36.1 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$2yp(y)\left(\frac{d}{dy}p(y)\right) - 3p(y)^2 - 4y^2 = 0$$

Which is now solved as first order ode for $p(y)$. Using the change of variables $p(y) = u(y)\,y$ on the above ode results in new ode in $u(y)$

$$2y^2u(y)\left(\left(\frac{d}{dy}u(y)\right)y+u(y)\right)-3u(y)^2\,y^2=4y^2$$

In canonical form the ODE is

$$\begin{aligned}u' &= F(y,u)\\ &= f(y)g(u)\\ &= \frac{u^2+4}{2uy}\end{aligned}$$

Where $f(y)=\frac{1}{2y}$ and $g(u)=\frac{u^2+4}{u}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+4}{u}}\,du=\frac{1}{2y}\,dy$$

$$\int\frac{1}{\frac{u^2+4}{u}}\,du=\int\frac{1}{2y}\,dy$$

$$\frac{\ln(u^2+4)}{2}=\frac{\ln(y)}{2}+c_2$$

Raising both side to exponential gives

$$\sqrt{u^2+4}=\mathrm{e}^{\frac{\ln(y)}{2}+c_2}$$

Which simplifies to

$$\sqrt{u^2+4}=c_3\sqrt{y}$$

Which simplifies to

$$\sqrt{u(y)^2+4}=c_3\sqrt{y}\,\mathrm{e}^{c_2}$$

The solution is

$$\sqrt{u(y)^2+4}=c_3\sqrt{y}\,\mathrm{e}^{c_2}$$

Replacing $u(y)$ in the above solution by $\frac{p(y)}{y}$ results in the solution for $p(y)$ in implicit form

$$\sqrt{\frac{p(y)^2}{y^2}+4}=c_3\sqrt{y}\,\mathrm{e}^{c_2}$$

$$\sqrt{\frac{p(y)^2+4y^2}{y^2}}=c_3\sqrt{y}\,\mathrm{e}^{c_2}$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\sqrt{\frac{y'^2 + 4y^2}{y^2}} = c_3 \sqrt{y}\, \mathrm{e}^{c_2}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-4 + c_3^2 \mathrm{e}^{2c_2} y}\, y \tag{1}$$

$$y' = -\sqrt{-4 + c_3^2 \mathrm{e}^{2c_2} y}\, y \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-4 + c_3^2 \mathrm{e}^{2c_2} y}\, y} dy = \int dx$$

$$\arctan\left(\frac{\sqrt{-4 + c_3^2 \mathrm{e}^{2c_2} y}}{2}\right) = x + c_4$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-4 + c_3^2 \mathrm{e}^{2c_2} y}\, y} dy = \int dx$$

$$-\arctan\left(\frac{\sqrt{-4 + c_3^2 \mathrm{e}^{2c_2} y}}{2}\right) = x + c_5$$

Summary

The solution(s) found are the following

$$y = \frac{4\left(\tan\left(x + c_4\right)^2 + 1\right) \mathrm{e}^{-2c_2}}{c_3^2} \tag{1}$$

$$y = \frac{4\left(\tan\left(x + c_5\right)^2 + 1\right) \mathrm{e}^{-2c_2}}{c_3^2} \tag{2}$$

Verification of solutions

$$y = \frac{4\left(\tan \left(x+c_4\right)^2+1\right) \mathrm{e}^{-2c_2}}{c_3^2}$$

Verified OK.

$$y = \frac{4\left(\tan \left(x+c_5\right)^2+1\right) \mathrm{e}^{-2c_2}}{c_3^2}$$

Verified OK.

Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 432.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y = 0}$$

15.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x} \tag{1}$$

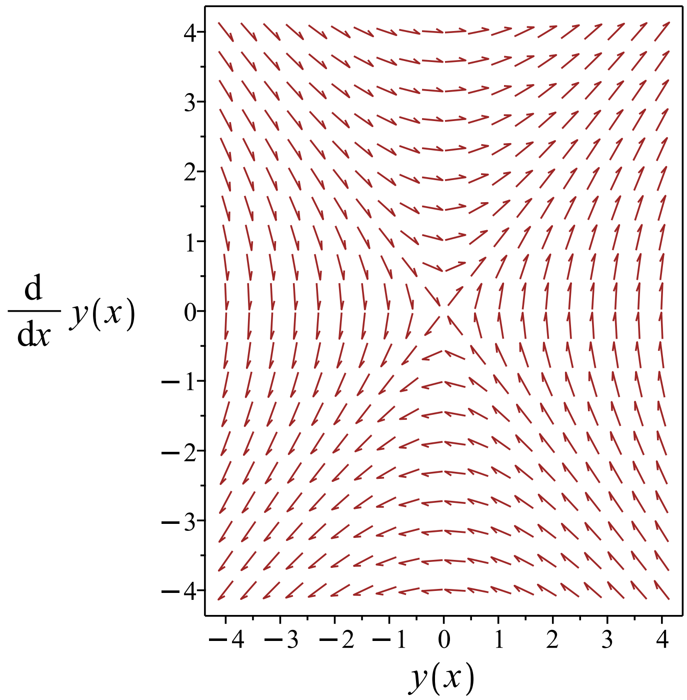

Figure 471: Slope field plot

Verification of solutions

$$y = c_1 e^x + c_2 e^{-x}$$

Verified OK.

15.1.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' - yy' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' - yy')\,dx = 0$$

$$\frac{y'^2}{2} - \frac{y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{y^2 + 2c_1} \tag{1}$$

$$y' = -\sqrt{y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{y^2+2c_1}}dy = \int dx$$
$$\ln\left(y+\sqrt{y^2+2c_1}\right) = x + c_2$$

Raising both side to exponential gives

$$y+\sqrt{y^2+2c_1} = \mathrm{e}^{x+c_2}$$

Which simplifies to

$$y+\sqrt{y^2+2c_1} = c_3\mathrm{e}^{x}$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{y^2+2c_1}}dy = \int dx$$
$$-\ln\left(y+\sqrt{y^2+2c_1}\right) = x + c_4$$

Raising both side to exponential gives

$$\frac{1}{y+\sqrt{y^2+2c_1}} = \mathrm{e}^{x+c_4}$$

Which simplifies to

$$\frac{1}{y+\sqrt{y^2+2c_1}} = c_5\mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\mathrm{e}^{2x}c_3^2-2c_1\right)\mathrm{e}^{-x}}{2c_3} \tag{1}$$
$$y = -\frac{\left(2c_1c_5^2\mathrm{e}^{2x}-1\right)\mathrm{e}^{-x}}{2c_5} \tag{2}$$

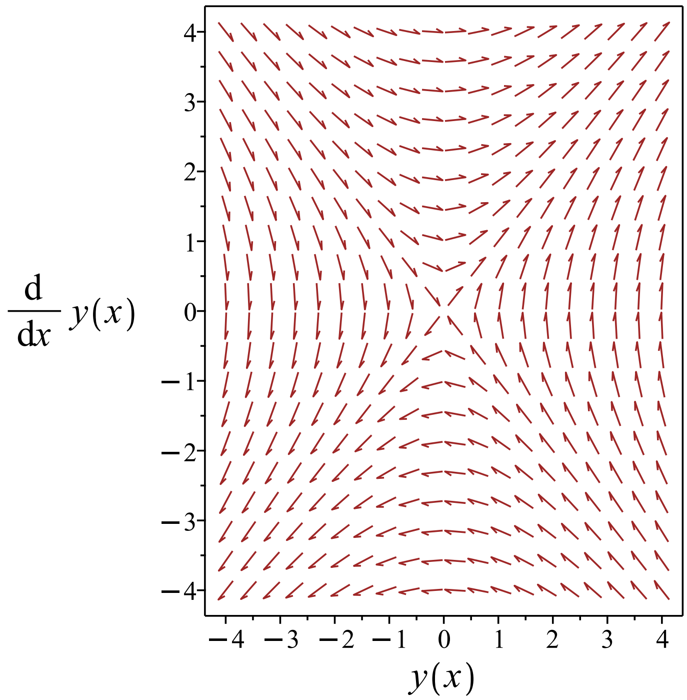

Figure 472: Slope field plot

Verification of solutions

$$y = \frac{(e^{2x}c_3^2 - 2c_1)\,e^{-x}}{2c_3}$$

Verified OK.

$$y = -\frac{(2c_1c_5^2e^{2x} - 1)\,e^{-x}}{2c_5}$$

Verified OK.

15.1.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 370: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= e^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\, dx \\ &= \mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} \tag{1}$$

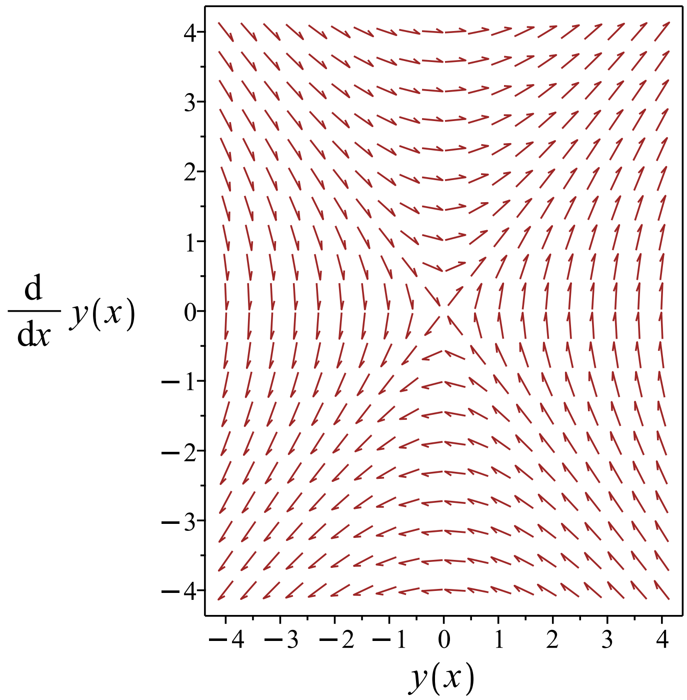

Figure 473: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2}$$

Verified OK.

15.1.4 Maple step by step solution

Let's solve

$y'' - y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 1 = 0$

Problem number: 433.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{3y'' - 2y' - 8y = 0}$$

15.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 3, B = -2, C = -8$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$3\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} - 8 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$3\lambda^2 - 2\lambda - 8 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 3, B = -2, C = -8$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{2}{(2)\,(3)} \pm \frac{1}{(2)\,(3)}\sqrt{-2^2 - (4)\,(3)\,(-8)} \\
&= \frac{1}{3} \pm \frac{5}{3}
\end{aligned}
$$

Hence

$$
\lambda_1 = \frac{1}{3} + \frac{5}{3}
$$
$$
\lambda_2 = \frac{1}{3} - \frac{5}{3}
$$

Which simplifies to

$$
\lambda_1 = 2
$$
$$
\lambda_2 = -\frac{4}{3}
$$

Since roots are real and distinct, then the solution is

$$
y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}
$$
$$
y = c_1 e^{(2)x} + c_2 e^{\left(-\frac{4}{3}\right)x}
$$

Or

$$
y = c_1 e^{2x} + c_2 e^{-\frac{4x}{3}}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = c_1 e^{2x} + c_2 e^{-\frac{4x}{3}} \tag{1}
$$

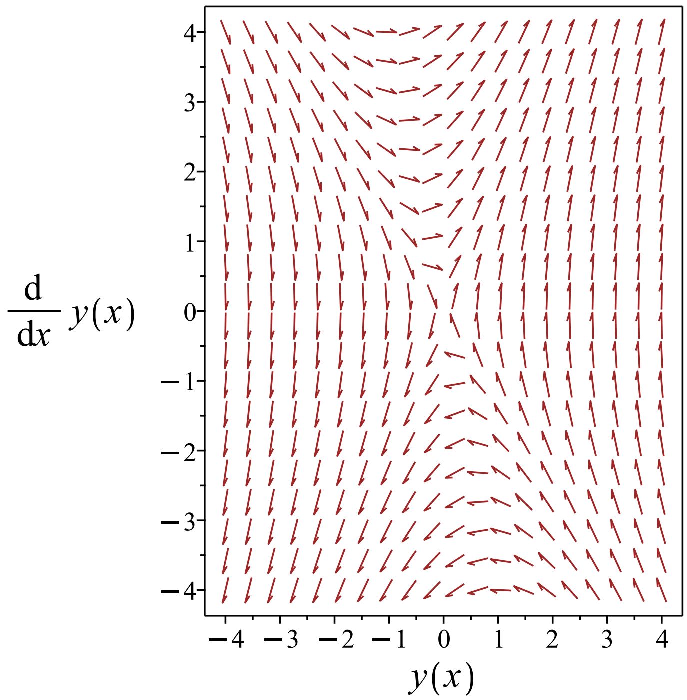

Figure 474: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{-\frac{4x}{3}}$$

Verified OK.

15.2.2 Solving using Kovacic algorithm

Writing the ode as

$$3y'' - 2y' - 8y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3 \\ B &= -2 \\ C &= -8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{9} \tag{6}$$

Comparing the above to (5) shows that

$$s = 25$$
$$t = 9$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{9} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 372: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{9}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{3}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{3}\,dx} \\ &= z_1 e^{\frac{x}{3}} \\ &= z_1\left(\mathrm{e}^{\frac{x}{3}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{4x}{3}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{3}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\frac{2x}{3}}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{3\,\mathrm{e}^{\frac{10x}{3}}}{10}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{4x}{3}}\right) + c_2\left(\mathrm{e}^{-\frac{4x}{3}}\left(\frac{3\,\mathrm{e}^{\frac{10x}{3}}}{10}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{4x}{3}} + \frac{3 c_2 \mathrm{e}^{2x}}{10} \tag{1}
$$

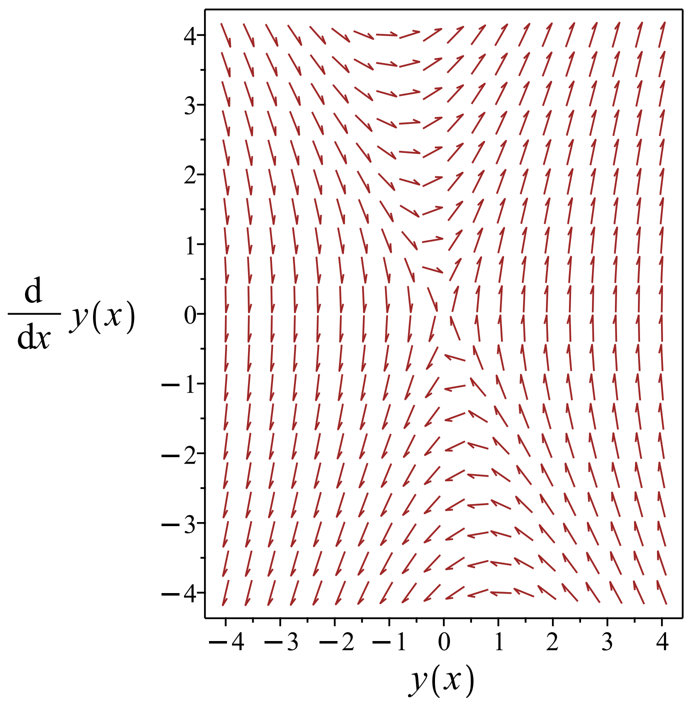

Figure 475: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{4x}{3}} + \frac{3 c_2 \mathrm{e}^{2x}}{10}
$$

Verified OK.

15.2.3 Maple step by step solution

Let's solve

$3y'' - 2y' - 8y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{2y'}{3} + \frac{8y}{3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{3} - \frac{8y}{3} = 0$

- Characteristic polynomial of ODE

  $r^2 - \frac{2}{3}r - \frac{8}{3} = 0$

- Factor the characteristic polynomial

  $\frac{(3r+4)(r-2)}{3} = 0$

- Roots of the characteristic polynomial

  $r = \left(2, -\frac{4}{3}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{2x}$

- 2nd solution of the ODE

  $y_2(x) = e^{-\frac{4x}{3}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{2x} + c_2 e^{-\frac{4x}{3}}$

Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 434.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 3y'' + 3y' - y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 2, y''(0) = 3]$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 3\lambda - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + x\,e^x c_2 + x^2 e^x c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^x \\
y_2 &= x e^x \\
y_3 &= x^2 e^x
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = e^x c_1 + x e^x c_2 + x^2 e^x c_3 \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = e^x c_1 + e^x c_2 + x e^x c_2 + 2x e^x c_3 + x^2 e^x c_3
$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$
2 = c_1 + c_2 \tag{2A}
$$

Taking two derivatives of the solution gives

$$
y'' = e^x c_1 + 2 e^x c_2 + x e^x c_2 + 2 e^x c_3 + 4x e^x c_3 + x^2 e^x c_3
$$

substituting $y'' = 3$ and $x = 0$ in the above gives

$$
3 = c_1 + 2c_2 + 2c_3 \tag{3A}
$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= 1 \\
c_3 &= 0
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = x e^x + e^x
$$

Which simplifies to

$$y = e^x(x+1)$$

Summary

The solution(s) found are the following

$$y = e^x(x+1) \tag{1}$$

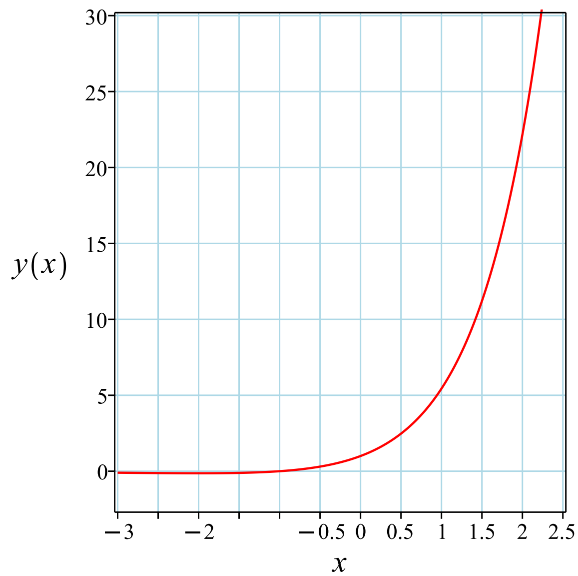

Figure 476: Solution plot

Verification of solutions

$$y = e^x(x+1)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 2y' + y = 0}$$

15.4.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(2)^2 - (4)(1)(1)} \\ &= -1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 1$. Therefore the solution is

$$y = c_1 e^{-x} + c_2 x e^{-x} \tag{1}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 x e^{-x} \tag{1}$$

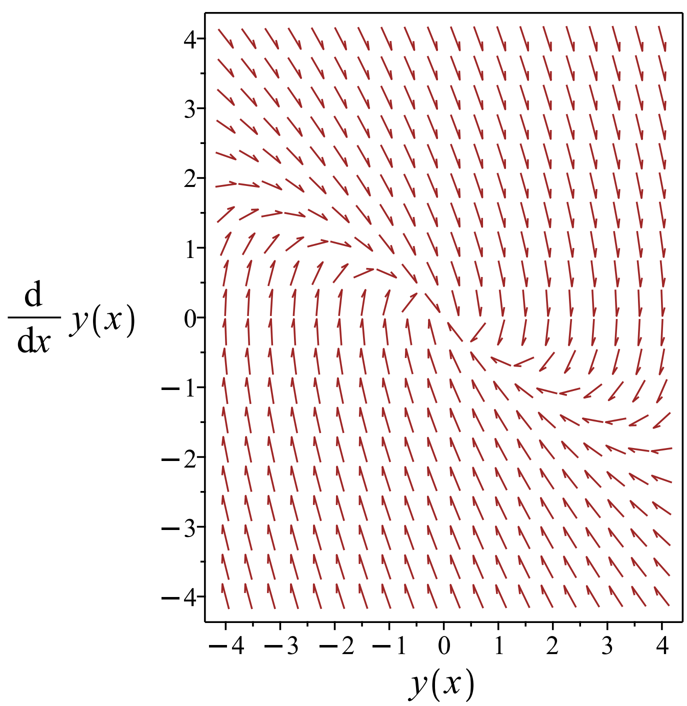

Figure 477: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 x e^{-x}$$

Verified OK.

15.4.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int 2\, dx} \\ &= \mathrm{e}^{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ (\mathrm{e}^{x} y)'' &= 0 \end{aligned}$$

Integrating once gives

$$(\mathrm{e}^{x} y)' = c_1$$

Integrating again gives

$$(\mathrm{e}^{x} y) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\mathrm{e}^{x}}$$

Or

$$y = c_1 x\, \mathrm{e}^{-x} + \mathrm{e}^{-x} c_2$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 x\, \mathrm{e}^{-x} + \mathrm{e}^{-x} c_2 \tag{1}$$

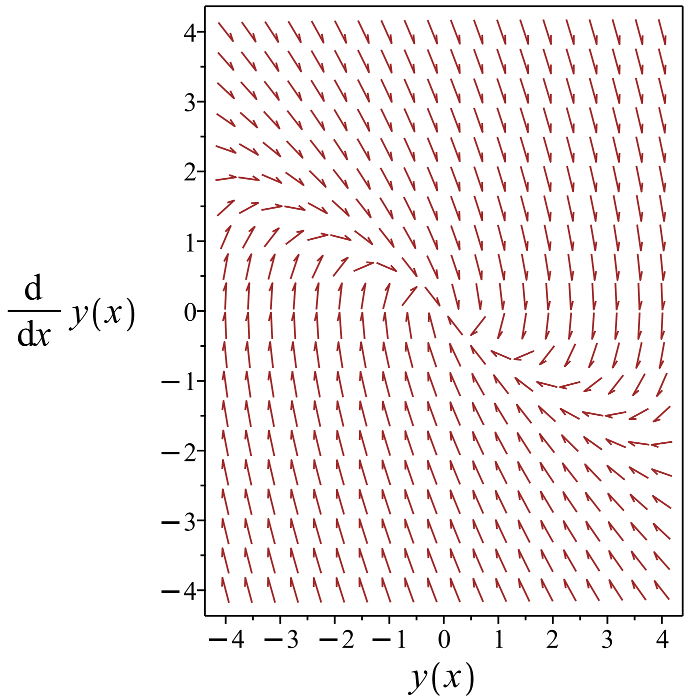

Figure 478: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} c_2$$

Verified OK.

15.4.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 374: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\, dx} \\ &= z_1 e^{-x} \\ &= z_1 \left(\mathrm{e}^{-x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\, dx \\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}(x)\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} \tag{1}$$

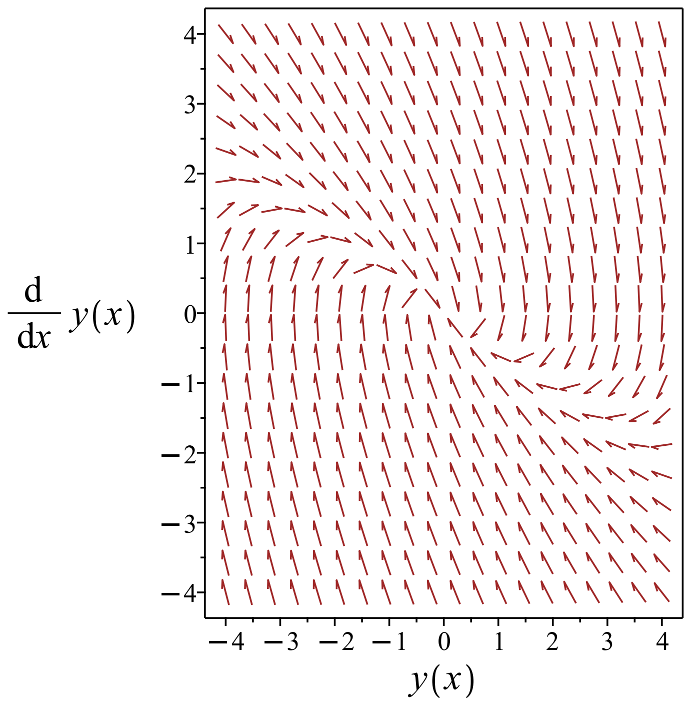

Figure 479: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x}$$

Verified OK.

15.4.4 Maple step by step solution

Let's solve

Problem number: 436.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{y'' - 4y' + 3y = 0}$$

With initial conditions

$$[y(0) = 6, y'(0) = 10]$$

15.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= 3 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 4y' + 3y = 0$$

The domain of $p(x) = -4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

15.5.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda \, e^{\lambda x} + 3 \, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(3)} \\ &= 2 \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 2 + 1 \\ \lambda_2 &= 2 - 1\end{aligned}$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(1)x}$$

Or

$$y = c_1 e^{3x} + e^x c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{3x} + e^x c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$6 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 3c_1 e^{3x} + e^x c_2$$

substituting $y' = 10$ and $x = 0$ in the above gives

$$10 = 3c_1 + c_2 \tag{2A}$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 2$$
$$c_2 = 4$$

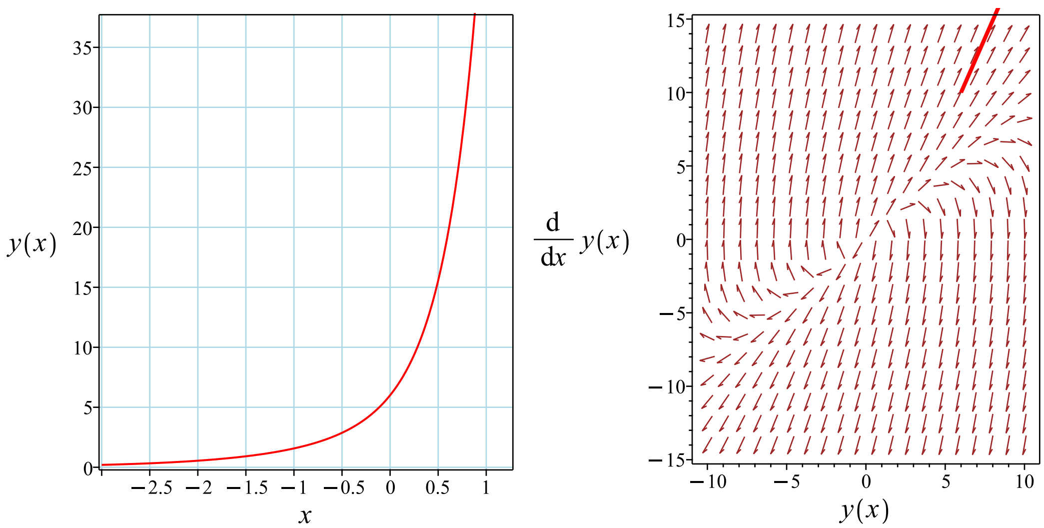
Substituting these values back in above solution results in

$$y = 2 e^{3x} + 4 e^x$$

Summary

The solution(s) found are the following

$$y = 2\,e^{3x} + 4\,e^{x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = 2\,e^{3x} + 4\,e^{x}$$

Verified OK.

15.5.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 376: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1\left(\mathrm{e}^{2x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{2x}}{2}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2\left(\mathrm{e}^x\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \mathrm{e}^x c_1 + \frac{c_2 \mathrm{e}^{3x}}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 6$ and $x = 0$ in the above gives

$$
6 = c_1 + \frac{c_2}{2} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \mathrm{e}^x c_1 + \frac{3c_2 \mathrm{e}^{3x}}{2}
$$

substituting $y' = 10$ and $x = 0$ in the above gives

$$
10 = c_1 + \frac{3c_2}{2} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 4 \\
c_2 &= 4
\end{aligned}
$$

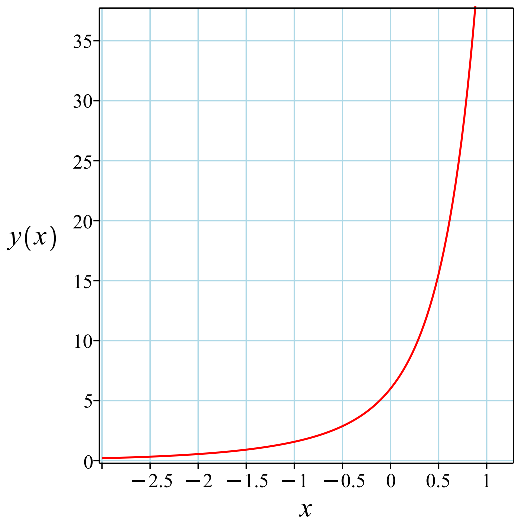
Substituting these values back in above solution results in

$$
y = 2\,\mathrm{e}^{3x} + 4\,\mathrm{e}^x
$$

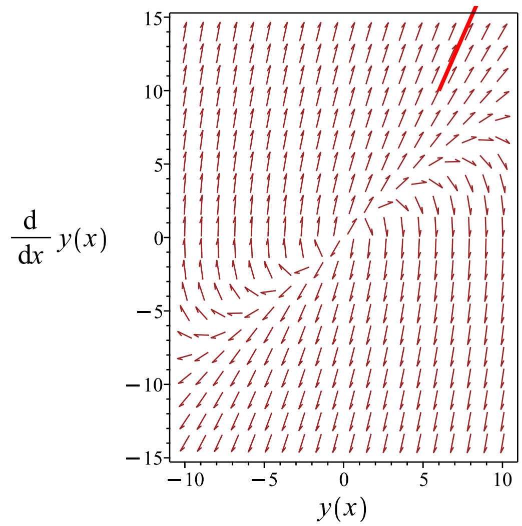
Summary

The solution(s) found are the following

$$
y = 2\,\mathrm{e}^{3x} + 4\,\mathrm{e}^x \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 2\,e^{3x} + 4\,e^{x}$$

Verified OK.

15.5.4 Maple step by step solution

Let's solve

$$\left[y'' - 4y' + 3y = 0, y(0) = 6, y'\Big|_{\{x=0\}} = 10\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 4r + 3 = 0$

- Factor the characteristic polynomial

  $(r - 1)(r - 3) = 0$

- Roots of the characteristic polynomial

  $r = (1, 3)$

- 1st solution of the ODE

$y_1(x) = e^x$

- 2nd solution of the ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = e^x c_1 + c_2 e^{3x}$

- □ Check validity of solution $y = e^x c_1 + c_2 e^{3x}$
  - Use initial condition $y(0) = 6$

    $6 = c_1 + c_2$
  - Compute derivative of the solution

    $y' = e^x c_1 + 3c_2 e^{3x}$
  - Use the initial condition $y'\Big|_{\{x=0\}} = 10$

    $10 = c_1 + 3c_2$
  - Solve for c_1 and c_2

    $\{c_1 = 4, c_2 = 2\}$
  - Substitute constant values into general solution and simplify

    $y = 2\,e^{3x} + 4\,e^x$

- Solution to the IVP

  $y = 2\,e^{3x} + 4\,e^x$

Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 437.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + 6y'' + 11y' + 6y = 0}$$

The characteristic equation is

$$\lambda^3 + 6\lambda^2 + 11\lambda + 6 = 0$$

The roots of the above equation are

$$\lambda_1 = -3$$
$$\lambda_2 = -2$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-2x} c_2 + \mathrm{e}^{-3x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \mathrm{e}^{-2x}$$
$$y_3 = \mathrm{e}^{-3x}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + e^{-2x} c_2 + e^{-3x} c_3 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + e^{-2x} c_2 + e^{-3x} c_3$$

Verified OK.

15.6.1 Maple step by step solution

Let's solve

$y''' + 6y'' + 11y' + 6y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = -6y_3(x) - 11y_2(x) - 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -6y_3(x) - 11y_2(x) - 6y_1(x)]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{bmatrix} \cdot \overrightarrow{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = e^{-3x} \cdot \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{-2x} \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-3x} \cdot \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix} + e^{-2x} c_2 \cdot \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + c_3 e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{c_1 e^{-3x}}{9} + \frac{e^{-2x} c_2}{4} + c_3 e^{-x}$$

Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 438.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2y' - 2y = 0}$$

15.7.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} - 2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -2$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(-2)} \\
&= 1 \pm \sqrt{3}
\end{aligned}
$$

Hence

$$
\begin{aligned}
\lambda_1 &= 1 + \sqrt{3} \\
\lambda_2 &= 1 - \sqrt{3}
\end{aligned}
$$

Which simplifies to

$$
\begin{aligned}
\lambda_1 &= 1 + \sqrt{3} \\
\lambda_2 &= 1 - \sqrt{3}
\end{aligned}
$$

Since roots are real and distinct, then the solution is

$$
\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{\left(1+\sqrt{3}\right)x} + c_2 e^{\left(1-\sqrt{3}\right)x}
\end{aligned}
$$

Or

$$
y = c_1 \mathrm{e}^{\left(1+\sqrt{3}\right)x} + c_2 \mathrm{e}^{\left(1-\sqrt{3}\right)x}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{\left(1+\sqrt{3}\right)x} + c_2 \mathrm{e}^{\left(1-\sqrt{3}\right)x} \tag{1}
$$

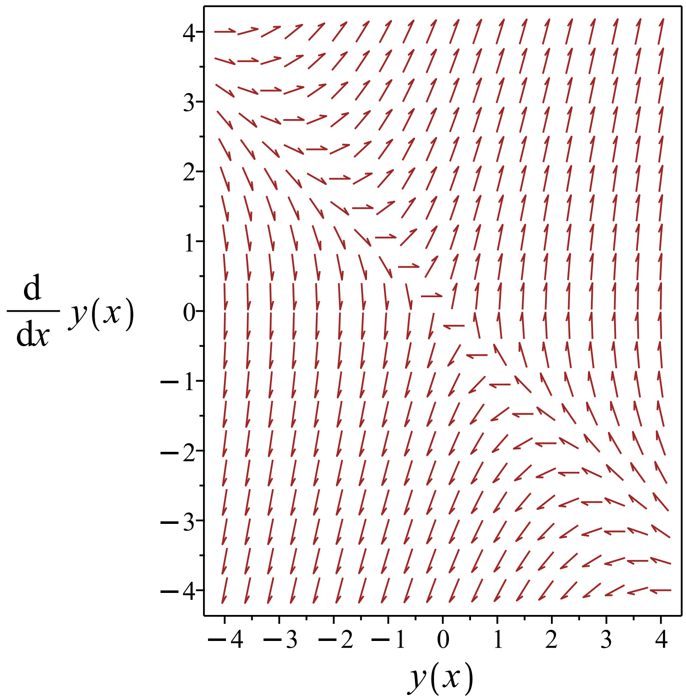

Figure 482: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{\left(1+\sqrt{3}\right)x} + c_2 \mathrm{e}^{\left(1-\sqrt{3}\right)x}$$

Verified OK.

15.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 3z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 379: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 3$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x\sqrt{3}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\left(\sqrt{3}-1\right)x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\sqrt{3}\,\mathrm{e}^{2x\sqrt{3}}}{6}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{-\left(\sqrt{3}-1\right)x}\right) + c_2\left(e^{-\left(\sqrt{3}-1\right)x}\left(\frac{\sqrt{3}\, e^{2x\sqrt{3}}}{6}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-\left(\sqrt{3}-1\right)x} + \frac{c_2\sqrt{3}\, e^{\left(1+\sqrt{3}\right)x}}{6} \tag{1}
$$

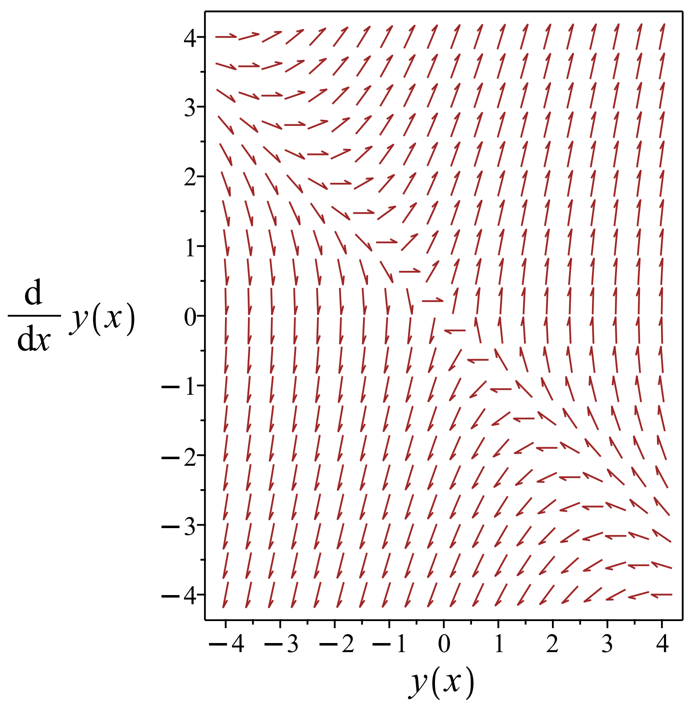

Figure 483: Slope field plot

Verification of solutions

$$
y = c_1 e^{-\left(\sqrt{3}-1\right)x} + \frac{c_2\sqrt{3}\, e^{\left(1+\sqrt{3}\right)x}}{6}
$$

Verified OK.

15.7.3 Maple step by step solution

Let's solve

$y'' - 2y' - 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 2r - 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm \left(\sqrt{12}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(1 - \sqrt{3}, 1 + \sqrt{3}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{\left(1-\sqrt{3}\right)x}$

- 2nd solution of the ODE

  $y_2(x) = e^{\left(1+\sqrt{3}\right)x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{\left(1-\sqrt{3}\right)x} + c_2 e^{\left(1+\sqrt{3}\right)x}$

[[_high_order, _missing_x]]
```

$$\boxed{y^{(6)}+2y^{(5)}+y'''' = 0}$$

The characteristic equation is

$$\lambda^6+2\lambda^5+\lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$
$$\lambda_5 = -1$$
$$\lambda_6 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1\mathrm{e}^{-x}+c_2x\,\mathrm{e}^{-x}+c_3+c_4x+c_5x^2+c_6x^3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = x\,e^{-x}$$
$$y_3 = 1$$
$$y_4 = x$$
$$y_5 = x^2$$
$$y_6 = x^3$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 x\,e^{-x} + c_3 + c_4 x + c_5 x^2 + c_6 x^3 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + c_2 x\,e^{-x} + c_3 + c_4 x + c_5 x^2 + c_6 x^3$$

Verified OK.

15.8.1 Maple step by step solution

Let's solve

$y^{(6)} + 2y^{(5)} + y'''' = 0$

- Highest derivative means the order of the ODE is 6

  $y^{(6)}$

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Define new variable $y_4(x)$

    $y_4(x) = y'''$

  ◦ Define new variable $y_5(x)$

$y_5(x) = y''''$

- Define new variable $y_6(x)$

  $y_6(x) = y^{(5)}$

- Isolate for $y_6'(x)$ using original ODE

  $y_6'(x) = -2y_6(x) - y_5(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_5(x) = y_4'(x), y_6(x) = y_5'(x), y_6'(x) = -2y_6(x) -$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \\ y_5(x) \\ y_6(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & -2 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & -2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right], \left[-1, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[0, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[0, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[0, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- First solution from eigenvalue -1

$$\vec{y}_1(x) = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, a

$$\vec{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda x}\vec{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda \mathrm{e}^{\lambda x}\left(x\overrightarrow{v}+\overrightarrow{p}\right)+\mathrm{e}^{\lambda x}\overrightarrow{v}=\mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v}+A\cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p}+\overrightarrow{v}=A\cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I)\cdot \overrightarrow{p}+\overrightarrow{v}=A\cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

$$(A-\lambda \cdot I)\cdot \overrightarrow{p}=\overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

$$\left(\left[\begin{array}{cccccc} 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & -1 & -2 \end{array}\right]-(-1)\cdot \left[\begin{array}{cccccc} 1 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{array}\right]\right)\cdot \overrightarrow{p}=\left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\overrightarrow{p}=\left[\begin{array}{c} -1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]$$

- Second solution from eigenvalue -1

$$\vec{y}_2(x) = e^{-x} \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right)$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_4 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, & \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_5 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, & \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_6 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1(x) + c_2 \vec{y}_2(x) + c_3 \vec{y}_3 + c_4 \vec{y}_4 + c_5 \vec{y}_5 + c_6 \vec{y}_6$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \mathrm{e}^{-x} c_2 \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right) + \begin{bmatrix} c_3 \\ 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = ((-x-1) c_2 - c_1) \mathrm{e}^{-x} + c_3$$

Problem number: 440.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{4y'' - 8y' + 5y = 0}$$

15.9.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 4, B = -8, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x} - 8\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 - 8\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = -8, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{8}{(2)(4)} \pm \frac{1}{(2)(4)} \sqrt{-8^2 - (4)(4)(5)} \\ &= 1 \pm \frac{i}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + \frac{i}{2} \\ \lambda_2 &= 1 - \frac{i}{2}\end{aligned}$$

Which simplifies to

$$\lambda_1 = 1 + \frac{i}{2}$$

$$\lambda_2 = 1 - \frac{i}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = \frac{1}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^x \left(c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$y = e^x \left(c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)\right) \tag{1}$$

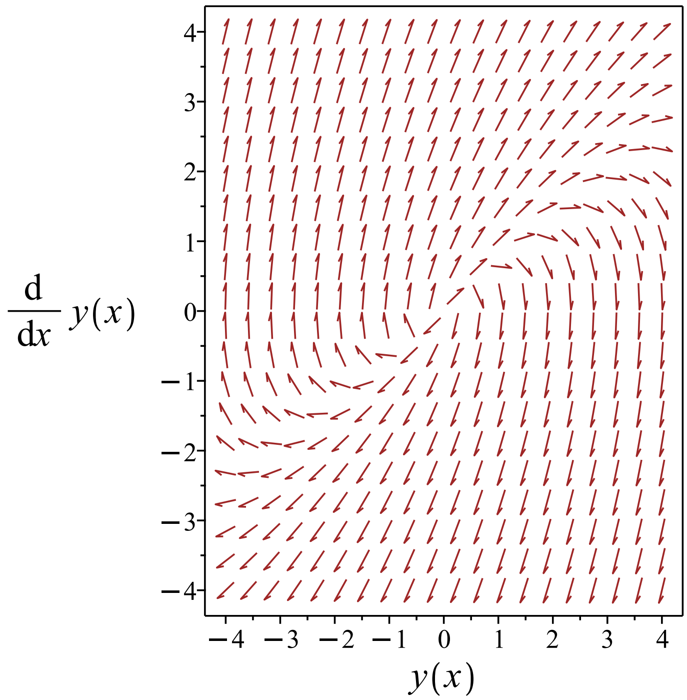

Figure 484: Slope field plot

Verification of solutions

$$y = e^{x}\left(c_1 \cos\left(\frac{x}{2}\right) + c_2 \sin\left(\frac{x}{2}\right)\right)$$

Verified OK.

15.9.2 Solving using Kovacic algorithm

Writing the ode as

$$4y'' - 8y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= -8 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 382: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{x}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8}{4}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}\cos\left(\frac{x}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-8}{4}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1\left(2\tan\left(\frac{x}{2}\right)\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^x \cos\left(\frac{x}{2}\right)\right) + c_2 \left(e^x \cos\left(\frac{x}{2}\right) \left(2 \tan\left(\frac{x}{2}\right)\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^x \cos\left(\frac{x}{2}\right) + 2 c_2 e^x \sin\left(\frac{x}{2}\right) \tag{1}$$

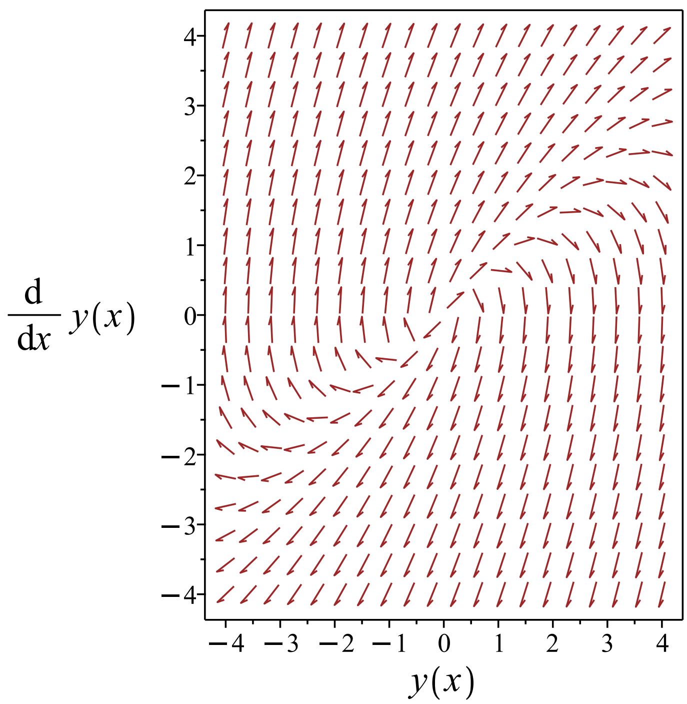

Figure 485: Slope field plot

Verification of solutions

$$y = c_1 e^x \cos\left(\frac{x}{2}\right) + 2 c_2 e^x \sin\left(\frac{x}{2}\right)$$

Verified OK.

15.9.3 Maple step by step solution

Let's solve

$4y'' - 8y' + 5y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = 2y' - \frac{5y}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - 2y' + \frac{5y}{4} = 0$

- Characteristic polynomial of ODE

  $r^2 - 2r + \frac{5}{4} = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-1})}{2}$

- Roots of the characteristic polynomial

  $r = \left(1 - \frac{\mathrm{I}}{2}, 1 + \frac{\mathrm{I}}{2}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^x \cos\left(\frac{x}{2}\right)$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^x \sin\left(\frac{x}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^x \cos\left(\frac{x}{2}\right) + c_2 \mathrm{e}^x \sin\left(\frac{x}{2}\right)$

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 8y = 0}$$

The characteristic equation is

$$\lambda^3 - 8 = 0$$

The roots of the above equation are

$$\lambda_1 = 2$$
$$\lambda_2 = -1 - i\sqrt{3}$$
$$\lambda_3 = -1 + i\sqrt{3}$$

Therefore the homogeneous solution is

$$y_h(x) = e^{2x} c_1 + e^{\left(-1-i\sqrt{3}\right)x} c_2 + e^{\left(-1+i\sqrt{3}\right)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{2x}$$
$$y_2 = e^{\left(-1-i\sqrt{3}\right)x}$$
$$y_3 = e^{\left(-1+i\sqrt{3}\right)x}$$

Summary

The solution(s) found are the following

$$y = e^{2x}c_1 + e^{(-1-i\sqrt{3})x}c_2 + e^{(-1+i\sqrt{3})x}c_3 \tag{1}$$

Verification of solutions

$$y = e^{2x}c_1 + e^{(-1-i\sqrt{3})x}c_2 + e^{(-1+i\sqrt{3})x}c_3$$

Verified OK.

15.10.1 Maple step by step solution

Let's solve

$y''' - 8y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 8y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 8y_1(x)]$

- Define vector

  $$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 8 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[-1 - \mathrm{I}\sqrt{3}, \begin{bmatrix} \frac{1}{\left(-1-\mathrm{I}\sqrt{3}\right)^2} \\ \frac{1}{-1-\mathrm{I}\sqrt{3}} \\ 1 \end{bmatrix}\right], \left[-1 + \mathrm{I}\sqrt{3}, \begin{bmatrix} \frac{1}{\left(-1+\mathrm{I}\sqrt{3}\right)^2} \\ \frac{1}{-1+\mathrm{I}\sqrt{3}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1 - \mathrm{I}\sqrt{3}, \begin{bmatrix} \frac{1}{\left(-1-\mathrm{I}\sqrt{3}\right)^2} \\ \frac{1}{-1-\mathrm{I}\sqrt{3}} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{\left(-1-I\sqrt{3}\right)x}\cdot\left[\begin{array}{c}\frac{1}{\left(-1-I\sqrt{3}\right)^{2}}\\ \frac{1}{-1-I\sqrt{3}}\\ 1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-x}\cdot\left(\cos\left(x\sqrt{3}\right)-I\sin\left(x\sqrt{3}\right)\right)\cdot\left[\begin{array}{c}\frac{1}{\left(-1-I\sqrt{3}\right)^{2}}\\ \frac{1}{-1-I\sqrt{3}}\\ 1\end{array}\right]$$

- Simplify expression

$$e^{-x}\cdot\left[\begin{array}{c}\frac{\cos\left(x\sqrt{3}\right)-I\sin\left(x\sqrt{3}\right)}{\left(-1-I\sqrt{3}\right)^{2}}\\ \frac{\cos\left(x\sqrt{3}\right)-I\sin\left(x\sqrt{3}\right)}{-1-I\sqrt{3}}\\ \cos\left(x\sqrt{3}\right)-I\sin\left(x\sqrt{3}\right)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_{2}(x)=e^{-x}\cdot\left[\begin{array}{c}-\frac{\cos\left(x\sqrt{3}\right)}{8}-\frac{\sin\left(x\sqrt{3}\right)\sqrt{3}}{8}\\ -\frac{\cos\left(x\sqrt{3}\right)}{4}+\frac{\sin\left(x\sqrt{3}\right)\sqrt{3}}{4}\\ \cos\left(x\sqrt{3}\right)\end{array}\right],\vec{y}_{3}(x)=e^{-x}\cdot\left[\begin{array}{c}-\frac{\cos\left(x\sqrt{3}\right)\sqrt{3}}{8}+\frac{\sin\left(x\sqrt{3}\right)}{8}\\ \frac{\cos\left(x\sqrt{3}\right)\sqrt{3}}{4}+\frac{\sin\left(x\sqrt{3}\right)}{4}\\ -\sin\left(x\sqrt{3}\right)\end{array}\right]\right]$$

- General solution to the system of ODEs

$$\vec{y}=c_{1}\vec{y}_{1}+c_{2}\vec{y}_{2}(x)+c_{3}\vec{y}_{3}(x)$$

- Substitute solutions into the general solution

$$\vec{y}=e^{2x}c_{1}\cdot\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]+e^{-x}c_{2}\cdot\left[\begin{array}{c}-\frac{\cos\left(x\sqrt{3}\right)}{8}-\frac{\sin\left(x\sqrt{3}\right)\sqrt{3}}{8}\\ -\frac{\cos\left(x\sqrt{3}\right)}{4}+\frac{\sin\left(x\sqrt{3}\right)\sqrt{3}}{4}\\ \cos\left(x\sqrt{3}\right)\end{array}\right]+c_{3}e^{-x}\cdot\left[\begin{array}{c}-\frac{\cos\left(x\sqrt{3}\right)\sqrt{3}}{8}+\frac{\sin\left(x\sqrt{3}\right)}{8}\\ \frac{\cos\left(x\sqrt{3}\right)\sqrt{3}}{4}+\frac{\sin\left(x\sqrt{3}\right)}{4}\\ -\sin\left(x\sqrt{3}\right)\end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y=-\frac{e^{-x}\left(\sqrt{3}\,c_{3}+c_{2}\right)\cos\left(x\sqrt{3}\right)}{8}-\frac{e^{-x}\left(c_{2}\sqrt{3}-c_{3}\right)\sin\left(x\sqrt{3}\right)}{8}+\frac{e^{2x}c_{1}}{4}$$

Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 442.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + 4y''' + 10y'' + 12y' + 5y = 0}$$

The characteristic equation is

$$\lambda^4 + 4\lambda^3 + 10\lambda^2 + 12\lambda + 5 = 0$$

The roots of the above equation are

$$\lambda_1 = -1 - 2i$$
$$\lambda_2 = -1 + 2i$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x} + \mathrm{e}^{(-1+2i)x} c_3 + \mathrm{e}^{(-1-2i)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= x\,\mathrm{e}^{-x} \\
y_3 &= \mathrm{e}^{(-1+2i)x} \\
y_4 &= \mathrm{e}^{(-1-2i)x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1\mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} + \mathrm{e}^{(-1+2i)x} c_3 + \mathrm{e}^{(-1-2i)x} c_4 \tag{1}
$$

Verification of solutions

$$
y = c_1\mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} + \mathrm{e}^{(-1+2i)x} c_3 + \mathrm{e}^{(-1-2i)x} c_4
$$

Verified OK.

15.11.1 Maple step by step solution

Let's solve

$y'''' + 4y''' + 10y'' + 12y' + 5y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Define new variable $y_4(x)$

    $y_4(x) = y'''$

  ◦ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -4y_4(x) - 10y_3(x) - 12y_2(x) - 5y_1(x)$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -4y_4(x) - 10y_3(x) - 12y_2(x) - 5y_1(x)]$$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -5 & -12 & -10 & -4 \end{array}\right] \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -5 & -12 & -10 & -4 \end{array}\right]$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right], \left[-1, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[-1-2\,\mathrm{I}, \left[\begin{array}{c} \frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]\right], \left[-1+2\,\mathrm{I}, \left[\begin{array}{c} \frac{11}{125} + \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} + \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} - \frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[\begin{array}{cc} -1, & \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right] \end{array}\right]$$

- First solution from eigenvalue -1

$$\overrightarrow{y}_{1}(x) = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, a

$$\overrightarrow{y}_{2}(x) = \mathrm{e}^{\lambda x} \left(x \overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_{2}(x)$ into the homogeneous system

$$\lambda \,\mathrm{e}^{\lambda x} \left(x \overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x} \overrightarrow{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x \overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda \,\mathrm{e}^{\lambda x} \left(x \overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x} \overrightarrow{v} = \mathrm{e}^{\lambda x} \left(\lambda x \overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_{2}(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

$$\left(\left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -5 & -12 & -10 & -4 \end{array}\right] - (-1) \cdot \left[\begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -1

$$\vec{y}_2(x) = e^{-x} \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1 - 2\,\mathrm{I}, \begin{bmatrix} \frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{bmatrix} \right]$$

- Solution from eigenpair

$$e^{(-1-2\,\mathrm{I})x} \cdot \begin{bmatrix} \frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-x} \cdot (\cos(2x) - \mathrm{I}\sin(2x)) \cdot \begin{bmatrix} \frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-x}\cdot\begin{bmatrix}\left(\frac{11}{125}-\frac{2\mathrm{I}}{125}\right)(\cos(2x)-\mathrm{I}\sin(2x))\\ \left(-\frac{3}{25}-\frac{4\mathrm{I}}{25}\right)(\cos(2x)-\mathrm{I}\sin(2x))\\ \left(-\frac{1}{5}+\frac{2\mathrm{I}}{5}\right)(\cos(2x)-\mathrm{I}\sin(2x))\\ \cos(2x)-\mathrm{I}\sin(2x)\end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x)=e^{-x}\cdot\begin{bmatrix}\frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125}\\ -\frac{3\cos(2x)}{25}-\frac{4\sin(2x)}{25}\\ -\frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5}\\ \cos(2x)\end{bmatrix},\vec{y}_4(x)=e^{-x}\cdot\begin{bmatrix}-\frac{11\sin(2x)}{125}-\frac{2\cos(2x)}{125}\\ \frac{3\sin(2x)}{25}-\frac{4\cos(2x)}{25}\\ \frac{\sin(2x)}{5}+\frac{2\cos(2x)}{5}\\ -\sin(2x)\end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y}=c_1\vec{y}_1(x)+c_2\vec{y}_2(x)+c_3\vec{y}_3(x)+c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y}=c_1e^{-x}\cdot\begin{bmatrix}-1\\1\\-1\\1\end{bmatrix}+e^{-x}c_2\cdot\left(x\cdot\begin{bmatrix}-1\\1\\-1\\1\end{bmatrix}+\begin{bmatrix}-1\\0\\0\\0\end{bmatrix}\right)+c_3e^{-x}\cdot\begin{bmatrix}\frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125}\\ -\frac{3\cos(2x)}{25}-\frac{4\sin(2x)}{25}\\ -\frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5}\\ \cos(2x)\end{bmatrix}+c_4e$$

- First component of the vector is the solution to the ODE

$$y=-\left(\frac{(-11c_3+2c_4)\cos(2x)}{125}+\frac{(2c_3+11c_4)\sin(2x)}{125}+(x+1)c_2+c_1\right)e^{-x}$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 443.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{y'' - 2y' + 2y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

15.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 2y' + 2y = 0$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

15.12.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(2)}\\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i\\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\lambda_1 = 1 + i$$
$$\lambda_2 = 1 - i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x}(-c_1 \sin(x) + c_2 \cos(x))$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 1$$

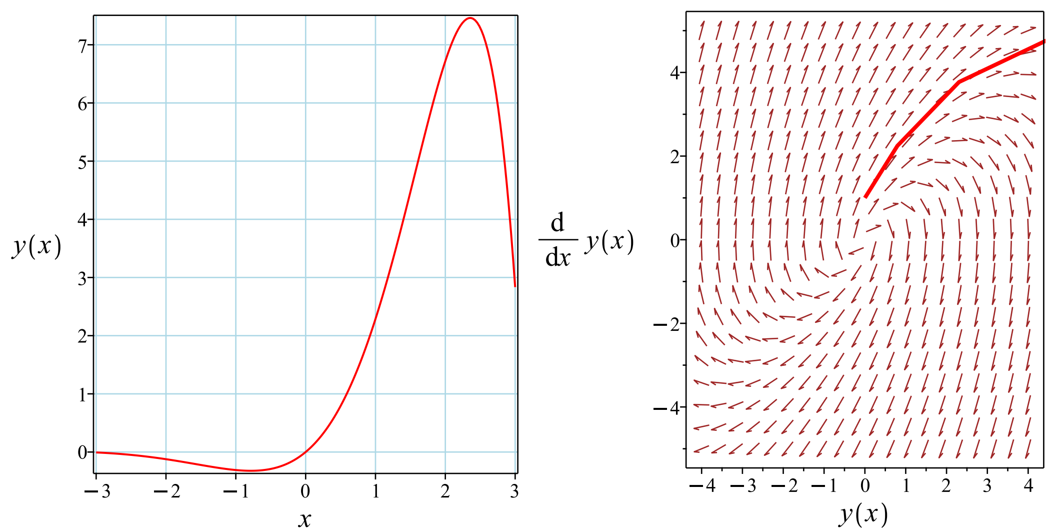
Substituting these values back in above solution results in

$$y = e^{x} \sin(x)$$

Summary

The solution(s) found are the following

$$y = e^x \sin(x) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = e^x \sin(x)$$

Verified OK.

15.12.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 386: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x})\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1(\tan(x))\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x \cos(x)) + c_2(\mathrm{e}^x \cos(x)(\tan(x)))
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^x \cos(x) + \mathrm{e}^x c_2 \sin(x) \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = c_1 \mathrm{e}^x \cos(x) - c_1 \mathrm{e}^x \sin(x) + \mathrm{e}^x c_2 \sin(x) + \mathrm{e}^x c_2 \cos(x)
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 0 \\
c_2 &= 1
\end{aligned}
$$

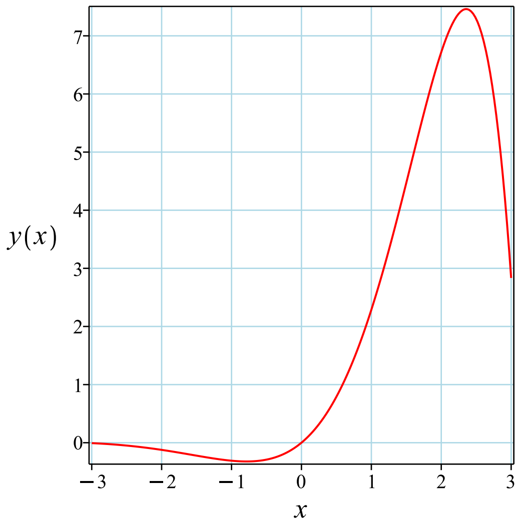
Substituting these values back in above solution results in

$$
y = \mathrm{e}^x \sin(x)
$$

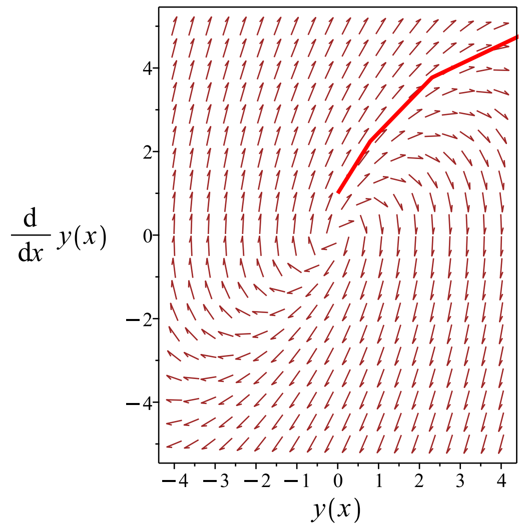
Summary

The solution(s) found are the following

$$
y = \mathrm{e}^x \sin(x) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = e^x \sin(x)$$

Verified OK.

15.12.4 Maple step by step solution

Let's solve

$$\left[y'' - 2y' + 2y = 0, y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''
- Characteristic polynomial of ODE

  $r^2 - 2r + 2 = 0$
- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (1 - \mathrm{I}, 1 + \mathrm{I})$
- 1st solution of the ODE

$y_1(x) = e^x \cos(x)$

- 2nd solution of the ODE

  $y_2(x) = e^x \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^x \cos(x) + e^x c_2 \sin(x)$

□ Check validity of solution $y = c_1 e^x \cos(x) + e^x c_2 \sin(x)$

  ◦ Use initial condition $y(0) = 0$

    $0 = c_1$

  ◦ Compute derivative of the solution

    $y' = c_1 e^x \cos(x) - c_1 e^x \sin(x) + e^x c_2 \sin(x) + e^x c_2 \cos(x)$

  ◦ Use the initial condition $y'\Big|_{\{x=0\}} = 1$

    $1 = c_1 + c_2$

  ◦ Solve for c_1 and c_2

    $\{c_1 = 0, c_2 = 1\}$

  ◦ Substitute constant values into general solution and simplify

    $y = e^x \sin(x)$

- Solution to the IVP

  $y = e^x \sin(x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{y'' - 2y' + 3y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 3]$$

15.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 3 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 2y' + 3y = 0$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

15.13.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + 3\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(3)}\\ &= 1 \pm i\sqrt{2}\end{aligned}$$

Hence

$$\lambda_1 = 1 + i\sqrt{2}$$
$$\lambda_2 = 1 - i\sqrt{2}$$

Which simplifies to

$$\lambda_1 = 1 + i\sqrt{2}$$
$$\lambda_2 = 1 - i\sqrt{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = \sqrt{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}\left(c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right)\right)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \mathrm{e}^{x}\left(c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right)\right) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \mathrm{e}^{x}\left(c_1 \cos\left(\sqrt{2}\, x\right) + c_2 \sin\left(\sqrt{2}\, x\right)\right) + \mathrm{e}^{x}\left(-c_1\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + c_2\sqrt{2}\, \cos\left(\sqrt{2}\, x\right)\right)$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = c_1 + \sqrt{2}\, c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = \sqrt{2}$$

Substituting these values back in above solution results in

$$y = \sqrt{2}\, e^{x} \sin\left(\sqrt{2}\, x\right) + e^{x} \cos\left(\sqrt{2}\, x\right)$$

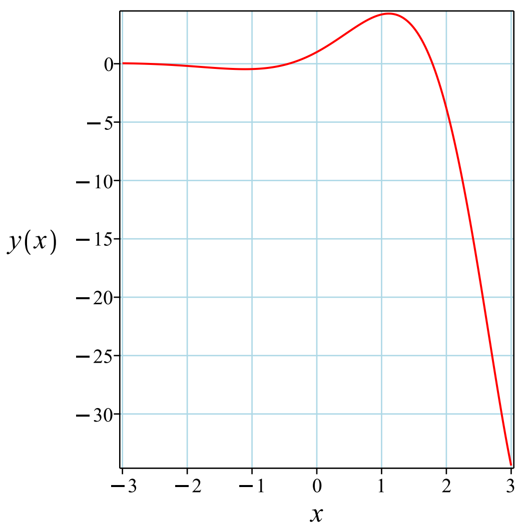
Which simplifies to

$$y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) e^{x}$$

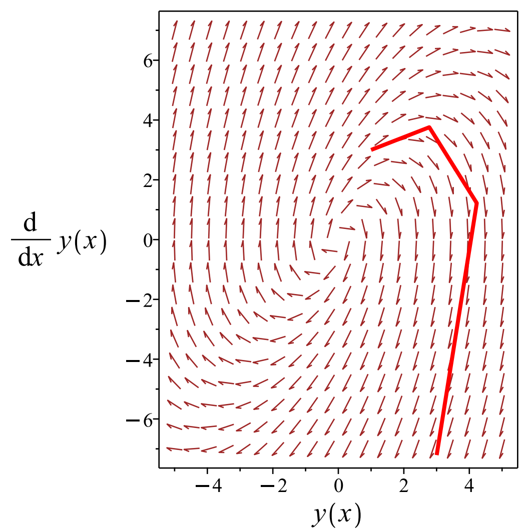
Summary

The solution(s) found are the following

$$y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) e^{x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) e^{x}$$

Verified OK.

15.13.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -2z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 388: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos\left(\sqrt{2}\, x\right)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1 (\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x} \cos\left(\sqrt{2}\, x\right)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\frac{\sqrt{2}\,\tan\left(\sqrt{2}\, x\right)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{x} \cos\left(\sqrt{2}\, x\right)\right) + c_2\left(\mathrm{e}^{x} \cos\left(\sqrt{2}\, x\right) \left(\frac{\sqrt{2}\,\tan\left(\sqrt{2}\, x\right)}{2}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{x} \cos\left(\sqrt{2}\, x\right) + \frac{c_2 \sqrt{2}\,\mathrm{e}^{x} \sin\left(\sqrt{2}\, x\right)}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$y' = c_1 e^x \cos\left(\sqrt{2}\, x\right) - c_1 e^x \sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \frac{c_2 \sqrt{2}\, e^x \sin\left(\sqrt{2}\, x\right)}{2} + c_2 e^x \cos\left(\sqrt{2}\, x\right)$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$3 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = \sqrt{2}\, e^x \sin\left(\sqrt{2}\, x\right) + e^x \cos\left(\sqrt{2}\, x\right)$$

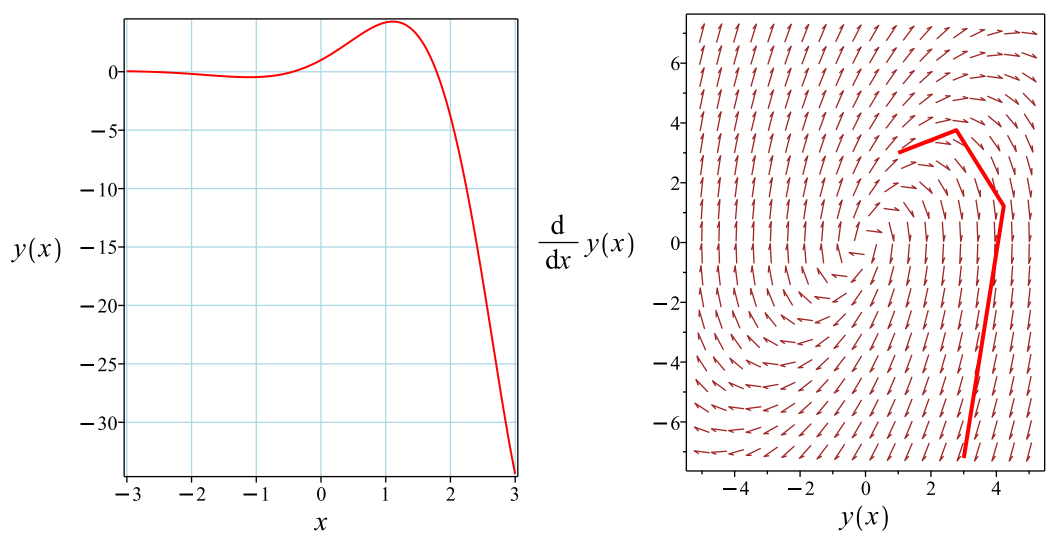
Which simplifies to

$$y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) e^x$$

Summary

The solution(s) found are the following

$$y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) e^x \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) e^{x}$$

Verified OK.

15.13.4 Maple step by step solution

Let's solve

$\left[y'' - 2y' + 3y = 0, y(0) = 1, y'\Big|_{\{x=0\}} = 3\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 2r + 3 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-8})}{2}$

- Roots of the characteristic polynomial

  $r = \left(1 - \mathrm{I}\sqrt{2}, 1 + \mathrm{I}\sqrt{2}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{x} \cos\left(\sqrt{2}\, x\right)$

- 2nd solution of the ODE

  $y_2(x) = e^{x} \sin\left(\sqrt{2}\, x\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{x} \cos\left(\sqrt{2}\, x\right) + e^{x} \sin\left(\sqrt{2}\, x\right) c_2$

□ Check validity of solution $y = c_1 e^{x} \cos\left(\sqrt{2}\, x\right) + e^{x} \sin\left(\sqrt{2}\, x\right) c_2$

- ○ Use initial condition $y(0) = 1$

  $1 = c_1$

- ○ Compute derivative of the solution

  $y' = c_1 e^{x} \cos\left(\sqrt{2}\, x\right) - c_1 e^{x} \sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + e^{x} \sin\left(\sqrt{2}\, x\right) c_2 + e^{x} \sqrt{2}\, \cos\left(\sqrt{2}\, x\right) c_2$

- Use the initial condition $y'\Big|_{\{x=0\}} = 3$

  $3 = c_1 + \sqrt{2}\, c_2$
- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = \sqrt{2}\}$
- Substitute constant values into general solution and simplify

  $y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) \mathrm{e}^{x}$

• Solution to the IVP

  $y = \left(\sqrt{2}\, \sin\left(\sqrt{2}\, x\right) + \cos\left(\sqrt{2}\, x\right)\right) \mathrm{e}^{x}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 445.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + 2y''' + 4y'' - 2y' - 5y = 0}$$

The characteristic equation is

$$\lambda^4 + 2\lambda^3 + 4\lambda^2 - 2\lambda - 5 = 0$$

The roots of the above equation are

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -1\\ \lambda_3 &= -1 - 2i\\ \lambda_4 &= -1 + 2i\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + \mathrm{e}^{x} c_2 + \mathrm{e}^{(-1+2i)x} c_3 + \mathrm{e}^{(-1-2i)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{(-1+2i)x}$$
$$y_4 = e^{(-1-2i)x}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + e^{x} c_2 + e^{(-1+2i)x} c_3 + e^{(-1-2i)x} c_4 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + e^{x} c_2 + e^{(-1+2i)x} c_3 + e^{(-1-2i)x} c_4$$

Verified OK.

15.14.1 Maple step by step solution

Let's solve

$y'''' + 2y''' + 4y'' - 2y' - 5y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -2y_4(x) - 4y_3(x) + 2y_2(x) + 5y_1(x)$

    Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -2y_4(x) - 4y_3(x) + 2y_2(x) + 5y_1(x)]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 5 & 2 & -4 & -2 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 5 & 2 & -4 & -2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-1-2\,\mathrm{I}, \begin{bmatrix} \frac{11}{125} - \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} - \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} + \frac{2\,\mathrm{I}}{5} \\ 1 \end{bmatrix}\right], \left[-1+2\,\mathrm{I}, \begin{bmatrix} \frac{11}{125} + \frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25} + \frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5} - \frac{2\,\mathrm{I}}{5} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_{1} = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_{2} = \mathrm{e}^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1-2\,\mathrm{I}, \left[\begin{array}{c} \frac{11}{125}-\frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25}-\frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5}+\frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{(-1-2\,\mathrm{I})x} \cdot \left[\begin{array}{c} \frac{11}{125}-\frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25}-\frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5}+\frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-x} \cdot \left(\cos(2x) - \mathrm{I}\sin(2x)\right) \cdot \left[\begin{array}{c} \frac{11}{125}-\frac{2\,\mathrm{I}}{125} \\ -\frac{3}{25}-\frac{4\,\mathrm{I}}{25} \\ -\frac{1}{5}+\frac{2\,\mathrm{I}}{5} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{-x} \cdot \left[\begin{array}{c} \left(\frac{11}{125}-\frac{2\,\mathrm{I}}{125}\right)\left(\cos(2x) - \mathrm{I}\sin(2x)\right) \\ \left(-\frac{3}{25}-\frac{4\,\mathrm{I}}{25}\right)\left(\cos(2x) - \mathrm{I}\sin(2x)\right) \\ \left(-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\right)\left(\cos(2x) - \mathrm{I}\sin(2x)\right) \\ \cos(2x) - \mathrm{I}\sin(2x) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = e^{-x} \cdot \left[\begin{array}{c} \frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125} \\ -\frac{3\cos(2x)}{25}-\frac{4\sin(2x)}{25} \\ -\frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5} \\ \cos(2x) \end{array}\right], \vec{y}_4(x) = e^{-x} \cdot \left[\begin{array}{c} -\frac{11\sin(2x)}{125}-\frac{2\cos(2x)}{125} \\ \frac{3\sin(2x)}{25}-\frac{4\cos(2x)}{25} \\ \frac{\sin(2x)}{5}+\frac{2\cos(2x)}{5} \\ -\sin(2x) \end{array}\right]\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-x} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right] + e^{x} c_2 \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right] + c_3 e^{-x} \cdot \left[\begin{array}{c} \frac{11\cos(2x)}{125}-\frac{2\sin(2x)}{125} \\ -\frac{3\cos(2x)}{25}-\frac{4\sin(2x)}{25} \\ -\frac{\cos(2x)}{5}+\frac{2\sin(2x)}{5} \\ \cos(2x) \end{array}\right] + c_4 e^{-x} \cdot \left[\begin{array}{c} -\frac{11\sin(2x)}{125}-2\mathrm{c}\ldots \\ \frac{3\sin(2x)}{25}-4\cos\ldots \\ \frac{\sin(2x)}{5}+2\cos(\ldots \\ -\sin(2x) \end{array}\right.$$

- First component of the vector is the solution to the ODE

$$y = \frac{((11c_3-2c_4)\cos(2x)+(-2c_3-11c_4)\sin(2x)-125c_1)\,\mathrm{e}^{-x}}{125} + \mathrm{e}^x c_2$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 446.
ODE order: 5.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y^{(5)}+4y''''+5y'''-6y'-4y=0}$$

The characteristic equation is

$$\lambda^5+4\lambda^4+5\lambda^3-6\lambda-4=0$$

The roots of the above equation are

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -2\\ \lambda_3 &= -1\\ \lambda_4 &= -1-i\\ \lambda_5 &= -1+i\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x)=c_1\mathrm{e}^{-x}+\mathrm{e}^{-2x}c_2+\mathrm{e}^{x}c_3+\mathrm{e}^{(-1+i)x}c_4+\mathrm{e}^{(-1-i)x}c_5$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= \mathrm{e}^{-2x} \\
y_3 &= \mathrm{e}^{x} \\
y_4 &= \mathrm{e}^{(-1+i)x} \\
y_5 &= \mathrm{e}^{(-1-i)x}
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-2x} c_2 + \mathrm{e}^{x} c_3 + \mathrm{e}^{(-1+i)x} c_4 + \mathrm{e}^{(-1-i)x} c_5 \tag{1}
$$

Verification of solutions

$$
y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{-2x} c_2 + \mathrm{e}^{x} c_3 + \mathrm{e}^{(-1+i)x} c_4 + \mathrm{e}^{(-1-i)x} c_5
$$

Verified OK.

15.15.1 Maple step by step solution

Let's solve

$y^{(5)} + 4y'''' + 5y''' - 6y' - 4y = 0$

- Highest derivative means the order of the ODE is 5

  $y^{(5)}$

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Define new variable $y_5(x)$

    $y_5(x) = y''''$

- Isolate for $y_5'(x)$ using original ODE

  $y_5'(x) = -4y_5(x) - 5y_4(x) + 6y_2(x) + 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_5(x) = y_4'(x), y_5'(x) = -4y_5(x) - 5y_4(x) + 6y_2(x)$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \\ y_5(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 4 & 6 & 0 & -5 & -4 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 4 & 6 & 0 & -5 & -4 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \left[\begin{array}{c}\frac{1}{16}\\ -\frac{1}{8}\\ \frac{1}{4}\\ -\frac{1}{2}\\ 1\end{array}\right]\right], \left[-1, \left[\begin{array}{c}1\\ -1\\ 1\\ -1\\ 1\end{array}\right]\right], \left[1, \left[\begin{array}{c}1\\ 1\\ 1\\ 1\\ 1\end{array}\right]\right], \left[-1-\mathrm{I}, \left[\begin{array}{c}-\frac{1}{4}\\ \frac{1}{4}+\frac{\mathrm{I}}{4}\\ -\frac{\mathrm{I}}{2}\\ -\frac{1}{2}+\frac{\mathrm{I}}{2}\\ 1\end{array}\right]\right], \left[-1+\mathrm{I}, \left[\begin{array}{c}-\frac{1}{4}\\ \frac{1}{4}-\frac{\mathrm{I}}{4}\\ \frac{\mathrm{I}}{2}\\ -\frac{1}{2}-\frac{\mathrm{I}}{2}\\ 1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c}\frac{1}{16}\\ -\frac{1}{8}\\ \frac{1}{4}\\ -\frac{1}{2}\\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-2x} \cdot \left[\begin{array}{c}\frac{1}{16}\\ -\frac{1}{8}\\ \frac{1}{4}\\ -\frac{1}{2}\\ 1\end{array}\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c}1\\ -1\\ 1\\ -1\\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-1 - I, \begin{bmatrix} -\frac{1}{4} \\ \frac{1}{4} + \frac{I}{4} \\ -\frac{I}{2} \\ -\frac{1}{2} + \frac{I}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{(-1-I)x} \cdot \begin{bmatrix} -\frac{1}{4} \\ \frac{1}{4}+\frac{I}{4} \\ -\frac{I}{2} \\ -\frac{1}{2}+\frac{I}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{-x} \cdot (\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -\frac{1}{4} \\ \frac{1}{4}+\frac{I}{4} \\ -\frac{I}{2} \\ -\frac{1}{2}+\frac{I}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-x} \cdot \begin{bmatrix} -\frac{\cos(x)}{4}+\frac{I\sin(x)}{4} \\ \left(\frac{1}{4}+\frac{I}{4}\right)(\cos(x) - I\sin(x)) \\ -\frac{I}{2}(\cos(x) - I\sin(x)) \\ \left(-\frac{1}{2}+\frac{I}{2}\right)(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_4(x) = e^{-x} \cdot \begin{bmatrix} -\frac{\cos(x)}{4} \\ \frac{\cos(x)}{4}+\frac{\sin(x)}{4} \\ -\frac{\sin(x)}{2} \\ -\frac{\cos(x)}{2}+\frac{\sin(x)}{2} \\ \cos(x) \end{bmatrix}, \vec{y}_5(x) = e^{-x} \cdot \begin{bmatrix} \frac{\sin(x)}{4} \\ \frac{\cos(x)}{4}-\frac{\sin(x)}{4} \\ -\frac{\cos(x)}{2} \\ \frac{\sin(x)}{2}+\frac{\cos(x)}{2} \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + c_4\vec{y}_4(x) + c_5\vec{y}_5(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-2x} \cdot \begin{bmatrix} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + e^{-x} c_2 \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + e^{x} c_3 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + c_4 e^{-x} \cdot \begin{bmatrix} -\frac{\cos(x)}{4} \\ \frac{\cos(x)}{4} + \frac{\sin(x)}{4} \\ -\frac{\sin(x)}{2} \\ -\frac{\cos(x)}{2} + \frac{\sin(x)}{2} \\ \cos(x) \end{bmatrix} + c_5 e^{-x} \cdot \Bigg[$$

- First component of the vector is the solution to the ODE

$$y = \left(e^{3x} c_3 + \left(-\frac{\cos(x) c_4}{4} + \frac{\sin(x) c_5}{4} + c_2\right) e^{x} + \frac{c_1}{16}\right) e^{-2x}$$

$$y_2 = \mathrm{e}^{x}$$
$$y_3 = \mathrm{e}^{ix}$$
$$y_4 = \mathrm{e}^{-ix}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{x} c_2 + \mathrm{e}^{ix} c_3 + \mathrm{e}^{-ix} c_4 \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{x} c_2 + \mathrm{e}^{ix} c_3 + \mathrm{e}^{-ix} c_4$$

Verified OK.

15.18.1 Maple step by step solution

Let's solve

$y'''' - y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \mathrm{e}^{x} c_2 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -c_3\sin(x) - \cos(x)\,c_4 \\ -\cos(x)\,c_3 + \sin(x)\,c_4 \\ c_3\sin(x) + \cos(x)\,c_4 \\ \cos(x)\,c_3 - \sin(x)\,c_4 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -c_1\mathrm{e}^{-x} + \mathrm{e}^{x}c_2 - \cos(x)\,c_4 - c_3\sin(x)$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 450.
ODE order: 5.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _quadrature]]
```

$$\boxed{y^{(5)} = 0}$$

The characteristic equation is

$$\lambda^5 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$
$$\lambda_5 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_5x^4 + c_4x^3 + c_3x^2 + c_2x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$
$$y_4 = x^3$$
$$y_5 = x^4$$

Summary

The solution(s) found are the following

$$y = c_5 x^4 + c_4 x^3 + c_3 x^2 + c_2 x + c_1 \tag{1}$$

Verification of solutions

$$y = c_5 x^4 + c_4 x^3 + c_3 x^2 + c_2 x + c_1$$

Verified OK.

15.19.1 Maple step by step solution

Let's solve

$y^{(5)} = 0$

- Highest derivative means the order of the ODE is 5

  $y^{(5)}$

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Define new variable $y_4(x)$

    $y_4(x) = y'''$

  - Define new variable $y_5(x)$

    $y_5(x) = y''''$

- Isolate for $y_5'(x)$ using original ODE

  $y_5'(x) = 0$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_5(x) = y_4'(x), y_5'(x) = 0]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \\ y_5(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right], \left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix}1\\0\\0\\0\\0\end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix}0\\0\\0\\0\\0\end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, & \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, & \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_4 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, & \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_5 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + c_4 \vec{y}_4 + c_5 \vec{y}_5$$

- Substitute solutions into the general solution

$$\vec{y} = \begin{bmatrix} c_1 \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = c_1$$

Verified OK.

15.20.1 Maple step by step solution

Let's solve

$y''' - 3y' - 2y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 3y_2(x) + 2y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 3y_2(x) + 2y_1(x)]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & 3 & 0 \end{bmatrix} \cdot \overrightarrow{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & 3 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue -1

$$\overrightarrow{y}_1(x) = \mathrm{e}^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, a

$$\overrightarrow{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x}A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

  $\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v}+\overrightarrow{p}\right)+\mathrm{e}^{\lambda x}\overrightarrow{v}=\mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v}+A\cdot\overrightarrow{p}\right)$

- Simplify equation

  $\lambda\overrightarrow{p}+\overrightarrow{v}=A\cdot\overrightarrow{p}$

- Make use of the identity matrix I

  $(\lambda\cdot I)\cdot\overrightarrow{p}+\overrightarrow{v}=A\cdot\overrightarrow{p}$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

  $(A-\lambda\cdot I)\cdot\overrightarrow{p}=\overrightarrow{v}$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

  $$\left(\left[\begin{array}{ccc}0 & 1 & 0\\ 0 & 0 & 1\\ 2 & 3 & 0\end{array}\right]-(-1)\cdot\left[\begin{array}{ccc}1 & 0 & 0\\ 0 & 1 & 0\\ 0 & 0 & 1\end{array}\right]\right)\cdot\overrightarrow{p}=\left[\begin{array}{c}1\\ -1\\ 1\end{array}\right]$$

- Choice of $\overrightarrow{p}$

  $$\overrightarrow{p}=\left[\begin{array}{c}1\\ 0\\ 0\end{array}\right]$$

- Second solution from eigenvalue -1

  $$\overrightarrow{y}_2(x)=\mathrm{e}^{-x}\cdot\left(x\cdot\left[\begin{array}{c}1\\ -1\\ 1\end{array}\right]+\left[\begin{array}{c}1\\ 0\\ 0\end{array}\right]\right)$$

- Consider eigenpair

  $$\left[2,\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

  $$\overrightarrow{y}_3=\mathrm{e}^{2x}\cdot\left[\begin{array}{c}\frac{1}{4}\\ \frac{1}{2}\\ 1\end{array}\right]$$

- General solution to the system of ODEs

  $\overrightarrow{y} = c_1 \overrightarrow{y}_1(x) + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3$
- Substitute solutions into the general solution

$$\overrightarrow{y} = c_1 e^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + e^{-x} c_2 \cdot \left(x \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix} \right) + e^{2x} c_3 \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$
- First component of the vector is the solution to the ODE

  $y = ((x+1) c_2 + c_1) e^{-x} + \frac{e^{2x} c_3}{4}$

Maple trace

$$y = c_1 + e^x c_2 + e^{\frac{x}{2}} c_3 \tag{1}$$

Verification of solutions

$$y = c_1 + e^x c_2 + e^{\frac{x}{2}} c_3$$

Verified OK.

15.21.1 Maple step by step solution

Let's solve

$2y''' - 3y'' + y' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = \frac{3y''}{2} - \frac{y'}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' - \frac{3y''}{2} + \frac{y'}{2} = 0$

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = \frac{3y_3(x)}{2} - \frac{y_2(x)}{2}$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \frac{3y_3(x)}{2} - \frac{y_2(x)}{2}\right]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -\frac{1}{2} & \frac{3}{2} \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -\frac{1}{2} & \frac{3}{2} \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[\frac{1}{2}, \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[\frac{1}{2}, \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \mathrm{e}^{\frac{x}{2}} \cdot \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{y} = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3$$

- Substitute solutions into the general solution

$$\overrightarrow{y} = c_2 \mathrm{e}^{\frac{x}{2}} \cdot \begin{bmatrix} 4 \\ 2 \\ 1 \end{bmatrix} + \mathrm{e}^{x} c_3 \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_1 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = 4 c_2 \mathrm{e}^{\frac{x}{2}} + \mathrm{e}^{x} c_3 + c_1$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.2 Homogeneous differential equations with constant coefficients. Exercises page 121
Problem number: 453.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + y'' = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 0, y''(0) = 1]$$

The characteristic equation is

$$\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = e^{-x}c_1 + c_2 + c_3 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= 1 \\
y_3 &= x
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \mathrm{e}^{-x} c_1 + c_2 + c_3 x \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 + c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -\mathrm{e}^{-x} c_1 + c_3
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = -c_1 + c_3 \tag{2A}
$$

Taking two derivatives of the solution gives

$$
y'' = \mathrm{e}^{-x} c_1
$$

substituting $y'' = 1$ and $x = 0$ in the above gives

$$
1 = c_1 \tag{3A}
$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= 0 \\
c_3 &= 1
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \mathrm{e}^{-x} + x
$$

Summary

The solution(s) found are the following

$$y = e^{-x} + x \tag{1}$$

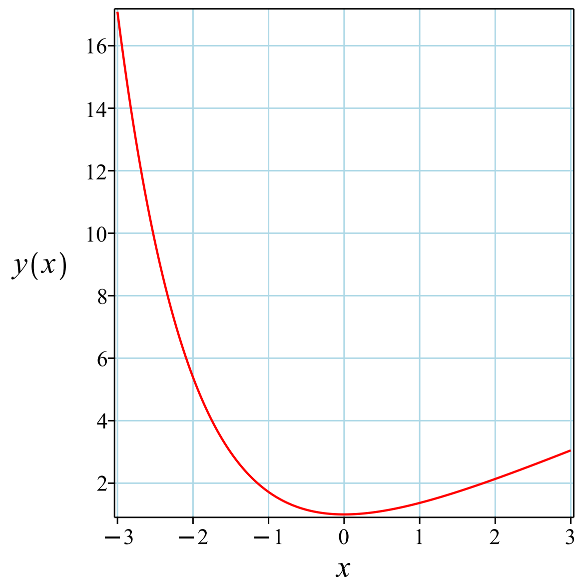

Figure 490: Solution plot

Verification of solutions

$$y = e^{-x} + x$$

Verified OK.

15.22.1 Maple step by step solution

Let's solve

$\left[y''' + y'' = 0, y(0) = 1, y'\Big|_{\{x=0\}} = 0, y''\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ∘ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ∘ Define new variable $y_2(x)$

$y_2(x) = y'$

- Define new variable $y_3(x)$

  $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = -y_3(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = -y_3(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 0 & -1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 0 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \left[\begin{array}{c} 0 \\ 0 \\ 0 \end{array}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = e^{-x} c_1 \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_2 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = e^{-x} c_1 + c_2$

- Use the initial condition $y(0) = 1$

  $1 = c_1 + c_2$

- Calculate the 1st derivative of the solution

  $y' = -e^{-x} c_1$

- Use the initial condition $y'\Big|_{\{x=0\}} = 0$

  $0 = -c_1$

- Calculate the 2nd derivative of the solution

  $y'' = e^{-x} c_1$

- Use the initial condition $y''\Big|_{\{x=0\}} = 1$

  $1 = c_1$

- Solve for the unknown coefficients
- The solution does not satisfy the initial conditions

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 3y' = 3}$$

16.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 0, f(x) = 3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+3y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=3, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x}+3\lambda\, e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+3\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=3, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-3}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{3^2-(4)(1)(0)}\\&=-\frac{3}{2}\pm\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{3}{2}+\frac{3}{2}\\\lambda_2&=-\frac{3}{2}-\frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-3\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-3)x}\end{aligned}$$

Or

$$y = c_1 + c_2 e^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-3x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 = 3$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + c_2 e^{-3x}\right) + (x)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 + c_2 e^{-3x} + x \tag{1}
$$

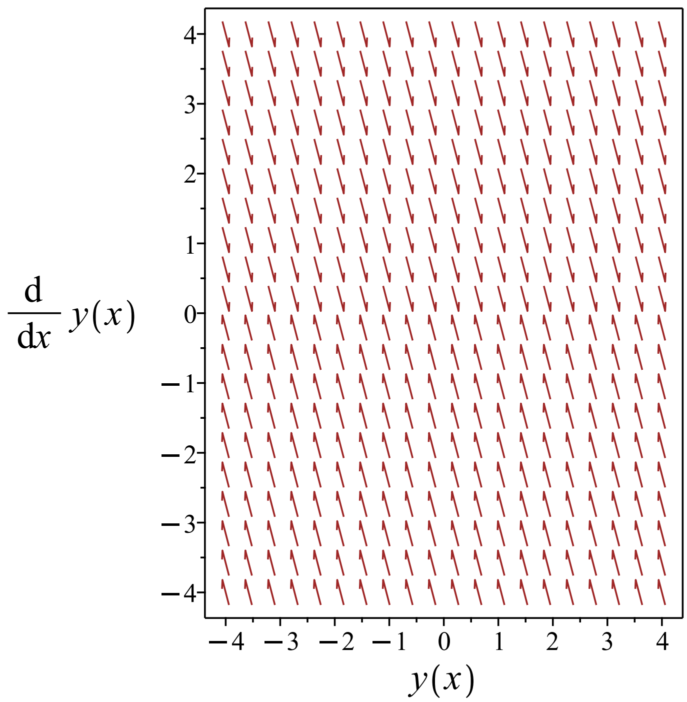

Figure 491: Slope field plot

Verification of solutions

$$
y = c_1 + c_2 e^{-3x} + x
$$

Verified OK.

16.1.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y''+3y')\,dx = \int 3dx$$
$$3y+y' = 3x+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = 3$$
$$q(x) = 3x+c_1$$

Hence the ode is

$$3y+y' = 3x+c_1$$

The integrating factor μ is

$$\mu = e^{\int 3dx}$$
$$= e^{3x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(3x+c_1)$$
$$\frac{d}{dx}(e^{3x}y) = (e^{3x})(3x+c_1)$$
$$d(e^{3x}y) = ((3x+c_1)e^{3x})\,dx$$

Integrating gives

$$e^{3x}y = \int (3x+c_1)e^{3x}\,dx$$
$$e^{3x}y = \frac{(3x+c_1-1)e^{3x}}{3}+c_2$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$y = \frac{e^{-3x}(3x+c_1-1)e^{3x}}{3}+c_2e^{-3x}$$

which simplifies to

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 e^{-3x}$$

Summary

The solution(s) found are the following

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 e^{-3x} \tag{1}$$

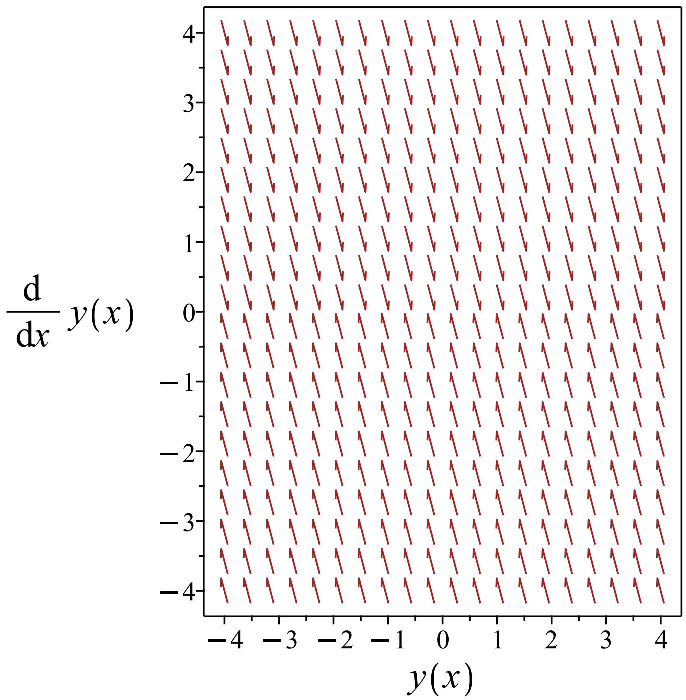

Figure 492: Slope field plot

Verification of solutions

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 e^{-3x}$$

Verified OK.

16.1.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 3p(x) - 3 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{-3p+3} dp = \int dx$$
$$-\frac{\ln(-p+1)}{3} = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{(-p+1)^{\frac{1}{3}}} = \mathrm{e}^{x+c_1}$$

Which simplifies to

$$\frac{1}{(-p+1)^{\frac{1}{3}}} = \mathrm{e}^{x} c_2$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{\mathrm{e}^{-3x}}{c_2^3} + 1$$

Integrating both sides gives

$$y = \int \frac{(\mathrm{e}^{3x} c_2^3 - 1)\,\mathrm{e}^{-3x}}{c_2^3} \mathrm{d}x$$
$$= \frac{\mathrm{e}^{-3x}}{3c_2^3} + \ln(\mathrm{e}^{x}) + c_3$$

Summary
The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-3x}}{3c_2^3} + \ln(\mathrm{e}^{x}) + c_3 \tag{1}$$

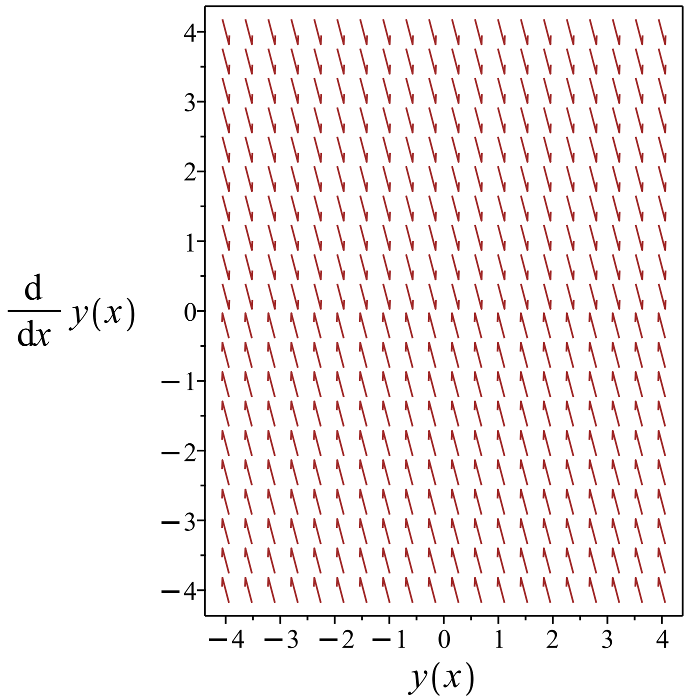

Figure 493: Slope field plot

Verification of solutions

$$y = \frac{e^{-3x}}{3c_2^3} + \ln(e^x) + c_3$$

Verified OK.

16.1.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 3y' = 3$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 3y')\, dx = \int 3dx$$

$$3y + y' = 3x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 3\\ q(x) &= 3x + c_1\end{aligned}$$

Hence the ode is

$$3y + y' = 3x + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 3dx}\\ &= e^{3x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(3x + c_1)\\ \frac{d}{dx}\left(e^{3x}y\right) &= \left(e^{3x}\right)(3x + c_1)\\ d\left(e^{3x}y\right) &= \left((3x + c_1)e^{3x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{3x}y &= \int (3x + c_1)e^{3x}\, dx\\ e^{3x}y &= \frac{(3x + c_1 - 1)e^{3x}}{3} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$y = \frac{e^{-3x}(3x + c_1 - 1)e^{3x}}{3} + c_2e^{-3x}$$

which simplifies to

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2e^{-3x}$$

Summary

The solution(s) found are the following

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2e^{-3x} \tag{1}$$

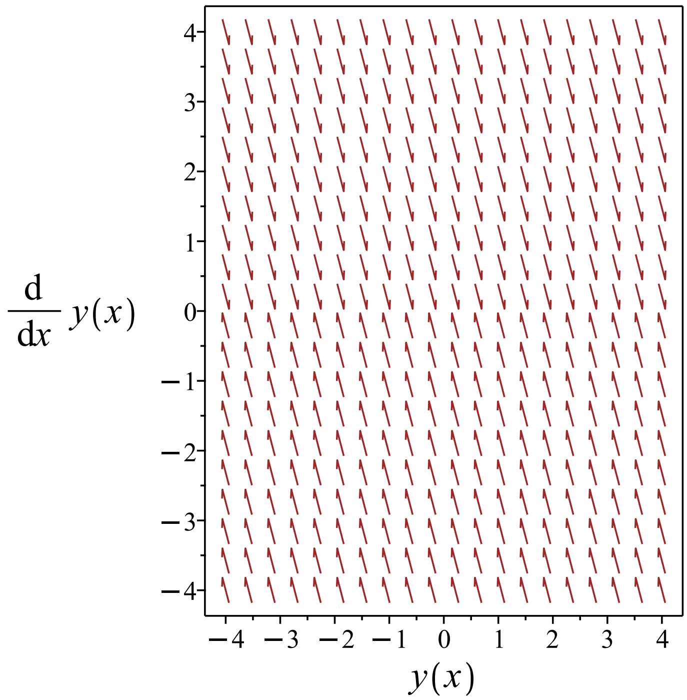

Figure 494: Slope field plot

Verification of solutions

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 e^{-3x}$$

Verified OK.

16.1.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 399: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\ &= z_1 e^{-\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 3y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-3x} + \frac{c_2}{3}
$$

Now we need to find the particular solution y_p to

$$
y'' + 3y' = 3
$$

Since the RHS of the ode $f(x)$ is a constant, because it does not depend on x, then let the particular solution be

$$
y_p = kx
$$

where k is a constant to be determined. Substituting $y = kx$ in the ODE gives

$$
3k = 3
$$

Therefore

$$
k = x
$$

Hence $y_p = x^2$. Therefore the complete solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= c_1 \mathrm{e}^{-3x} + \frac{c_2}{3} + (x)
\end{aligned}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{-3x} + \frac{c_2}{3}\right) + (x)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-3x} + \frac{c_2}{3} + x \tag{1}
$$

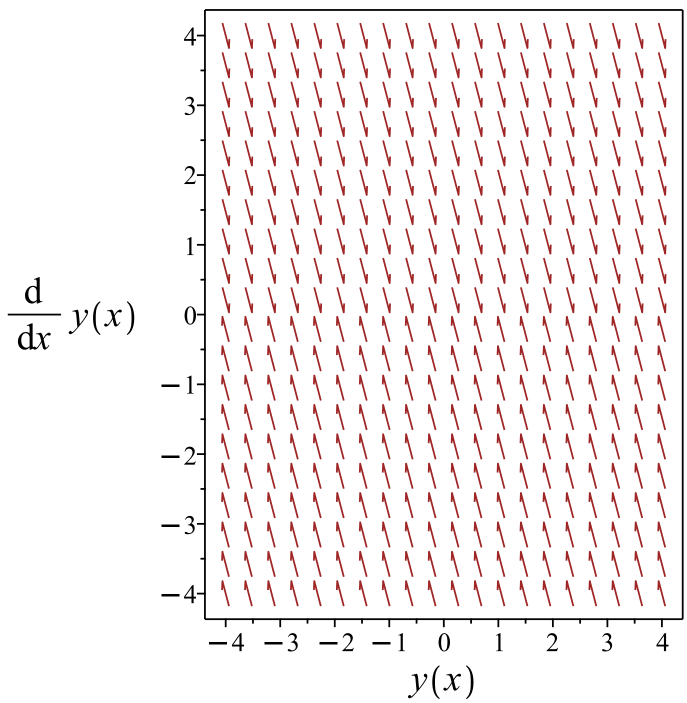

Figure 495: Slope field plot

Verification of solutions

$$
y = c_1 e^{-3x} + \frac{c_2}{3} + x
$$

Verified OK.

16.1.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1\\
q(x) &= 3\\
r(x) &= 0\\
s(x) &= 3
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0\\
q'(x) &= 0
\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$3y + y' = \int 3\,dx$$

We now have a first order ode to solve which is

$$3y + y' = 3x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= 3 \\
q(x) &= 3x + c_1
\end{aligned}$$

Hence the ode is

$$3y + y' = 3x + c_1$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int 3dx} \\
&= e^{3x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)(3x + c_1) \\
\frac{d}{dx}\left(e^{3x}y\right) &= \left(e^{3x}\right)(3x + c_1) \\
d\left(e^{3x}y\right) &= \left((3x + c_1)e^{3x}\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^{3x}y &= \int (3x + c_1)e^{3x}\, dx \\
e^{3x}y &= \frac{(3x + c_1 - 1)e^{3x}}{3} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$y = \frac{e^{-3x}(3x + c_1 - 1)e^{3x}}{3} + c_2 e^{-3x}$$

which simplifies to

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 e^{-3x}$$

Summary

The solution(s) found are the following

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 e^{-3x} \tag{1}$$

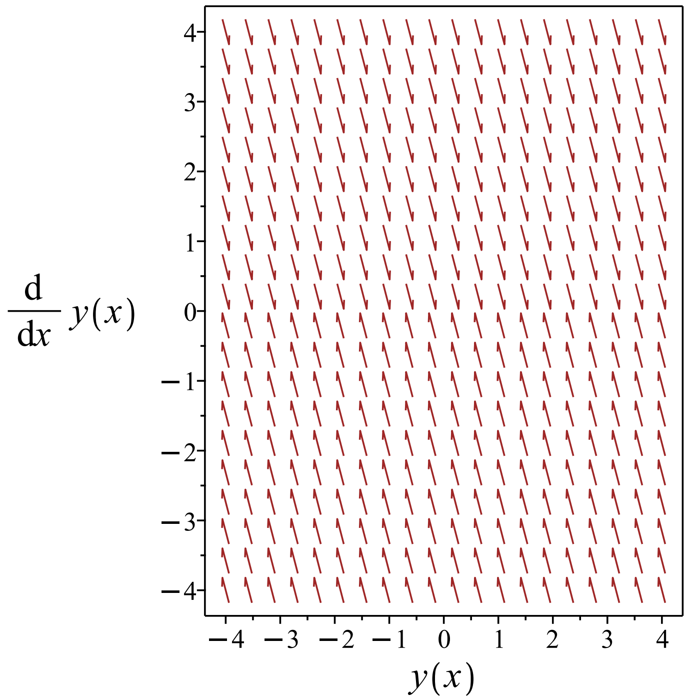

Figure 496: Slope field plot

Verification of solutions

$$y = x + \frac{c_1}{3} - \frac{1}{3} + c_2 \mathrm{e}^{-3x}$$

Verified OK.

16.1.7 Maple step by step solution

Let's solve

$y'' + 3y' = 3$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r = 0$

- Factor the characteristic polynomial

  $r(r + 3) = 0$

- Roots of the characteristic polynomial

$r = (-3, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 3\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & 1 \\ -3\,\mathrm{e}^{-3x} & 0 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3\,\mathrm{e}^{-3x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\mathrm{e}^{-3x} \left(\int \mathrm{e}^{3x} dx\right) + \int 1 dx$

  - Compute integrals

    $y_p(x) = -\frac{1}{3} + x$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 - \frac{1}{3} + x$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 7y' = (x-1)^2}$$

16.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -7, C = 0, f(x) = (x-1)^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 7y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -7, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 7\lambda\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 7\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -7, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{7}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-7^2 - (4)\,(1)\,(0)}\\ &= \frac{7}{2} \pm \frac{7}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{7}{2} + \frac{7}{2}$$
$$\lambda_2 = \frac{7}{2} - \frac{7}{2}$$

Which simplifies to

$$\lambda_1 = 7$$
$$\lambda_2 = 0$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(7)x} + c_2 e^{(0)x}$$

Or

$$y = c_1 e^{7x} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{7x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{7x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2, x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_3 x^3 + A_2 x^2 + A_1 x$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-21x^2 A_3 - 14x A_2 + 6x A_3 - 7A_1 + 2A_2 = (x-1)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{37}{343}, A_2 = \frac{6}{49}, A_3 = -\frac{1}{21}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{21}x^3 + \frac{6}{49}x^2 - \frac{37}{343}x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{7x} + c_2) + \left(-\frac{1}{21}x^3 + \frac{6}{49}x^2 - \frac{37}{343}x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{7x} + c_2 - \frac{x^3}{21} + \frac{6x^2}{49} - \frac{37x}{343} \tag{1}$$

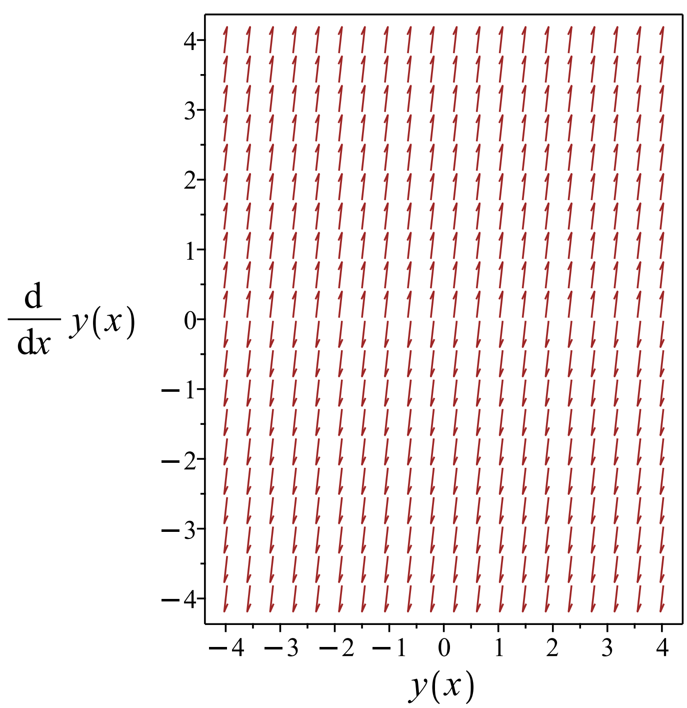

Figure 497: Slope field plot

Verification of solutions

$$y = c_1 e^{7x} + c_2 - \frac{x^3}{21} + \frac{6x^2}{49} - \frac{37x}{343}$$

Verified OK.

16.2.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y''-7y')\,dx = \int (x-1)^2\,dx$$
$$-7y+y' = \frac{(x-1)^3}{3}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = -7$$
$$q(x) = \frac{1}{3}x^3-x^2+x-\frac{1}{3}+c_1$$

Hence the ode is

$$-7y+y' = \frac{1}{3}x^3-x^2+x-\frac{1}{3}+c_1$$

The integrating factor μ is

$$\mu = e^{\int (-7)dx}$$
$$= e^{-7x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{1}{3}x^3-x^2+x-\frac{1}{3}+c_1\right)$$
$$\frac{d}{dx}\left(e^{-7x}y\right) = \left(e^{-7x}\right)\left(\frac{1}{3}x^3-x^2+x-\frac{1}{3}+c_1\right)$$
$$d\left(e^{-7x}y\right) = \left(\frac{(x^3-3x^2+3c_1+3x-1)\,e^{-7x}}{3}\right)\,dx$$

Integrating gives

$$e^{-7x}y = \int \frac{(x^3-3x^2+3c_1+3x-1)\,e^{-7x}}{3}\,dx$$
$$e^{-7x}y = -\frac{(343x^3-882x^2+1029c_1+777x-232)\,e^{-7x}}{7203}+c_2$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-7x}$ results in

$$y = -\frac{\mathrm{e}^{7x}(343x^3 - 882x^2 + 1029c_1 + 777x - 232)\,\mathrm{e}^{-7x}}{7203} + c_2\mathrm{e}^{7x}$$

which simplifies to

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2\mathrm{e}^{7x}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2\mathrm{e}^{7x} \tag{1}$$

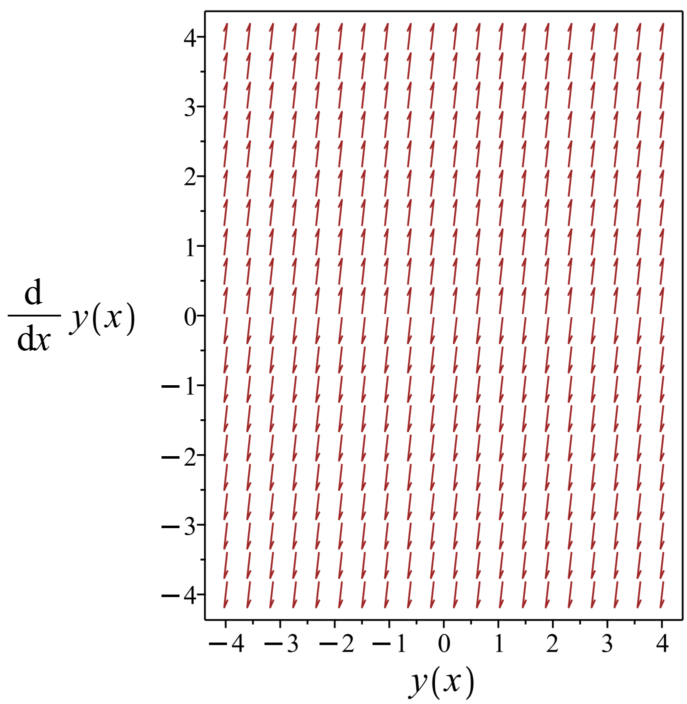

Figure 498: Slope field plot

Verification of solutions

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2\mathrm{e}^{7x}$$

Verified OK.

16.2.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 7p(x) - (x-1)^2 = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -7 \\ q(x) &= (x-1)^2 \end{aligned}$$

Hence the ode is

$$p'(x) - 7p(x) = (x-1)^2$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-7)dx} \\ &= e^{-7x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left((x-1)^2\right) \\ \frac{d}{dx}\left(e^{-7x}p\right) &= \left(e^{-7x}\right)\left((x-1)^2\right) \\ d\left(e^{-7x}p\right) &= \left((x-1)^2 e^{-7x}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-7x}p &= \int (x-1)^2 e^{-7x} dx \\ e^{-7x}p &= -\frac{(49x^2 - 84x + 37) e^{-7x}}{343} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-7x}$ results in

$$p(x) = -\frac{e^{7x}(49x^2 - 84x + 37)\,e^{-7x}}{343} + c_1 e^{7x}$$

which simplifies to

$$p(x) = -\frac{x^2}{7} + \frac{12x}{49} - \frac{37}{343} + c_1 e^{7x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{x^2}{7} + \frac{12x}{49} - \frac{37}{343} + c_1 e^{7x}$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{x^2}{7} + \frac{12x}{49} - \frac{37}{343} + c_1 e^{7x}\, dx \\ &= \frac{6x^2}{49} - \frac{37x}{343} - \frac{x^3}{21} + \frac{c_1 e^{7x}}{7} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{6x^2}{49} - \frac{37x}{343} - \frac{x^3}{21} + \frac{c_1 e^{7x}}{7} + c_2 \tag{1}$$

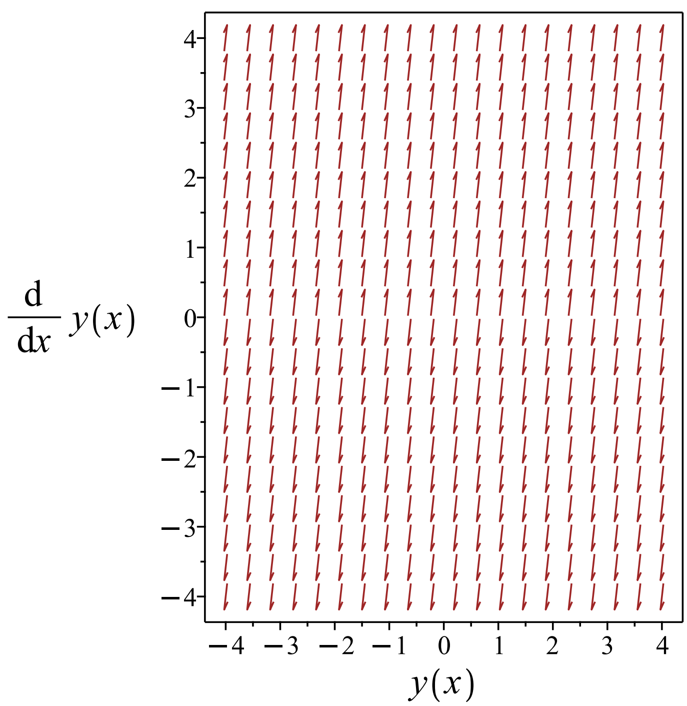

Figure 499: Slope field plot

Verification of solutions

$$y = \frac{6x^2}{49} - \frac{37x}{343} - \frac{x^3}{21} + \frac{c_1 e^{7x}}{7} + c_2$$

Verified OK.

16.2.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 7y' = (x-1)^2$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 7y')\, dx = \int (x-1)^2\, dx$$

$$-7y + y' = \frac{(x-1)^3}{3} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -7$$
$$q(x) = \frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1$$

Hence the ode is

$$-7y + y' = \frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1$$

The integrating factor μ is

$$\mu = e^{\int (-7)dx}$$
$$= e^{-7x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1\right)$$
$$\frac{d}{dx}\left(e^{-7x} y\right) = \left(e^{-7x}\right)\left(\frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1\right)$$
$$d\left(e^{-7x} y\right) = \left(\frac{(x^3 - 3x^2 + 3c_1 + 3x - 1)\, e^{-7x}}{3}\right) dx$$

Integrating gives

$$e^{-7x}y = \int \frac{(x^3 - 3x^2 + 3c_1 + 3x - 1)\, e^{-7x}}{3}\, dx$$

$$e^{-7x}y = -\frac{(343x^3 - 882x^2 + 1029c_1 + 777x - 232)\, e^{-7x}}{7203} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-7x}$ results in

$$y = -\frac{e^{7x}(343x^3 - 882x^2 + 1029c_1 + 777x - 232)\, e^{-7x}}{7203} + c_2 e^{7x}$$

which simplifies to

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2 e^{7x}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2 e^{7x} \tag{1}$$

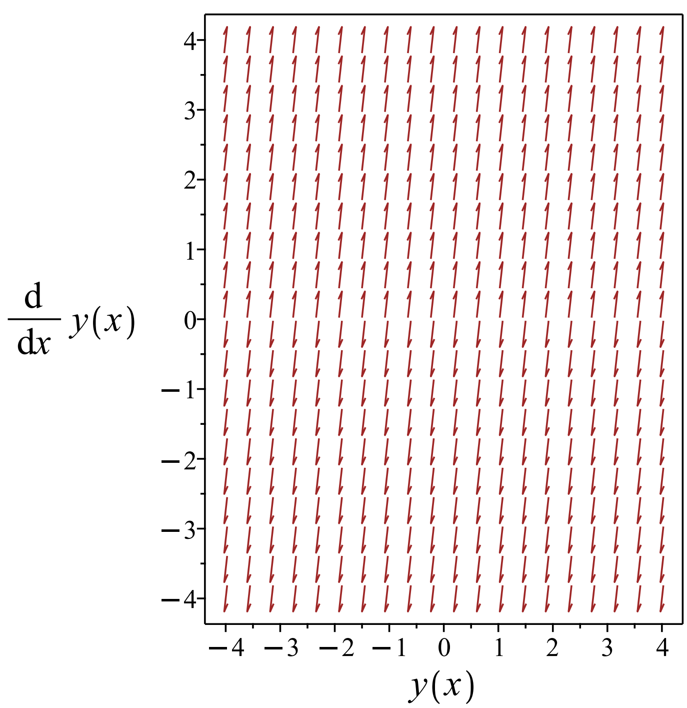

Figure 500: Slope field plot

Verification of solutions

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2 e^{7x}$$

Verified OK.

16.2.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 7y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -7 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{49}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 49 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{49z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 401: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{49}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{7x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-7}{1}\,dx} \\ &= z_1 e^{\frac{7x}{2}} \\ &= z_1\left(\mathrm{e}^{\frac{7x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-7}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{7x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{7x}}{7}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2\left(1\left(\frac{\mathrm{e}^{7x}}{7}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-7y'=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h=c_1+\frac{c_2 \mathrm{e}^{7x}}{7}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2+x+1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1,x,x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1,\frac{\mathrm{e}^{7x}}{7}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x,x^2,x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p=A_3x^3+A_2x^2+A_1x$$

The unknowns $\{A_1,A_2,A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-21x^2A_3-14xA_2+6xA_3-7A_1+2A_2=(x-1)^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=-\frac{37}{343},A_2=\frac{6}{49},A_3=-\frac{1}{21}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{1}{21}x^3 + \frac{6}{49}x^2 - \frac{37}{343}x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 e^{7x}}{7}\right) + \left(-\frac{1}{21}x^3 + \frac{6}{49}x^2 - \frac{37}{343}x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + \frac{c_2 e^{7x}}{7} - \frac{x^3}{21} + \frac{6x^2}{49} - \frac{37x}{343} \tag{1}$$

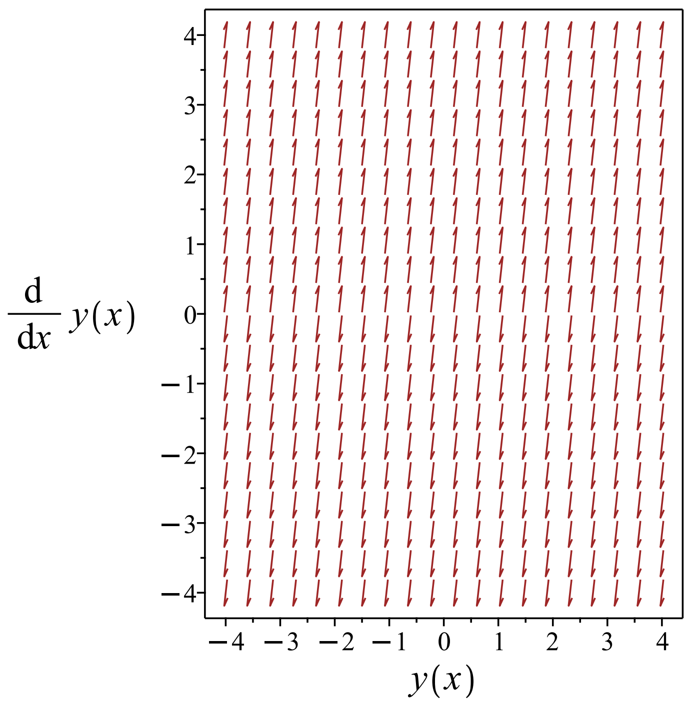

Figure 501: Slope field plot

Verification of solutions

$$y = c_1 + \frac{c_2 e^{7x}}{7} - \frac{x^3}{21} + \frac{6x^2}{49} - \frac{37x}{343}$$

Verified OK.

16.2.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x)&=1\\ q(x)&=-7\\ r(x)&=0\\ s(x)&=(x-1)^2\end{aligned}$$

Hence

$$\begin{aligned}p''(x)&=0\\ q'(x)&=0\end{aligned}$$

Therefore (1) becomes

$$0-(0)+(0)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+(q(x)-p'(x))\,y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+(q(x)-p'(x))\,y=\int s(x)\;dx$$

Substituting the above values for p,q,r,s gives

$$-7y+y'=\int (x-1)^2\;dx$$

We now have a first order ode to solve which is

$$-7y+y'=\frac{(x-1)^3}{3}+c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -7 \\ q(x) &= \frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1 \end{aligned}$$

Hence the ode is

$$-7y + y' = \frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-7)dx} \\ &= e^{-7x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1\right) \\ \frac{d}{dx}\left(e^{-7x}y\right) &= \left(e^{-7x}\right)\left(\frac{1}{3}x^3 - x^2 + x - \frac{1}{3} + c_1\right) \\ d\left(e^{-7x}y\right) &= \left(\frac{(x^3 - 3x^2 + 3c_1 + 3x - 1)\, e^{-7x}}{3}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-7x}y &= \int \frac{(x^3 - 3x^2 + 3c_1 + 3x - 1)\, e^{-7x}}{3}\, dx \\ e^{-7x}y &= -\frac{(343x^3 - 882x^2 + 1029c_1 + 777x - 232)\, e^{-7x}}{7203} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-7x}$ results in

$$y = -\frac{e^{7x}(343x^3 - 882x^2 + 1029c_1 + 777x - 232)\, e^{-7x}}{7203} + c_2 e^{7x}$$

which simplifies to

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2 e^{7x}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2 e^{7x} \tag{1}$$

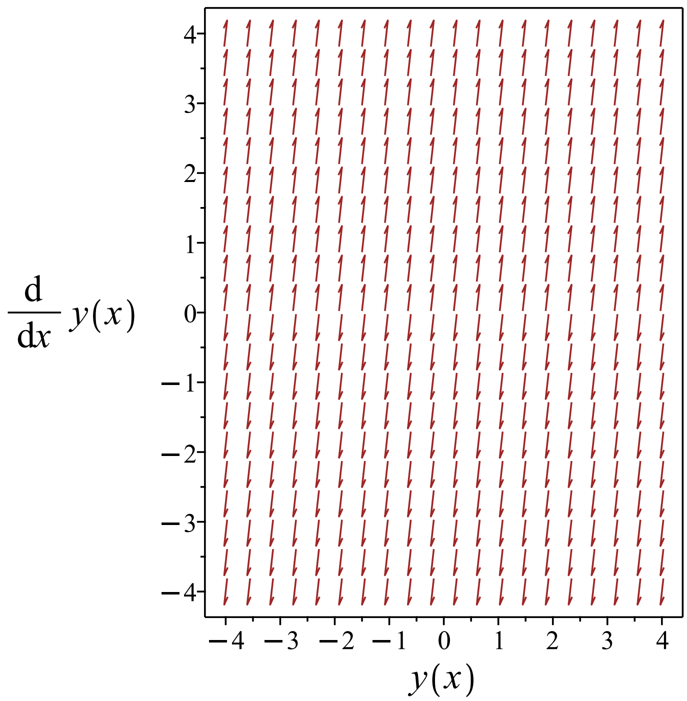

Figure 502: Slope field plot

Verification of solutions

$$y = -\frac{x^3}{21} + \frac{6x^2}{49} - \frac{c_1}{7} - \frac{37x}{343} + \frac{232}{7203} + c_2 e^{7x}$$

Verified OK.

16.2.7 Maple step by step solution

Let's solve

$y'' - 7y' = (x-1)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 7r = 0$

- Factor the characteristic polynomial

  $r(r-7) = 0$

- Roots of the characteristic polynomial

  $r = (0, 7)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{7x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{7x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = (x-1)^2\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{7x} \\ 0 & 7\,e^{7x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 7\,e^{7x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\left(\int (x-1)^2 dx\right)}{7} + \frac{e^{7x}\left(\int (x-1)^2 e^{-7x} dx\right)}{7}$

  - Compute integrals

    $y_p(x) = -\frac{1}{21}x^3 + \frac{6}{49}x^2 - \frac{37}{343}x + \frac{232}{7203}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 e^{7x} - \frac{x^3}{21} + \frac{6x^2}{49} - \frac{37x}{343} + \frac{232}{7203}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 3y' = e^x}$$

16.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 0, f(x) = e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+3y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=3, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+3\lambda \,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+3\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=3, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-3}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{3^2-(4)\,(1)\,(0)}\\&=-\frac{3}{2}\pm\frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{3}{2}+\frac{3}{2}\\\lambda_2&=-\frac{3}{2}-\frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-3\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-3)x}\end{aligned}$$

Or

$$y = c_1 + c_2 e^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + c_2 e^{-3x}\right) + \left(\frac{e^x}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + c_2 e^{-3x} + \frac{e^x}{4} \tag{1}
$$

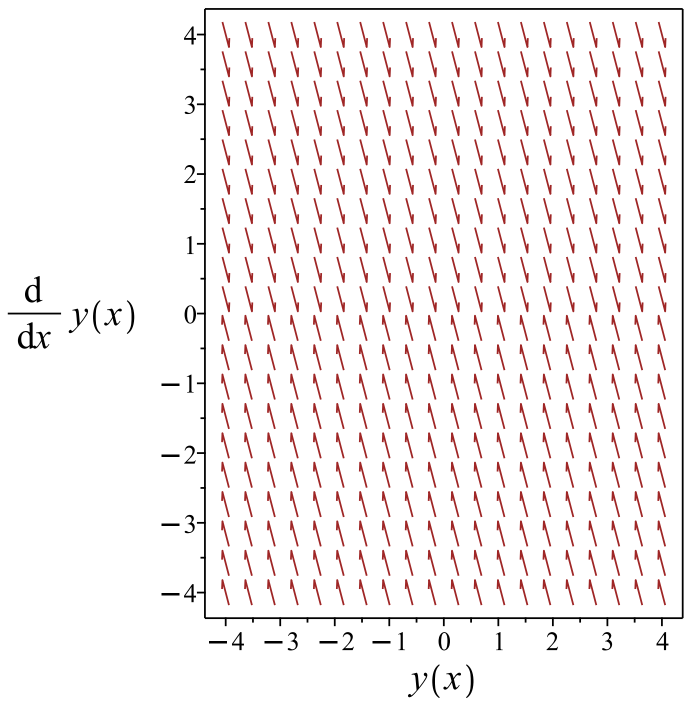

Figure 503: Slope field plot

Verification of solutions

$$
y = c_1 + c_2 e^{-3x} + \frac{e^x}{4}
$$

Verified OK.

16.3.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int (y'' + 3y')\, dx &= \int \mathrm{e}^{x} dx \\
3y + y' &= \mathrm{e}^{x} + c_1
\end{aligned}
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= 3 \\
q(x) &= \mathrm{e}^{x} + c_1
\end{aligned}
$$

Hence the ode is

$$
3y + y' = \mathrm{e}^{x} + c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 3dx} \\
&= \mathrm{e}^{3x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\mathrm{e}^{x} + c_1\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{3x} y\right) &= \left(\mathrm{e}^{3x}\right)\left(\mathrm{e}^{x} + c_1\right) \\
\mathrm{d}\left(\mathrm{e}^{3x} y\right) &= \left(\left(\mathrm{e}^{x} + c_1\right) \mathrm{e}^{3x}\right)\, \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{3x} y &= \int \left(\mathrm{e}^{x} + c_1\right) \mathrm{e}^{3x}\, \mathrm{d}x \\
\mathrm{e}^{3x} y &= \frac{\mathrm{e}^{4x}}{4} + \frac{c_1 \mathrm{e}^{3x}}{3} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{3x}$ results in

$$
y = \mathrm{e}^{-3x}\left(\frac{\mathrm{e}^{4x}}{4} + \frac{c_1 \mathrm{e}^{3x}}{3}\right) + c_2 \mathrm{e}^{-3x}
$$

which simplifies to

$$y = \frac{(3\,e^{4x} + 4c_1 e^{3x} + 12c_2)\,e^{-3x}}{12}$$

Summary

The solution(s) found are the following

$$y = \frac{(3\,e^{4x} + 4c_1 e^{3x} + 12c_2)\,e^{-3x}}{12} \tag{1}$$

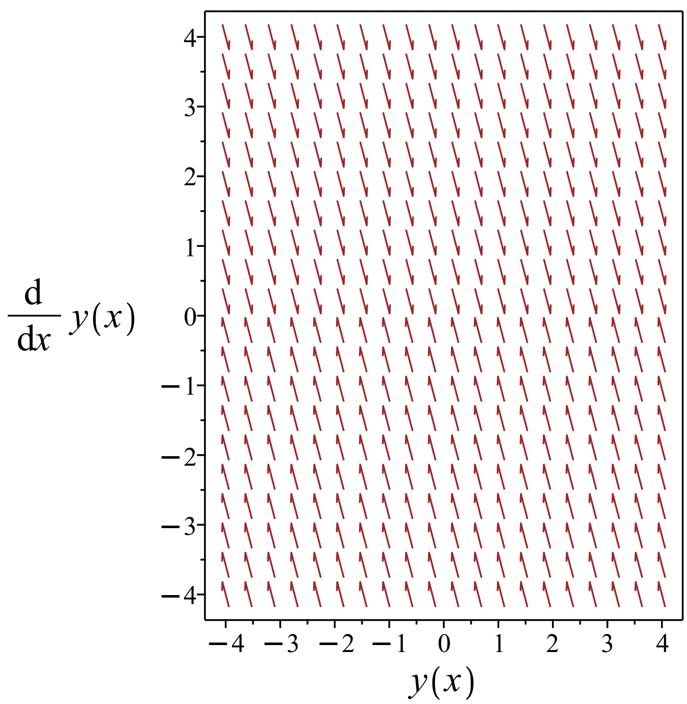

Figure 504: Slope field plot

Verification of solutions

$$y = \frac{(3\,e^{4x} + 4c_1 e^{3x} + 12c_2)\,e^{-3x}}{12}$$

Verified OK.

16.3.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 3p(x) - e^x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 3 \\ q(x) &= e^x \end{aligned}$$

Hence the ode is

$$p'(x) + 3p(x) = e^x$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 3dx} \\ &= e^{3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(e^x\right) \\ \frac{d}{dx}\left(e^{3x}p\right) &= \left(e^{3x}\right)\left(e^x\right) \\ d\left(e^{3x}p\right) &= e^{4x}\, dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{3x}p &= \int e^{4x}\, dx \\ e^{3x}p &= \frac{e^{4x}}{4} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$p(x) = \frac{e^{4x}e^{-3x}}{4} + c_1 e^{-3x}$$

which simplifies to

$$p(x) = \frac{(e^{4x} + 4c_1)\, e^{-3x}}{4}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{(e^{4x} + 4c_1)\, e^{-3x}}{4}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{(e^{4x} + 4c_1)\, e^{-3x}}{4}\, dx \\ &= -\frac{c_1 e^{-3x}}{3} + \frac{e^x}{4} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1 e^{-3x}}{3} + \frac{e^x}{4} + c_2 \tag{1}$$

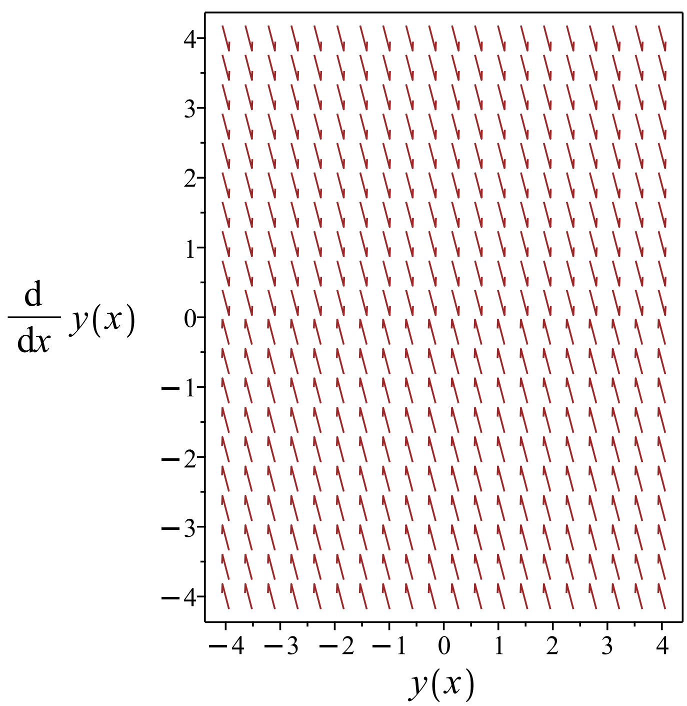

Figure 505: Slope field plot

Verification of solutions

$$y = -\frac{c_1 e^{-3x}}{3} + \frac{e^x}{4} + c_2$$

Verified OK.

16.3.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 3y' = e^x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 3y')\, dx = \int e^x dx$$
$$3y + y' = e^x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 3$$
$$q(x) = e^x + c_1$$

Hence the ode is

$$3y + y' = e^x + c_1$$

The integrating factor μ is

$$\mu = e^{\int 3dx}$$
$$= e^{3x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(e^x + c_1)$$
$$\frac{d}{dx}(e^{3x} y) = (e^{3x})(e^x + c_1)$$
$$d(e^{3x} y) = ((e^x + c_1) e^{3x})\, dx$$

Integrating gives

$$e^{3x}y = \int (e^{x} + c_1)\, e^{3x}\, dx$$
$$e^{3x}y = \frac{e^{4x}}{4} + \frac{c_1 e^{3x}}{3} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$y = e^{-3x}\left(\frac{e^{4x}}{4} + \frac{c_1 e^{3x}}{3}\right) + c_2 e^{-3x}$$

which simplifies to

$$y = \frac{(3\, e^{4x} + 4c_1 e^{3x} + 12c_2)\, e^{-3x}}{12}$$

Summary

The solution(s) found are the following

$$y = \frac{(3\, e^{4x} + 4c_1 e^{3x} + 12c_2)\, e^{-3x}}{12} \tag{1}$$

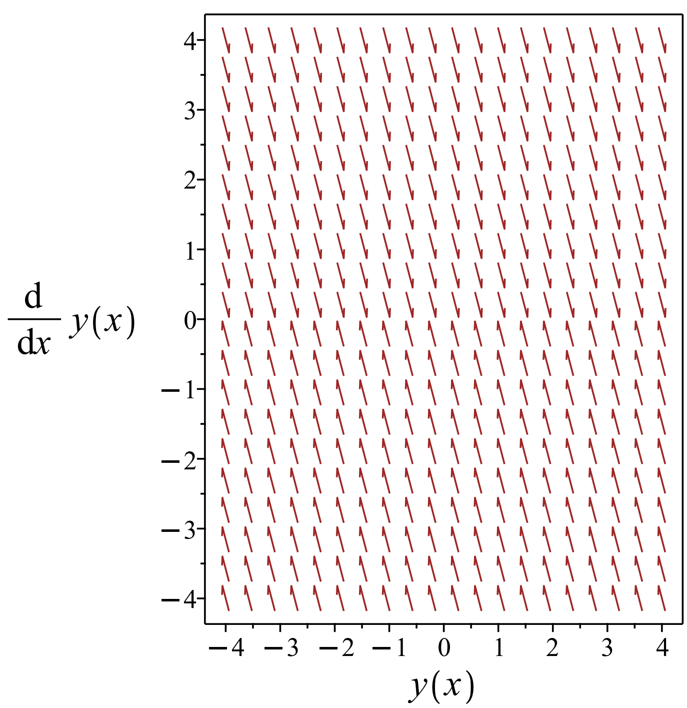

Figure 506: Slope field plot

Verification of solutions

$$y = \frac{(3\,e^{4x} + 4c_1 e^{3x} + 12c_2)\,e^{-3x}}{12}$$

Verified OK.

16.3.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 403: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\, dx} \\ &= z_1 e^{-\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-3x}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} + \frac{c_2}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{1}{3}, \mathrm{e}^{-3x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \mathrm{e}^x = \mathrm{e}^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + \frac{c_2}{3}\right) + \left(\frac{e^x}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-3x} + \frac{c_2}{3} + \frac{e^x}{4} \tag{1}$$

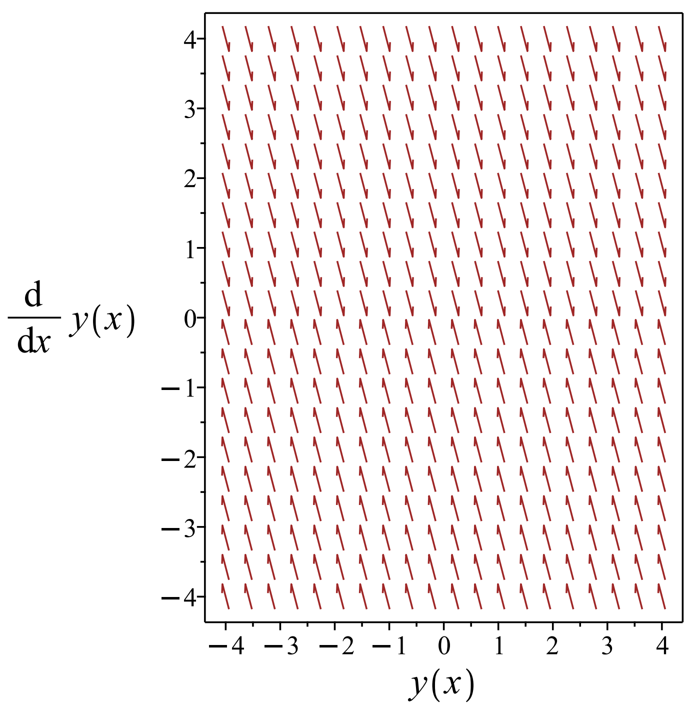

Figure 507: Slope field plot

Verification of solutions

$$y = c_1 e^{-3x} + \frac{c_2}{3} + \frac{e^x}{4}$$

Verified OK.

16.3.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1\\
q(x) &= 3\\
r(x) &= 0\\
s(x) &= \mathrm{e}^{x}
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0\\
q'(x) &= 0
\end{aligned}$$

Therefore (1) becomes

$$0-(0)+(0)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y'+(q(x)-p'(x))\,y)'=s(x)$$

Integrating gives

$$p(x)\,y'+(q(x)-p'(x))\,y=\int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$3y+y'=\int \mathrm{e}^{x}\,dx$$

We now have a first order ode to solve which is

$$3y+y'=\mathrm{e}^{x}+c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= 3 \\
q(x) &= e^x + c_1
\end{aligned}$$

Hence the ode is

$$3y + y' = e^x + c_1$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int 3dx} \\
&= e^{3x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(e^x + c_1\right) \\
\frac{d}{dx}\left(e^{3x}y\right) &= \left(e^{3x}\right)\left(e^x + c_1\right) \\
d\left(e^{3x}y\right) &= \left(\left(e^x + c_1\right)e^{3x}\right)\, dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
e^{3x}y &= \int \left(e^x + c_1\right)e^{3x}\, dx \\
e^{3x}y &= \frac{e^{4x}}{4} + \frac{c_1 e^{3x}}{3} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$y = e^{-3x}\left(\frac{e^{4x}}{4} + \frac{c_1 e^{3x}}{3}\right) + c_2 e^{-3x}$$

which simplifies to

$$y = \frac{\left(3\,e^{4x} + 4c_1 e^{3x} + 12c_2\right)e^{-3x}}{12}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(3\,e^{4x} + 4c_1 e^{3x} + 12c_2\right)e^{-3x}}{12} \tag{1}$$

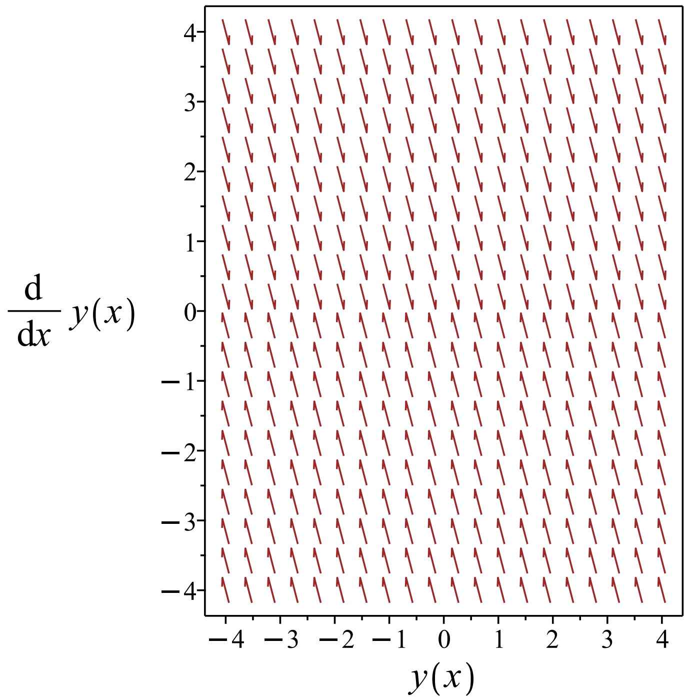

Figure 508: Slope field plot

Verification of solutions

$$y = \frac{(3\,\mathrm{e}^{4x} + 4c_1\mathrm{e}^{3x} + 12c_2)\,\mathrm{e}^{-3x}}{12}$$

Verified OK.

16.3.7 Maple step by step solution

Let's solve

$y'' + 3y' = \mathrm{e}^{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r = 0$

- Factor the characteristic polynomial

  $r(r+3) = 0$

- Roots of the characteristic polynomial

$r = (-3, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \mathrm{e}^{x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & 1 \\ -3\,\mathrm{e}^{-3x} & 0 \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3\,\mathrm{e}^{-3x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-3x}\left(\int \mathrm{e}^{4x} dx\right)}{3} + \frac{\left(\int \mathrm{e}^{x} dx\right)}{3}$

  ◦ Compute integrals

  $y_p(x) = \frac{\mathrm{e}^{x}}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3x} + c_2 + \frac{\mathrm{e}^{x}}{4}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 7y' = e^{-7x}}$$

16.4.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 7, C = 0, f(x) = e^{-7x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+7y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=7, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x}+7\lambda\, e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+7\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=7, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-7}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{7^2-(4)\,(1)\,(0)}\\&=-\frac{7}{2}\pm\frac{7}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-\frac{7}{2}+\frac{7}{2}\\\lambda_2&=-\frac{7}{2}-\frac{7}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-7\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-7)x}\end{aligned}$$

Or

$$y = c_1 + c_2 e^{-7x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-7x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-7x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-7x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-7x}\}$$

Since e^{-7x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^{-7x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\, e^{-7x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-7A_1 e^{-7x} = e^{-7x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{7}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\, e^{-7x}}{7}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + c_2 \mathrm{e}^{-7x}\right) + \left(-\frac{x\,\mathrm{e}^{-7x}}{7}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + c_2 \mathrm{e}^{-7x} - \frac{x\,\mathrm{e}^{-7x}}{7} \tag{1}
$$

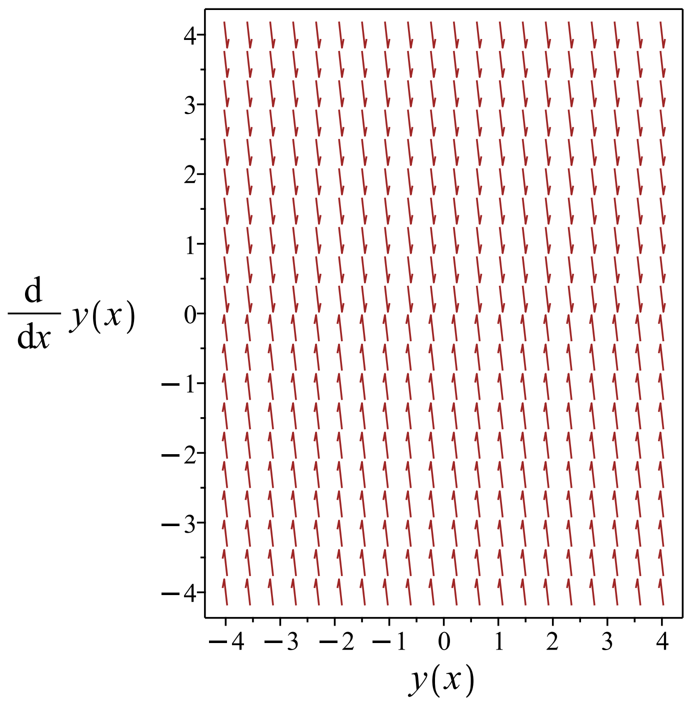

Figure 509: Slope field plot

Verification of solutions

$$
y = c_1 + c_2 \mathrm{e}^{-7x} - \frac{x\,\mathrm{e}^{-7x}}{7}
$$

Verified OK.

16.4.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int (y'' + 7y')\, dx &= \int \mathrm{e}^{-7x} dx \\
7y + y' &= -\frac{\mathrm{e}^{-7x}}{7} + c_1
\end{aligned}
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= 7 \\
q(x) &= -\frac{\mathrm{e}^{-7x}}{7} + c_1
\end{aligned}
$$

Hence the ode is

$$
7y + y' = -\frac{\mathrm{e}^{-7x}}{7} + c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 7dx} \\
&= \mathrm{e}^{7x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(-\frac{\mathrm{e}^{-7x}}{7} + c_1\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{7x} y\right) &= \left(\mathrm{e}^{7x}\right)\left(-\frac{\mathrm{e}^{-7x}}{7} + c_1\right) \\
\mathrm{d}\left(\mathrm{e}^{7x} y\right) &= \left(c_1 \mathrm{e}^{7x} - \frac{1}{7}\right) \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{7x} y &= \int c_1 \mathrm{e}^{7x} - \frac{1}{7} \,\mathrm{d}x \\
\mathrm{e}^{7x} y &= -\frac{x}{7} + \frac{c_1 \mathrm{e}^{7x}}{7} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{7x}$ results in

$$y = e^{-7x}\left(-\frac{x}{7} + \frac{c_1 e^{7x}}{7}\right) + c_2 e^{-7x}$$

which simplifies to

$$y = \frac{(-x + 7c_2) e^{-7x}}{7} + \frac{c_1}{7}$$

Summary

The solution(s) found are the following

$$y = \frac{(-x + 7c_2) e^{-7x}}{7} + \frac{c_1}{7} \tag{1}$$

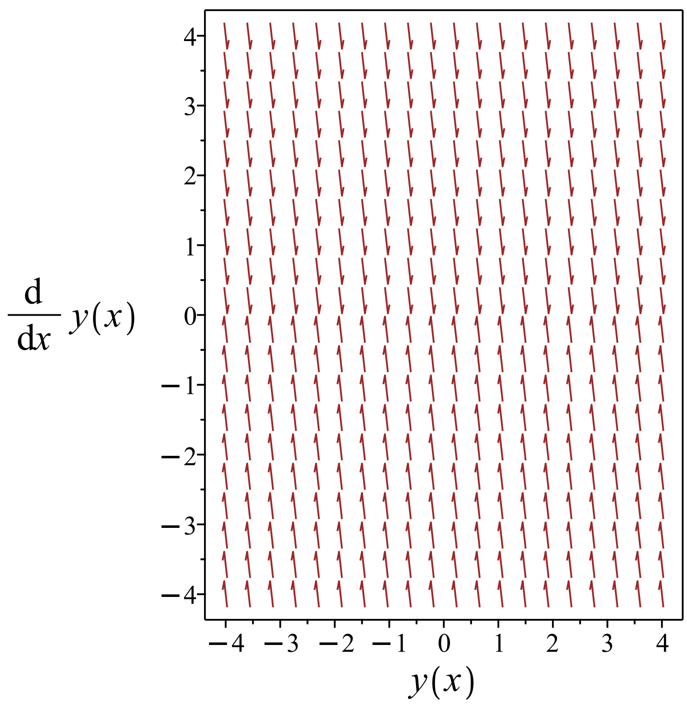

Figure 510: Slope field plot

Verification of solutions

$$y = \frac{(-x + 7c_2) e^{-7x}}{7} + \frac{c_1}{7}$$

Verified OK.

16.4.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 7p(x) - e^{-7x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 7 \\ q(x) &= e^{-7x} \end{aligned}$$

Hence the ode is

$$p'(x) + 7p(x) = e^{-7x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 7dx} \\ &= e^{7x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(e^{-7x}\right) \\ \frac{d}{dx}\left(e^{7x}p\right) &= \left(e^{7x}\right)\left(e^{-7x}\right) \\ d\left(e^{7x}p\right) &= dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{7x}p &= \int dx \\ e^{7x}p &= x + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{7x}$ results in

$$p(x) = x\,e^{-7x} + c_1 e^{-7x}$$

which simplifies to

$$p(x) = e^{-7x}(x + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{-7x}(x + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int e^{-7x}(x + c_1)\,dx \\ &= -\frac{(7x + 7c_1 + 1)\,e^{-7x}}{49} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{(7x + 7c_1 + 1)\,e^{-7x}}{49} + c_2 \tag{1}$$

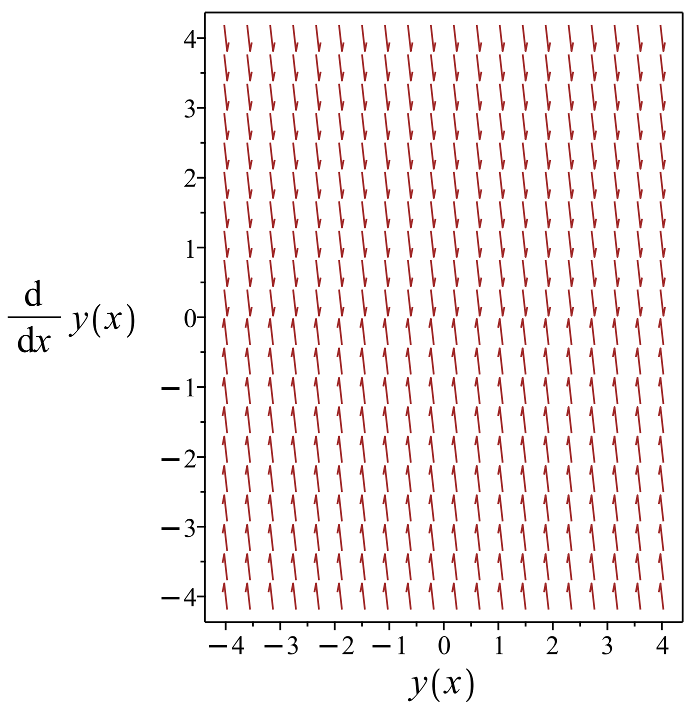

Figure 511: Slope field plot

Verification of solutions

$$y = -\frac{(7x+7c_1+1)\,\mathrm{e}^{-7x}}{49}+c_2$$

Verified OK.

16.4.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y''+7y' = \mathrm{e}^{-7x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y''+7y')\,dx = \int \mathrm{e}^{-7x}dx$$
$$7y+y' = -\frac{\mathrm{e}^{-7x}}{7}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = 7$$
$$q(x) = -\frac{\mathrm{e}^{-7x}}{7}+c_1$$

Hence the ode is

$$7y+y' = -\frac{\mathrm{e}^{-7x}}{7}+c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int 7dx}$$
$$= \mathrm{e}^{7x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(-\frac{\mathrm{e}^{-7x}}{7}+c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{7x}y) = (\mathrm{e}^{7x})\left(-\frac{\mathrm{e}^{-7x}}{7}+c_1\right)$$
$$\mathrm{d}(\mathrm{e}^{7x}y) = \left(c_1\mathrm{e}^{7x}-\frac{1}{7}\right)\,\mathrm{d}x$$

Integrating gives

$$e^{7x}y = \int c_1 e^{7x} - \frac{1}{7}\,dx$$
$$e^{7x}y = -\frac{x}{7} + \frac{c_1 e^{7x}}{7} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{7x}$ results in

$$y = e^{-7x}\left(-\frac{x}{7} + \frac{c_1 e^{7x}}{7}\right) + c_2 e^{-7x}$$

which simplifies to

$$y = \frac{(-x + 7c_2)\,e^{-7x}}{7} + \frac{c_1}{7}$$

Summary

The solution(s) found are the following

$$y = \frac{(-x + 7c_2)\,e^{-7x}}{7} + \frac{c_1}{7} \tag{1}$$

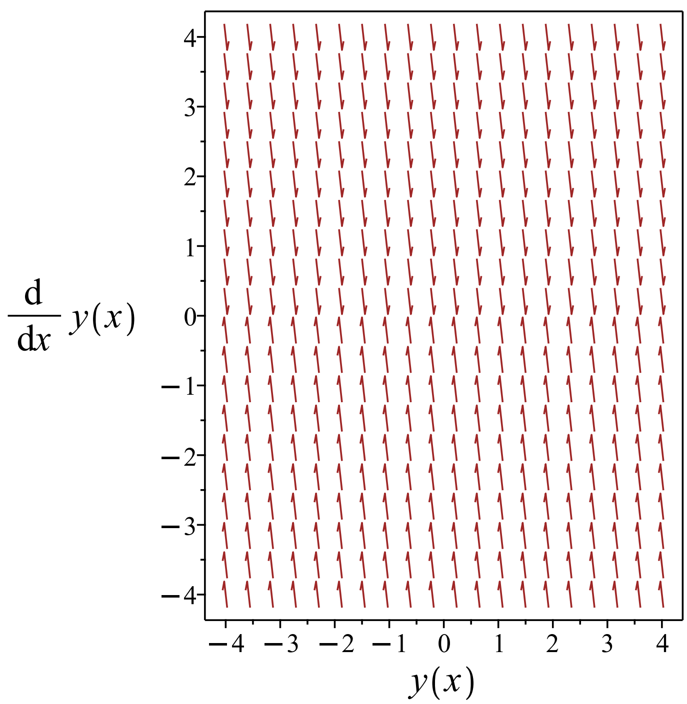

Figure 512: Slope field plot

Verification of solutions

$$y = \frac{(-x + 7c_2)\,\mathrm{e}^{-7x}}{7} + \frac{c_1}{7}$$

Verified OK.

16.4.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 7y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 7 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{49}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 49 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{49z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 405: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{49}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{7x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{7}{1}\,dx} \\
&= z_1 e^{-\frac{7x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{7x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-7x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{7}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-7x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{7x}}{7}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-7x}\right) + c_2 \left(\mathrm{e}^{-7x} \left(\frac{\mathrm{e}^{7x}}{7}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 7y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-7x} + \frac{c_2}{7}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{-7x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-7x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{1}{7}, \mathrm{e}^{-7x}\right\}$$

Since e^{-7x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-7x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-7x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-7A_1 \mathrm{e}^{-7x} = \mathrm{e}^{-7x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{7}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,\mathrm{e}^{-7x}}{7}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-7x} + \frac{c_2}{7}\right) + \left(-\frac{x\,\mathrm{e}^{-7x}}{7}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-7x} + \frac{c_2}{7} - \frac{x\,\mathrm{e}^{-7x}}{7} \tag{1}$$

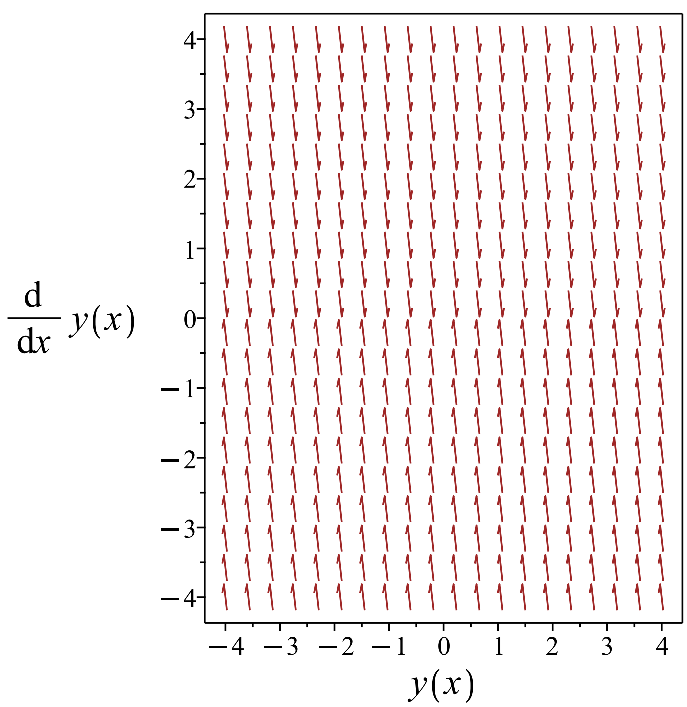

Figure 513: Slope field plot

Verification of solutions

$$y = c_1 e^{-7x} + \frac{c_2}{7} - \frac{x\, e^{-7x}}{7}$$

Verified OK.

16.4.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 7 \\ r(x) &= 0 \\ s(x) &= e^{-7x} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + (q(x) - p'(x))\, y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$7y + y' = \int e^{-7x}\, dx$$

We now have a first order ode to solve which is

$$7y + y' = -\frac{e^{-7x}}{7} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 7 \\ q(x) &= -\frac{e^{-7x}}{7} + c_1 \end{aligned}$$

Hence the ode is

$$7y + y' = -\frac{e^{-7x}}{7} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 7dx} \\ &= e^{7x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(-\frac{e^{-7x}}{7} + c_1\right) \\ \frac{d}{dx}\left(e^{7x} y\right) &= \left(e^{7x}\right)\left(-\frac{e^{-7x}}{7} + c_1\right) \\ d\left(e^{7x} y\right) &= \left(c_1 e^{7x} - \frac{1}{7}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{7x} y &= \int c_1 e^{7x} - \frac{1}{7} \, dx \\ e^{7x} y &= -\frac{x}{7} + \frac{c_1 e^{7x}}{7} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{7x}$ results in

$$y = e^{-7x}\left(-\frac{x}{7} + \frac{c_1 e^{7x}}{7}\right) + c_2 e^{-7x}$$

which simplifies to

$$y = \frac{(-x + 7c_2)\,\mathrm{e}^{-7x}}{7} + \frac{c_1}{7}$$

Summary

The solution(s) found are the following

$$y = \frac{(-x + 7c_2)\,\mathrm{e}^{-7x}}{7} + \frac{c_1}{7} \tag{1}$$

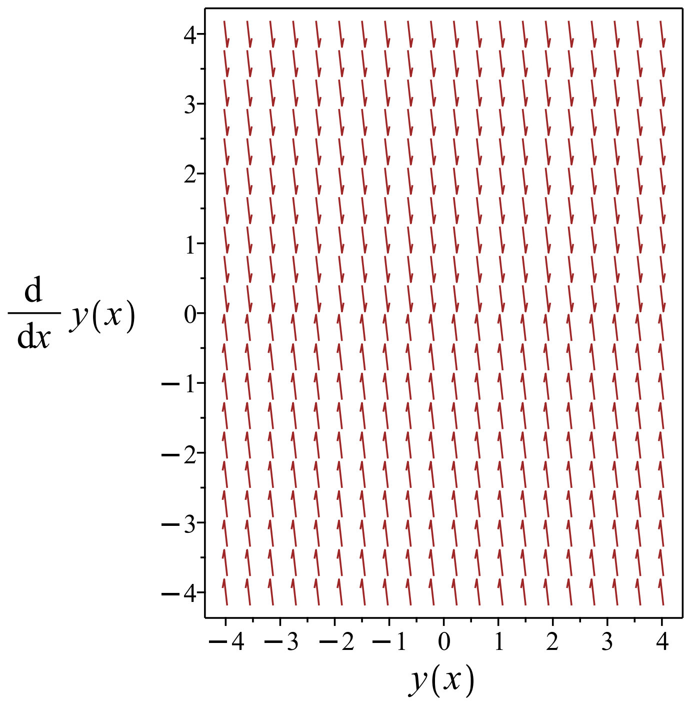

Figure 514: Slope field plot

Verification of solutions

$$y = \frac{(-x + 7c_2)\,\mathrm{e}^{-7x}}{7} + \frac{c_1}{7}$$

Verified OK.

16.4.7 Maple step by step solution

Let's solve

$y'' + 7y' = e^{-7x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 7r = 0$

- Factor the characteristic polynomial

  $r(r + 7) = 0$

- Roots of the characteristic polynomial

  $r = (-7, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-7x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-7x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^{-7x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-7x} & 1 \\ -7\,e^{-7x} & 0 \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 7\,e^{-7x}$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{e^{-7x}\left(\int 1 dx\right)}{7} + \frac{\left(\int e^{-7x} dx\right)}{7}$$

- Compute integrals

$$y_p(x) = -\frac{e^{-7x}(7x+1)}{49}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{-7x} + c_2 - \frac{e^{-7x}(7x+1)}{49}$$

Problem number: 478.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 8y' + 16y = (1 - x)\,\mathrm{e}^{4x}}$$

16.5.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -8, C = 16, f(x) = (1 - x)\,\mathrm{e}^{4x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 8y' + 16y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -8, C = 16$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 8\lambda\, e^{\lambda x} + 16\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 8\lambda + 16 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -8, C = 16$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{8}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-8)^2 - (4)\,(1)\,(16)} \\ &= 4\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -4$. Therefore the solution is

$$y = c_1 e^{4x} + c_2 e^{4x} x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{4x} + c_2 x\, e^{4x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(1 - x)\, e^{4x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{4x}x, e^{4x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{4x}x, e^{4x}\}$$

Since e^{4x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{4x}, e^{4x} x\}]$$

Since $e^{4x} x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{4x}, x^3 e^{4x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{4x} + A_2 x^3 e^{4x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{4x} + 6A_2 x \, e^{4x} = (1 - x) \, e^{4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -\frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{4x}}{2} - \frac{x^3 e^{4x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{4x} + c_2 x \, e^{4x}\right) + \left(\frac{x^2 e^{4x}}{2} - \frac{x^3 e^{4x}}{6}\right) \end{aligned}$$

Which simplifies to

$$y = e^{4x}(c_2 x + c_1) + \frac{x^2 e^{4x}}{2} - \frac{x^3 e^{4x}}{6}$$

Summary
The solution(s) found are the following

$$y = e^{4x}(c_2 x + c_1) + \frac{x^2 e^{4x}}{2} - \frac{x^3 e^{4x}}{6} \tag{1}$$

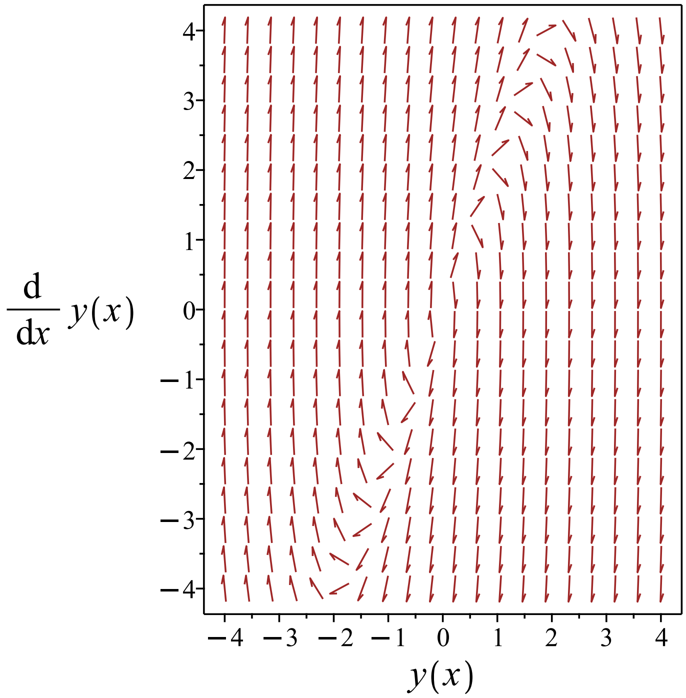

Figure 515: Slope field plot

Verification of solutions

$$y = e^{4x}(c_2 x + c_1) + \frac{x^2 e^{4x}}{2} - \frac{x^3 e^{4x}}{6}$$

Verified OK.

16.5.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -8$. Therefore, there is an integrating factor given by

$$
\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\,dx} \\
&= e^{\int -8\,dx} \\
&= \mathrm{e}^{-4x}
\end{aligned}
$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= \mathrm{e}^{-4x}(1-x)\,\mathrm{e}^{4x} \\
\left(\mathrm{e}^{-4x}y\right)'' &= \mathrm{e}^{-4x}(1-x)\,\mathrm{e}^{4x}
\end{aligned}
$$

Integrating once gives

$$
\left(\mathrm{e}^{-4x}y\right)' = -\frac{x(x-2)}{2} + c_1
$$

Integrating again gives

$$
\left(\mathrm{e}^{-4x}y\right) = -\frac{x(x^2-6c_1-3x)}{6} + c_2
$$

Hence the solution is

$$
y = \frac{-\frac{x(x^2-6c_1-3x)}{6} + c_2}{\mathrm{e}^{-4x}}
$$

Or

$$
y = -\frac{x^3\mathrm{e}^{4x}}{6} + c_1 x\,\mathrm{e}^{4x} + \frac{x^2\mathrm{e}^{4x}}{2} + c_2\mathrm{e}^{4x}
$$

Summary

The solution(s) found are the following

$$
y = -\frac{x^3\mathrm{e}^{4x}}{6} + c_1 x\,\mathrm{e}^{4x} + \frac{x^2\mathrm{e}^{4x}}{2} + c_2\mathrm{e}^{4x} \tag{1}
$$

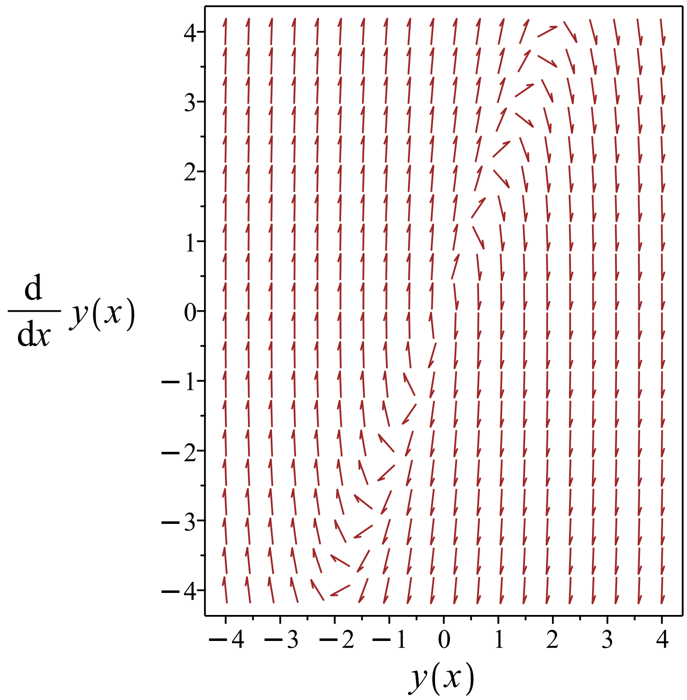

Figure 516: Slope field plot

Verification of solutions

$$y = -\frac{x^3 e^{4x}}{6} + c_1 x\, e^{4x} + \frac{x^2 e^{4x}}{2} + c_2 e^{4x}$$

Verified OK.

16.5.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 8y' + 16y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -8 \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 407: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-8}{1}\,dx} \\ &= z_1 e^{4x} \\ &= z_1\left(\mathrm{e}^{4x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{4x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-8}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{8x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{4x}\right) + c_2 \left(\mathrm{e}^{4x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 8y' + 16y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{4x} + c_2 x\,\mathrm{e}^{4x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
(1 - x)\,\mathrm{e}^{4x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{4x} x, \mathrm{e}^{4x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\mathrm{e}^{4x} x, \mathrm{e}^{4x}\}
$$

Since e^{4x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x^2 \mathrm{e}^{4x}, \mathrm{e}^{4x} x\}]
$$

Since $\mathrm{e}^{4x} x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x^2 \mathrm{e}^{4x}, x^3 \mathrm{e}^{4x}\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 \mathrm{e}^{4x} + A_2 x^3 \mathrm{e}^{4x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \mathrm{e}^{4x} + 6A_2 x\,\mathrm{e}^{4x} = (1 - x)\,\mathrm{e}^{4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -\frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 \mathrm{e}^{4x}}{2} - \frac{x^3 \mathrm{e}^{4x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{4x} + c_2 x\,\mathrm{e}^{4x}\right) + \left(\frac{x^2 \mathrm{e}^{4x}}{2} - \frac{x^3 \mathrm{e}^{4x}}{6}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{4x}(c_2 x + c_1) + \frac{x^2 \mathrm{e}^{4x}}{2} - \frac{x^3 \mathrm{e}^{4x}}{6}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{4x}(c_2 x + c_1) + \frac{x^2 \mathrm{e}^{4x}}{2} - \frac{x^3 \mathrm{e}^{4x}}{6} \tag{1}$$

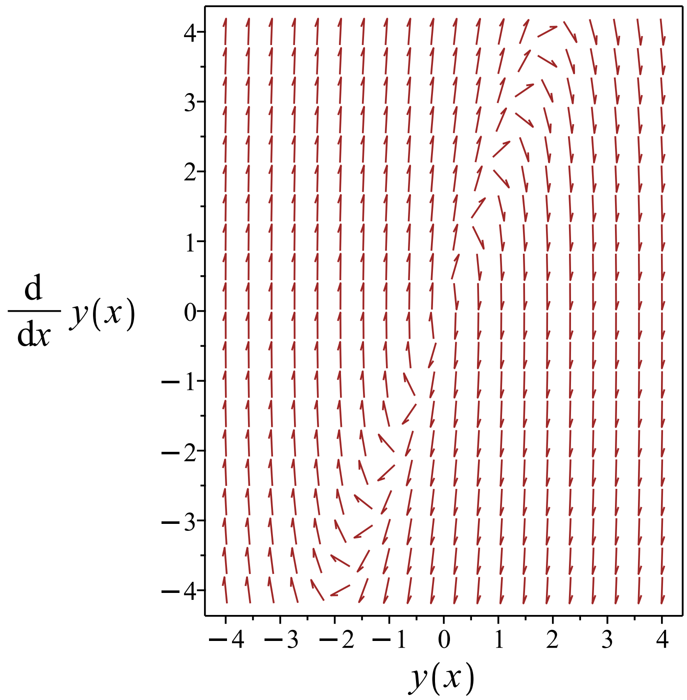

Figure 517: Slope field plot

Verification of solutions

$$y = e^{4x}(c_2 x + c_1) + \frac{x^2 e^{4x}}{2} - \frac{x^3 e^{4x}}{6}$$

Verified OK.

16.5.4 Maple step by step solution

Let's solve

$y'' - 8y' + 16y = (1 - x) e^{4x}$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -e^{4x} x + 8y' - 16y + e^{4x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - 8y' + 16y = -(x - 1) e^{4x}$

- Characteristic polynomial of homogeneous ODE

$r^2 - 8r + 16 = 0$

- Factor the characteristic polynomial

$(r-4)^2 = 0$

- Root of the characteristic polynomial

$r = 4$

- 1st solution of the homogeneous ODE

$y_1(x) = e^{4x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

$y_2(x) = e^{4x}x$

- General solution of the ODE

$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y = c_1 e^{4x} + c_2 x\, e^{4x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = -(x-1)\, e^{4x}\right]$

  ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{4x} & e^{4x}x \\ 4\, e^{4x} & 4\, e^{4x}x + e^{4x} \end{bmatrix}$

  ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{8x}$

  ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{4x}\left(\int x(x-1)\, dx - \left(\int (x-1)\, dx\right) x\right)$

  ○ Compute integrals

  $y_p(x) = -\frac{e^{4x} x^2 (x-3)}{6}$

- Substitute particular solution into general solution to ODE

$y = c_1 e^{4x} + c_2 x\, e^{4x} - \frac{e^{4x} x^2 (x-3)}{6}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 10y' + 25y = e^{5x}}$$

16.6.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -10, C = 25, f(x) = e^{5x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 10y' + 25y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -10, C = 25$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 10\lambda\, e^{\lambda x} + 25\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 10\lambda + 25 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -10, C = 25$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{10}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-10)^2 - (4)(1)(25)}\\ &= 5\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -5$. Therefore the solution is

$$y = c_1 e^{5x} + c_2 x\, e^{5x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{5x} + c_2 x\, e^{5x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{5x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{5x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{5x}, e^{5x}\}$$

Since e^{5x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{5x}\}]$$

Since $x\,e^{5x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2e^{5x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^2e^{5x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1e^{5x} = e^{5x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2e^{5x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1e^{5x} + c_2x\,e^{5x}\right) + \left(\frac{x^2e^{5x}}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{5x}(c_2x + c_1) + \frac{x^2e^{5x}}{2}$$

Summary

The solution(s) found are the following

$$y = e^{5x}(c_2 x + c_1) + \frac{x^2 e^{5x}}{2} \tag{1}$$

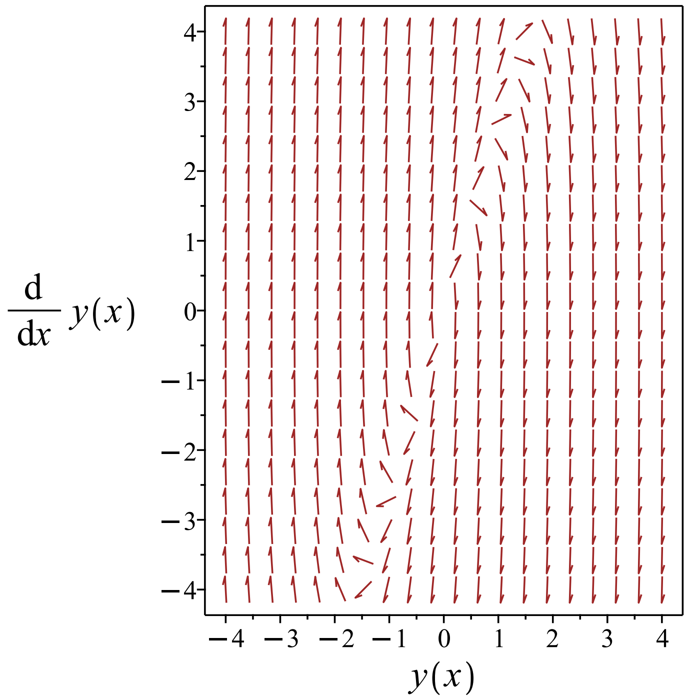

Figure 518: Slope field plot

Verification of solutions

$$y = e^{5x}(c_2 x + c_1) + \frac{x^2 e^{5x}}{2}$$

Verified OK.

16.6.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -10$. Therefore, there is an integrating factor given by

$$
\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\,dx} \\
&= e^{\int -10\,dx} \\
&= \mathrm{e}^{-5x}
\end{aligned}
$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= \mathrm{e}^{-5x}\mathrm{e}^{5x} \\
\left(\mathrm{e}^{-5x}y\right)'' &= \mathrm{e}^{-5x}\mathrm{e}^{5x}
\end{aligned}
$$

Integrating once gives

$$
\left(\mathrm{e}^{-5x}y\right)' = x + c_1
$$

Integrating again gives

$$
\left(\mathrm{e}^{-5x}y\right) = \frac{x(x+2c_1)}{2} + c_2
$$

Hence the solution is

$$
y = \frac{\frac{x(x+2c_1)}{2} + c_2}{\mathrm{e}^{-5x}}
$$

Or

$$
y = c_1 x\,\mathrm{e}^{5x} + \frac{x^2\mathrm{e}^{5x}}{2} + c_2\mathrm{e}^{5x}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\,\mathrm{e}^{5x} + \frac{x^2\mathrm{e}^{5x}}{2} + c_2\mathrm{e}^{5x} \tag{1}
$$

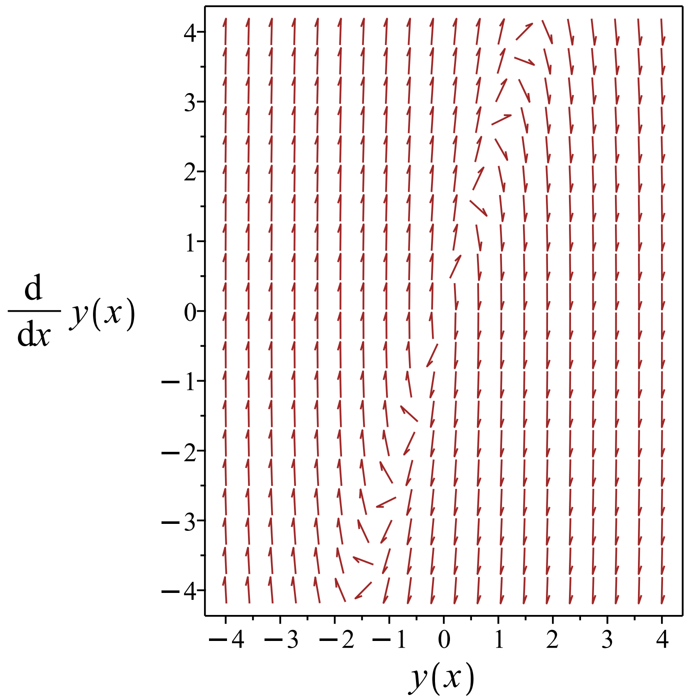

Figure 519: Slope field plot

Verification of solutions

$$y = c_1 x\, e^{5x} + \frac{x^2 e^{5x}}{2} + c_2 e^{5x}$$

Verified OK.

16.6.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 10y' + 25y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -10 \\ C &= 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 409: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-10}{1}\,dx} \\ &= z_1 e^{5x} \\ &= z_1\left(\mathrm{e}^{5x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{5x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-10}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{10x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{5x}\right) + c_2 \left(e^{5x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 10y' + 25y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{5x} + c_2 x\, e^{5x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
e^{5x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{e^{5x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\, e^{5x}, e^{5x}\}
$$

Since e^{5x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x\, e^{5x}\}]
$$

Since $x\, e^{5x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$
[\{x^2 e^{5x}\}]
$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{5x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{5x} = e^{5x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{5x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{5x} + c_2 x\, e^{5x}\right) + \left(\frac{x^2 e^{5x}}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{5x}(c_2 x + c_1) + \frac{x^2 e^{5x}}{2}$$

Summary

The solution(s) found are the following

$$y = e^{5x}(c_2 x + c_1) + \frac{x^2 e^{5x}}{2} \tag{1}$$

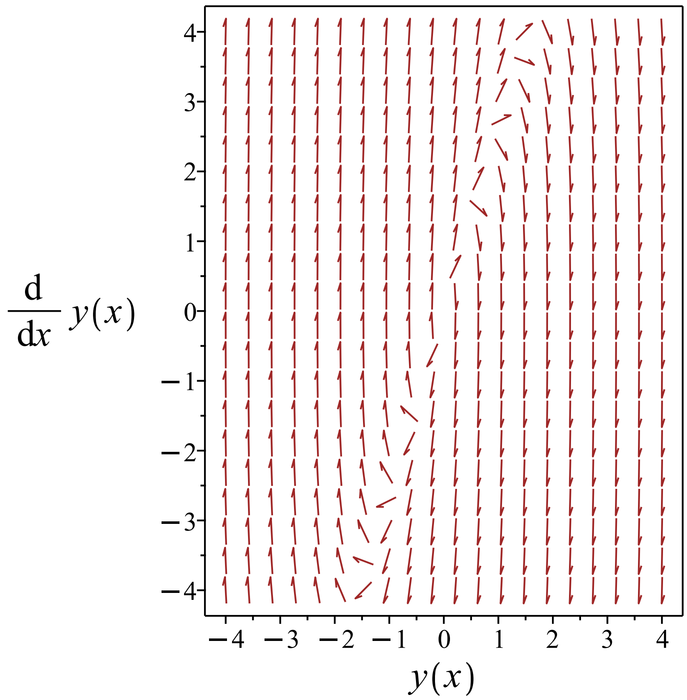

Figure 520: Slope field plot

Verification of solutions

$$y = e^{5x}(c_2 x + c_1) + \frac{x^2 e^{5x}}{2}$$

Verified OK.

16.6.4 Maple step by step solution

Let's solve

$y'' - 10y' + 25y = e^{5x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 10r + 25 = 0$

- Factor the characteristic polynomial

  $(r-5)^2 = 0$

- Root of the characteristic polynomial

$r = 5$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{5x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{5x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{5x} + c_2 x\,e^{5x} + y_p(x)$

- □ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))}dx\right), f(x) = e^{5x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \left[\begin{array}{cc} e^{5x} & x\,e^{5x} \\ 5\,e^{5x} & e^{5x} + 5x\,e^{5x} \end{array}\right]$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{10x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = e^{5x}\left(-\left(\int x dx\right) + \left(\int 1 dx\right) x\right)$

  - Compute integrals

    $y_p(x) = \frac{x^2 e^{5x}}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,e^{5x} + c_1 e^{5x} + \frac{x^2 e^{5x}}{2}$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{4y'' - 3y' = x\,\mathrm{e}^{\frac{3x}{4}}}$$

16.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4, B = -3, C = 0, f(x) = x\,\mathrm{e}^{\frac{3x}{4}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$4y''-3y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=4, B=-3, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 \mathrm{e}^{\lambda x}-3\lambda\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2-3\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=4, B=-3, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{3}{(2)\,(4)}\pm\frac{1}{(2)\,(4)}\sqrt{-3^2-(4)\,(4)\,(0)}\\&=\frac{3}{8}\pm\frac{3}{8}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=\frac{3}{8}+\frac{3}{8}\\\lambda_2&=\frac{3}{8}-\frac{3}{8}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=\frac{3}{4}\\\lambda_2&=0\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{\left(\frac{3}{4}\right)x}+c_2e^{(0)x}\end{aligned}$$

Or

$$y = c_1 e^{\frac{3x}{4}} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\frac{3x}{4}} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\,e^{\frac{3x}{4}}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$\left[\left\{x\,e^{\frac{3x}{4}}, e^{\frac{3x}{4}}\right\}\right]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, e^{\frac{3x}{4}}\right\}$$

Since $e^{\frac{3x}{4}}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$\left[\left\{x\,e^{\frac{3x}{4}}, x^2 e^{\frac{3x}{4}}\right\}\right]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{\frac{3x}{4}} + A_2 x^2 e^{\frac{3x}{4}}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 e^{\frac{3x}{4}} + 8A_2 e^{\frac{3x}{4}} + 6A_2 x\,e^{\frac{3x}{4}} = x\,e^{\frac{3x}{4}}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{4}{9}, A_2 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{4x\,e^{\frac{3x}{4}}}{9} + \frac{x^2 e^{\frac{3x}{4}}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\frac{3x}{4}} + c_2\right) + \left(-\frac{4x\,e^{\frac{3x}{4}}}{9} + \frac{x^2 e^{\frac{3x}{4}}}{6}\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 e^{\frac{3x}{4}} + c_2 - \frac{4x\,e^{\frac{3x}{4}}}{9} + \frac{x^2 e^{\frac{3x}{4}}}{6} \tag{1}$$

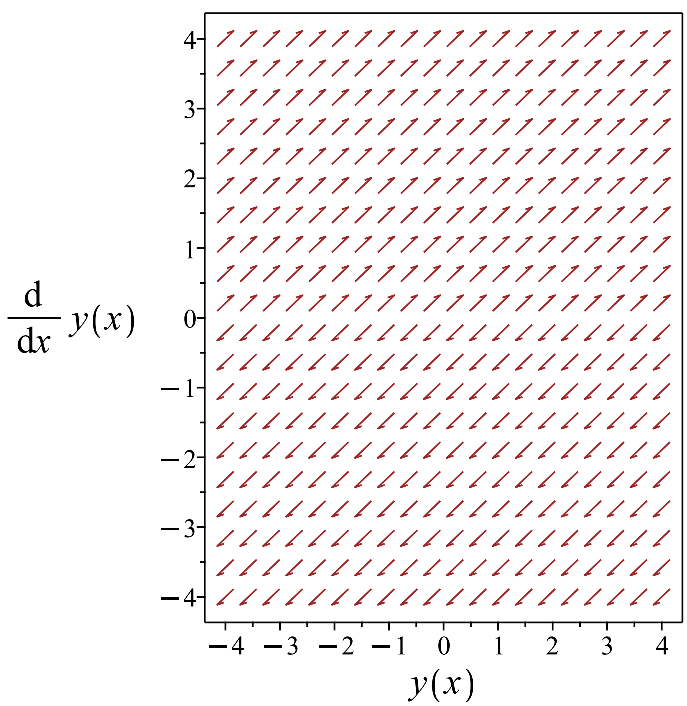

Figure 521: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 e^{\frac{3x}{4}} + c_2 - \frac{4x\,e^{\frac{3x}{4}}}{9} + \frac{x^2 e^{\frac{3x}{4}}}{6}$$

Verified OK.

16.7.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (4y'' - 3y')\,dx = \int x\,\mathrm{e}^{\frac{3x}{4}}\,dx$$

$$4y' - 3y = \frac{4(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{4}$$
$$q(x) = \frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}$$

Hence the ode is

$$y' - \frac{3y}{4} = \frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{3}{4}dx}$$
$$= \mathrm{e}^{-\frac{3x}{4}}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\right)$$

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-\frac{3x}{4}}y\right) = \left(\mathrm{e}^{-\frac{3x}{4}}\right)\left(\frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\right)$$

$$\mathrm{d}\left(\mathrm{e}^{-\frac{3x}{4}}y\right) = \left(\frac{x}{3} - \frac{4}{9} + \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{4}\right)\,\mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{-\frac{3x}{4}}y = \int \frac{x}{3} - \frac{4}{9} + \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{4}\,\mathrm{d}x$$

$$\mathrm{e}^{-\frac{3x}{4}}y = \frac{x^2}{6} - \frac{4x}{9} - \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{3} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{3x}{4}}$ results in

$$y = e^{\frac{3x}{4}} \left(\frac{x^2}{6} - \frac{4x}{9} - \frac{c_1 e^{-\frac{3x}{4}}}{3} \right) + c_2 e^{\frac{3x}{4}}$$

which simplifies to

$$y = \frac{(3x^2 + 18c_2 - 8x) e^{\frac{3x}{4}}}{18} - \frac{c_1}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{(3x^2 + 18c_2 - 8x) e^{\frac{3x}{4}}}{18} - \frac{c_1}{3} \tag{1}$$

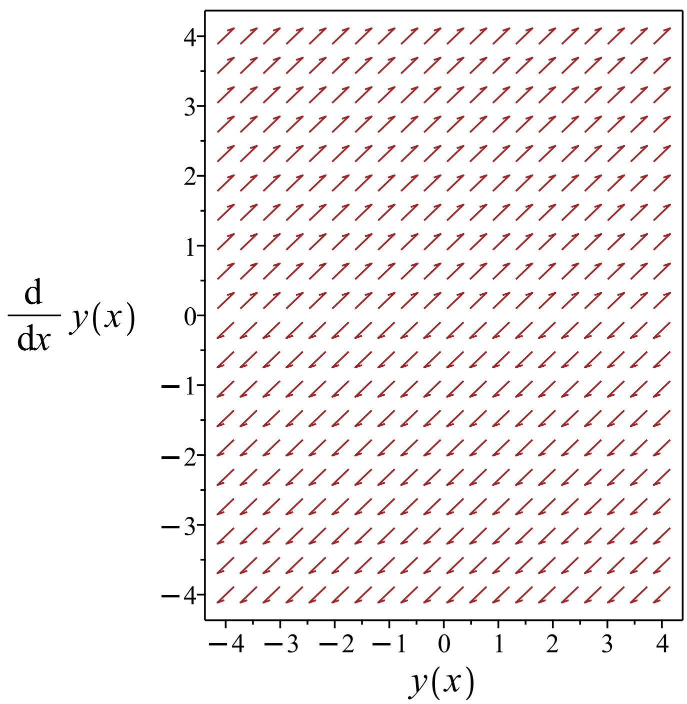

Figure 522: Slope field plot

Verification of solutions

$$y = \frac{(3x^2 + 18c_2 - 8x) e^{\frac{3x}{4}}}{18} - \frac{c_1}{3}$$

Verified OK.

16.7.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$4p'(x) - 3p(x) - x\,e^{\frac{3x}{4}} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$p(x) = -\frac{3}{4}$$
$$q(x) = \frac{x\,e^{\frac{3x}{4}}}{4}$$

Hence the ode is

$$p'(x) - \frac{3p(x)}{4} = \frac{x\,e^{\frac{3x}{4}}}{4}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{4}dx}$$
$$= e^{-\frac{3x}{4}}$$

The ode becomes

$$\frac{d}{dx}(\mu p) = (\mu)\left(\frac{x\,e^{\frac{3x}{4}}}{4}\right)$$
$$\frac{d}{dx}\left(e^{-\frac{3x}{4}}p\right) = \left(e^{-\frac{3x}{4}}\right)\left(\frac{x\,e^{\frac{3x}{4}}}{4}\right)$$
$$d\left(e^{-\frac{3x}{4}}p\right) = \left(\frac{x}{4}\right)\,dx$$

Integrating gives

$$e^{-\frac{3x}{4}} p = \int \frac{x}{4} \, dx$$
$$e^{-\frac{3x}{4}} p = \frac{x^2}{8} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{3x}{4}}$ results in

$$p(x) = \frac{x^2 e^{\frac{3x}{4}}}{8} + c_1 e^{\frac{3x}{4}}$$

which simplifies to

$$p(x) = e^{\frac{3x}{4}} \left(\frac{x^2}{8} + c_1\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{\frac{3x}{4}} \left(\frac{x^2}{8} + c_1\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{e^{\frac{3x}{4}} (x^2 + 8c_1)}{8} \, dx \\ &= \frac{(9x^2 + 72c_1 - 24x + 32) e^{\frac{3x}{4}}}{54} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{(9x^2 + 72c_1 - 24x + 32) e^{\frac{3x}{4}}}{54} + c_2 \tag{1}$$

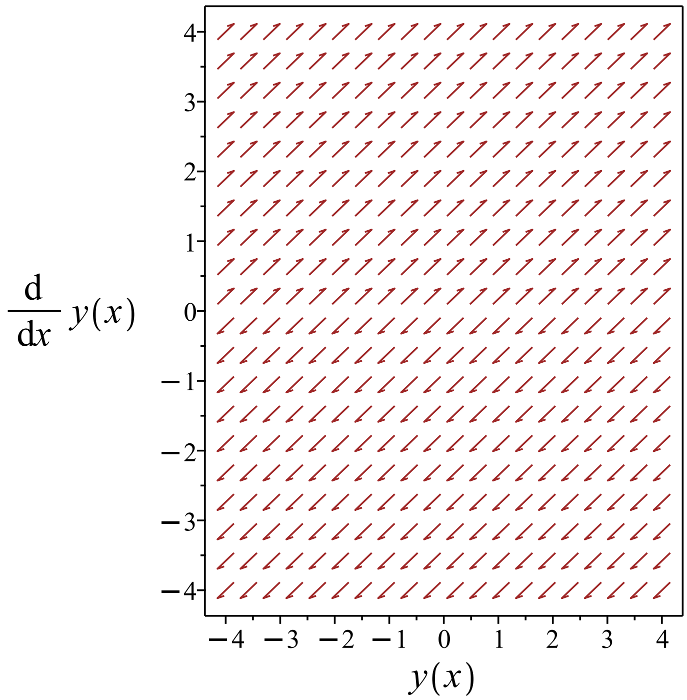

Figure 523: Slope field plot

Verification of solutions

$$y = \frac{(9x^2 + 72c_1 - 24x + 32)\,e^{\frac{3x}{4}}}{54} + c_2$$

Verified OK.

16.7.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$4y'' - 3y' = x\,e^{\frac{3x}{4}}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (4y'' - 3y')\,dx = \int x\,e^{\frac{3x}{4}}\,dx$$

$$4y' - 3y = \frac{4(3x-4)\,e^{\frac{3x}{4}}}{9} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{3}{4}\\ q(x) &= \frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\end{aligned}$$

Hence the ode is

$$y' - \frac{3y}{4} = \frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{3}{4}dx}\\ &= \mathrm{e}^{-\frac{3x}{4}}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-\frac{3x}{4}}y\right) &= \left(\mathrm{e}^{-\frac{3x}{4}}\right)\left(\frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\right)\\ \mathrm{d}\left(\mathrm{e}^{-\frac{3x}{4}}y\right) &= \left(\frac{x}{3} - \frac{4}{9} + \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{4}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{-\frac{3x}{4}}y &= \int \frac{x}{3} - \frac{4}{9} + \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{4}\,\mathrm{d}x\\ \mathrm{e}^{-\frac{3x}{4}}y &= \frac{x^2}{6} - \frac{4x}{9} - \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{3} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-\frac{3x}{4}}$ results in

$$y = \mathrm{e}^{\frac{3x}{4}}\left(\frac{x^2}{6} - \frac{4x}{9} - \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{3}\right) + c_2\mathrm{e}^{\frac{3x}{4}}$$

which simplifies to

$$y = \frac{(3x^2 + 18c_2 - 8x)\,\mathrm{e}^{\frac{3x}{4}}}{18} - \frac{c_1}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{(3x^2 + 18c_2 - 8x)\,\mathrm{e}^{\frac{3x}{4}}}{18} - \frac{c_1}{3} \tag{1}$$

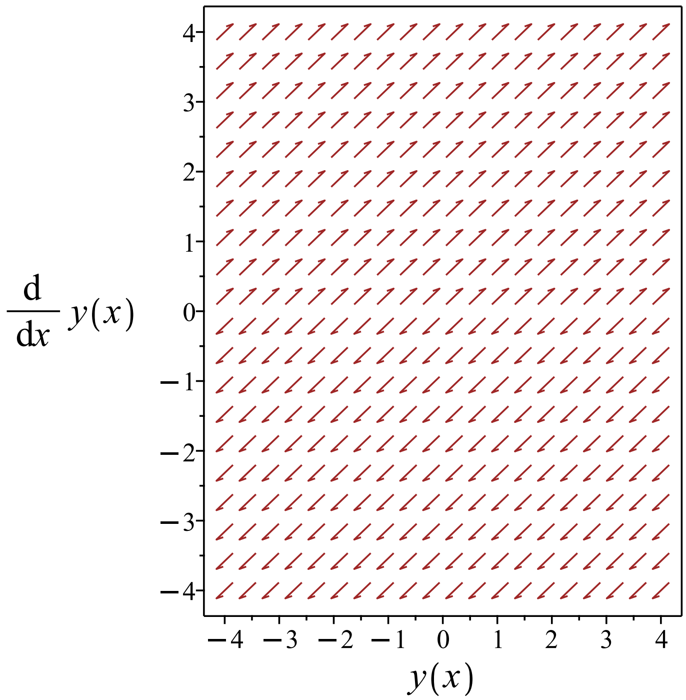

Figure 524: Slope field plot

Verification of solutions

$$y = \frac{(3x^2 + 18c_2 - 8x)\,\mathrm{e}^{\frac{3x}{4}}}{18} - \frac{c_1}{3}$$

Verified OK.

16.7.5 Solving using Kovacic algorithm

Writing the ode as

$$4y'' - 3y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 4 \\
B &= -3 \\
C &= 0
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{9}{64} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 9 \\
t &= 64
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \frac{9z(x)}{64} \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 411: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{64}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{8}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3}{4}\,dx} \\ &= z_1 e^{\frac{3x}{8}} \\ &= z_1\left(\mathrm{e}^{\frac{3x}{8}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{4}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{3x}{4}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$4y'' - 3y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{4c_2\mathrm{e}^{\frac{3x}{4}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3} \\ 0 & \mathrm{e}^{\frac{3x}{4}} \end{vmatrix}$$

Therefore

$$W = (1)\left(\mathrm{e}^{\frac{3x}{4}}\right) - \left(\frac{4\,\mathrm{e}^{\frac{3x}{4}}}{3}\right)(0)$$

Which simplifies to

$$W = e^{\frac{3x}{4}}$$

Which simplifies to

$$W = e^{\frac{3x}{4}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4 e^{\frac{3x}{2}} x}{3}}{4 e^{\frac{3x}{4}}} dx$$

Which simplifies to

$$u_1 = -\int \frac{x e^{\frac{3x}{4}}}{3} dx$$

Hence

$$u_1 = -\frac{4(3x-4) e^{\frac{3x}{4}}}{27}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x e^{\frac{3x}{4}}}{4 e^{\frac{3x}{4}}} dx$$

Which simplifies to

$$u_2 = \int \frac{x}{4} dx$$

Hence

$$u_2 = \frac{x^2}{8}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{4(3x-4) e^{\frac{3x}{4}}}{27} + \frac{x^2 e^{\frac{3x}{4}}}{6}$$

Which simplifies to

$$y_p(x) = \frac{e^{\frac{3x}{4}} (9x^2 - 24x + 32)}{54}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + \frac{4c_2 e^{\frac{3x}{4}}}{3}\right) + \left(\frac{e^{\frac{3x}{4}}(9x^2 - 24x + 32)}{54}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + \frac{4c_2 e^{\frac{3x}{4}}}{3} + \frac{e^{\frac{3x}{4}}(9x^2 - 24x + 32)}{54} \tag{1}
$$

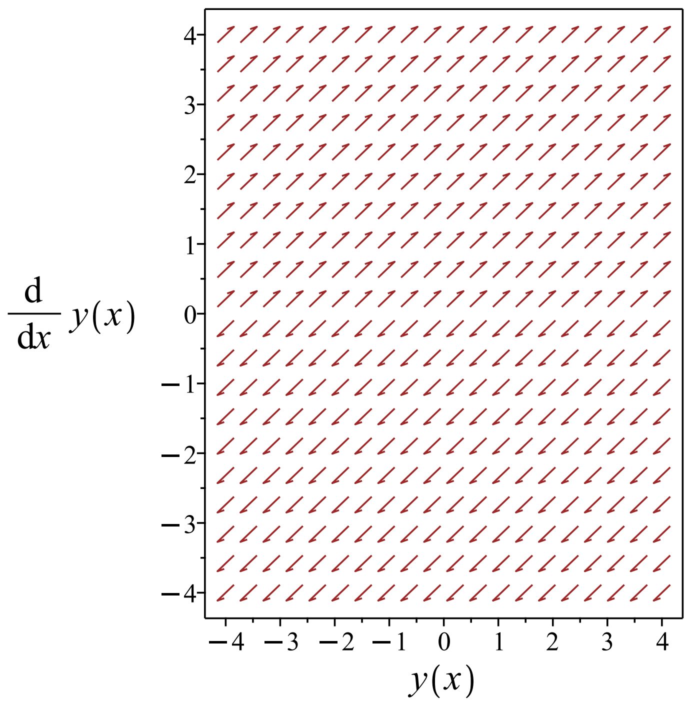

Figure 525: Slope field plot

Verification of solutions

$$
y = c_1 + \frac{4c_2 e^{\frac{3x}{4}}}{3} + \frac{e^{\frac{3x}{4}}(9x^2 - 24x + 32)}{54}
$$

Verified OK.

16.7.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 4\\
q(x) &= -3\\
r(x) &= 0\\
s(x) &= x\,\mathrm{e}^{\frac{3x}{4}}
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0\\
q'(x) &= 0
\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$4y' - 3y = \int x\,\mathrm{e}^{\frac{3x}{4}}\,dx$$

We now have a first order ode to solve which is

$$4y' - 3y = \frac{4(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{3}{4} \\ q(x) &= \frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4} \end{aligned}$$

Hence the ode is

$$y' - \frac{3y}{4} = \frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{3}{4}dx} \\ &= \mathrm{e}^{-\frac{3x}{4}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-\frac{3x}{4}}y\right) &= \left(\mathrm{e}^{-\frac{3x}{4}}\right)\left(\frac{(3x-4)\,\mathrm{e}^{\frac{3x}{4}}}{9} + \frac{c_1}{4}\right) \\ \mathrm{d}\left(\mathrm{e}^{-\frac{3x}{4}}y\right) &= \left(\frac{x}{3} - \frac{4}{9} + \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{4}\right)\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{-\frac{3x}{4}}y &= \int \frac{x}{3} - \frac{4}{9} + \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{4}\,\mathrm{d}x \\ \mathrm{e}^{-\frac{3x}{4}}y &= \frac{x^2}{6} - \frac{4x}{9} - \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{3} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-\frac{3x}{4}}$ results in

$$y = \mathrm{e}^{\frac{3x}{4}}\left(\frac{x^2}{6} - \frac{4x}{9} - \frac{c_1\mathrm{e}^{-\frac{3x}{4}}}{3}\right) + c_2\mathrm{e}^{\frac{3x}{4}}$$

which simplifies to

$$y = \frac{(3x^2 + 18c_2 - 8x)\,\mathrm{e}^{\frac{3x}{4}}}{18} - \frac{c_1}{3}$$

Summary
The solution(s) found are the following

$$y = \frac{(3x^2 + 18c_2 - 8x)\, e^{\frac{3x}{4}}}{18} - \frac{c_1}{3} \tag{1}$$

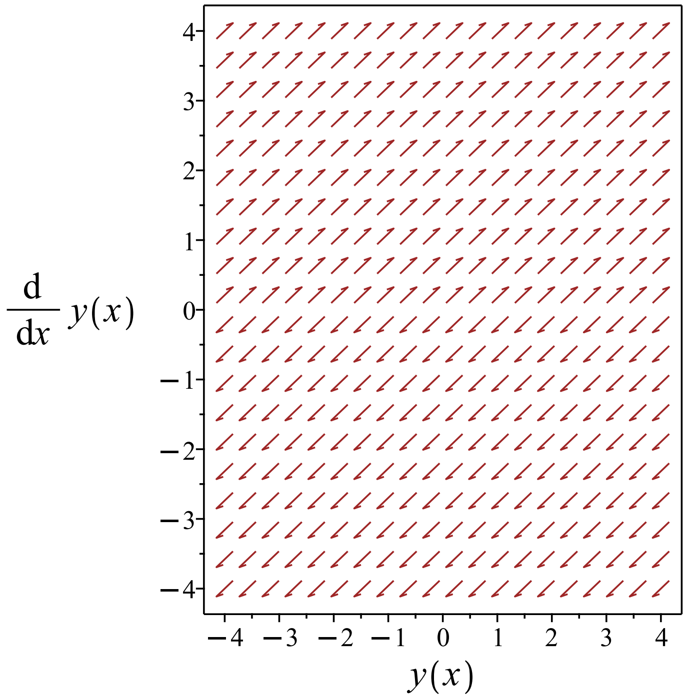

Figure 526: Slope field plot

Verification of solutions

$$y = \frac{(3x^2 + 18c_2 - 8x)\, e^{\frac{3x}{4}}}{18} - \frac{c_1}{3}$$

Verified OK.

16.7.7 Maple step by step solution

Let's solve

$4y'' - 3y' = x\, e^{\frac{3x}{4}}$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = \frac{3y'}{4} + \frac{x\,e^{\frac{3x}{4}}}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{3y'}{4} = \frac{x\,e^{\frac{3x}{4}}}{4}$

- Characteristic polynomial of homogeneous ODE

  $r^2 - \frac{3}{4}r = 0$

- Factor the characteristic polynomial

  $\frac{r(4r-3)}{4} = 0$

- Roots of the characteristic polynomial

  $r = \left(0, \frac{3}{4}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{\frac{3x}{4}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{\frac{3x}{4}} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \frac{x\,e^{\frac{3x}{4}}}{4}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{\frac{3x}{4}} \\ 0 & \frac{3\,e^{\frac{3x}{4}}}{4} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \frac{3\,e^{\frac{3x}{4}}}{4}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\left(\int x\,e^{\frac{3x}{4}}dx\right)}{3} + \frac{e^{\frac{3x}{4}}\left(\int x dx\right)}{3}$

- ○ Compute integrals

$$y_p(x) = \frac{e^{\frac{3x}{4}}(9x^2-24x+32)}{54}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 + c_2 e^{\frac{3x}{4}} + \frac{e^{\frac{3x}{4}}(9x^2-24x+32)}{54}$$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 4y' = e^{4x}x}$$

16.8.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 0, f(x) = e^{4x}x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(0)}\\ &= 2 \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 2 + 2\\ \lambda_2 &= 2 - 2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 4\\ \lambda_2 &= 0\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(4)x} + c_2 e^{(0)x}\end{aligned}$$

Or

$$y = c_1 e^{4x} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{4x} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{4x} x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{4x} x, e^{4x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{4x}\}$$

Since e^{4x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{4x}, e^{4x} x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{4x} + A_2 e^{4x} x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{4x} + 8A_1 x\, e^{4x} + 4A_2 e^{4x} = e^{4x} x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}, A_2 = -\frac{1}{16}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{4x}}{8} - \frac{e^{4x} x}{16}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 e^{4x} + c_2) + \left(\frac{x^2 e^{4x}}{8} - \frac{e^{4x} x}{16}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 e^{4x} + c_2 + \frac{x^2 e^{4x}}{8} - \frac{e^{4x} x}{16} \tag{1}$$

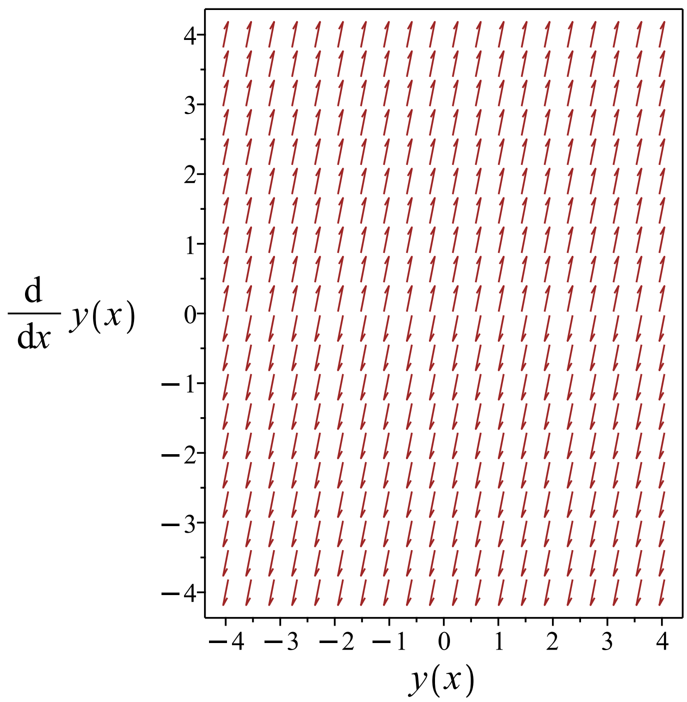

Figure 527: Slope field plot

Verification of solutions

$$y = c_1 e^{4x} + c_2 + \frac{x^2 e^{4x}}{8} - \frac{e^{4x} x}{16}$$

Verified OK.

16.8.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 4y')\, dx = \int \mathrm{e}^{4x} x dx$$
$$-4y + y' = \frac{(4x-1)\,\mathrm{e}^{4x}}{16} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -4$$
$$q(x) = \frac{(4x-1)\,\mathrm{e}^{4x}}{16} + c_1$$

Hence the ode is

$$-4y + y' = \frac{(4x-1)\,\mathrm{e}^{4x}}{16} + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int (-4)dx}$$
$$= \mathrm{e}^{-4x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{(4x-1)\,\mathrm{e}^{4x}}{16} + c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-4x} y\right) = \left(\mathrm{e}^{-4x}\right)\left(\frac{(4x-1)\,\mathrm{e}^{4x}}{16} + c_1\right)$$
$$\mathrm{d}\left(\mathrm{e}^{-4x} y\right) = \left(\frac{x}{4} - \frac{1}{16} + c_1 \mathrm{e}^{-4x}\right) \mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{-4x} y = \int \frac{x}{4} - \frac{1}{16} + c_1 \mathrm{e}^{-4x}\, \mathrm{d}x$$
$$\mathrm{e}^{-4x} y = \frac{x^2}{8} - \frac{x}{16} - \frac{c_1 \mathrm{e}^{-4x}}{4} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$y = e^{4x}\left(\frac{x^2}{8} - \frac{x}{16} - \frac{c_1 e^{-4x}}{4}\right) + c_2 e^{4x}$$

which simplifies to

$$y = \frac{(2x^2 + 16c_2 - x)\, e^{4x}}{16} - \frac{c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{(2x^2 + 16c_2 - x)\, e^{4x}}{16} - \frac{c_1}{4} \tag{1}$$

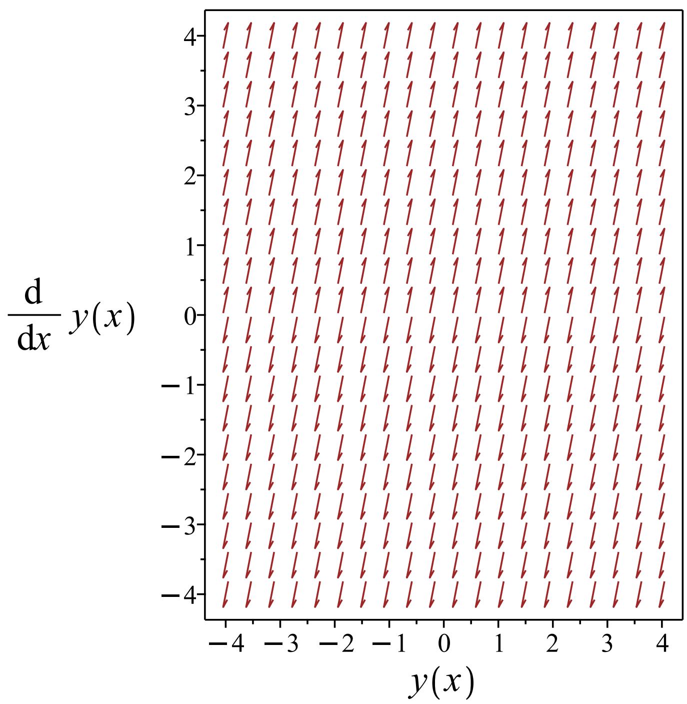

Figure 528: Slope field plot

Verification of solutions

$$y = \frac{(2x^2 + 16c_2 - x)\, e^{4x}}{16} - \frac{c_1}{4}$$

Verified OK.

16.8.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 4p(x) - e^{4x}x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= e^{4x}x \end{aligned}$$

Hence the ode is

$$p'(x) - 4p(x) = e^{4x}x$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-4)dx} \\ &= e^{-4x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(e^{4x}x\right) \\ \frac{d}{dx}\left(e^{-4x}p\right) &= \left(e^{-4x}\right)\left(e^{4x}x\right) \\ d\left(e^{-4x}p\right) &= x\,dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-4x}p &= \int x\,dx \\ e^{-4x}p &= \frac{x^2}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$p(x) = \frac{x^2 e^{4x}}{2} + c_1 e^{4x}$$

which simplifies to

$$p(x) = e^{4x}\left(\frac{x^2}{2} + c_1\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{4x}\left(\frac{x^2}{2} + c_1\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{e^{4x}(x^2 + 2c_1)}{2}\, dx \\ &= \frac{(8x^2 + 16c_1 - 4x + 1)\, e^{4x}}{64} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{(8x^2 + 16c_1 - 4x + 1)\, e^{4x}}{64} + c_2 \tag{1}$$

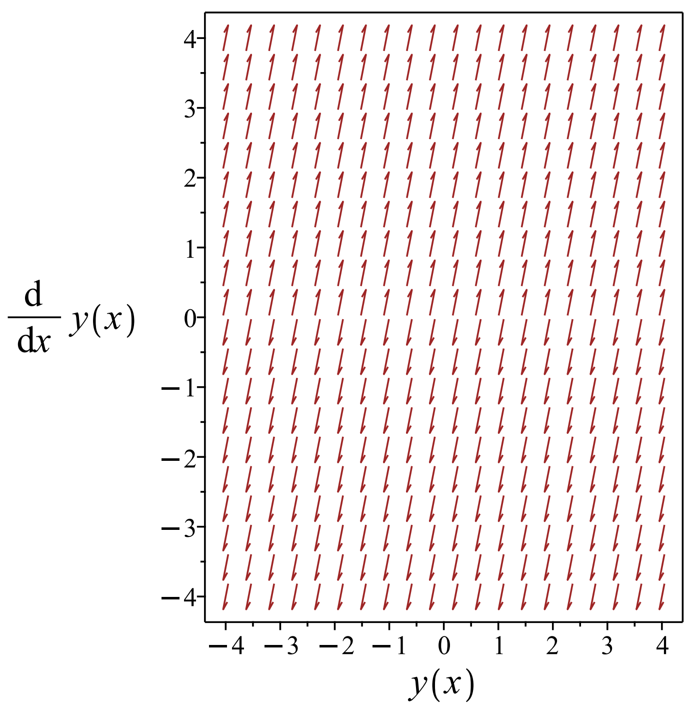

Figure 529: Slope field plot

Verification of solutions

$$y = \frac{(8x^2 + 16c_1 - 4x + 1)\,\mathrm{e}^{4x}}{64} + c_2$$

Verified OK.

16.8.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 4y' = \mathrm{e}^{4x} x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 4y')\, dx = \int \mathrm{e}^{4x} x dx$$

$$-4y + y' = \frac{(4x - 1)\,\mathrm{e}^{4x}}{16} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -4$$
$$q(x) = \frac{(4x - 1)\,\mathrm{e}^{4x}}{16} + c_1$$

Hence the ode is

$$-4y + y' = \frac{(4x - 1)\,\mathrm{e}^{4x}}{16} + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int (-4) dx}$$
$$= \mathrm{e}^{-4x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{(4x - 1)\,\mathrm{e}^{4x}}{16} + c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{-4x} y) = (\mathrm{e}^{-4x})\left(\frac{(4x - 1)\,\mathrm{e}^{4x}}{16} + c_1\right)$$
$$\mathrm{d}(\mathrm{e}^{-4x} y) = \left(\frac{x}{4} - \frac{1}{16} + c_1 \mathrm{e}^{-4x}\right)\,\mathrm{d}x$$

Integrating gives

$$e^{-4x}y = \int \frac{x}{4} - \frac{1}{16} + c_1 e^{-4x}\, dx$$
$$e^{-4x}y = \frac{x^2}{8} - \frac{x}{16} - \frac{c_1 e^{-4x}}{4} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$y = e^{4x}\left(\frac{x^2}{8} - \frac{x}{16} - \frac{c_1 e^{-4x}}{4}\right) + c_2 e^{4x}$$

which simplifies to

$$y = \frac{(2x^2 + 16c_2 - x)\, e^{4x}}{16} - \frac{c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{(2x^2 + 16c_2 - x)\, e^{4x}}{16} - \frac{c_1}{4} \tag{1}$$

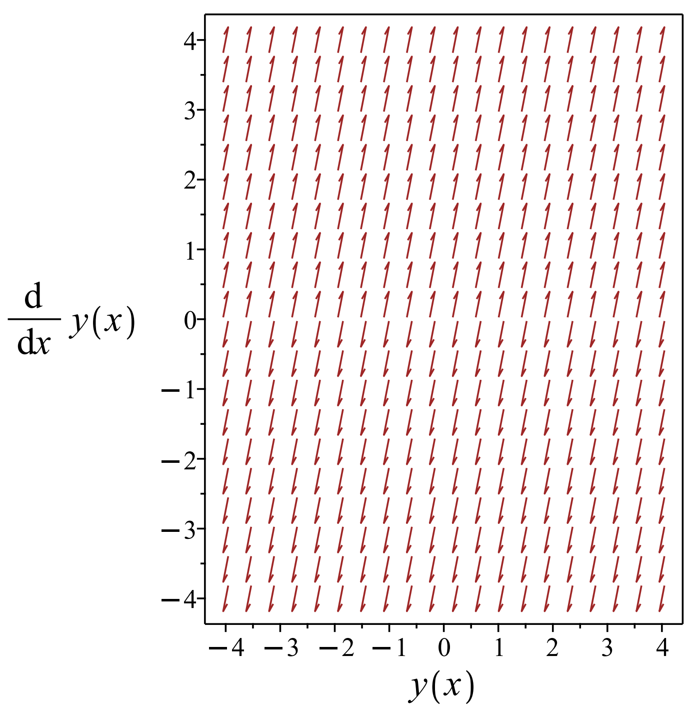

Figure 530: Slope field plot

Verification of solutions

$$y = \frac{(2x^2 + 16c_2 - x)\,e^{4x}}{16} - \frac{c_1}{4}$$

Verified OK.

16.8.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 413: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\
&= z_1 e^{2x} \\
&= z_1\left(\mathrm{e}^{2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{\mathrm{e}^{4x}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' - 4y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + \frac{c_2 \mathrm{e}^{4x}}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = \frac{\mathrm{e}^{4x}}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{\mathrm{e}^{4x}}{4} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{\mathrm{e}^{4x}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{\mathrm{e}^{4x}}{4} \\ 0 & \mathrm{e}^{4x} \end{vmatrix}$$

Therefore

$$W = (1)\left(e^{4x}\right) - \left(\frac{e^{4x}}{4}\right)(0)$$

Which simplifies to

$$W = e^{4x}$$

Which simplifies to

$$W = e^{4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{e^{8x}x}{4}}{e^{4x}}dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{4x}x}{4}dx$$

Hence

$$u_1 = -\frac{(4x-1)\,e^{4x}}{64}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{4x}x}{e^{4x}}dx$$

Which simplifies to

$$u_2 = \int x dx$$

Hence

$$u_2 = \frac{x^2}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{(4x-1)\,e^{4x}}{64} + \frac{x^2 e^{4x}}{8}$$

Which simplifies to

$$y_p(x) = \frac{e^{4x}(8x^2 - 4x + 1)}{64}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 e^{4x}}{4}\right) + \left(\frac{e^{4x}(8x^2 - 4x + 1)}{64}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + \frac{c_2 e^{4x}}{4} + \frac{e^{4x}(8x^2 - 4x + 1)}{64} \tag{1}$$

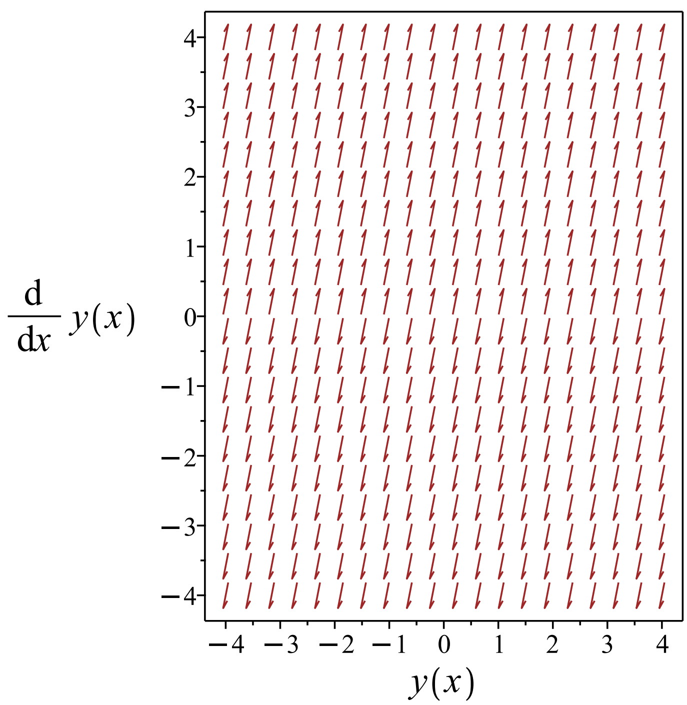

Figure 531: Slope field plot

Verification of solutions

$$y = c_1 + \frac{c_2 e^{4x}}{4} + \frac{e^{4x}(8x^2 - 4x + 1)}{64}$$

Verified OK.

16.8.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1 \\
q(x) &= -4 \\
r(x) &= 0 \\
s(x) &= \mathrm{e}^{4x} x
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$-4y + y' = \int \mathrm{e}^{4x} x\,dx$$

We now have a first order ode to solve which is

$$-4y + y' = \frac{(4x-1)\,\mathrm{e}^{4x}}{16} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -4 \\ q(x) &= \frac{(4x-1)\,e^{4x}}{16} + c_1 \end{aligned}$$

Hence the ode is

$$-4y + y' = \frac{(4x-1)\,e^{4x}}{16} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-4)dx} \\ &= e^{-4x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{(4x-1)\,e^{4x}}{16} + c_1\right) \\ \frac{d}{dx}\left(e^{-4x}y\right) &= \left(e^{-4x}\right)\left(\frac{(4x-1)\,e^{4x}}{16} + c_1\right) \\ d\left(e^{-4x}y\right) &= \left(\frac{x}{4} - \frac{1}{16} + c_1 e^{-4x}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-4x}y &= \int \frac{x}{4} - \frac{1}{16} + c_1 e^{-4x}\, dx \\ e^{-4x}y &= \frac{x^2}{8} - \frac{x}{16} - \frac{c_1 e^{-4x}}{4} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-4x}$ results in

$$y = e^{4x}\left(\frac{x^2}{8} - \frac{x}{16} - \frac{c_1 e^{-4x}}{4}\right) + c_2 e^{4x}$$

which simplifies to

$$y = \frac{(2x^2 + 16c_2 - x)\,e^{4x}}{16} - \frac{c_1}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{(2x^2 + 16c_2 - x)\,e^{4x}}{16} - \frac{c_1}{4} \tag{1}$$

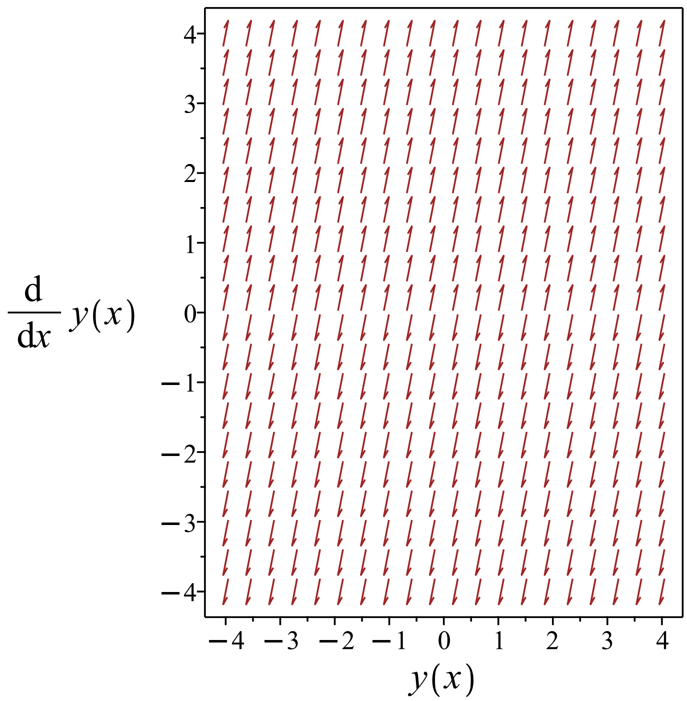

Figure 532: Slope field plot

Verification of solutions

$$y = \frac{(2x^2 + 16c_2 - x)\,e^{4x}}{16} - \frac{c_1}{4}$$

Verified OK.

16.8.7 Maple step by step solution

Let's solve

$y'' - 4y' = e^{4x}x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 4r = 0$

- Factor the characteristic polynomial

  $r(r-4) = 0$
- Roots of the characteristic polynomial

  $r = (0, 4)$
- 1st solution of the homogeneous ODE

  $y_1(x) = 1$
- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{4x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{4x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{4x}x\right]$
- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{4x} \\ 0 & 4e^{4x} \end{bmatrix}$
- Compute Wronskian

  $W(y_1(x), y_2(x)) = 4e^{4x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\left(\int e^{4x}x dx\right)}{4} + \frac{e^{4x}\left(\int x dx\right)}{4}$
- Compute integrals

  $y_p(x) = \frac{e^{4x}(8x^2-4x+1)}{64}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 e^{4x} + \frac{e^{4x}(8x^2-4x+1)}{64}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 25y = \cos(5x)}$$

16.9.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 25, f(x) = \cos(5x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 25y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=0, C=25$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 25\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 25 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=1, B=0, C=25$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(25)}\\ &= \pm 5i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +5i\\ \lambda_2 &= -5i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 5i\\ \lambda_2 &= -5i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 5$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(5x) + c_2 \sin(5x))$$

Or

$$y = c_1 \cos(5x) + c_2 \sin(5x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(5x) + c_2 \sin(5x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(5x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(5x), \sin(5x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(5x), \sin(5x)\}$$

Since $\cos(5x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\cos(5x), x\sin(5x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos(5x) + A_2 x \sin(5x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-10A_1 \sin(5x) + 10A_2 \cos(5x) = \cos(5x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x \sin(5x)}{10}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(5x) + c_2 \sin(5x)) + \left(\frac{x \sin(5x)}{10}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(5x) + c_2 \sin(5x) + \frac{x \sin(5x)}{10} \tag{1}
$$

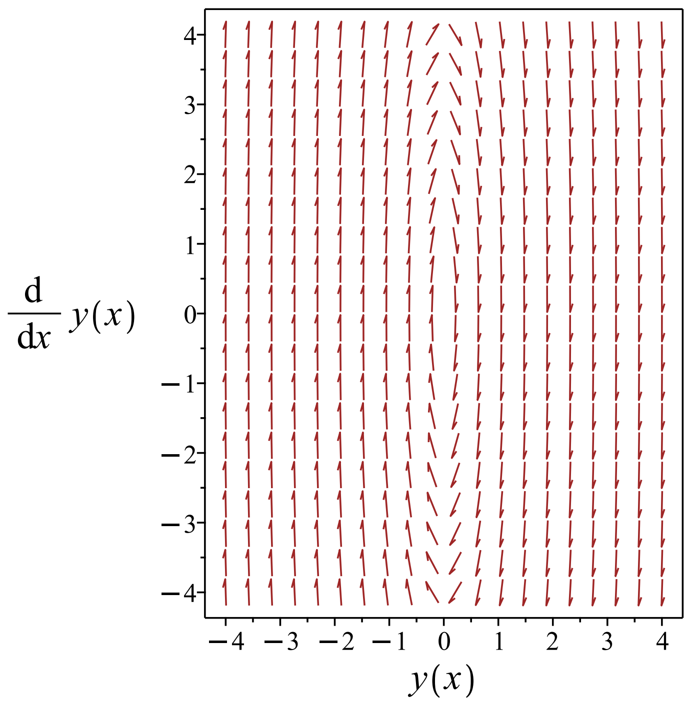

Figure 533: Slope field plot

Verification of solutions

$$
y = c_1 \cos(5x) + c_2 \sin(5x) + \frac{x \sin(5x)}{10}
$$

Verified OK.

16.9.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 25y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 25 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-25}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -25 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -25z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 415: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -25$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(5x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(5x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(5x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(5x) \int \frac{1}{\cos(5x)^2}\,dx \\ &= \cos(5x)\left(\frac{\tan(5x)}{5}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(5x)) + c_2\left(\cos(5x)\left(\frac{\tan(5x)}{5}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 25y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(5x) + \frac{c_2 \sin(5x)}{5}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(5x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(5x), \sin(5x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(5x)}{5}, \cos(5x)\right\}$$

Since $\cos(5x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\cos(5x), x\sin(5x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos(5x) + A_2 x \sin(5x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-10A_1 \sin(5x) + 10A_2 \cos(5x) = \cos(5x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x \sin(5x)}{10}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \cos(5x) + \frac{c_2 \sin(5x)}{5}\right) + \left(\frac{x \sin(5x)}{10}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(5x) + \frac{c_2 \sin(5x)}{5} + \frac{x \sin(5x)}{10} \tag{1}
$$

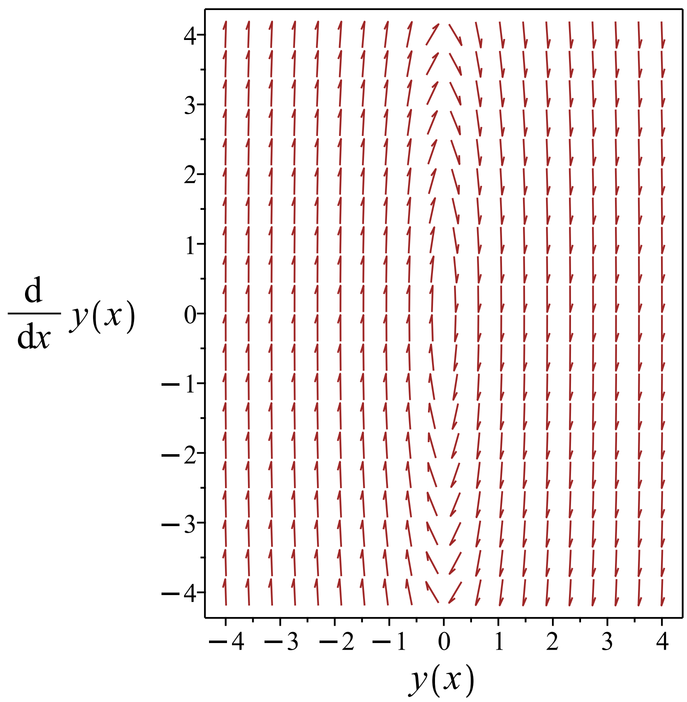

Figure 534: Slope field plot

Verification of solutions

$$

16.9.3 Maple step by step solution

Let's solve

$y'' + 25y = \cos(5x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 25 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-100})}{2}$

- Roots of the characteristic polynomial

  $r = (-5\,\mathrm{I}, 5\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(5x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(5x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(5x) + c_2 \sin(5x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cos(5x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(5x) & \sin(5x) \\ -5\sin(5x) & 5\cos(5x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 5$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(5x)\left(\int \sin(10x)dx\right)}{10} + \frac{\sin(5x)\left(\int \cos(5x)^2 dx\right)}{5}$$

- Compute integrals

$$y_p(x) = \frac{\cos(5x)}{100} + \frac{x\sin(5x)}{10}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(5x) + c_2 \sin(5x) + \frac{\cos(5x)}{100} + \frac{x\sin(5x)}{10}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = -\cos(x) + \sin(x)}$$

16.10.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = -\cos(x) + \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-\cos(x) + \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\cos(x), x\sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos(x) + A_2 x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \sin(x) + 2A_2 \cos(x) = -\cos(x) + \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\cos(x)}{2} - \frac{x\sin(x)}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(-\frac{x\cos(x)}{2} - \frac{x\sin(x)}{2}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) - \frac{x\cos(x)}{2} - \frac{x\sin(x)}{2} \tag{1}
$$

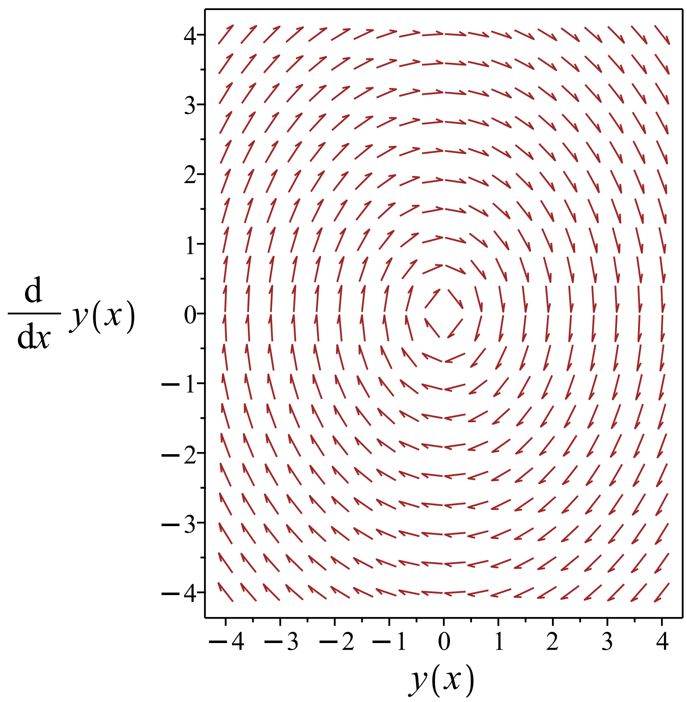

Figure 535: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) - \frac{x\cos(x)}{2} - \frac{x\sin(x)}{2}
$$

Verified OK.

16.10.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 417: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x) (\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x) (\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-\cos(x) + \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\cos(x), x\sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x \cos(x) + A_2 x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \sin(x) + 2A_2 \cos(x) = -\cos(x) + \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\cos(x)}{2} - \frac{x\sin(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(-\frac{x\cos(x)}{2} - \frac{x\sin(x)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) - \frac{x \cos(x)}{2} - \frac{x \sin(x)}{2} \tag{1}$$

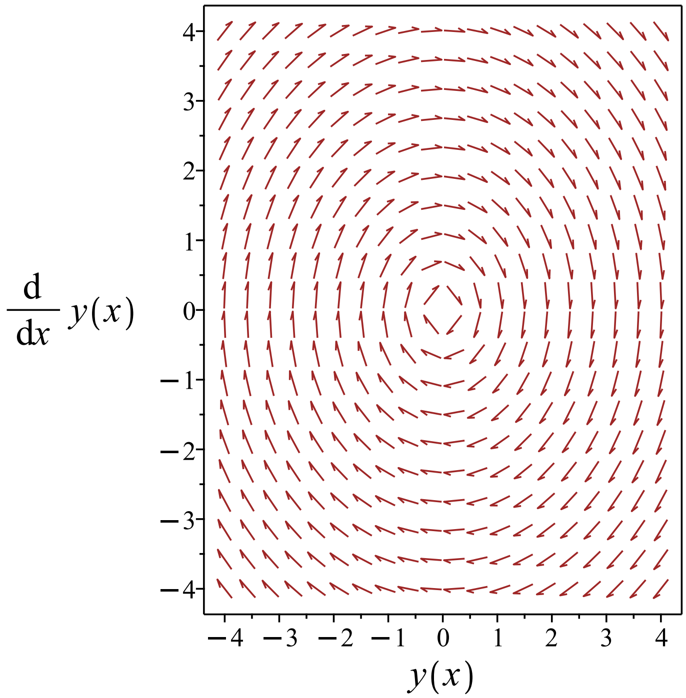

Figure 536: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) - \frac{x \cos(x)}{2} - \frac{x \sin(x)}{2}$$

Verified OK.

16.10.3 Maple step by step solution

Let's solve

$y'' + y = -\cos(x) + \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2+1=0$

- Use quadratic formula to solve for r

$r=\frac{0\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r=(-\mathrm{I},\mathrm{I})$

- 1st solution of the homogeneous ODE

$y_1(x)=\cos(x)$

- 2nd solution of the homogeneous ODE

$y_2(x)=\sin(x)$

- General solution of the ODE

$y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

$y=c_1\cos(x)+c_2\sin(x)+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

$\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=-\cos(x)+\sin(x)\right]$

- Wronskian of solutions of the homogeneous equation

$W(y_1(x),y_2(x))=\begin{bmatrix}\cos(x)&\sin(x)\\-\sin(x)&\cos(x)\end{bmatrix}$

- Compute Wronskian

$W(y_1(x),y_2(x))=1$

- Substitute functions into equation for $y_p(x)$

$y_p(x)=\cos(x)\left(\int\sin(x)(\cos(x)-\sin(x))dx\right)-\sin(x)\left(\int\cos(x)(\cos(x)-\sin(x))dx\right)$

- Compute integrals

$y_p(x)=\frac{(-x-1)\cos(x)}{2}-\frac{x\sin(x)}{2}$

- Substitute particular solution into general solution to ODE

$y=c_1\cos(x)+c_2\sin(x)+\frac{(-x-1)\cos(x)}{2}-\frac{x\sin(x)}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 16y = \sin(4x + \alpha)}$$

16.11.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 16, f(x) = \sin(4x + \alpha)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 16y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 16$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 16\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 16 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 16$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(16)} \\ &= \pm 4i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +4i \\ \lambda_2 &= -4i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 4i \\ \lambda_2 &= -4i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 4$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(4x) + c_2 \sin(4x))$$

Or

$$y = c_1 \cos(4x) + c_2 \sin(4x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(4x) + c_2 \sin(4x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(4x) \\ y_2 &= \sin(4x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(4x) & \sin(4x) \\ \frac{d}{dx}(\cos(4x)) & \frac{d}{dx}(\sin(4x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(4x) & \sin(4x) \\ -4\sin(4x) & 4\cos(4x) \end{vmatrix}$$

Therefore

$$W = (\cos(4x))(4\cos(4x)) - (\sin(4x))(-4\sin(4x))$$

Which simplifies to

$$W = 4\cos(4x)^2 + 4\sin(4x)^2$$

Which simplifies to

$$W = 4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(4x)\sin(4x+\alpha)}{4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(4x)\sin(4x+\alpha)}{4}dx$$

Hence

$$u_1 = -\frac{x\cos(\alpha)}{8} + \frac{\sin(8x+\alpha)}{64}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(4x)\sin(4x+\alpha)}{4}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(4x)\sin(4x+\alpha)}{4}dx$$

Hence

$$u_2 = \frac{x\sin(\alpha)}{8} - \frac{\cos(8x+\alpha)}{64}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{x\cos(\alpha)}{8} + \frac{\sin(8x+\alpha)}{64}\right)\cos(4x) + \left(\frac{x\sin(\alpha)}{8} - \frac{\cos(8x+\alpha)}{64}\right)\sin(4x)$$

Which simplifies to

$$y_p(x) = -\frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(4x) + c_2 \sin(4x)) + \left(-\frac{x \cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(4x) + c_2 \sin(4x) - \frac{x \cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64} \tag{1}
$$

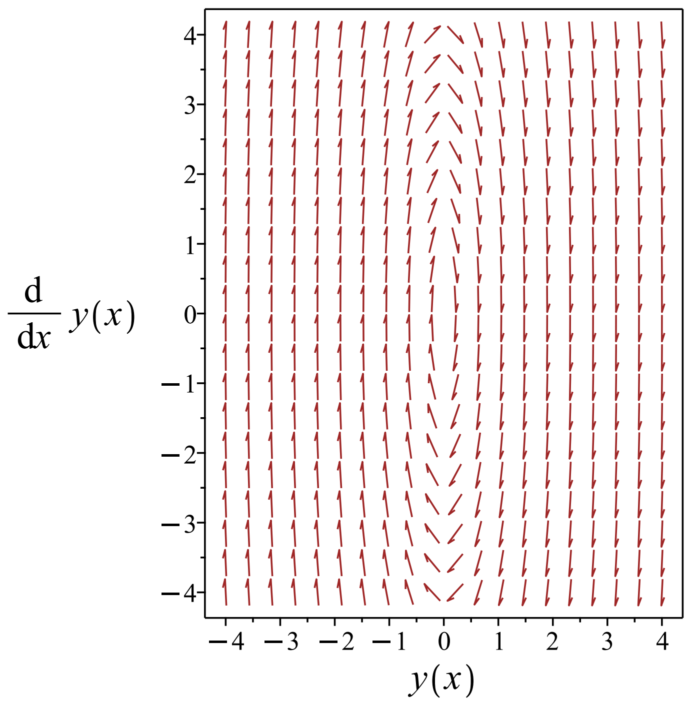

Figure 537: Slope field plot

Verification of solutions

$$
y = c_1 \cos(4x) + c_2 \sin(4x) - \frac{x \cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}
$$

Verified OK.

16.11.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 16y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 16 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-16}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -16 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -16z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 419: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -16$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(4x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(4x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(4x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= \cos(4x) \int \frac{1}{\cos(4x)^2} \, dx \\ &= \cos(4x) \left(\frac{\tan(4x)}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(4x)) + c_2 \left(\cos(4x) \left(\frac{\tan(4x)}{4}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 16y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(4x) + \frac{c_2 \sin(4x)}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(4x)$$

$$y_2 = \frac{\sin(4x)}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(4x) & \frac{\sin(4x)}{4} \\ \frac{d}{dx}(\cos(4x)) & \frac{d}{dx}\left(\frac{\sin(4x)}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(4x) & \frac{\sin(4x)}{4} \\ -4\sin(4x) & \cos(4x) \end{vmatrix}$$

Therefore

$$W = (\cos(4x))(\cos(4x)) - \left(\frac{\sin(4x)}{4}\right)(-4\sin(4x))$$

Which simplifies to

$$W = \cos(4x)^2 + \sin(4x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(4x)\sin(4x+\alpha)}{4}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(4x)\sin(4x+\alpha)}{4} dx$$

Hence

$$u_1 = -\frac{x\cos(\alpha)}{8} + \frac{\sin(8x+\alpha)}{64}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(4x)\sin(4x+\alpha)}{1} dx$$

Which simplifies to

$$u_2 = \int \cos(4x)\sin(4x+\alpha)\, dx$$

Hence

$$u_2 = \frac{x\sin(\alpha)}{2} - \frac{\cos(8x+\alpha)}{16}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{x\cos(\alpha)}{8} + \frac{\sin(8x+\alpha)}{64}\right)\cos(4x) + \frac{\left(\frac{x\sin(\alpha)}{2} - \frac{\cos(8x+\alpha)}{16}\right)\sin(4x)}{4}$$

Which simplifies to

$$y_p(x) = -\frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(4x) + \frac{c_2\sin(4x)}{4}\right) + \left(-\frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(4x) + \frac{c_2\sin(4x)}{4} - \frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64} \tag{1}$$

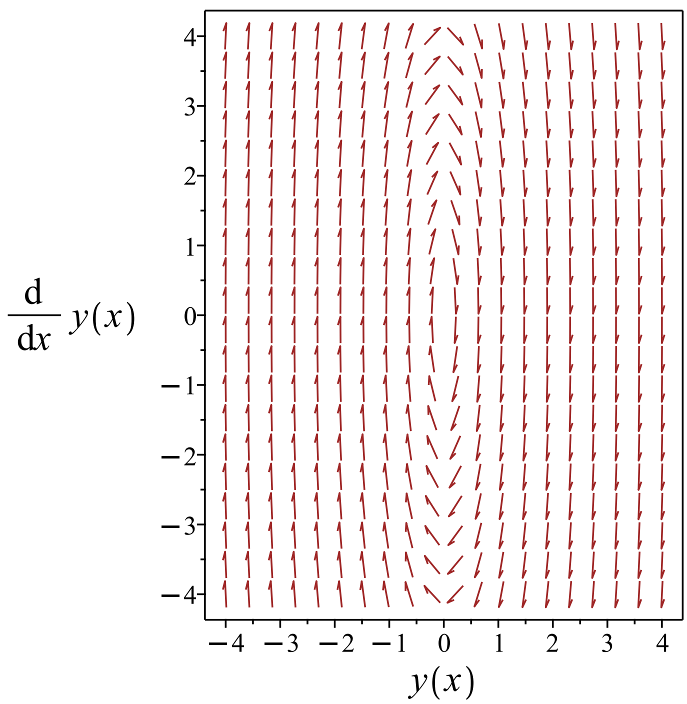

Figure 538: Slope field plot

Verification of solutions

$$y = c_1\cos(4x) + \frac{c_2\sin(4x)}{4} - \frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}$$

Verified OK.

16.11.3 Maple step by step solution

Let's solve

$y'' + 16y = \sin(4x + \alpha)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 16 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-64})}{2}$

- Roots of the characteristic polynomial

  $r = (-4\,\mathrm{I}, 4\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(4x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(4x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(4x) + c_2 \sin(4x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(4x + \alpha)\right]$

- ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(4x) & \sin(4x) \\ -4\sin(4x) & 4\cos(4x) \end{bmatrix}$

- ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 4$

- ◦ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(4x)\left(\int \sin(4x)\sin(4x+\alpha)dx\right)}{4} + \frac{\sin(4x)\left(\int \cos(4x)\sin(4x+\alpha)dx\right)}{4}$$

- Compute integrals

$$y_p(x) = -\frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(4x) + c_2 \sin(4x) - \frac{x\cos(4x+\alpha)}{8} + \frac{\sin(4x+\alpha)}{64}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y''+4y'+8y = e^{2x}(\sin(2x)+\cos(2x))}$$

16.12.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 8, f(x) = e^{2x}(\sin(2x)+\cos(2x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y''+4y'+8y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x) = 0$$

Where in the above $A=1, B=4, C=8$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+4\lambda\,\mathrm{e}^{\lambda x}+8\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+4\lambda+8=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=4, C=8$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-4}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{4^2-(4)\,(1)\,(8)}\\&=-2\pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-2+2i\\\lambda_2&=-2-2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=-2+2i\\\lambda_2&=-2-2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2}=\alpha\pm i\beta$$

Where $\alpha=-2$ and $\beta=2$. Therefore the final solution, when using Euler relation, can be written as

$$y=e^{\alpha x}(c_1\cos(\beta x)+c_2\sin(\beta x))$$

Which becomes

$$y=e^{-2x}(c_1\cos\,(2x)+c_2\sin\,(2x))$$

Therefore the homogeneous solution y_h is

$$y_h=\mathrm{e}^{-2x}(c_1\cos\,(2x)+c_2\sin\,(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x}(\sin(2x) + \cos(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\cos(2x), e^{2x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}\cos(2x), e^{-2x}\sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x}\cos(2x) + A_2 e^{2x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-16A_1 e^{2x}\sin(2x) + 16A_2 e^{2x}\cos(2x) + 16A_1 e^{2x}\cos(2x) + 16A_2 e^{2x}\sin(2x)\\&= e^{2x}(\sin(2x) + \cos(2x))\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{16}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{2x}\sin(2x)}{16}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(e^{-2x}(c_1\cos(2x) + c_2\sin(2x))\right) + \left(\frac{e^{2x}\sin(2x)}{16}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(2x) + c_2 \sin(2x)) + \frac{e^{2x} \sin(2x)}{16} \tag{1}$$

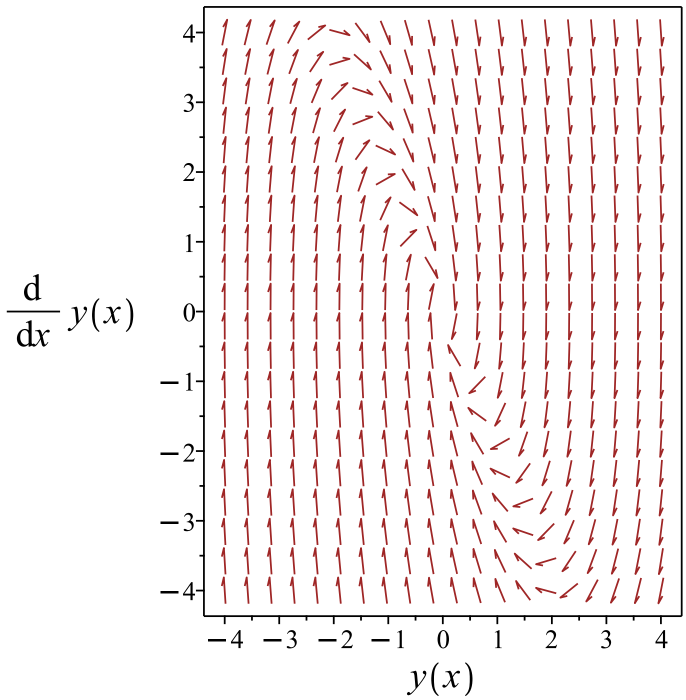

Figure 539: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(2x) + c_2 \sin(2x)) + \frac{e^{2x} \sin(2x)}{16}$$

Verified OK.

16.12.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 8y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 421: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{4}{1} \, dx} \\
&= z_1 e^{-2x} \\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x} \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-4x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-2x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 8y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(2x)\, \mathrm{e}^{-2x} c_1 + \frac{\sin(2x)\, \mathrm{e}^{-2x} c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{2x} (\sin(2x) + \cos(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\cos(2x), e^{2x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-2x}\cos(2x), \frac{e^{-2x}\sin(2x)}{2}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{2x}\cos(2x) + A_2 e^{2x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-16A_1 e^{2x}\sin(2x) + 16A_2 e^{2x}\cos(2x) + 16A_1 e^{2x}\cos(2x) + 16A_2 e^{2x}\sin(2x)\\&= e^{2x}(\sin(2x) + \cos(2x))\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{16}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{2x}\sin(2x)}{16}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\&= \left(\cos(2x)\,e^{-2x}c_1 + \frac{\sin(2x)\,e^{-2x}c_2}{2}\right) + \left(\frac{e^{2x}\sin(2x)}{16}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(2x)\,e^{-2x}c_1 + \frac{\sin(2x)\,e^{-2x}c_2}{2} + \frac{e^{2x}\sin(2x)}{16} \tag{1}$$

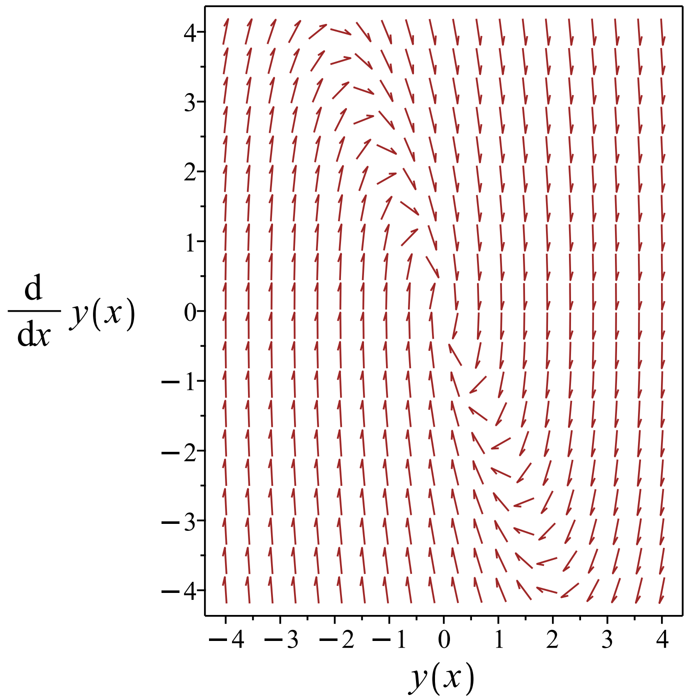

Figure 540: Slope field plot

Verification of solutions

$$y = \cos(2x)\,e^{-2x}c_1 + \frac{\sin(2x)\,e^{-2x}c_2}{2} + \frac{e^{2x}\sin(2x)}{16}$$

Verified OK.

16.12.3 Maple step by step solution

Let's solve

$y'' + 4y' + 8y = e^{2x}(\sin(2x) + \cos(2x))$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 8 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-4)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (-2 - 2\,\mathrm{I}, -2 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x} \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-2x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(2x)\,\mathrm{e}^{-2x} c_1 + \sin(2x)\,\mathrm{e}^{-2x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \mathrm{e}^{2x}(\sin(2x) + \cos(2x)\right)$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x}\cos(2x) & \mathrm{e}^{-2x}\sin(2x) \\ -2\,\mathrm{e}^{-2x}\cos(2x) - 2\,\mathrm{e}^{-2x}\sin(2x) & -2\,\mathrm{e}^{-2x}\sin(2x) + 2\,\mathrm{e}^{-2x}\cos(2x) \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-4x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\mathrm{e}^{-2x}\left(\cos(2x)\left(\int(-1+\cos(4x)-\sin(4x))\mathrm{e}^{4x} dx\right)+\sin(2x)\left(\int(1+\sin(4x)+\cos(4x))\mathrm{e}^{4x} dx\right)\right)}{4}$

  ◦ Compute integrals

  $y_p(x) = \frac{\mathrm{e}^{2x}\sin(2x)}{16}$

- Substitute particular solution into general solution to ODE

  $y = \sin(2x)\,\mathrm{e}^{-2x} c_2 + \cos(2x)\,\mathrm{e}^{-2x} c_1 + \frac{\mathrm{e}^{2x}\sin(2x)}{16}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 4y' + 8y = \mathrm{e}^{2x}(-\cos(2x) + \sin(2x))}$$

16.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 8, f(x) = \mathrm{e}^{2x}(-\cos(2x) + \sin(2x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 8y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 8$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\lambda\, \mathrm{e}^{\lambda x} + 8\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 8 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 8$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(8)}\\ &= 2 \pm 2i\end{aligned}$$

Hence

$$\lambda_1 = 2 + 2i$$
$$\lambda_2 = 2 - 2i$$

Which simplifies to

$$\lambda_1 = 2 + 2i$$
$$\lambda_2 = 2 - 2i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{2x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x}(-\cos(2x) + \sin(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\cos(2x), e^{2x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(2x), e^{2x}\sin(2x)\}$$

Since $e^{2x}\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{2x}\cos(2x), x\,e^{2x}\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{2x}\cos(2x) + A_2 x\,e^{2x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1e^{2x}\sin(2x) + 4A_2e^{2x}\cos(2x) = e^{2x}(-\cos(2x) + \sin(2x))$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{2x}\cos(2x)}{4} - \frac{x\,e^{2x}\sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(e^{2x}(c_1\cos(2x) + c_2\sin(2x))\right) + \left(-\frac{x\,e^{2x}\cos(2x)}{4} - \frac{x\,e^{2x}\sin(2x)}{4}\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{x e^{2x} \cos(2x)}{4} - \frac{x e^{2x} \sin(2x)}{4} \tag{1}$$

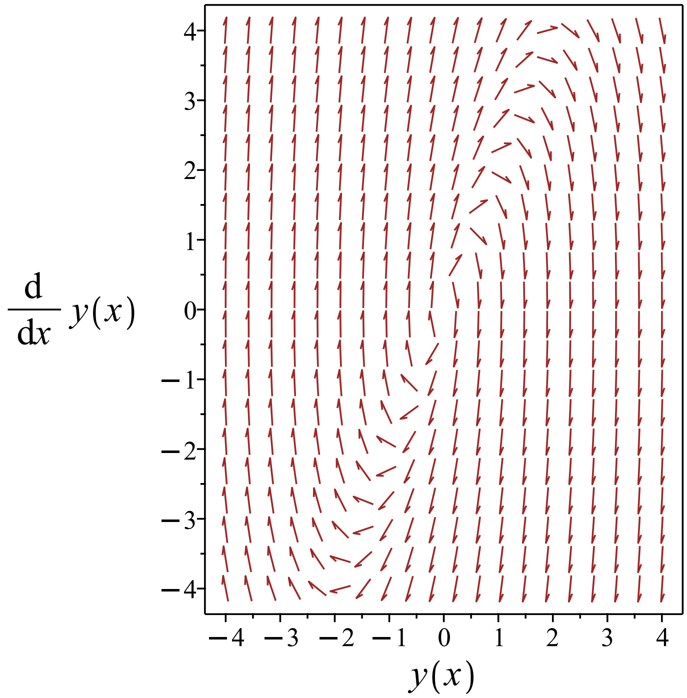

Figure 541: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{x e^{2x} \cos(2x)}{4} - \frac{x e^{2x} \sin(2x)}{4}$$

Verified OK.

16.13.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 8y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= -4 \\
C &= 8
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-4}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -4 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -4z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 423: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1\left(\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x} \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{2x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{2x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 8y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{2x} \cos(2x)\, c_1 + \frac{\mathrm{e}^{2x} \sin(2x)\, c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-e^{2x}(\cos(2x) - \sin(2x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\cos(2x), e^{2x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{2x}\cos(2x), \frac{e^{2x}\sin(2x)}{2}\right\}$$

Since $e^{2x}\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{2x}\cos(2x), x\,e^{2x}\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{2x}\cos(2x) + A_2 x\,e^{2x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1e^{2x}\sin(2x) + 4A_2e^{2x}\cos(2x) = e^{2x}(-\cos(2x) + \sin(2x))$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{2x}\cos(2x)}{4} - \frac{x\,e^{2x}\sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}\cos(2x)\,c_1 + \frac{e^{2x}\sin(2x)\,c_2}{2}\right) + \left(-\frac{x\,e^{2x}\cos(2x)}{4} - \frac{x\,e^{2x}\sin(2x)}{4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{2x} \cos(2x) c_1 + \frac{e^{2x} \sin(2x) c_2}{2} - \frac{x e^{2x} \cos(2x)}{4} - \frac{x e^{2x} \sin(2x)}{4} \tag{1}$$

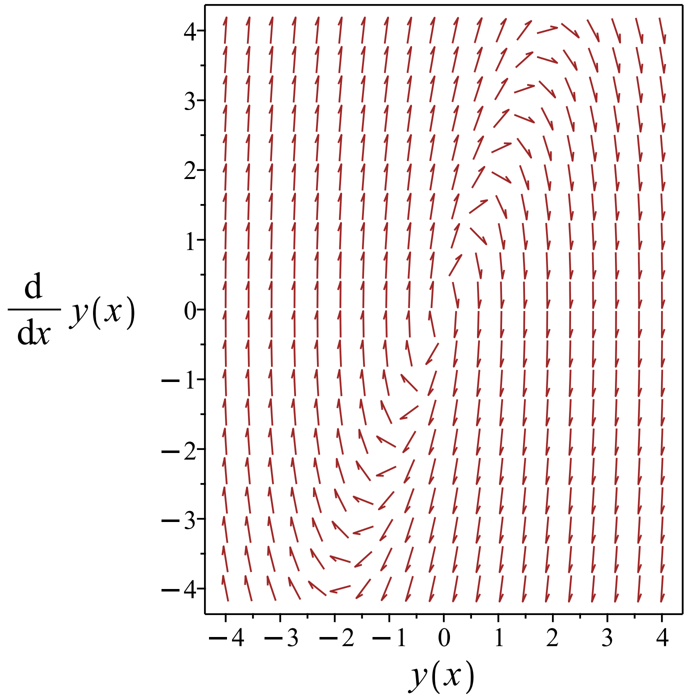

Figure 542: Slope field plot

Verification of solutions

$$y = e^{2x} \cos(2x) c_1 + \frac{e^{2x} \sin(2x) c_2}{2} - \frac{x e^{2x} \cos(2x)}{4} - \frac{x e^{2x} \sin(2x)}{4}$$

Verified OK.

16.13.3 Maple step by step solution

Let's solve

$y'' - 4y' + 8y = e^{2x}(-\cos(2x) + \sin(2x))$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$$y'' = -e^{2x} \cos(2x) + e^{2x} \sin(2x) + 4y' - 8y$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y'' - 4y' + 8y = -e^{2x}(\cos(2x) - \sin(2x))$$

- Characteristic polynomial of homogeneous ODE

$$r^2 - 4r + 8 = 0$$

- Use quadratic formula to solve for r

$$r = \frac{4 \pm (\sqrt{-16})}{2}$$

- Roots of the characteristic polynomial

$$r = (2 - 2\mathrm{I}, 2 + 2\mathrm{I})$$

- 1st solution of the homogeneous ODE

$$y_1(x) = e^{2x} \cos(2x)$$

- 2nd solution of the homogeneous ODE

$$y_2(x) = e^{2x} \sin(2x)$$

- General solution of the ODE

$$y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$$

- Substitute in solutions of the homogeneous ODE

$$y = e^{2x} \cos(2x) c_1 + e^{2x} \sin(2x) c_2 + y_p(x)$$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -e^{2x}(\cos(2x) - \sin(2x\right.$$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{2x} \cos(2x) & e^{2x} \sin(2x) \\ 2e^{2x} \cos(2x) - 2e^{2x} \sin(2x) & 2e^{2x} \sin(2x) + 2e^{2x} \cos(2x) \end{bmatrix}$$

- Compute Wronskian

$$W(y_1(x), y_2(x)) = 2e^{4x}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{e^{2x}\left(\cos(2x)\left(\int(-\sin(4x)+1-\cos(4x))dx\right)-\sin(2x)\left(\int(-\cos(4x)-1+\sin(4x))dx\right)\right)}{4}$$

- Compute integrals

$$y_p(x) = -\frac{e^{2x}(-\sin(2x)+\cos(2x)+4x\cos(2x)+4x\sin(2x))}{16}$$

- Substitute particular solution into general solution to ODE

$$y = e^{2x}\cos(2x)\, c_1 + e^{2x}\sin(2x)\, c_2 - \frac{e^{2x}(-\sin(2x)+\cos(2x)+4x\cos(2x)+4x\sin(2x))}{16}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 6y' + 13y = e^{-3x} \cos(2x)}$$

16.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 6, C = 13, f(x) = e^{-3x} \cos(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 13y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 13$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda e^{\lambda x} + 13 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 13 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 13$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{6^2 - (4)(1)(13)} \\ &= -3 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -3 + 2i \\ \lambda_2 &= -3 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -3 + 2i \\ \lambda_2 &= -3 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -3$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-3x} \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-3x} \cos(2x), e^{-3x} \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-3x} \cos(2x), e^{-3x} \sin(2x)\}$$

Since $e^{-3x} \cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^{-3x} \cos(2x), x e^{-3x} \sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x e^{-3x} \cos(2x) + A_2 x e^{-3x} \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-3x} \sin(2x) + 4A_2 e^{-3x} \cos(2x) = e^{-3x} \cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x e^{-3x} \sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x))\right) + \left(\frac{x e^{-3x} \sin(2x)}{4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x)) + \frac{x e^{-3x} \sin(2x)}{4} \tag{1}$$

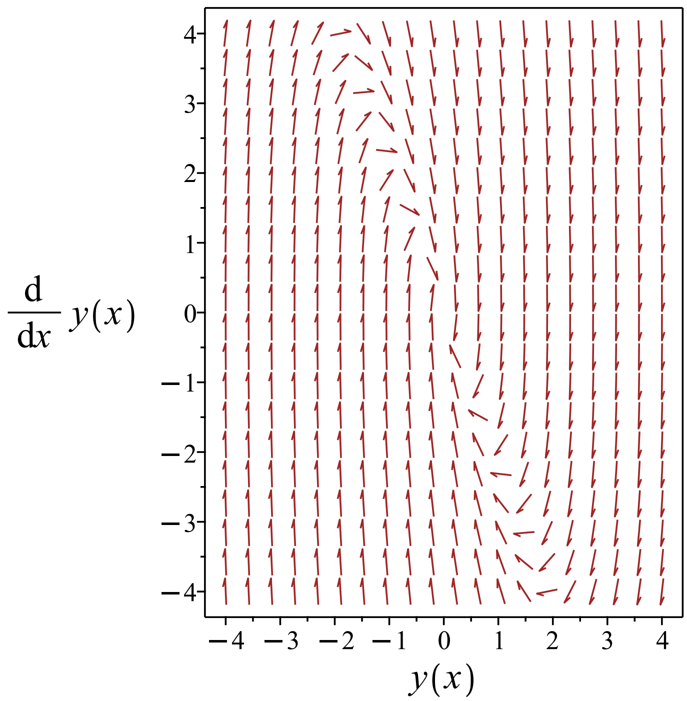

Figure 543: Slope field plot

Verification of solutions

$$y = e^{-3x}(c_1 \cos(2x) + c_2 \sin(2x)) + \frac{x e^{-3x} \sin(2x)}{4}$$

Verified OK.

16.14.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 13y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 6 \\
C &= 13
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-4}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -4 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -4z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 425: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{6}{1} \, dx} \\ &= z_1 e^{-3x} \\ &= z_1 \left(\mathrm{e}^{-3x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x} \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-6x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-3x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-3x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 6y' + 13y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-3x} \cos(2x)\, c_1 + \frac{\mathrm{e}^{-3x} \sin(2x)\, c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{-3x} \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-3x}\cos(2x), e^{-3x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-3x}\cos(2x), \frac{e^{-3x}\sin(2x)}{2}\right\}$$

Since $e^{-3x}\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-3x}\cos(2x), x\,e^{-3x}\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{-3x}\cos(2x) + A_2 x\,e^{-3x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-3x}\sin(2x) + 4A_2 e^{-3x}\cos(2x) = e^{-3x}\cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x\,e^{-3x}\sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-3x}\cos(2x)\,c_1 + \frac{e^{-3x}\sin(2x)\,c_2}{2}\right) + \left(\frac{x\,e^{-3x}\sin(2x)}{4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-3x} \cos(2x) c_1 + \frac{e^{-3x} \sin(2x) c_2}{2} + \frac{x e^{-3x} \sin(2x)}{4} \tag{1}$$

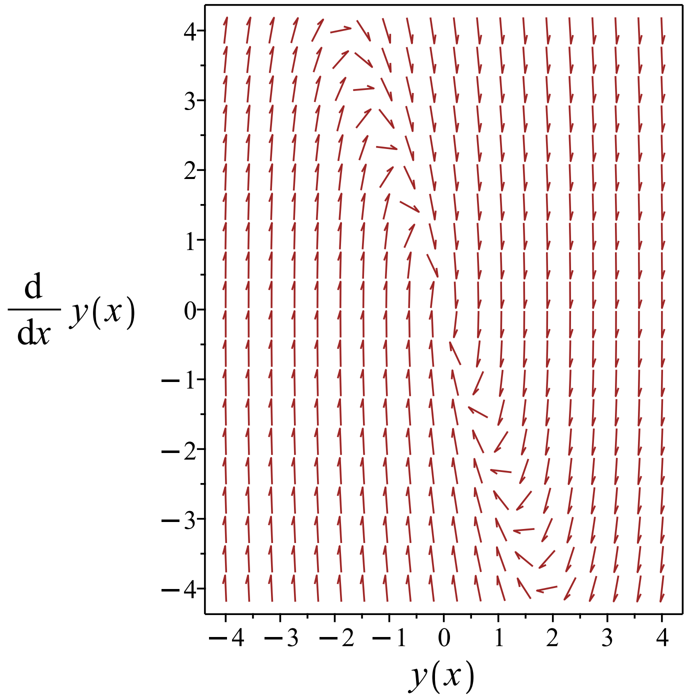

Figure 544: Slope field plot

Verification of solutions

$$y = e^{-3x} \cos(2x) c_1 + \frac{e^{-3x} \sin(2x) c_2}{2} + \frac{x e^{-3x} \sin(2x)}{4}$$

Verified OK.

16.14.3 Maple step by step solution

Let's solve

$y'' + 6y' + 13y = e^{-3x} \cos(2x)$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 6r + 13 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-6)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-3 - 2\,\mathrm{I}, -3 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x} \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-3x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{-3x} \cos(2x) c_1 + \mathrm{e}^{-3x} \sin(2x) c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \mathrm{e}^{-3x}\cos(2x)\right]$

  ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x}\cos(2x) & \mathrm{e}^{-3x}\sin(2x) \\ -3\,\mathrm{e}^{-3x}\cos(2x) - 2\,\mathrm{e}^{-3x}\sin(2x) & -3\,\mathrm{e}^{-3x}\sin(2x) + 2\,\mathrm{e}^{-3x}\cos(2x) \end{bmatrix}$

  ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-6x}$

  ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-3x}\left(\cos(2x)(\int \sin(4x)dx) - 2\sin(2x)\left(\int \cos(2x)^2 dx\right)\right)}{4}$

  ○ Compute integrals

  $y_p(x) = \frac{(4x\sin(2x)+\cos(2x))\mathrm{e}^{-3x}}{16}$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{-3x}\cos(2x) c_1 + \mathrm{e}^{-3x}\sin(2x) c_2 + \frac{(4x\sin(2x)+\cos(2x))\mathrm{e}^{-3x}}{16}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + k^2 y = k \sin(kx + \alpha)}$$

16.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = k^2, f(x) = k \sin(kx + \alpha)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + k^2 y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=0, C=k^2$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + k^2 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$k^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=1, B=0, C=k^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(k^2)} \\ &= \pm\sqrt{-k^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-k^2} \\ \lambda_2 &= -\sqrt{-k^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-k^2} \\ \lambda_2 &= -\sqrt{-k^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\sqrt{-k^2}\right)x} + c_2 e^{\left(-\sqrt{-k^2}\right)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{-k^2}\,x} + c_2 \mathrm{e}^{-\sqrt{-k^2}\,x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{\sqrt{-k^2}\,x} + c_2 \mathrm{e}^{-\sqrt{-k^2}\,x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^{\sqrt{-k^2}\, x} \\ y_2 &= \mathrm{e}^{-\sqrt{-k^2}\, x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{\sqrt{-k^2}\, x} & \mathrm{e}^{-\sqrt{-k^2}\, x} \\ \frac{d}{dx}\left(\mathrm{e}^{\sqrt{-k^2}\, x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-\sqrt{-k^2}\, x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{\sqrt{-k^2}\, x} & \mathrm{e}^{-\sqrt{-k^2}\, x} \\ \sqrt{-k^2}\, \mathrm{e}^{\sqrt{-k^2}\, x} & -\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{\sqrt{-k^2}\, x}\right)\left(-\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x}\right) - \left(\mathrm{e}^{-\sqrt{-k^2}\, x}\right)\left(\sqrt{-k^2}\, \mathrm{e}^{\sqrt{-k^2}\, x}\right)$$

Which simplifies to

$$W = -2\, \mathrm{e}^{\sqrt{-k^2}\, x} \sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x}$$

Which simplifies to

$$W = -2\sqrt{-k^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{-\sqrt{-k^2}\, x} k \sin(kx+\alpha)}{-2\sqrt{-k^2}}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{e^{-\sqrt{-k^2}\, x} k \sin(kx+\alpha)}{2\sqrt{-k^2}} dx$$

Hence

$$u_1 = -\frac{-\frac{x\, e^{-\sqrt{-k^2}\, x}}{4} - \frac{x\, e^{-\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{4} - \frac{\sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{4k^2} + \frac{\sqrt{-k^2}\, x\, e^{-\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)}{2k} + \frac{\sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{4k^2}}{1+\tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{\sqrt{-k^2}\, x} k \sin(kx+\alpha)}{-2\sqrt{-k^2}}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{e^{\sqrt{-k^2}\, x} k \sin(kx+\alpha)}{2\sqrt{-k^2}} dx$$

Hence

$$u_2 = \frac{-\frac{x\, e^{\sqrt{-k^2}\, x}}{4} + \frac{x\, e^{\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{4} - \frac{\sqrt{-k^2}\, e^{\sqrt{-k^2}\, x}}{4k^2} + \frac{\sqrt{-k^2}\, x\, e^{\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)}{2k} + \frac{\sqrt{-k^2}\, e^{\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{4k^2}}{1+\tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}$$

Which simplifies to

$$u_1 = -\frac{\left(\left(\sin(kx+\alpha)\, kx - \cos(kx+\alpha)\right)\sqrt{-k^2} + x\, k^2 \cos(kx+\alpha)\right) e^{-\sqrt{-k^2}\, x}}{4k^2}$$

$$u_2 = -\frac{e^{\sqrt{-k^2}\, x}\left(\left(-\sin(kx+\alpha)\, kx + \cos(kx+\alpha)\right)\sqrt{-k^2} + x\, k^2 \cos(kx+\alpha)\right)}{4k^2}$$

Therefore the particular solution, from equation (1) is

$$
\begin{aligned}
& y_p(x) \\
& = -\frac{\left(\left(\sin \left(k x+\alpha\right) k x-\cos \left(k x+\alpha\right)\right) \sqrt{-k^2}+x\, k^2 \cos \left(k x+\alpha\right)\right) \mathrm{e}^{-\sqrt{-k^2}\, x} \mathrm{e}^{\sqrt{-k^2}\, x}}{4 k^2} \\
& \quad -\frac{\mathrm{e}^{\sqrt{-k^2}\, x}\left(\left(-\sin \left(k x+\alpha\right) k x+\cos \left(k x+\alpha\right)\right) \sqrt{-k^2}+x\, k^2 \cos \left(k x+\alpha\right)\right) \mathrm{e}^{-\sqrt{-k^2}\, x}}{4 k^2}
\end{aligned}
$$

Which simplifies to

$$
y_p(x)=-\frac{x \cos \left(k x+\alpha\right)}{2}
$$

Therefore the general solution is

$$
\begin{aligned}
y & =y_h+y_p \\
& =\left(c_1 \mathrm{e}^{\sqrt{-k^2}\, x}+c_2 \mathrm{e}^{-\sqrt{-k^2}\, x}\right)+\left(-\frac{x \cos \left(k x+\alpha\right)}{2}\right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y=c_1 \mathrm{e}^{\sqrt{-k^2}\, x}+c_2 \mathrm{e}^{-\sqrt{-k^2}\, x}-\frac{x \cos \left(k x+\alpha\right)}{2} \tag{1}
$$

<u>Verification of solutions</u>

$$
y=c_1 \mathrm{e}^{\sqrt{-k^2}\, x}+c_2 \mathrm{e}^{-\sqrt{-k^2}\, x}-\frac{x \cos \left(k x+\alpha\right)}{2}
$$

Verified OK.

16.15.2 Solving using Kovacic algorithm

Writing the ode as

$$
y''+k^2 y=0 \tag{1}
$$

$$
A y''+B y'+C y=0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
& A=1 \\
& B=0 \\
& C=k^2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-k^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -k^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = (-k^2)\, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 427: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -k^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{-k^2}\,x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1\\ &= \mathrm{e}^{\sqrt{-k^2}\,x}\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-k^2}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{\sqrt{-k^2}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-k^2}\, x}}\, dx \\ &= \mathrm{e}^{\sqrt{-k^2}\, x} \left(\frac{\sqrt{-k^2}\, \mathrm{e}^{-2\sqrt{-k^2}\, x}}{2k^2} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{\sqrt{-k^2}\, x} \right) + c_2 \left(\mathrm{e}^{\sqrt{-k^2}\, x} \left(\frac{\sqrt{-k^2}\, \mathrm{e}^{-2\sqrt{-k^2}\, x}}{2k^2} \right) \right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + k^2 y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{\sqrt{-k^2}\, x} + \frac{c_2 \sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x}}{2k^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{\sqrt{-k^2}\,x}$$
$$y_2 = \frac{\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{\sqrt{-k^2}\,x} & \frac{\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2} \\ \frac{d}{dx}\left(\mathrm{e}^{\sqrt{-k^2}\,x}\right) & \frac{d}{dx}\left(\frac{\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{\sqrt{-k^2}\,x} & \frac{\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2} \\ \sqrt{-k^2}\,\mathrm{e}^{\sqrt{-k^2}\,x} & \frac{\mathrm{e}^{-\sqrt{-k^2}\,x}}{2} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{\sqrt{-k^2}\,x}\right)\left(\frac{\mathrm{e}^{-\sqrt{-k^2}\,x}}{2}\right) - \left(\frac{\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2}\right)\left(\sqrt{-k^2}\,\mathrm{e}^{\sqrt{-k^2}\,x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{\sqrt{-k^2}\, x} \mathrm{e}^{-\sqrt{-k^2}\, x}$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x} \sin(kx+\alpha)}{2k}}{1}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x} \sin(kx+\alpha)}{2k} dx$$

Hence

$$u_1 = -\frac{\frac{x\,\mathrm{e}^{-\sqrt{-k^2}\, x}}{4} - \frac{x\,\mathrm{e}^{-\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{4} - \frac{\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x}}{4k^2} + \frac{\sqrt{-k^2}\, x\, \mathrm{e}^{-\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)}{2k} + \frac{\sqrt{-k^2}\, \mathrm{e}^{-\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{4k^2}}{1+\tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{\sqrt{-k^2}\, x} k \sin(kx+\alpha)}{1}\, dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{\sqrt{-k^2}\, x} k \sin(kx+\alpha)\, dx$$

Hence

$$u_2 = \frac{xk\,\mathrm{e}^{\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right) - \frac{\sqrt{-k^2}\, \mathrm{e}^{\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)}{k} + \frac{\sqrt{-k^2}\, x\, \mathrm{e}^{\sqrt{-k^2}\, x}}{2} - \frac{\sqrt{-k^2}\, x\, \mathrm{e}^{\sqrt{-k^2}\, x} \tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}{2}}{1+\tan\left(\frac{kx}{2}+\frac{\alpha}{2}\right)^2}$$

Which simplifies to

$$u_1 = -\frac{\left(\left(\sin\left(kx+\alpha\right)kx-\cos\left(kx+\alpha\right)\right)\sqrt{-k^2}+x\,k^2\cos\left(kx+\alpha\right)\right)\mathrm{e}^{-\sqrt{-k^2}\,x}}{4k^2}$$

$$u_2 = \frac{\mathrm{e}^{\sqrt{-k^2}\,x}\left(\left(\cos\left(kx+\alpha\right)kx-\sin\left(kx+\alpha\right)\right)\sqrt{-k^2}+k^2x\sin\left(kx+\alpha\right)\right)}{2k}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) \\ &= -\frac{\left(\left(\sin\left(kx+\alpha\right)kx-\cos\left(kx+\alpha\right)\right)\sqrt{-k^2}+x\,k^2\cos\left(kx+\alpha\right)\right)\mathrm{e}^{-\sqrt{-k^2}\,x}\mathrm{e}^{\sqrt{-k^2}\,x}}{4k^2} \\ &+\frac{\mathrm{e}^{\sqrt{-k^2}\,x}\left(\left(\cos\left(kx+\alpha\right)kx-\sin\left(kx+\alpha\right)\right)\sqrt{-k^2}+k^2x\sin\left(kx+\alpha\right)\right)\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{4k^3} \end{aligned}$$

Which simplifies to

$$y_p(x) = \frac{-2x\,k^2\cos\left(kx+\alpha\right)+\sqrt{-k^2}\,\cos\left(kx+\alpha\right)+k\sin\left(kx+\alpha\right)}{4k^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{\sqrt{-k^2}\,x}+\frac{c_2\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2}\right) \\ &\quad+\left(\frac{-2x\,k^2\cos\left(kx+\alpha\right)+\sqrt{-k^2}\,\cos\left(kx+\alpha\right)+k\sin\left(kx+\alpha\right)}{4k^2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = c_1\mathrm{e}^{\sqrt{-k^2}\,x}+\frac{c_2\sqrt{-k^2}\,\mathrm{e}^{-\sqrt{-k^2}\,x}}{2k^2} \\ +\frac{-2x\,k^2\cos\left(kx+\alpha\right)+\sqrt{-k^2}\,\cos\left(kx+\alpha\right)+k\sin\left(kx+\alpha\right)}{4k^2} \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 e^{\sqrt{-k^2}\, x} + \frac{c_2 \sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{2k^2} + \frac{-2x\, k^2 \cos(kx+\alpha) + \sqrt{-k^2}\, \cos(kx+\alpha) + k \sin(kx+\alpha)}{4k^2}$$

Verified OK.

16.15.3 Maple step by step solution

Let's solve

$y'' + k^2 y = k \sin(kx+\alpha)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $k^2 + r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm \left(\sqrt{-4k^2}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(\sqrt{-k^2}, -\sqrt{-k^2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{\sqrt{-k^2}\, x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\sqrt{-k^2}\, x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = k \sin(kx+\alpha)\right]$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\sqrt{-k^2}\,x} & e^{-\sqrt{-k^2}\,x} \\ \sqrt{-k^2}\, e^{\sqrt{-k^2}\,x} & -\sqrt{-k^2}\, e^{-\sqrt{-k^2}\,x} \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = -2\sqrt{-k^2}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = \frac{k\left(e^{\sqrt{-k^2}\,x}\left(\int e^{-\sqrt{-k^2}\,x}\sin(kx+\alpha)dx\right) - e^{-\sqrt{-k^2}\,x}\left(\int e^{\sqrt{-k^2}\,x}\sin(kx+\alpha)dx\right)\right)}{2\sqrt{-k^2}}$$

- Compute integrals

  $$y_p(x) = \frac{-\cos(kx+\alpha)kx + \sin(kx+\alpha)}{2k}$$

- Substitute particular solution into general solution to ODE

  $$y = c_1 e^{\sqrt{-k^2}\,x} + c_2 e^{-\sqrt{-k^2}\,x} + \frac{-\cos(kx+\alpha)kx + \sin(kx+\alpha)}{2k}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + k^2 y = k}$$

16.16.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = k^2, f(x) = k$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + k^2 y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = k^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + k^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$k^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = k^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(k^2)}\\ &= \pm\sqrt{-k^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-k^2}\\ \lambda_2 &= -\sqrt{-k^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-k^2}\\ \lambda_2 &= -\sqrt{-k^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{\left(\sqrt{-k^2}\right)x} + c_2 e^{\left(-\sqrt{-k^2}\right)x}\end{aligned}$$

Or

$$y = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{\sqrt{-k^2}\, x}, e^{-\sqrt{-k^2}\, x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$k^2 A_1 = k$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{k}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{k}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x}\right) + \left(\frac{1}{k}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x} + \frac{1}{k} \tag{1}$$

Verification of solutions

$$y = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x} + \frac{1}{k}$$

Verified OK.

16.16.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + k^2 y'y - y'k = 0$$

Integrating the above w.r.t x gives

$$\int \left(y'y'' + k^2 y'y - y'k\right) dx = 0$$
$$\frac{y'^2}{2} + \frac{k^2 y^2}{2} - yk = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-k^2 y^2 + 2yk + 2c_1} \tag{1}$$
$$y' = -\sqrt{-k^2 y^2 + 2yk + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-k^2 y^2 + 2ky + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{\sqrt{k^2}\,\left(y - \frac{1}{k}\right)}{\sqrt{-k^2 y^2 + 2yk + 2c_1}}\right)}{\sqrt{k^2}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-k^2y^2+2ky+2c_1}}dy = \int dx$$

$$-\frac{\arctan\left(\frac{\sqrt{k^2}\left(y-\frac{1}{k}\right)}{\sqrt{-k^2y^2+2yk+2c_1}}\right)}{\sqrt{k^2}} = x + c_3$$

Summary

The solution(s) found are the following

$$\frac{\arctan\left(\frac{\sqrt{k^2}\left(y-\frac{1}{k}\right)}{\sqrt{-k^2y^2+2yk+2c_1}}\right)}{\sqrt{k^2}} = x + c_2 \tag{1}$$

$$-\frac{\arctan\left(\frac{\sqrt{k^2}\left(y-\frac{1}{k}\right)}{\sqrt{-k^2y^2+2yk+2c_1}}\right)}{\sqrt{k^2}} = x + c_3 \tag{2}$$

Verification of solutions

$$\frac{\arctan\left(\frac{\sqrt{k^2}\left(y-\frac{1}{k}\right)}{\sqrt{-k^2y^2+2yk+2c_1}}\right)}{\sqrt{k^2}} = x + c_2$$

Verified OK.

$$-\frac{\arctan\left(\frac{\sqrt{k^2}\left(y-\frac{1}{k}\right)}{\sqrt{-k^2y^2+2yk+2c_1}}\right)}{\sqrt{k^2}} = x + c_3$$

Verified OK.

16.16.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + k^2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= k^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-k^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -k^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-k^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 429: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -k^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{-k^2}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{\sqrt{-k^2}\, x} \end{aligned}$$

Which simplifies to

$$y_1 = e^{\sqrt{-k^2}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= e^{\sqrt{-k^2}\, x} \int \frac{1}{e^{2\sqrt{-k^2}\, x}}\, dx \\
&= e^{\sqrt{-k^2}\, x} \left(\frac{\sqrt{-k^2}\, e^{-2\sqrt{-k^2}\, x}}{2k^2} \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{\sqrt{-k^2}\, x} \right) + c_2 \left(e^{\sqrt{-k^2}\, x} \left(\frac{\sqrt{-k^2}\, e^{-2\sqrt{-k^2}\, x}}{2k^2} \right) \right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + k^2 y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{\sqrt{-k^2}\, x} + \frac{c_2 \sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{2k^2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{2k^2}, e^{\sqrt{-k^2}\, x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$k^2 A_1 = k$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{k}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{k}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\sqrt{-k^2}\, x} + \frac{c_2 \sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{2k^2}\right) + \left(\frac{1}{k}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{\sqrt{-k^2}\, x} + \frac{c_2 \sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{2k^2} + \frac{1}{k} \tag{1}$$

Verification of solutions

$$y = c_1 e^{\sqrt{-k^2}\, x} + \frac{c_2 \sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x}}{2k^2} + \frac{1}{k}$$

Verified OK.

16.16.4 Maple step by step solution

Let's solve

$y'' + k^2 y = k$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $k^2 + r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm \left(\sqrt{-4k^2}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(\sqrt{-k^2}, -\sqrt{-k^2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{\sqrt{-k^2}\, x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\sqrt{-k^2}\, x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = k\right]$$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\sqrt{-k^2}\, x} & e^{-\sqrt{-k^2}\, x} \\ \sqrt{-k^2}\, e^{\sqrt{-k^2}\, x} & -\sqrt{-k^2}\, e^{-\sqrt{-k^2}\, x} \end{bmatrix}$$

- Compute Wronskian

$$W(y_1(x), y_2(x)) = -2\sqrt{-k^2}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{k\left(e^{\sqrt{-k^2}\, x}\left(\int e^{-\sqrt{-k^2}\, x} dx\right) - e^{-\sqrt{-k^2}\, x}\left(\int e^{\sqrt{-k^2}\, x} dx\right)\right)}{2\sqrt{-k^2}}$$

- Compute integrals

$$y_p(x) = \frac{1}{k}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{\sqrt{-k^2}\, x} + c_2 e^{-\sqrt{-k^2}\, x} + \frac{1}{k}$$

Problem number: 490.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{y''' + y = x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y = 0$$

The characteristic equation is

$$\lambda^3 + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = \frac{1}{2} - \frac{i\sqrt{3}}{2}$$
$$\lambda_3 = \frac{1}{2} + \frac{i\sqrt{3}}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + \mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + \mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}$$
$$y_3 = \mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}$$

Now the particular solution to the given ODE is found

$$y''' + y = x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{\left(\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}, \mathrm{e}^{\left(\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}, \mathrm{e}^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2 x + A_1 = x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + e^{\left(\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3\right) + (x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + e^{\left(\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + x \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + e^{\left(\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + x$$

Verified OK.

16.17.1 Maple step by step solution

Let's solve

$y''' + y = x$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = x - y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x - y_1(x)]$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & 0 & 0 \end{array}\right] \cdot \vec{y}(x) + \left[\begin{array}{c} 0 \\ 0 \\ x \end{array}\right]$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ x \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -1 & 0 & 0 \end{array}\right]$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right], \left[\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right], \left[\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{\frac{1}{2} + \frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[\frac{1}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{\left(\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)x} \cdot \left[\begin{array}{c} \frac{1}{\left(\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{\frac{x}{2}} \cdot \left(\cos\left(\frac{x\sqrt{3}}{2}\right) - \mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right)\right) \cdot \left[\begin{array}{c} \frac{1}{\left(\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{1}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$\mathrm{e}^{\frac{x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)-\mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right)}{\left(\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)-\mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right)}{\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) - \mathrm{I}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{\frac{x}{2}} \cdot \begin{bmatrix} -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}, \vec{y}_3(x) = e^{\frac{x}{2}} \cdot \begin{bmatrix} \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ -\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^{-x} & e^{\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ -e^{-x} & e^{\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{-x} & e^{\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -e^{\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \phi(0)^{-1}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{-x} & e^{\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ -e^{-x} & e^{\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{-x} & e^{\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -e^{\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix} \cdot \begin{bmatrix} 1 & -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ -1 & \frac{1}{2} & \frac{\sqrt{3}}{2} \\ 1 & 1 & 0 \end{bmatrix}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{2e^{\frac{3x}{2}}e^{-x}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-x}}{3} & \frac{\left(e^{\frac{3x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}+e^{\frac{3x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)-1\right)e^{-x}}{3} & \frac{\left(e^{\frac{3x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{}\right.}{} \\ -\frac{\left(e^{\frac{3x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}-e^{\frac{3x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)+1\right)e^{-x}}{3} & \frac{2e^{\frac{3x}{2}}e^{-x}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-x}}{3} & \frac{\left(e^{\frac{3x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{}\right.}{} \\ -\frac{\left(e^{\frac{3x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}+e^{\frac{3x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)-1\right)e^{-x}}{3} & -\frac{\left(e^{\frac{3x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}-e^{\frac{3x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)+1\right)e^{-x}}{3} & \frac{2e^{\frac{3x}{2}}e^{-x}\cdots}{3} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$$

- Take the derivative of the particular solution

$$\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$$

- Substitute particular solution and its derivative into the system of ODEs

$$\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$$A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$$

- Cancel like terms

$$\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$$

- Multiply by the inverse of the fundamental matrix

$$\vec{v}'(x) = \Phi(x)^{-1} \cdot \vec{f}(x)$$

- Integrate to solve for $\vec{v}(x)$

$$\vec{v}(x) = \int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{e^{-x}\left(-e^{\frac{3x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}+3x\, e^{x}-e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)+1\right)}{3} \\ \frac{e^{-x}\left(-2\, e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)+3\, e^{x}-1\right)}{3} \\ \frac{\left(e^{\frac{3x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}-e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)+1\right)e^{-x}}{3} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \left[\begin{array}{c} \frac{e^{-x}\left(-e^{\frac{3x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}+3x\, e^{x}-e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)+1\right)}{3} \\ \frac{e^{-x}\left(-2\, e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)+3\, e^{x}-1\right)}{3} \\ \frac{\left(e^{\frac{3x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}-e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)+1\right)e^{-x}}{3} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = e^{-x}\left(-\frac{e^{\frac{3x}{2}}\left(-c_3\sqrt{3}+c_2+\frac{2}{3}\right)\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{e^{\frac{3x}{2}}\left(\left(c_2-\frac{2}{3}\right)\sqrt{3}+c_3\right)\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} + x\, e^{x} + c_1 + \frac{1}{3}\right)$$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 491.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + 6y'' + 11y' + 6y = 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + 6y'' + 11y' + 6y = 0$$

The characteristic equation is

$$\lambda^3 + 6\lambda^2 + 11\lambda + 6 = 0$$

The roots of the above equation are

$$\lambda_1 = -3$$
$$\lambda_2 = -2$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + e^{-2x} c_2 + e^{-3x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{-2x}$$
$$y_3 = e^{-3x}$$

Now the particular solution to the given ODE is found

$$y''' + 6y'' + 11y' + 6y = 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-3x}, e^{-2x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$6A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + e^{-2x} c_2 + e^{-3x} c_3\right) + \left(\frac{1}{6}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + e^{-2x} c_2 + e^{-3x} c_3 + \frac{1}{6} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + e^{-2x} c_2 + e^{-3x} c_3 + \frac{1}{6}$$

Verified OK.

16.18.1 Maple step by step solution

Let's solve

$y''' + 6y'' + 11y' + 6y = 1$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - ◦ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ◦ Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = 1 - 6y_3(x) - 11y_2(x) - 6y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 1 - 6y_3(x) - 11y_2(x) - 6y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -6 & -11 & -6 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix}\right], \left[-2, \begin{bmatrix} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \left[\begin{array}{c} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = e^{-3x} \cdot \left[\begin{array}{c} \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[-2, \left[\begin{array}{c} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = e^{-2x} \cdot \left[\begin{array}{c} \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = e^{-x} \cdot \left[\begin{array}{c} 1 \\ -1 \\ 1 \end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3 + \overrightarrow{y}_p(x)$$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} \frac{e^{-3x}}{9} & \frac{e^{-2x}}{4} & e^{-x} \\ -\frac{e^{-3x}}{3} & -\frac{e^{-2x}}{2} & -e^{-x} \\ e^{-3x} & e^{-2x} & e^{-x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \phi(0)^{-1}$
- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} \frac{e^{-3x}}{9} & \frac{e^{-2x}}{4} & e^{-x} \\ -\frac{e^{-3x}}{3} & -\frac{e^{-2x}}{2} & -e^{-x} \\ e^{-3x} & e^{-2x} & e^{-x} \end{bmatrix} \cdot \begin{bmatrix} \frac{1}{9} & \frac{1}{4} & 1 \\ -\frac{1}{3} & -\frac{1}{2} & -1 \\ 1 & 1 & 1 \end{bmatrix}^{-1}$$
- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} e^{-3x} - 3e^{-2x} + 3e^{-x} & \frac{3e^{-3x}}{2} - 4e^{-2x} + \frac{5e^{-x}}{2} & \frac{e^{-3x}}{2} - e^{-2x} + \frac{e^{-x}}{2} \\ -3e^{-3x} + 6e^{-2x} - 3e^{-x} & -\frac{9e^{-3x}}{2} + 8e^{-2x} - \frac{5e^{-x}}{2} & -\frac{3e^{-3x}}{2} + 2e^{-2x} - \frac{e^{-x}}{2} \\ 9e^{-3x} - 12e^{-2x} + 3e^{-x} & \frac{27e^{-3x}}{2} - 16e^{-2x} + \frac{5e^{-x}}{2} & \frac{9e^{-3x}}{2} - 4e^{-2x} + \frac{e^{-x}}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \Phi(x)^{-1} \cdot \vec{f}(x)$
- Integrate to solve for $\vec{v}(x)$

$\vec{v}(x) = \int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} -\frac{e^{-x}}{2} + \frac{e^{-2x}}{2} - \frac{e^{-3x}}{6} + \frac{1}{6} \\ \frac{e^{-3x}}{2} - e^{-2x} + \frac{e^{-x}}{2} \\ -\frac{3\,e^{-3x}}{2} + 2\,e^{-2x} - \frac{e^{-x}}{2} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \begin{bmatrix} -\frac{e^{-x}}{2} + \frac{e^{-2x}}{2} - \frac{e^{-3x}}{6} + \frac{1}{6} \\ \frac{e^{-3x}}{2} - e^{-2x} + \frac{e^{-x}}{2} \\ -\frac{3\,e^{-3x}}{2} + 2\,e^{-2x} - \frac{e^{-x}}{2} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{1}{6} + \frac{(-3+2c_1)e^{-3x}}{18} + \frac{(2+c_2)e^{-2x}}{4} + \frac{(-1+2c_3)e^{-x}}{2}$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 492.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + y' = 2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^{ix}c_2 + e^{-ix}c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^{ix}$$
$$y_3 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y''' + y' = 2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{ix}, e^{-ix}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = 2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + e^{ix} c_2 + e^{-ix} c_3\right) + (2x) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 + e^{ix} c_2 + e^{-ix} c_3 + 2x \tag{1}$$

Verification of solutions

$$y = c_1 + e^{ix} c_2 + e^{-ix} c_3 + 2x$$

Verified OK.

16.19.1 Maple step by step solution

Let's solve

$y''' + y' = 2$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = 2 - y_2(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 2 - y_2(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 2 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 2 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}x} \cdot \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = \begin{bmatrix} \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3(x) + \overrightarrow{y}_p(x)$

- ☐ Fundamental matrix
  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

    $$\phi(x) = \begin{bmatrix} 1 & -\cos(x) & \sin(x) \\ 0 & \sin(x) & \cos(x) \\ 0 & \cos(x) & -\sin(x) \end{bmatrix}$$

  - The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

    $\Phi(x) = \phi(x) \cdot \phi(0)^{-1}$

  - Substitute the value of $\phi(x)$ and $\phi(0)$

    $$\Phi(x) = \begin{bmatrix} 1 & -\cos(x) & \sin(x) \\ 0 & \sin(x) & \cos(x) \\ 0 & \cos(x) & -\sin(x) \end{bmatrix} \cdot \begin{bmatrix} 1 & -1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}^{-1}$$

  - Evaluate and simplify to get the fundamental matrix

    $$\Phi(x) = \begin{bmatrix} 1 & \sin(x) & 1-\cos(x) \\ 0 & \cos(x) & \sin(x) \\ 0 & -\sin(x) & \cos(x) \end{bmatrix}$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(x)$ and solve for $\overrightarrow{v}(x)$

    $\overrightarrow{y}_p(x) = \Phi(x) \cdot \overrightarrow{v}(x)$

  - Take the derivative of the particular solution

    $\overrightarrow{y}_p'(x) = \Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x)$

  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \Phi(x) \cdot \overrightarrow{v}'(x) = A \cdot \Phi(x) \cdot \overrightarrow{v}(x) + \overrightarrow{f}(x)$

  - Cancel like terms

    $\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

  - Multiply by the inverse of the fundamental matrix

$\vec{v}'(x) = \Phi(x)^{-1} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{y}_p(x) = \begin{bmatrix} 2x - 2\sin(x) \\ 2 - 2\cos(x) \\ 2\sin(x) \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2(x) + c_3 \vec{y}_3(x) + \begin{bmatrix} 2x - 2\sin(x) \\ 2 - 2\cos(x) \\ 2\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

  $y = (c_3 - 2)\sin(x) - c_2\cos(x) + 2x + c_1$

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + y'' = 3}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y'' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= 1 \\
y_3 &= x
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$
y''' + y'' = 3
$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
1
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' - y = 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y = 0$$

The characteristic equation is

$$\lambda^4 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + e^{x} c_2 + e^{ix} c_3 + e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = e^{x}$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' - y = 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{ix}, e^{-x}, e^{-ix}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + \mathrm{e}^{x} c_2 + \mathrm{e}^{ix} c_3 + \mathrm{e}^{-ix} c_4\right) + (-1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{x} c_2 + \mathrm{e}^{ix} c_3 + \mathrm{e}^{-ix} c_4 - 1 \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + \mathrm{e}^{x} c_2 + \mathrm{e}^{ix} c_3 + \mathrm{e}^{-ix} c_4 - 1$$

Verified OK.

16.21.1 Maple step by step solution

Let's solve

$y'''' - y = 1$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Define new variable $y_4(x)$

    $y_4(x) = y'''$

  - Isolate for $y_4'(x)$ using original ODE

$y_4'(x) = 1 + y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 1 + y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \left[\begin{array}{c}-1\\1\\-1\\1\end{array}\right]\right], \left[1, \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]\right], \left[-\mathrm{I}, \left[\begin{array}{c}-\mathrm{I}\\-1\\\mathrm{I}\\1\end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c}\mathrm{I}\\-1\\-\mathrm{I}\\1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c}-1\\1\\-1\\1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-x} \cdot \left[\begin{array}{c}-1\\1\\-1\\1\end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \mathrm{e}^{x} \cdot \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-\mathrm{I}x} \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$$

☐ Fundamental matrix

  ◦ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\sin(x) & -\cos(x) \\ e^{-x} & e^{x} & -\cos(x) & \sin(x) \\ -e^{-x} & e^{x} & \sin(x) & \cos(x) \\ e^{-x} & e^{x} & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \phi(0)^{-1}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} -e^{-x} & e^{x} & -\sin(x) & -\cos(x) \\ e^{-x} & e^{x} & -\cos(x) & \sin(x) \\ -e^{-x} & e^{x} & \sin(x) & \cos(x) \\ e^{-x} & e^{x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \begin{bmatrix} -1 & 1 & 0 & -1 \\ 1 & 1 & -1 & 0 \\ -1 & 1 & 0 & 1 \\ 1 & 1 & 1 & 0 \end{bmatrix}^{-1}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} \\ \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} \\ -\frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\cos(x)}{2} & -\frac{e^{-x}}{4} + \frac{e^{x}}{4} - \frac{\sin(x)}{2} & \frac{e^{-x}}{4} + \frac{e^{x}}{4} + \frac{\cos(x)}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(x) = \Phi(x)^{-1} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} \frac{\cos(x)}{2} + \frac{e^x}{4} - 1 + \frac{e^{-x}}{4} \\ -\frac{e^{-x}}{4} + \frac{e^x}{4} - \frac{\sin(x)}{2} \\ \frac{e^{-x}}{4} + \frac{e^x}{4} - \frac{\cos(x)}{2} \\ -\frac{e^{-x}}{4} + \frac{e^x}{4} + \frac{\sin(x)}{2} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3(x) + c_4 \vec{y}_4(x) + \begin{bmatrix} \frac{\cos(x)}{2} + \frac{e^x}{4} - 1 + \frac{e^{-x}}{4} \\ -\frac{e^{-x}}{4} + \frac{e^x}{4} - \frac{\sin(x)}{2} \\ \frac{e^{-x}}{4} + \frac{e^x}{4} - \frac{\cos(x)}{2} \\ -\frac{e^{-x}}{4} + \frac{e^x}{4} + \frac{\sin(x)}{2} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -c_1 e^{-x} + e^x c_2 + \frac{\cos(x)}{2} + \frac{e^x}{4} - 1 + \frac{e^{-x}}{4} - \cos(x)\, c_4 - c_3 \sin(x)$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 495.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' - y' = 2}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y' = 0$$

The characteristic equation is

$$\lambda^4 - \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$
$$\lambda_4 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + e^x c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^x$$
$$y_3 = e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}$$
$$y_4 = e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}$$

Now the particular solution to the given ODE is found

$$y'''' - y' = 2$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, e^x, e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}, e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 = 2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + e^x c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_4\right) + (-2x) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 + e^x c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_4 - 2x \tag{1}$$

Verification of solutions

$$y = c_1 + e^x c_2 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_3 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_4 - 2x$$

Verified OK.

16.22.1 Maple step by step solution

Let's solve

$y'''' - y' = 2$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

$$y_3(x) = y''$$

- Define new variable $y_4(x)$

  $$y_4(x) = y'''$$

- Isolate for $y_4'(x)$ using original ODE

  $$y_4'(x) = 2 + y_2(x)$$

  Convert linear ODE into a system of first order ODEs

  $$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 2 + y_2(x)]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 2 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 2 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 1 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right], \left[-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right], \left[-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_{1} = \left[\begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_{2} = \mathrm{e}^{x} \cdot \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{1}{2}-\frac{I\sqrt{3}}{2}, \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)x} \cdot \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{-\frac{x}{2}} \cdot \left(\cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right)\right) \cdot \left[\begin{array}{c} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{3}} \\ \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{-\frac{x}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right)}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{3}} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right)}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^{2}} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right)}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \mathrm{e}^{-\frac{x}{2}} \cdot \begin{bmatrix} \cos\left(\frac{x\sqrt{3}}{2}\right) \\ -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}, \vec{y}_4(x) = \mathrm{e}^{-\frac{x}{2}} \cdot \begin{bmatrix} -\sin\left(\frac{x\sqrt{3}}{2}\right) \\ -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ -\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($
  $\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -\mathrm{e}^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \\ 0 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ 0 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ 0 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -\mathrm{e}^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t
  $\Phi(x) = \phi(x) \cdot \phi(0)^{-1}$
- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} 1 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -\mathrm{e}^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \\ 0 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ 0 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & \mathrm{e}^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ 0 & \mathrm{e}^x & \mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -\mathrm{e}^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix} \cdot \begin{bmatrix} 1 & 1 & 1 \\ 0 & 1 & -\frac{1}{2} \\ 0 & 1 & -\frac{1}{2} \\ 0 & 1 & 1 \end{bmatrix}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & -1 + \frac{e}{3} \\ 0 & \frac{e^x}{3} + \frac{2\,e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos(}{3} \\ 0 & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^x}{3} + \frac{2\,e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos(}{3} \\ 0 & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^x}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^x}{3} + \end{bmatrix}$$

- ☐ Find a particular solution of the system of ODEs using variation of parameters
  - Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

    $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
  - Take the derivative of the particular solution

    $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
  - Substitute particular solution and its derivative into the system of ODEs

    $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
  - The fundamental matrix has columns that are solutions to the homogeneous system so its der

    $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
  - Cancel like terms

    $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
  - Multiply by the inverse of the fundamental matrix

    $\vec{v}'(x) = \Phi(x)^{-1} \cdot \vec{f}(x)$
  - Integrate to solve for $\vec{v}(x)$

    $\vec{v}(x) = \int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\,ds$
  - Plug $\vec{v}(x)$ into the equation for the particular solution

    $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \Phi(s)^{-1} \cdot \vec{f}(s)\,ds\right)$
  - Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{2\,e^{x}}{3} - 2x + \frac{2\,e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \frac{2\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{2\,e^{x}}{3} - 2 + \frac{4\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ -\frac{2\,e^{-\frac{x}{2}}\left(\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}+\cos\left(\frac{x\sqrt{3}}{2}\right)-e^{\frac{3x}{2}}\right)}{3} \\ \frac{2\,e^{-\frac{x}{2}}\left(e^{\frac{3x}{2}}+\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}-\cos\left(\frac{x\sqrt{3}}{2}\right)\right)}{3} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \left[\begin{array}{c} \frac{2\,e^{x}}{3} - 2x + \frac{2\,e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \frac{2\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{2\,e^{x}}{3} - 2 + \frac{4\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ -\frac{2\,e^{-\frac{x}{2}}\left(\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}+\cos\left(\frac{x\sqrt{3}}{2}\right)-e^{\frac{3x}{2}}\right)}{3} \\ \frac{2\,e^{-\frac{x}{2}}\left(e^{\frac{3x}{2}}+\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}-\cos\left(\frac{x\sqrt{3}}{2}\right)\right)}{3} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{e^{-\frac{x}{2}}(3c_3-2)\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - e^{-\frac{x}{2}}\left(c_4 - \frac{2\sqrt{3}}{3}\right)\sin\left(\frac{x\sqrt{3}}{2}\right) + \frac{(3c_2+2)e^{x}}{3} - 2x + c_1$$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 496.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_x]]`

$$\boxed{y'''' - y'' = 3}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y'' = 0$$

The characteristic equation is

$$\lambda^4 - \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 x + e^x c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned}
y_1 &= e^{-x} \\
y_2 &= 1 \\
y_3 &= x \\
y_4 &= e^x
\end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - y'' = 3$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^x, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 = 3$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 + c_3 x + \mathrm{e}^{x} c_4\right) + \left(-\frac{3x^2}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x + \mathrm{e}^{x} c_4 - \frac{3x^2}{2} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x + \mathrm{e}^{x} c_4 - \frac{3x^2}{2}$$

Verified OK.

Problem number: 497.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_x]]`

$$\boxed{y'''' - y''' = 4}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - y''' = 0$$

The characteristic equation is

$$\lambda^4 - \lambda^3 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_3x^2 + c_2x + c_1 + e^x c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$
$$y_4 = e^x$$

Now the particular solution to the given ODE is found

$$y'''' - y''' = 4$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, e^x\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^3$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1 = 4$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{2}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{2x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_3 x^2 + c_2 x + c_1 + e^x c_4\right) + \left(-\frac{2x^3}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_3 x^2 + c_2 x + c_1 + e^x c_4 - \frac{2x^3}{3} \tag{1}$$

Verification of solutions

$$y = c_3 x^2 + c_2 x + c_1 + e^x c_4 - \frac{2x^3}{3}$$

Verified OK.

Problem number: 499.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{y'''' + 2y''' + y'' = e^{4x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2y''' + y'' = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 x\, e^{-x} + c_3 + c_4 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = x\, e^{-x}$$
$$y_3 = 1$$
$$y_4 = x$$

Now the particular solution to the given ODE is found

$$y'''' + 2y''' + y'' = e^{4x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{4x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{4x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x\, e^{-x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{4x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$400A_1 e^{4x} = e^{4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{400}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{4x}}{400}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{-x} + c_2 x\, e^{-x} + c_3 + c_4 x) + \left(\frac{e^{4x}}{400}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_2 x + c_1) + c_4 x + c_3 + \frac{e^{4x}}{400}$$

<u>Summary</u>
The solution(s) found are the following

$$y = e^{-x}(c_2 x + c_1) + c_4 x + c_3 + \frac{e^{4x}}{400} \tag{1}$$

<u>Verification of solutions</u>

$$y = e^{-x}(c_2 x + c_1) + c_4 x + c_3 + \frac{e^{4x}}{400}$$

Verified OK.

$$y_4 = x$$

Now the particular solution to the given ODE is found

$$y'''' + 2y''' + y'' = e^{-x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x e^{-x}, e^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^{-x}\}]$$

Since $x e^{-x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{-x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{-x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 x\, e^{-x} + c_3 + c_4 x\right) + \left(\frac{x^2 e^{-x}}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_2 x + c_1) + c_4 x + c_3 + \frac{x^2 e^{-x}}{2}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_2 x + c_1) + c_4 x + c_3 + \frac{x^2 e^{-x}}{2} \tag{1}$$

Verification of solutions

$$y = e^{-x}(c_2 x + c_1) + c_4 x + c_3 + \frac{x^2 e^{-x}}{2}$$

Verified OK.

Problem number: 501.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _missing_y]]`

$$\boxed{y'''' + 2y''' + y'' = x\,\mathrm{e}^{-x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2y''' + y'' = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 x e^{-x} + c_3 + c_4 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{-x} \\ y_2 &= x e^{-x} \\ y_3 &= 1 \\ y_4 &= x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' + 2y''' + y'' = x e^{-x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x e^{-x}, e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x e^{-x}, e^{-x}\}$$

Since e^{-x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^{-x}, x^2 e^{-x}\}]$$

Since $x e^{-x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^{-x}, x^3 e^{-x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 e^{-x} + A_2 x^3 e^{-x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1\mathrm{e}^{-x} - 12A_2\mathrm{e}^{-x} + 6A_2x\,\mathrm{e}^{-x} = x\,\mathrm{e}^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 1, A_2 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2\mathrm{e}^{-x} + \frac{x^3\mathrm{e}^{-x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x} + c_2x\,\mathrm{e}^{-x} + c_3 + c_4x\right) + \left(x^2\mathrm{e}^{-x} + \frac{x^3\mathrm{e}^{-x}}{6}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x}(c_2x + c_1) + c_4x + c_3 + x^2\mathrm{e}^{-x} + \frac{x^3\mathrm{e}^{-x}}{6}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_2x + c_1) + c_4x + c_3 + x^2\mathrm{e}^{-x} + \frac{x^3\mathrm{e}^{-x}}{6} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-x}(c_2x + c_1) + c_4x + c_3 + x^2\mathrm{e}^{-x} + \frac{x^3\mathrm{e}^{-x}}{6}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _linear, _nonhomogeneous]]`

$$\boxed{y'''' + 4y'' + 4y = \sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 4y'' + 4y = 0$$

The characteristic equation is

$$\lambda^4 + 4\lambda^2 + 4 = 0$$

The roots of the above equation are

$$\lambda_1 = i\sqrt{2}$$
$$\lambda_2 = -i\sqrt{2}$$
$$\lambda_3 = i\sqrt{2}$$
$$\lambda_4 = -i\sqrt{2}$$

Therefore the homogeneous solution is

$$y_h(x) = \mathrm{e}^{i\sqrt{2}\,x} c_1 + x\,\mathrm{e}^{i\sqrt{2}\,x} c_2 + \mathrm{e}^{-i\sqrt{2}\,x} c_3 + x\,\mathrm{e}^{-i\sqrt{2}\,x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{i\sqrt{2}\,x}$$
$$y_2 = x\,\mathrm{e}^{i\sqrt{2}\,x}$$
$$y_3 = \mathrm{e}^{-i\sqrt{2}\,x}$$
$$y_4 = x\,\mathrm{e}^{-i\sqrt{2}\,x}$$

Now the particular solution to the given ODE is found

$$y'''' + 4y'' + 4y = \sin(2x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{x\,\mathrm{e}^{i\sqrt{2}\,x}, x\,\mathrm{e}^{-i\sqrt{2}\,x}, \mathrm{e}^{i\sqrt{2}\,x}, \mathrm{e}^{-i\sqrt{2}\,x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(2x) + A_2 \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \cos(2x) + 4A_2 \sin(2x) = \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\sin(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{i\sqrt{2}\,x} c_1 + x\,e^{i\sqrt{2}\,x} c_2 + e^{-i\sqrt{2}\,x} c_3 + x\,e^{-i\sqrt{2}\,x} c_4\right) + \left(\frac{\sin(2x)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = (c_2 x + c_1)\,e^{i\sqrt{2}\,x} + (c_4 x + c_3)\,e^{-i\sqrt{2}\,x} + \frac{\sin(2x)}{4}$$

Summary

The solution(s) found are the following

$$y = (c_2 x + c_1)\,e^{i\sqrt{2}\,x} + (c_4 x + c_3)\,e^{-i\sqrt{2}\,x} + \frac{\sin(2x)}{4} \tag{1}$$

Verification of solutions

$$y = (c_2 x + c_1)\,e^{i\sqrt{2}\,x} + (c_4 x + c_3)\,e^{-i\sqrt{2}\,x} + \frac{\sin(2x)}{4}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 504.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' + 4y'' + 4y = x \sin(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 4y'' + 4y = 0$$

The characteristic equation is

$$\lambda^4 + 4\lambda^2 + 4 = 0$$

The roots of the above equation are

$$\lambda_1 = i\sqrt{2}$$
$$\lambda_2 = -i\sqrt{2}$$
$$\lambda_3 = i\sqrt{2}$$
$$\lambda_4 = -i\sqrt{2}$$

Therefore the homogeneous solution is

$$y_h(x) = e^{i\sqrt{2}\,x}c_1 + x\,e^{i\sqrt{2}\,x}c_2 + e^{-i\sqrt{2}\,x}c_3 + x\,e^{-i\sqrt{2}\,x}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{i\sqrt{2}\,x}$$
$$y_2 = x\,e^{i\sqrt{2}\,x}$$
$$y_3 = e^{-i\sqrt{2}\,x}$$
$$y_4 = x\,e^{-i\sqrt{2}\,x}$$

Now the particular solution to the given ODE is found

$$y'''' + 4y'' + 4y = x\sin(2x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\cos(2x), x\sin(2x), \cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{x\,e^{i\sqrt{2}\,x}, x\,e^{-i\sqrt{2}\,x}, e^{i\sqrt{2}\,x}, e^{-i\sqrt{2}\,x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1x\cos(2x) + A_2x\sin(2x) + A_3\cos(2x) + A_4\sin(2x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$16A_1\sin(2x) + 4A_1x\cos(2x) - 16A_2\cos(2x) + 4A_2x\sin(2x) + 4A_3\cos(2x) + 4A_4\sin(2x) = x\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}, A_3 = 1, A_4 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x \sin(2x)}{4} + \cos(2x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{i\sqrt{2}\,x} c_1 + x\, e^{i\sqrt{2}\,x} c_2 + e^{-i\sqrt{2}\,x} c_3 + x\, e^{-i\sqrt{2}\,x} c_4\right) + \left(\frac{x \sin(2x)}{4} + \cos(2x)\right) \end{aligned}$$

Which simplifies to

$$y = (c_2 x + c_1)\, e^{i\sqrt{2}\,x} + (c_4 x + c_3)\, e^{-i\sqrt{2}\,x} + \frac{x \sin(2x)}{4} + \cos(2x)$$

Summary

The solution(s) found are the following

$$y = (c_2 x + c_1)\, e^{i\sqrt{2}\,x} + (c_4 x + c_3)\, e^{-i\sqrt{2}\,x} + \frac{x \sin(2x)}{4} + \cos(2x) \tag{1}$$

Verification of solutions

$$y = (c_2 x + c_1)\, e^{i\sqrt{2}\,x} + (c_4 x + c_3)\, e^{-i\sqrt{2}\,x} + \frac{x \sin(2x)}{4} + \cos(2x)$$

Verified OK.

ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_high_order, _linear, _nonhomogeneous]]`

$$\boxed{y'''' + 2n^2 y'' + n^4 y = a \sin(nx + \alpha)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 2n^2 y'' + n^4 y = 0$$

The characteristic equation is

$$\lambda^4 + 2\lambda^2 n^2 + n^4 = 0$$

The roots of the above equation are

$$\lambda_1 = in$$
$$\lambda_2 = -in$$
$$\lambda_3 = in$$
$$\lambda_4 = -in$$

Therefore the homogeneous solution is

$$y_h(x) = e^{inx}c_1 + x\,e^{inx}c_2 + e^{-inx}c_3 + x\,e^{-inx}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{inx}$$
$$y_2 = x\,e^{inx}$$
$$y_3 = e^{-inx}$$
$$y_4 = x\,e^{-inx}$$

Now the particular solution to the given ODE is found

$$y'''' + 2n^2y'' + n^4y = a\sin(nx+\alpha)$$

Let the particular solution be

$$y_p = U_1y_1 + U_2y_2 + U_3y_3 + U_4y_4$$

Where y_i are the basis solutions found above for the homogeneous solution y_h and $U_i(x)$ are functions to be determined as follows

$$U_i = (-1)^{n-i}\int \frac{F(x)W_i(x)}{aW(x)}\,dx$$

Where $W(x)$ is the Wronskian and $W_i(x)$ is the Wronskian that results after deleting the last row and the i-th column of the determinant and n is the order of the ODE or equivalently, the number of basis solutions, and a is the coefficient of the leading derivative in the ODE, and $F(x)$ is the RHS of the ODE. Therefore, the first step is to find the Wronskian $W(x)$. This is given by

$$W(x) = \begin{vmatrix} y_1 & y_2 & y_3 & y_4 \\ y_1' & y_2' & y_3' & y_4' \\ y_1'' & y_2'' & y_3'' & y_4'' \\ y_1''' & y_2''' & y_3''' & y_4''' \end{vmatrix}$$

Substituting the fundamental set of solutions y_i found above in the Wronskian gives

$$W = \begin{bmatrix} e^{inx} & x\,e^{inx} & e^{-inx} & x\,e^{-inx} \\ in\,e^{inx} & e^{inx}(inx+1) & -in\,e^{-inx} & e^{-inx}(-inx+1) \\ -n^2e^{inx} & e^{inx}n(-nx+2i) & -n^2e^{-inx} & -2n\,e^{-inx}\left(\frac{nx}{2}+i\right) \\ -in^3e^{inx} & -e^{inx}n^2(inx+3) & in^3e^{-inx} & e^{-inx}n^2(inx-3) \end{bmatrix}$$

$$|W| = 16\,e^{2inx}e^{-2inx}n^4$$

The determinant simplifies to

$$|W| = 16n^4$$

Now we determine W_i for each U_i.

$$W_1(x) = \det \begin{bmatrix} x\,e^{inx} & e^{-inx} & x\,e^{-inx} \\ e^{inx}(inx+1) & -in\,e^{-inx} & e^{-inx}(-inx+1) \\ e^{inx}n(-nx+2i) & -n^2e^{-inx} & -2n\,e^{-inx}\left(\frac{nx}{2}+i\right) \end{bmatrix}$$
$$= -4\,e^{-inx}n(nx-i)$$

$$W_2(x) = \det \begin{bmatrix} e^{inx} & e^{-inx} & x\,e^{-inx} \\ in\,e^{inx} & -in\,e^{-inx} & e^{-inx}(-inx+1) \\ -n^2e^{inx} & -n^2e^{-inx} & -2n\,e^{-inx}\left(\frac{nx}{2}+i\right) \end{bmatrix}$$
$$= -4n^2e^{-inx}$$

$$W_3(x) = \det \begin{bmatrix} e^{inx} & x\,e^{inx} & x\,e^{-inx} \\ in\,e^{inx} & e^{inx}(inx+1) & e^{-inx}(-inx+1) \\ -n^2e^{inx} & e^{inx}n(-nx+2i) & -2n\,e^{-inx}\left(\frac{nx}{2}+i\right) \end{bmatrix}$$
$$= -4\,e^{inx}n(nx+i)$$

$$W_4(x) = \det \begin{bmatrix} e^{inx} & x\,e^{inx} & e^{-inx} \\ in\,e^{inx} & e^{inx}(inx+1) & -in\,e^{-inx} \\ -n^2e^{inx} & e^{inx}n(-nx+2i) & -n^2e^{-inx} \end{bmatrix}$$
$$= -4n^2e^{inx}$$

Now we are ready to evaluate each $U_i(x)$.

$$\begin{aligned} U_1 &= (-1)^{4-1}\int \frac{F(x)W_1(x)}{aW(x)}\,dx \\ &= (-1)^3\int \frac{(a\sin(nx+\alpha))\left(-4\,e^{-inx}n(nx-i)\right)}{(1)\left(16n^4\right)}\,dx \\ &= -\int \frac{-4a\sin(nx+\alpha)\,e^{-inx}n(nx-i)}{16n^4}\,dx \\ &= -\int \left(-\frac{a\sin(nx+\alpha)\,e^{-inx}(nx-i)}{4n^3}\right)dx \\ &= -\left(\int -\frac{a\sin(nx+\alpha)\,e^{-inx}(nx-i)}{4n^3}dx\right) \end{aligned}$$

$$
\begin{aligned}
U_2 &= (-1)^{4-2} \int \frac{F(x)W_2(x)}{aW(x)}\,dx \\
&= (-1)^2 \int \frac{(a\sin(nx+\alpha))\left(-4n^2\mathrm{e}^{-inx}\right)}{(1)\left(16n^4\right)}\,dx \\
&= \int \frac{-4a\sin(nx+\alpha)\,n^2\mathrm{e}^{-inx}}{16n^4}\,dx \\
&= \int \left(-\frac{a\sin(nx+\alpha)\,\mathrm{e}^{-inx}}{4n^2}\right)dx \\
&= \frac{-\frac{ax\,\mathrm{e}^{-inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n} + \frac{iax\,\mathrm{e}^{-inx}}{8n} - \frac{ia\,\mathrm{e}^{-inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n^2} - \frac{iax\,\mathrm{e}^{-inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2}{8n}}{n\left(1+\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2\right)}
\end{aligned}
$$

$$
\begin{aligned}
U_3 &= (-1)^{4-3} \int \frac{F(x)W_3(x)}{aW(x)}\,dx \\
&= (-1)^1 \int \frac{(a\sin(nx+\alpha))\left(-4\,\mathrm{e}^{inx}n(nx+i)\right)}{(1)\left(16n^4\right)}\,dx \\
&= -\int \frac{-4a\sin(nx+\alpha)\,\mathrm{e}^{inx}n(nx+i)}{16n^4}\,dx \\
&= -\int \left(-\frac{a\sin(nx+\alpha)\,\mathrm{e}^{inx}(nx+i)}{4n^3}\right)dx \\
&= -\left(\int -\frac{a\sin(nx+\alpha)\,\mathrm{e}^{inx}(nx+i)}{4n^3}dx\right)
\end{aligned}
$$

$$
\begin{aligned}
U_4 &= (-1)^{4-4} \int \frac{F(x)W_4(x)}{aW(x)}\,dx \\
&= (-1)^0 \int \frac{(a\sin(nx+\alpha))\left(-4n^2\mathrm{e}^{inx}\right)}{(1)\left(16n^4\right)}\,dx \\
&= \int \frac{-4a\sin(nx+\alpha)\,n^2\mathrm{e}^{inx}}{16n^4}\,dx \\
&= \int \left(-\frac{a\sin(nx+\alpha)\,\mathrm{e}^{inx}}{4n^2}\right)dx \\
&= \frac{-\frac{ax\,\mathrm{e}^{inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n} - \frac{iax\,\mathrm{e}^{inx}}{8n} + \frac{ia\,\mathrm{e}^{inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n^2} + \frac{iax\,\mathrm{e}^{inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2}{8n}}{n\left(1+\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2\right)}
\end{aligned}
$$

Now that all the U_i functions have been determined, the particular solution is found from

$$
y_p = U_1y_1 + U_2y_2 + U_3y_3 + U_4y_4
$$

Hence

$$y_p = \left(-\left(\int -\frac{a \sin(nx+\alpha)\,\mathrm{e}^{-inx}(nx-i)}{4n^3}dx\right)\right)\left(\mathrm{e}^{inx}\right)$$
$$+\left(\frac{-\frac{ax\,\mathrm{e}^{-inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n}+\frac{iax\,\mathrm{e}^{-inx}}{8n}-\frac{ia\,\mathrm{e}^{-inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n^2}-\frac{iax\,\mathrm{e}^{-inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2}{8n}}{n\left(1+\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2\right)}\right)\left(x\,\mathrm{e}^{inx}\right)$$
$$+\left(-\left(\int -\frac{a \sin(nx+\alpha)\,\mathrm{e}^{inx}(nx+i)}{4n^3}dx\right)\right)\left(\mathrm{e}^{-inx}\right)$$
$$+\left(\frac{-\frac{ax\,\mathrm{e}^{inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n}-\frac{iax\,\mathrm{e}^{inx}}{8n}+\frac{ia\,\mathrm{e}^{inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)}{4n^2}+\frac{iax\,\mathrm{e}^{inx}\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2}{8n}}{n\left(1+\tan\left(\frac{nx}{2}+\frac{\alpha}{2}\right)^2\right)}\right)\left(x\,\mathrm{e}^{-inx}\right)$$

Therefore the particular solution is

$$y_p = -\frac{\left(n\,x^2\sin(nx+\alpha)-\left(\int \sin(nx+\alpha)\,\mathrm{e}^{inx}(nx+i)\,dx\right)\mathrm{e}^{-inx}+\left(\int \sin(nx+\alpha)\,\mathrm{e}^{-inx}(-nx+i)\,dx\right)\mathrm{e}^{i}}{4n^3}$$

Which simplifies to

$$y_p = -\frac{\left((i\sin(nx)+\cos(nx))\left(\int(-nx\sin(2nx+\alpha)-nx\sin(\alpha)+\cos(\alpha)-\cos(2nx+\alpha))\,dx\right)+(i\sin}{}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(\mathrm{e}^{inx}c_1 + x\,\mathrm{e}^{inx}c_2 + \mathrm{e}^{-inx}c_3 + x\,\mathrm{e}^{-inx}c_4\right)$$
$$+\left(-\frac{\left((i\sin(nx)+\cos(nx))\left(\int(-nx\sin(2nx+\alpha)-nx\sin(\alpha)+\cos(\alpha)-\cos(2nx+\alpha))\,dx\right)+(i\,\mathrm{s}}{}\right.$$

Which simplifies to

$$y = (c_4x+c_3)\,\mathrm{e}^{-inx}+(c_2x+c_1)\,\mathrm{e}^{inx}$$
$$-\frac{\left((i\sin(nx)+\cos(nx))\left(\int(-nx\sin(2nx+\alpha)-nx\sin(\alpha)+\cos(\alpha)-\cos(2nx+\alpha))\,dx\right)+(i\sin(n}{}$$

Summary

The solution(s) found are the following

$$y = (c_4x+c_3)\,\mathrm{e}^{-inx}+(c_2x+c_1)\,\mathrm{e}^{inx} \tag{1}$$
$$-\frac{\left((i\sin(nx)+\cos(nx))\left(\int(-nx\sin(2nx+\alpha)-nx\sin(\alpha)+\cos(\alpha)-\cos(2nx+\alpha))\,dx\right)+(i\sin(n}{}$$

Verification of solutions

$$y = (c_4x + c_3)\,\mathrm{e}^{-inx} + (c_2x + c_1)\,\mathrm{e}^{inx}$$
$$- \frac{((i\sin(nx) + \cos(nx))\left(\int(-nx\sin(2nx+\alpha) - nx\sin(\alpha) + \cos(\alpha) - \cos(2nx+\alpha))\,dx\right) + (i\sin(n$$

Verified OK.

Problem number: 506.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' - 2n^2y'' + n^4y = \cos(nx + \alpha)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 2n^2y'' + n^4y = 0$$

The characteristic equation is

$$\lambda^4 - 2\lambda^2n^2 + n^4 = 0$$

The roots of the above equation are

$$\lambda_1 = n$$
$$\lambda_2 = n$$
$$\lambda_3 = -n$$
$$\lambda_4 = -n$$

Therefore the homogeneous solution is

$$y_h(x) = e^{nx}c_1 + x\,e^{nx}c_2 + e^{-nx}c_3 + x\,e^{-nx}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^{nx} \\ y_2 &= x\,e^{nx} \\ y_3 &= e^{-nx} \\ y_4 &= x\,e^{-nx} \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - 2n^2y'' + n^4y = \cos(nx + \alpha)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(nx + \alpha)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(nx + \alpha), \sin(nx + \alpha)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,e^{nx}, x\,e^{-nx}, e^{nx}, e^{-nx}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(nx + \alpha) + A_2\sin(nx + \alpha)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1n^4\cos(nx+\alpha) + A_2n^4\sin(nx+\alpha) - 2n^2(-A_1n^2\cos(nx+\alpha) - A_2n^2\sin(nx+\alpha)) + n^4(A_1\cos(nx + \alpha) + A_2\sin(nx + \alpha)) = \cos(nx + \alpha)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4n^4}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(nx+\alpha)}{4n^4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{nx}c_1 + x\,e^{nx}c_2 + e^{-nx}c_3 + x\,e^{-nx}c_4\right) + \left(\frac{\cos(nx+\alpha)}{4n^4}\right) \end{aligned}$$

Which simplifies to

$$y = (c_4x + c_3)\,e^{-nx} + e^{nx}(c_2x + c_1) + \frac{\cos(nx+\alpha)}{4n^4}$$

Summary

The solution(s) found are the following

$$y = (c_4x + c_3)\,e^{-nx} + e^{nx}(c_2x + c_1) + \frac{\cos(nx+\alpha)}{4n^4} \tag{1}$$

Verification of solutions

$$y = (c_4x + c_3)\,e^{-nx} + e^{nx}(c_2x + c_1) + \frac{\cos(nx+\alpha)}{4n^4}$$

Verified OK.

Problem number: 507.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' + 4y''' + 6y'' + 4y' + y = \sin(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + 4y''' + 6y'' + 4y' + y = 0$$

The characteristic equation is

$$\lambda^4 + 4\lambda^3 + 6\lambda^2 + 4\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = -1$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x} + x^2 \mathrm{e}^{-x} c_3 + x^3 \mathrm{e}^{-x} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = x \,\mathrm{e}^{-x}$$
$$y_3 = x^2 \mathrm{e}^{-x}$$
$$y_4 = x^3 \mathrm{e}^{-x}$$

Now the particular solution to the given ODE is found

$$y'''' + 4y''' + 6y'' + 4y' + y = \sin(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x \,\mathrm{e}^{-x}, x^2 \mathrm{e}^{-x}, x^3 \mathrm{e}^{-x}, \mathrm{e}^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 \cos(x) - 4A_2 \sin(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\sin(x)}{4}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} + x^2 \mathrm{e}^{-x} c_3 + x^3 \mathrm{e}^{-x} c_4\right) + \left(-\frac{\sin(x)}{4}\right)\end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x}\left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) - \frac{\sin(x)}{4}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}\left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) - \frac{\sin(x)}{4} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-x}\left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) - \frac{\sin(x)}{4}$$

Verified OK.

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 4y''' + 6y'' - 4y' + y = 0$$

The characteristic equation is

$$\lambda^4 - 4\lambda^3 + 6\lambda^2 - 4\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$
$$\lambda_4 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + x\, e^x c_2 + x^2 e^x c_3 + x^3 e^x c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^x \\ y_2 &= x\, e^x \\ y_3 &= x^2 e^x \\ y_4 &= x^3 e^x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - 4y''' + 6y'' - 4y' + y = e^x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^x, x^2 e^x, x^3 e^x, e^x\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^x\}]$$

Since $x\, e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^x\}]$$

Since $x^2 e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3 e^x\}]$$

Since $x^3 e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4 e^x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^4 e^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$24A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{24}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^4 e^x}{24}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + x e^x c_2 + x^2 e^x c_3 + x^3 e^x c_4\right) + \left(\frac{x^4 e^x}{24}\right) \end{aligned}$$

Which simplifies to

$$y = e^x \left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) + \frac{x^4 e^x}{24}$$

Summary

The solution(s) found are the following

$$y = e^x \left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) + \frac{x^4 e^x}{24} \tag{1}$$

Verification of solutions

$$y = e^x \left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) + \frac{x^4 e^x}{24}$$

Verified OK.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' - 4y''' + 6y'' - 4y' + y = x\,\mathrm{e}^{x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 4y''' + 6y'' - 4y' + y = 0$$

The characteristic equation is

$$\lambda^4 - 4\lambda^3 + 6\lambda^2 - 4\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$
$$\lambda_4 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + x e^x c_2 + x^2 e^x c_3 + x^3 e^x c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$\begin{aligned} y_1 &= e^x \\ y_2 &= x e^x \\ y_3 &= x^2 e^x \\ y_4 &= x^3 e^x \end{aligned}$$

Now the particular solution to the given ODE is found

$$y'''' - 4y''' + 6y'' - 4y' + y = x e^x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x e^x, e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^x, x^2 e^x, x^3 e^x, e^x\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^x, x^2 e^x\}]$$

Since $x e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 e^x, x^3 e^x\}]$$

Since $x^2 e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3 e^x, x^4 e^x\}]$$

Since $x^3 e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4 e^x, x^5 e^x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^4 e^x + A_2 x^5 e^x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$120 A_2 x\, e^x + 24 A_1 e^x = x\, e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{120}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^5 e^x}{120}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + x\, e^x c_2 + x^2 e^x c_3 + x^3 e^x c_4\right) + \left(\frac{x^5 e^x}{120}\right) \end{aligned}$$

Which simplifies to

$$y = e^x \left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) + \frac{x^5 e^x}{120}$$

Summary

The solution(s) found are the following

$$y = e^x \left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) + \frac{x^5 e^x}{120} \tag{1}$$

Verification of solutions

$$y = e^x \left(c_4 x^3 + c_3 x^2 + c_2 x + c_1\right) + \frac{x^5 e^x}{120}$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 2y' + y = -2}$$

16.37.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 1, f(x) = -2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(2)^2 - (4)\,(1)\,(1)}\\ &= -1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 1$. Therefore the solution is

$$y = c_1 e^{-x} + c_2 x\, e^{-x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-x} + c_2 x\, e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{-x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = -2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x}\right) + (-2) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x}(c_2 x + c_1) - 2$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_2 x + c_1) - 2 \tag{1}$$

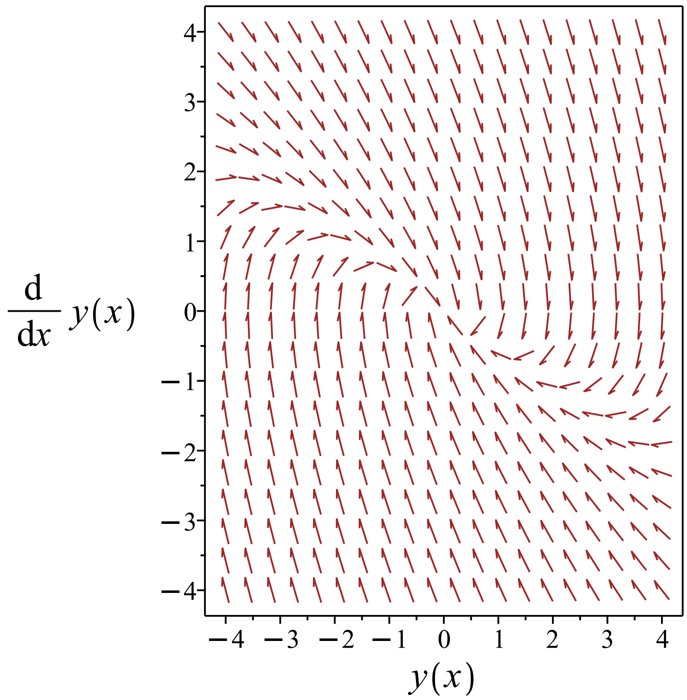

Figure 545: Slope field plot

Verification of solutions

$$y = e^{-x}(c_2 x + c_1) - 2$$

Verified OK.

16.37.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int 2\, dx} \\ &= e^{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= -2\,\mathrm{e}^{x} \\
(\mathrm{e}^{x}y)'' &= -2\,\mathrm{e}^{x}
\end{aligned}
$$

Integrating once gives

$$
(\mathrm{e}^{x}y)' = -2\,\mathrm{e}^{x} + c_1
$$

Integrating again gives

$$
(\mathrm{e}^{x}y) = c_1x - 2\,\mathrm{e}^{x} + c_2
$$

Hence the solution is

$$
y = \frac{c_1x - 2\,\mathrm{e}^{x} + c_2}{\mathrm{e}^{x}}
$$

Or

$$
y = c_1x\,\mathrm{e}^{-x} + \mathrm{e}^{-x}c_2 - 2
$$

Summary

The solution(s) found are the following

$$
y = c_1x\,\mathrm{e}^{-x} + \mathrm{e}^{-x}c_2 - 2 \tag{1}
$$

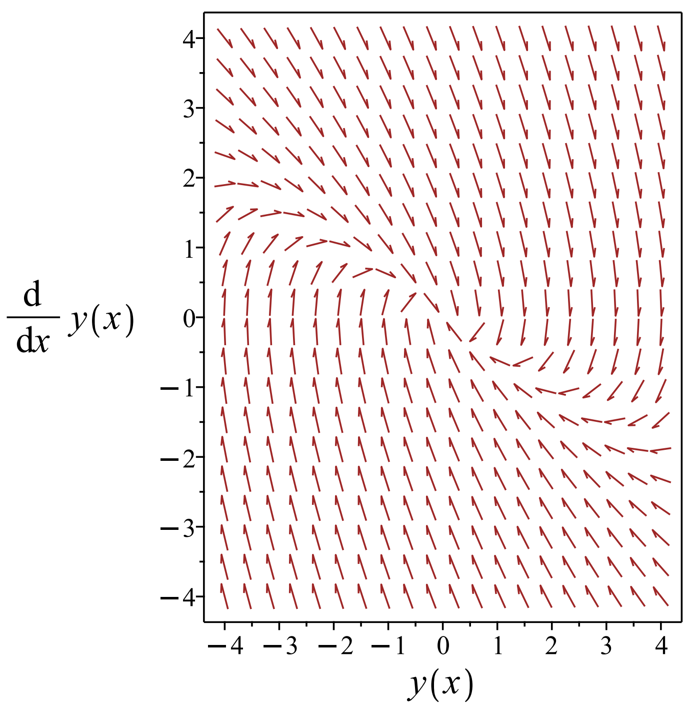

Figure 546: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} c_2 - 2$$

Verified OK.

16.37.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 436: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-2x}}{\left(y_1\right)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
y'' + 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-x} + c_2 x \, e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x \, e^{-x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = -2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 x \, e^{-x}\right) + (-2) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_2 x + c_1) - 2$$

Summary
The solution(s) found are the following

$$y = e^{-x}(c_2 x + c_1) - 2 \tag{1}$$

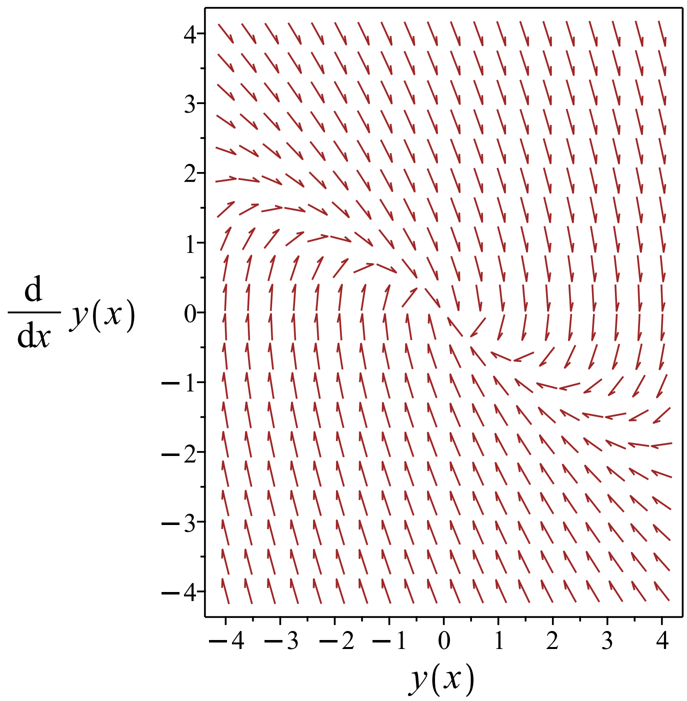

Figure 547: Slope field plot

Verification of solutions

$$y = e^{-x}(c_2 x + c_1) - 2$$

Verified OK.

16.37.4 Maple step by step solution

Let's solve

$y'' + 2y' + y = -2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r+1)^2 = 0$

- Root of the characteristic polynomial

  $r = -1$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = -2\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & x\,\mathrm{e}^{-x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{-x} - x\,\mathrm{e}^{-x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = 2\,\mathrm{e}^{-x}\left(\int x\,\mathrm{e}^{x}dx - \left(\int \mathrm{e}^{x}dx\right)x\right)$

- Compute integrals

  $y_p(x) = -2$

- Substitute particular solution into general solution to ODE

  $y = c_2 x \,\mathrm{e}^{-x} + c_1 \mathrm{e}^{-x} - 2$

16.38.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 0, f(x) = -2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+2y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=2, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+2\lambda\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+2\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=2, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-2}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{2^2-(4)\,(1)\,(0)}\\&=-1\pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-1+1\\\lambda_2&=-1-1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=0\\\lambda_2&=-2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{(0)x}+c_2e^{(-2)x}\end{aligned}$$

Or

$$y = c_1 + \mathrm{e}^{-2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + \mathrm{e}^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, \mathrm{e}^{-2x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 = -2$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \mathrm{e}^{-2x} c_2\right) + (-x) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 + \mathrm{e}^{-2x} c_2 - x \tag{1}$$

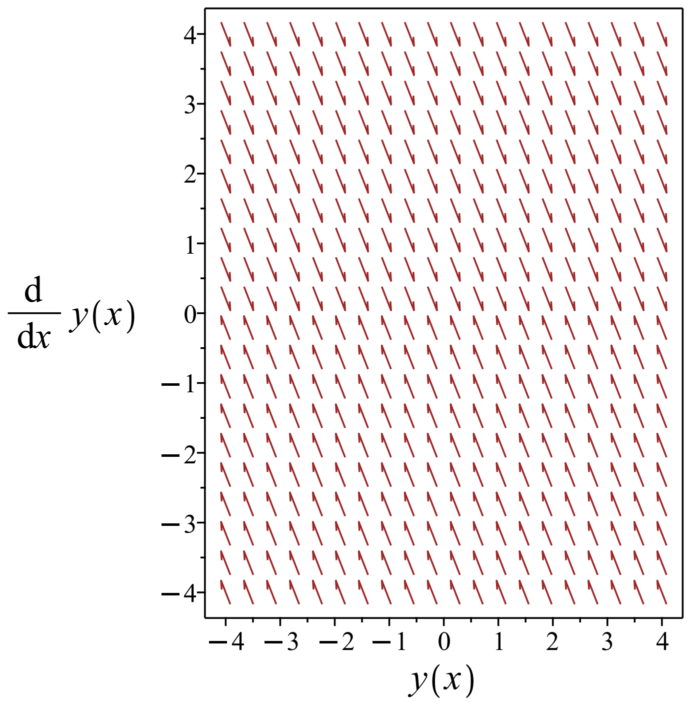

Figure 548: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 + \mathrm{e}^{-2x} c_2 - x$$

Verified OK.

16.38.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\, dx = \int (-2)\, dx$$
$$2y + y' = -2x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = -2x + c_1$$

Hence the ode is

$$2y + y' = -2x + c_1$$

The integrating factor μ is

$$\mu = e^{\int 2dx}$$
$$= e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(-2x + c_1)$$
$$\frac{d}{dx}(e^{2x}y) = (e^{2x})(-2x + c_1)$$
$$d(e^{2x}y) = ((-2x + c_1) e^{2x})\, dx$$

Integrating gives

$$e^{2x}y = \int (-2x + c_1) e^{2x}\, dx$$
$$e^{2x}y = -\frac{e^{2x}(2x - c_1 - 1)}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = -\frac{e^{-2x}e^{2x}(2x - c_1 - 1)}{2} + e^{-2x}c_2$$

which simplifies to

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x} c_2$$

Summary

The solution(s) found are the following

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x} c_2 \tag{1}$$

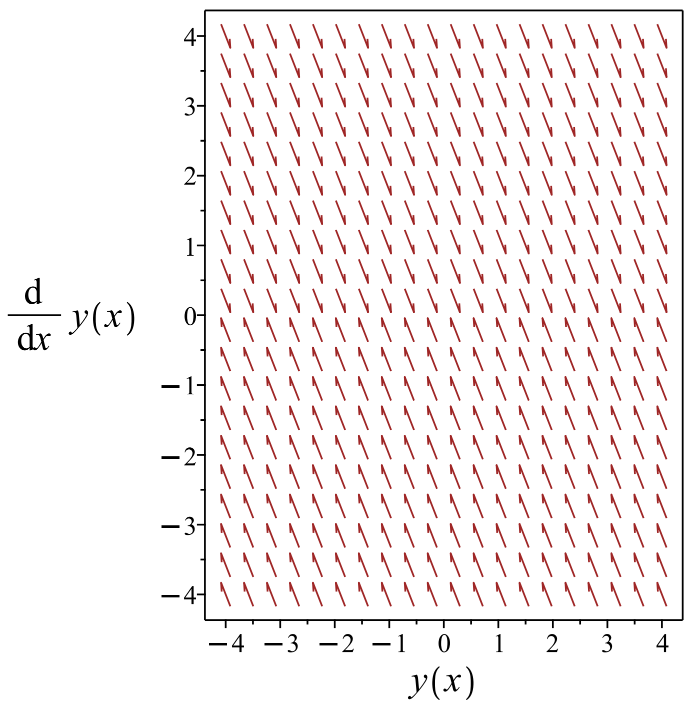

Figure 549: Slope field plot

Verification of solutions

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x} c_2$$

Verified OK.

16.38.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x) + 2 = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\int \frac{1}{-2p-2}dp = \int dx$$
$$-\frac{\ln(-p-1)}{2} = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{-p-1}} = e^{x+c_1}$$

Which simplifies to

$$\frac{1}{\sqrt{-p-1}} = e^{x}c_2$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\frac{e^{-2x}}{c_2^2} - 1$$

Integrating both sides gives

$$y = \int -\frac{(e^{2x}c_2^2 + 1)e^{-2x}}{c_2^2}\, dx$$
$$= \frac{e^{-2x}}{2c_2^2} - \ln(e^x) + c_3$$

Summary
The solution(s) found are the following

$$y = \frac{e^{-2x}}{2c_2^2} - \ln(e^x) + c_3 \tag{1}$$

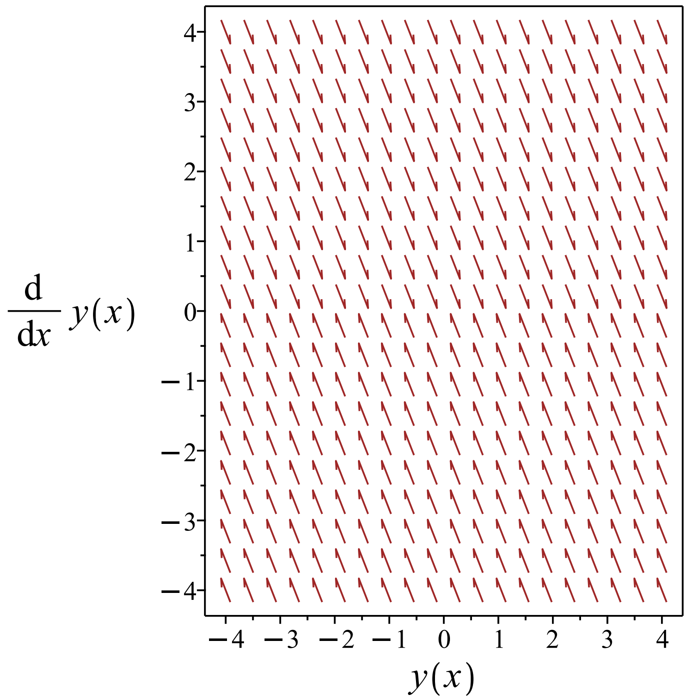

Figure 550: Slope field plot

Verification of solutions

$$y = \frac{e^{-2x}}{2c_2^2} - \ln\left(e^x\right) + c_3$$

Verified OK.

16.38.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 2y' = -2$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\, dx = \int (-2)\, dx$$
$$2y + y' = -2x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= -2x + c_1 \end{aligned}$$

Hence the ode is

$$2y + y' = -2x + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 2dx} \\ &= \mathrm{e}^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(-2x + c_1) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{2x} y\right) &= \left(\mathrm{e}^{2x}\right)(-2x + c_1) \\ \mathrm{d}\left(\mathrm{e}^{2x} y\right) &= \left((-2x + c_1)\,\mathrm{e}^{2x}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{2x} y &= \int (-2x + c_1)\,\mathrm{e}^{2x}\,\mathrm{d}x \\ \mathrm{e}^{2x} y &= -\frac{\mathrm{e}^{2x}(2x - c_1 - 1)}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$y = -\frac{\mathrm{e}^{-2x}\mathrm{e}^{2x}(2x - c_1 - 1)}{2} + \mathrm{e}^{-2x} c_2$$

which simplifies to

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + \mathrm{e}^{-2x} c_2$$

<u>Summary</u>
The solution(s) found are the following

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + \mathrm{e}^{-2x} c_2 \tag{1}$$

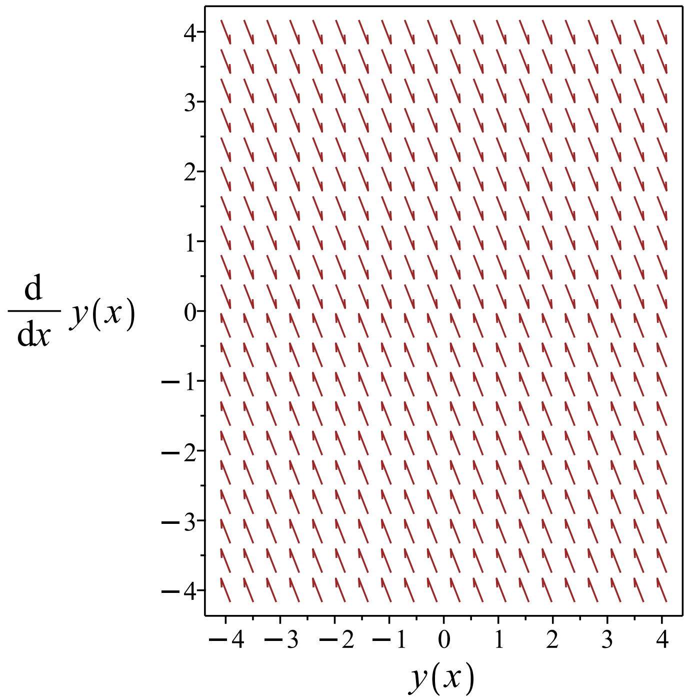

Figure 551: Slope field plot

<u>Verification of solutions</u>

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x} c_2$$

Verified OK.

16.38.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 438: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{\left(y_1\right)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{\left(y_1\right)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2}
$$

Now we need to find the particular solution y_p to

$$
y'' + 2y' = -2
$$

Since the RHS of the ode $f(x)$ is a constant, because it does not depend on x, then let the particular solution be

$$
y_p = kx
$$

where k is a constant to be determined. Substituting $y = kx$ in the ODE gives

$$
2k = -2
$$

Therefore

$$
k = -x
$$

Hence $y_p = -x^2$. Therefore the complete solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= c_1 \mathrm{e}^{-2x} + \frac{c_2}{2} + (-x)
\end{aligned}
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{-2x} + \frac{c_2}{2}\right) + (-x)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-2x} + \frac{c_2}{2} - x \tag{1}
$$

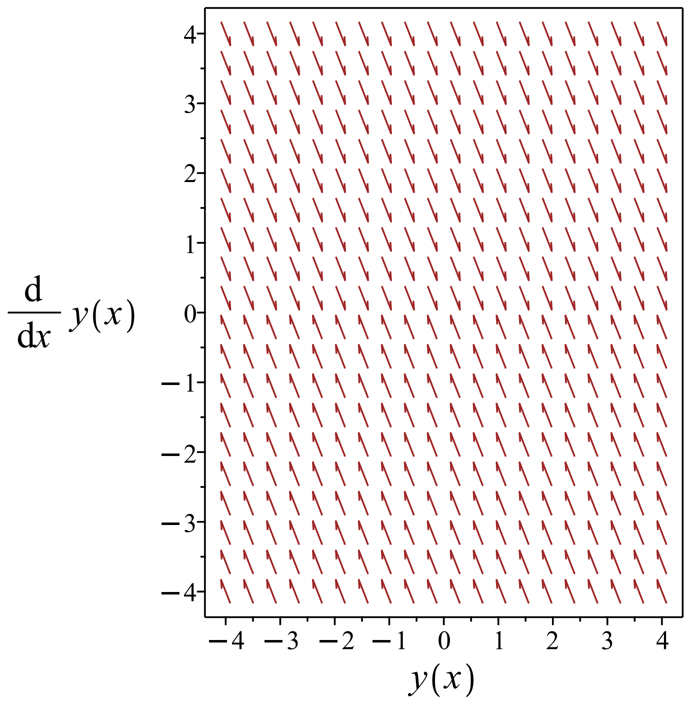

Figure 552: Slope field plot

Verification of solutions

$$
y = c_1 e^{-2x} + \frac{c_2}{2} - x
$$

Verified OK.

16.38.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x) &= 1\\ q(x) &= 2\\ r(x) &= 0\\ s(x) &= -2\end{aligned}$$

Hence

$$\begin{aligned}p''(x) &= 0\\ q'(x) &= 0\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$2y + y' = \int -2\,dx$$

We now have a first order ode to solve which is

$$2y + y' = -2x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= -2x + c_1 \end{aligned}$$

Hence the ode is

$$2y + y' = -2x + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 2dx} \\ &= e^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)(-2x + c_1) \\ \frac{d}{dx}(e^{2x}y) &= (e^{2x})(-2x + c_1) \\ d(e^{2x}y) &= ((-2x + c_1)e^{2x})\ dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{2x}y &= \int (-2x + c_1)e^{2x}\,dx \\ e^{2x}y &= -\frac{e^{2x}(2x - c_1 - 1)}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = -\frac{e^{-2x}e^{2x}(2x - c_1 - 1)}{2} + e^{-2x}c_2$$

which simplifies to

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x}c_2$$

Summary

The solution(s) found are the following

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x}c_2 \tag{1}$$

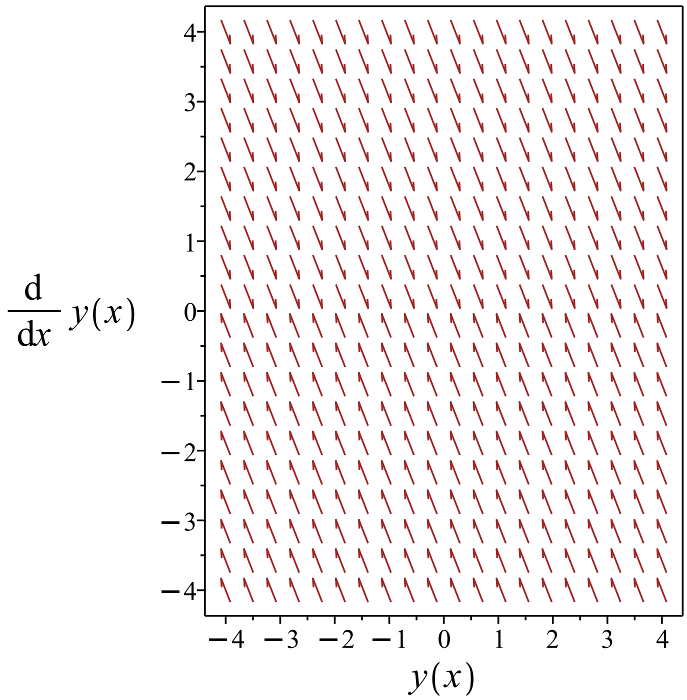

Figure 553: Slope field plot

Verification of solutions

$$y = -x + \frac{c_1}{2} + \frac{1}{2} + e^{-2x} c_2$$

Verified OK.

16.38.7 Maple step by step solution

Let's solve

$y'' + 2y' = -2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r = 0$

- Factor the characteristic polynomial

  $r(r + 2) = 0$

- Roots of the characteristic polynomial

$r = (-2, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -2\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & 1 \\ -2\,\mathrm{e}^{-2x} & 0 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \mathrm{e}^{-2x} \left(\int \mathrm{e}^{2x} dx\right) - \left(\int 1 dx\right)$

  - Compute integrals

    $y_p(x) = \frac{1}{2} - x$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + \frac{1}{2} - x$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 9y = 9}$$

16.39.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = 9$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)}\\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i\\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i\\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(3x), \sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_1 = 9$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(3x) + c_2 \sin(3x)) + (1) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(3x) + c_2 \sin(3x) + 1 \tag{1}$$

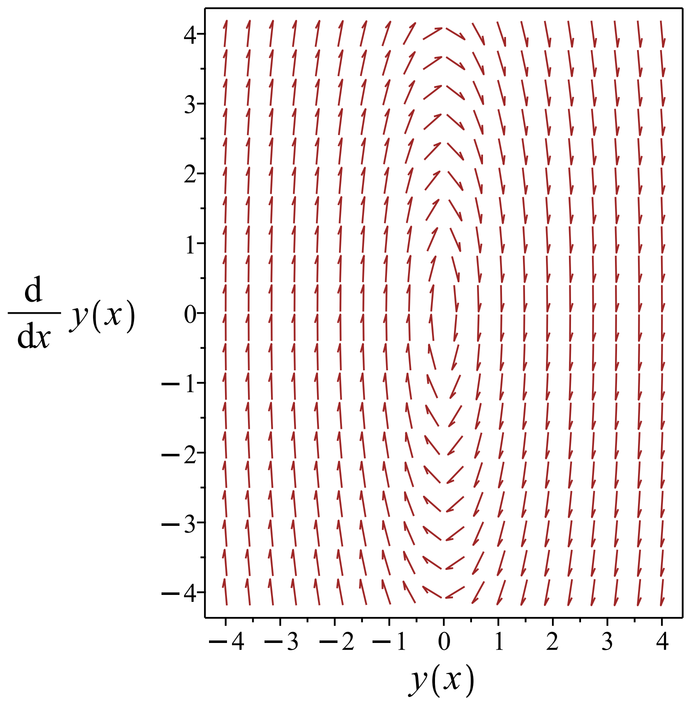

Figure 554: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + c_2 \sin(3x) + 1$$

Verified OK.

16.39.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + 9yy' - 9y' = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + 9yy' - 9y')\, dx = 0$$
$$\frac{y'^2}{2} + \frac{9y^2}{2} - 9y = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-9y^2 + 18y + 2c_1} \tag{1}$$

$$y' = -\sqrt{-9y^2 + 18y + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-9y^2 + 2c_1 + 18y}} dy = \int dx$$

$$\frac{\arctan\left(\frac{3y-3}{\sqrt{-9y^2+18y+2c_1}}\right)}{3} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-9y^2 + 2c_1 + 18y}} dy = \int dx$$

$$-\frac{\arctan\left(\frac{3y-3}{\sqrt{-9y^2+18y+2c_1}}\right)}{3} = x + c_3$$

Summary

The solution(s) found are the following

$$\frac{\arctan\left(\frac{3y-3}{\sqrt{-9y^2+18y+2c_1}}\right)}{3} = x + c_2 \tag{1}$$

$$-\frac{\arctan\left(\frac{3y-3}{\sqrt{-9y^2+18y+2c_1}}\right)}{3} = x + c_3 \tag{2}$$

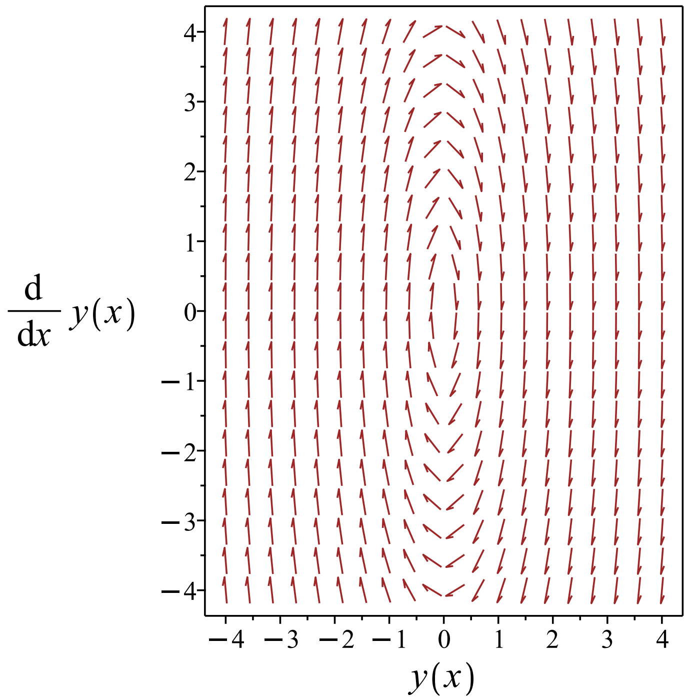

Figure 555: Slope field plot

Verification of solutions

$$\frac{\arctan\left(\frac{3y-3}{\sqrt{-9y^2+18y+2c_1}}\right)}{3} = x + c_2$$

Verified OK.

$$-\frac{\arctan\left(\frac{3y-3}{\sqrt{-9y^2+18y+2c_1}}\right)}{3} = x + c_3$$

Verified OK.

16.39.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 440: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1 \\ &= \cos(3x)\end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2}\,dx \\ &= \cos(3x)\left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2\left(\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(3x)}{3}, \cos(3x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$9A_1 = 9$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}\right) + (1) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + 1 \tag{1}$$

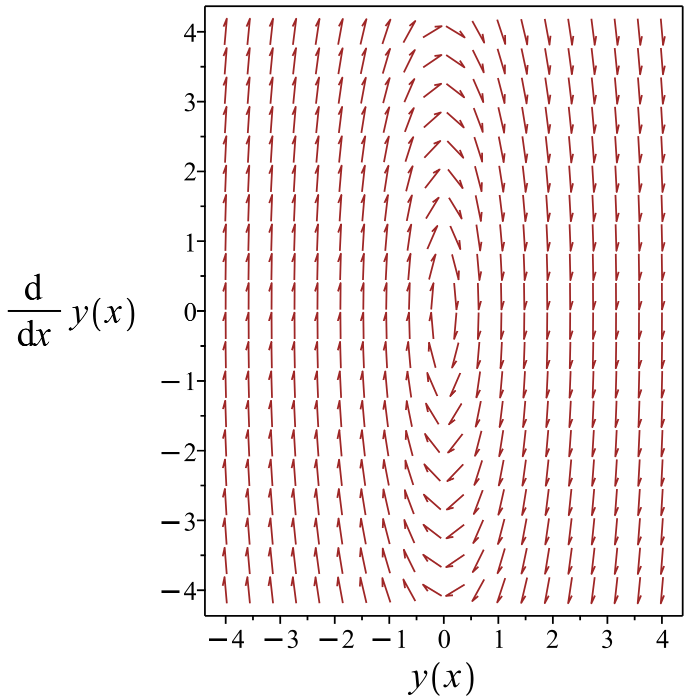

Figure 556: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} + 1$$

Verified OK.

16.39.4 Maple step by step solution

Let's solve

$y'' + 9y = 9$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

$r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 9\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -3\cos(3x)\left(\int \sin(3x)\, dx\right) + 3\sin(3x)\left(\int \cos(3x)\, dx\right)$

  - Compute integrals

    $y_p(x) = 1$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + 1$

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + y'' = 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' + y'' = 0$$

The characteristic equation is

$$\lambda^3 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 x$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= e^{-x} \\
y_2 &= 1 \\
y_3 &= x
\end{aligned}
$$

Now the particular solution to the given ODE is found

$$y''' + y'' = 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 + c_3 x\right) + \left(\frac{x^2}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x + \frac{x^2}{2} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + c_2 + c_3 x + \frac{x^2}{2}$$

Verified OK.

[[_3rd_order, _missing_x]]
```

$$\boxed{5y''' - 7y'' = 3}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$5y''' - 7y'' = 0$$

The characteristic equation is

$$5\lambda^3 - 7\lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = \frac{7}{5}$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_2x + c_1 + e^{\frac{7x}{5}} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = e^{\frac{7x}{5}}$$

Now the particular solution to the given ODE is found

$$5y''' - 7y'' = 3$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^3$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$6A_1 = 2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{3}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^3}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_3 x^2 + c_2 x + c_1 + e^{-\frac{x}{3}} c_4\right) + \left(\frac{x^3}{3}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_3 x^2 + c_2 x + c_1 + e^{-\frac{x}{3}} c_4 + \frac{x^3}{3} \tag{1}$$

Verification of solutions

$$y = c_3 x^2 + c_2 x + c_1 + e^{-\frac{x}{3}} c_4 + \frac{x^3}{3}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 517.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' - 2y''' + 2y'' - 2y' + y = 1}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 2y''' + 2y'' - 2y' + y = 0$$

The characteristic equation is

$$\lambda^4 - 2\lambda^3 + 2\lambda^2 - 2\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = i$$
$$\lambda_2 = -i$$
$$\lambda_3 = 1$$
$$\lambda_4 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + x e^x c_2 + e^{ix} c_3 + e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = x e^x$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' - 2y''' + 2y'' - 2y' + y = 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^x, e^x, e^{ix}, e^{-ix}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + x\, e^x c_2 + e^{ix} c_3 + e^{-ix} c_4\right) + (1) \end{aligned}$$

Which simplifies to

$$y = e^{-ix} c_4 + e^{ix} c_3 + e^x (c_2 x + c_1) + 1$$

Summary

The solution(s) found are the following

$$y = e^{-ix} c_4 + e^{ix} c_3 + e^x (c_2 x + c_1) + 1 \tag{1}$$

Verification of solutions

$$y = e^{-ix} c_4 + e^{ix} c_3 + e^x (c_2 x + c_1) + 1$$

Verified OK.

16.44.1 Maple step by step solution

Let's solve

$y'''' - 2y''' + 2y'' - 2y' + y = 1$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

$y_4(x) = y'''$

- Isolate for $y_4'(x)$ using original ODE

  $y_4'(x) = 1 + 2y_4(x) - 2y_3(x) + 2y_2(x) - y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 1 + 2y_4(x) - 2y_3(x) + 2y_2(x) - y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 2 & -2 & 2 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 2 & -2 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A

- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]\right], \left[1, \left[\begin{array}{c}0\\0\\0\\0\end{array}\right]\right], \left[-\mathrm{I}, \left[\begin{array}{c}-\mathrm{I}\\-1\\\mathrm{I}\\1\end{array}\right]\right], \left[\mathrm{I}, \left[\begin{array}{c}\mathrm{I}\\-1\\-\mathrm{I}\\1\end{array}\right]\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[1, \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]\right]$$

- First solution from eigenvalue 1

$$\vec{y}_1(x) = \mathrm{e}^{x} \cdot \left[\begin{array}{c}1\\1\\1\\1\end{array}\right]$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\vec{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda x}\vec{v} = \left(\mathrm{e}^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda x}\vec{v} = \mathrm{e}^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{y}_2(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 2 & -2 & 2 \end{array}\right]-1\cdot\left[\begin{array}{cccc} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{array}\right]\right)\cdot\vec{p}=\left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]$$

- Choice of $\vec{p}$

$$\vec{p}=\left[\begin{array}{c} -1 \\ 0 \\ 0 \\ 0 \end{array}\right]$$

- Second solution from eigenvalue 1

$$\vec{y}_2(x)=\mathrm{e}^{x}\cdot\left(x\cdot\left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]+\left[\begin{array}{c} -1 \\ 0 \\ 0 \\ 0 \end{array}\right]\right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I},\left[\begin{array}{c} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}x}\cdot\left[\begin{array}{c} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^x & (x-1)e^x & -\sin(x) & -\cos(x) \\ e^x & x e^x & -\cos(x) & \sin(x) \\ e^x & x e^x & \sin(x) & \cos(x) \\ e^x & x e^x & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{x} & (x-1)\,e^{x} & -\sin(x) & -\cos(x) \\ e^{x} & x\,e^{x} & -\cos(x) & \sin(x) \\ e^{x} & x\,e^{x} & \sin(x) & \cos(x) \\ e^{x} & x\,e^{x} & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -1 & 0 & -1 \\ 1 & 0 & -1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} -(x-1)\,e^{x} & x\,e^{x} - \frac{e^{x}}{2} + \frac{\cos(x)}{2} + \frac{\sin(x)}{2} & -x\,e^{x} + e^{x} - \cos(x) & x\,e^{x} - \frac{e^{x}}{2} + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \\ -x\,e^{x} & \frac{e^{x}}{2} + x\,e^{x} + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} & -x\,e^{x} + \sin(x) & \frac{e^{x}}{2} + x\,e^{x} - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \\ -x\,e^{x} & \frac{e^{x}}{2} + x\,e^{x} - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} & -x\,e^{x} + \cos(x) & \frac{e^{x}}{2} + x\,e^{x} + \frac{\sin(x)}{2} - \frac{\cos(x)}{2} \\ -x\,e^{x} & \frac{e^{x}}{2} + x\,e^{x} + \frac{\sin(x)}{2} - \frac{\cos(x)}{2} & -x\,e^{x} - \sin(x) & \frac{e^{x}}{2} + x\,e^{x} + \frac{\cos(x)}{2} + \frac{\sin(x)}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

$$\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} x\,e^x - \frac{3\,e^x}{2} + 1 + \frac{\sin(x)}{2} + \frac{\cos(x)}{2} \\ x\,e^x - \frac{e^x}{2} + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \\ x\,e^x - \frac{e^x}{2} + 1 - \frac{\sin(x)}{2} - \frac{\cos(x)}{2} \\ x\,e^x - \frac{e^x}{2} + 1 + \frac{\sin(x)}{2} - \frac{\cos(x)}{2} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \begin{bmatrix} x\,e^x - \frac{3\,e^x}{2} + 1 + \frac{\sin(x)}{2} + \frac{\cos(x)}{2} \\ x\,e^x - \frac{e^x}{2} + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \\ x\,e^x - \frac{e^x}{2} + 1 - \frac{\sin(x)}{2} - \frac{\cos(x)}{2} \\ x\,e^x - \frac{e^x}{2} + 1 + \frac{\sin(x)}{2} - \frac{\cos(x)}{2} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{((2x-2)c_2+2x+2c_1-3)e^x}{2} + \frac{(-2c_4+1)\cos(x)}{2} + 1 + \frac{(-2c_3+1)\sin(x)}{2}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 4y' + 4y = x^2}$$

16.45.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 4, f(x) = x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-4)^2 - (4)(1)(4)}\\ &= 2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -2$. Therefore the solution is

$$y = c_1 e^{2x} + c_2 x\, e^{2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x} c_1 + c_2 x\, e^{2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_3x^2 + 4A_2x - 8xA_3 + 4A_1 - 4A_2 + 2A_3 = x^2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{8}, A_2 = \frac{1}{2}, A_3 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{4}x^2 + \frac{1}{2}x + \frac{3}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{2x}c_1 + c_2x\,\mathrm{e}^{2x}\right) + \left(\frac{1}{4}x^2 + \frac{1}{2}x + \frac{3}{8}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{2x}(c_2x + c_1) + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{2x}(c_2x + c_1) + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8} \tag{1}$$

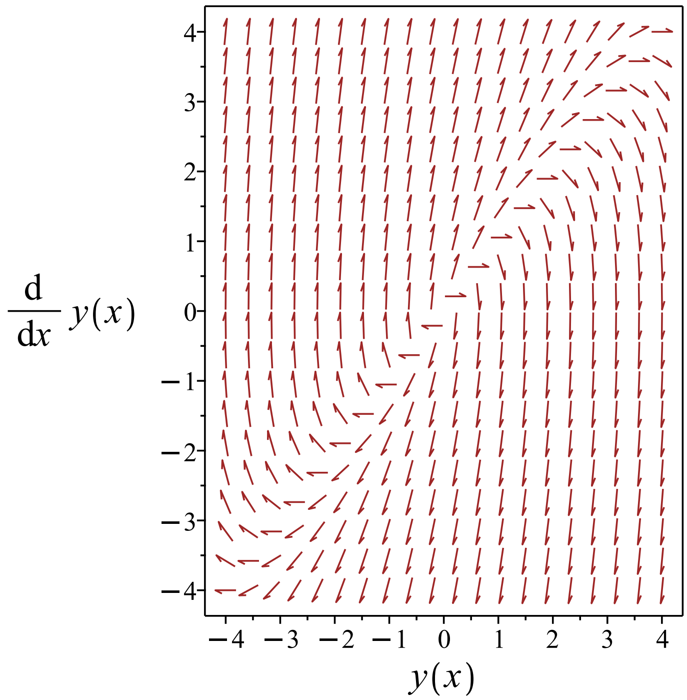

Figure 557: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2x + c_1) + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$$

Verified OK.

16.45.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -4\, dx} \\ &= e^{-2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = \mathrm{e}^{-2x}x^2$$
$$\left(\mathrm{e}^{-2x}y\right)'' = \mathrm{e}^{-2x}x^2$$

Integrating once gives

$$\left(\mathrm{e}^{-2x}y\right)' = -\frac{(2x^2+2x+1)\,\mathrm{e}^{-2x}}{4} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-2x}y\right) = \frac{(2x^2+4x+3)\,\mathrm{e}^{-2x}}{8} + c_1x + c_2$$

Hence the solution is

$$y = \frac{\frac{(2x^2+4x+3)\mathrm{e}^{-2x}}{8} + c_1x + c_2}{\mathrm{e}^{-2x}}$$

Or

$$y = c_1x\,\mathrm{e}^{2x} + \mathrm{e}^{2x}c_2 + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$$

Summary

The solution(s) found are the following

$$y = c_1x\,\mathrm{e}^{2x} + \mathrm{e}^{2x}c_2 + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8} \tag{1}$$

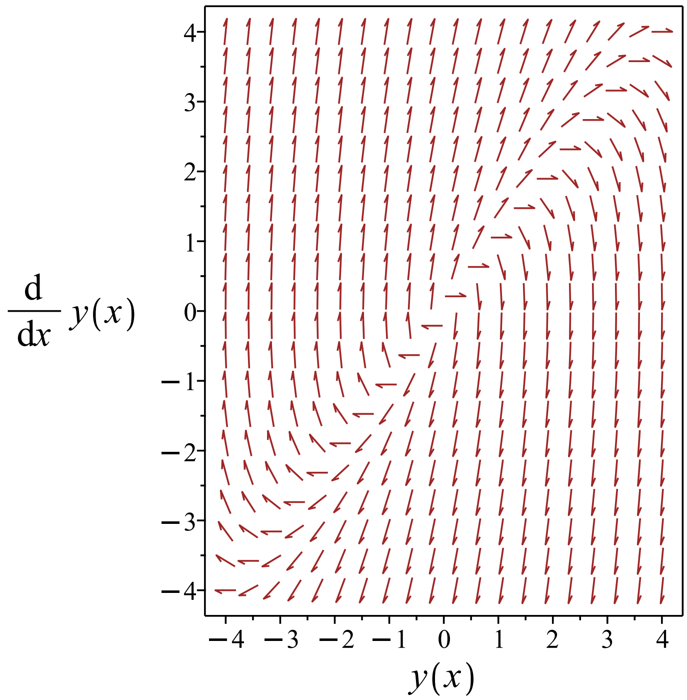

Figure 558: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{2x} + \mathrm{e}^{2x} c_2 + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$$

Verified OK.

16.45.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 443: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4}{1}\,dx} \\ &= z_1 e^{2x} \\ &= z_1\left(\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(\mathrm{e}^{2x}) + c_2(\mathrm{e}^{2x}(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^{2x}c_1 + c_2x\,\mathrm{e}^{2x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x^2
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x, x^2\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^{2x}, \mathrm{e}^{2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_3x^2 + A_2x + A_1
$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
4A_3x^2 + 4A_2x - 8xA_3 + 4A_1 - 4A_2 + 2A_3 = x^2
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{3}{8}, A_2 = \frac{1}{2}, A_3 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{4}x^2 + \frac{1}{2}x + \frac{3}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}c_1 + c_2 x\, e^{2x}\right) + \left(\frac{1}{4}x^2 + \frac{1}{2}x + \frac{3}{8}\right) \end{aligned}$$

Which simplifies to

$$y = e^{2x}(c_2 x + c_1) + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_2 x + c_1) + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8} \tag{1}$$

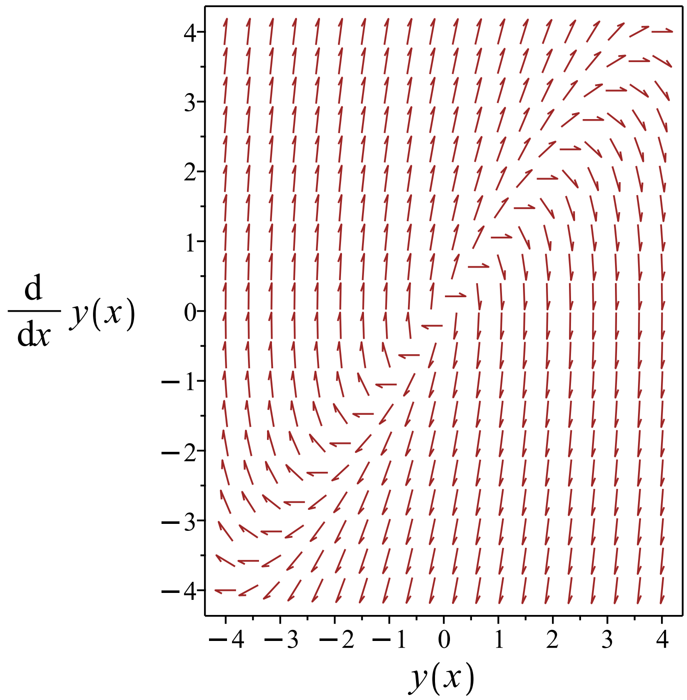

Figure 559: Slope field plot

Verification of solutions

$$y = e^{2x}(c_2x + c_1) + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$$

Verified OK.

16.45.4 Maple step by step solution

Let's solve

$y'' - 4y' + 4y = x^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r - 2)^2 = 0$

- Root of the characteristic polynomial

$r = 2$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{2x} c_1 + c_2 x\,\mathrm{e}^{2x} + y_p(x)$

- ☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{2x} & x\,\mathrm{e}^{2x} \\ 2\,\mathrm{e}^{2x} & \mathrm{e}^{2x} + 2x\,\mathrm{e}^{2x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{4x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \mathrm{e}^{2x}\left(-\left(\int x^3 \mathrm{e}^{-2x} dx\right) + \left(\int \mathrm{e}^{-2x} x^2 dx\right) x\right)$

  - Compute integrals

    $y_p(x) = \frac{1}{4}x^2 + \frac{1}{2}x + \frac{3}{8}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,\mathrm{e}^{2x} + \mathrm{e}^{2x} c_1 + \frac{x^2}{4} + \frac{x}{2} + \frac{3}{8}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 8y' = 8x}$$

16.46.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 8, C = 0, f(x) = 8x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+8y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=1, B=8, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+8\lambda\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+8\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=8, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-8}{(2)\,(1)}\pm\frac{1}{(2)\,(1)}\sqrt{8^2-(4)\,(1)\,(0)}\\&=-4\pm 4\end{aligned}$$

Hence

$$\lambda_1=-4+4$$
$$\lambda_2=-4-4$$

Which simplifies to

$$\lambda_1=0$$
$$\lambda_2=-8$$

Since roots are real and distinct, then the solution is

$$y=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}$$
$$y=c_1e^{(0)x}+c_2e^{(-8)x}$$

Or

$$y = c_1 + c_2 e^{-8x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-8x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-8x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^2 + A_1 x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$16xA_2 + 8A_1 + 2A_2 = 8x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{8}, A_2 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{2}x^2 - \frac{1}{8}x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + c_2 e^{-8x}\right) + \left(\frac{1}{2}x^2 - \frac{1}{8}x\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2 e^{-8x} + \frac{x^2}{2} - \frac{x}{8} \tag{1}$$

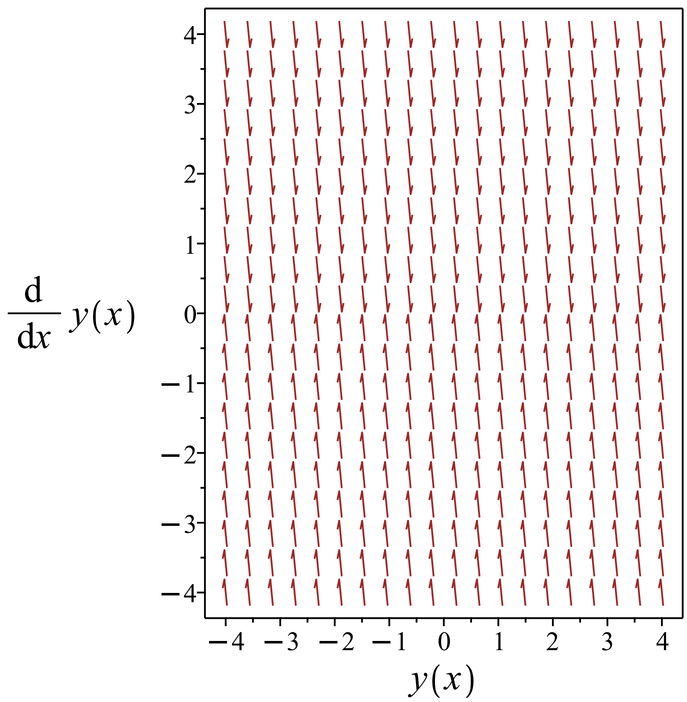

Figure 560: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^{-8x} + \frac{x^2}{2} - \frac{x}{8}$$

Verified OK.

16.46.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 8y')\,dx = \int 8x dx$$
$$8y + y' = 4x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 8$$
$$q(x) = 4x^2 + c_1$$

Hence the ode is

$$8y + y' = 4x^2 + c_1$$

The integrating factor μ is

$$\mu = e^{\int 8dx}$$
$$= e^{8x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(4x^2 + c_1\right)$$
$$\frac{d}{dx}\left(e^{8x} y\right) = \left(e^{8x}\right)\left(4x^2 + c_1\right)$$
$$d\left(e^{8x} y\right) = \left(\left(4x^2 + c_1\right) e^{8x}\right) dx$$

Integrating gives

$$e^{8x} y = \int \left(4x^2 + c_1\right) e^{8x}\, dx$$
$$e^{8x} y = \frac{\left(32x^2 + 8c_1 - 8x + 1\right) e^{8x}}{64} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{8x}$ results in

$$y = \frac{e^{-8x}\left(32x^2 + 8c_1 - 8x + 1\right) e^{8x}}{64} + c_2 e^{-8x}$$

which simplifies to

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x} \tag{1}$$

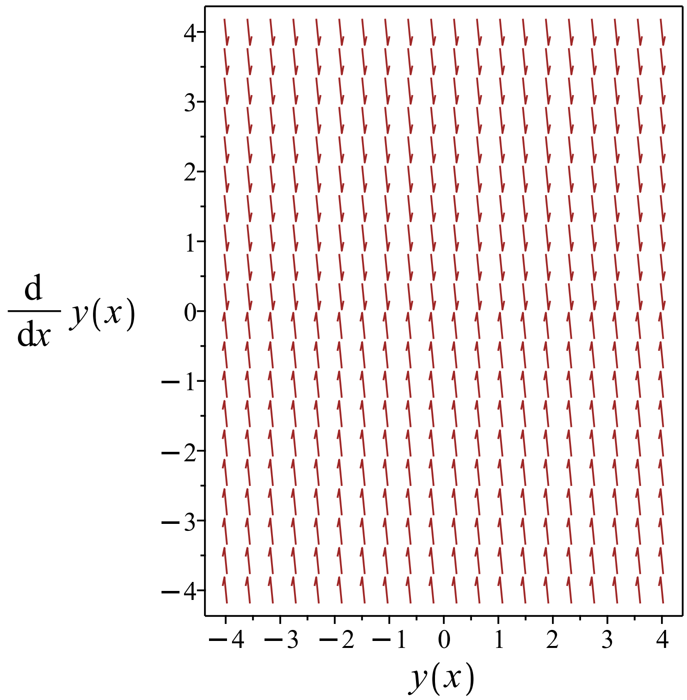

Figure 561: Slope field plot

Verification of solutions

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x}$$

Verified OK.

16.46.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 8p(x) - 8x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 8 \\ q(x) &= 8x \end{aligned}$$

Hence the ode is

$$p'(x) + 8p(x) = 8x$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 8dx} \\ &= \mathrm{e}^{8x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)(8x) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{8x} p\right) &= \left(\mathrm{e}^{8x}\right)(8x) \\ \mathrm{d}\left(\mathrm{e}^{8x} p\right) &= \left(8x\,\mathrm{e}^{8x}\right) \mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{8x} p &= \int 8x\,\mathrm{e}^{8x}\,\mathrm{d}x \\ \mathrm{e}^{8x} p &= \frac{(8x-1)\,\mathrm{e}^{8x}}{8} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{8x}$ results in

$$p(x) = \frac{e^{-8x}(8x-1)\,e^{8x}}{8} + c_1 e^{-8x}$$

which simplifies to

$$p(x) = x - \frac{1}{8} + c_1 e^{-8x}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = x - \frac{1}{8} + c_1 e^{-8x}$$

Integrating both sides gives

$$\begin{aligned} y &= \int x - \frac{1}{8} + c_1 e^{-8x}\, dx \\ &= \frac{x^2}{2} - \frac{x}{8} - \frac{c_1 e^{-8x}}{8} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{2} - \frac{x}{8} - \frac{c_1 e^{-8x}}{8} + c_2 \tag{1}$$

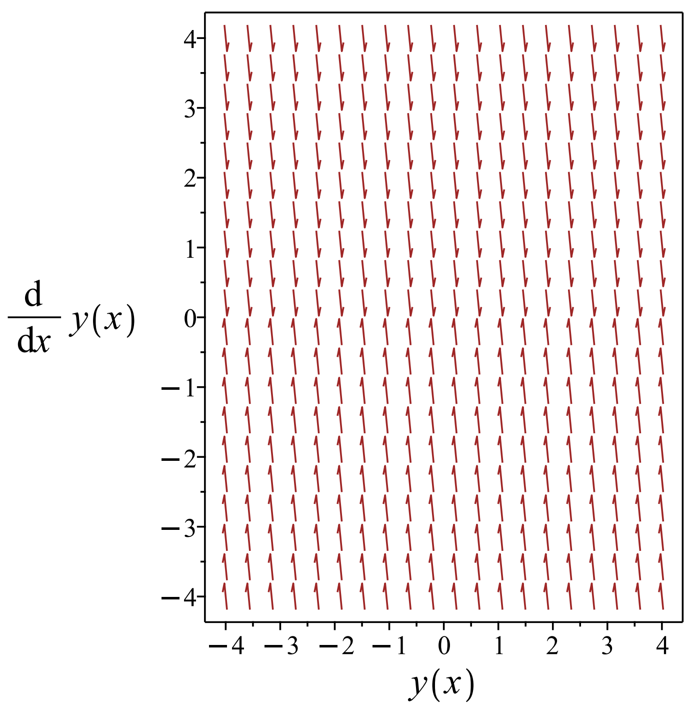

Figure 562: Slope field plot

Verification of solutions

$$y = \frac{x^2}{2} - \frac{x}{8} - \frac{c_1 \mathrm{e}^{-8x}}{8} + c_2$$

Verified OK.

16.46.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 8y' = 8x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 8y')\, dx = \int 8x dx$$
$$8y + y' = 4x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 8$$
$$q(x) = 4x^2 + c_1$$

Hence the ode is

$$8y + y' = 4x^2 + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int 8dx}$$
$$= \mathrm{e}^{8x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(4x^2 + c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{8x} y\right) = \left(\mathrm{e}^{8x}\right)\left(4x^2 + c_1\right)$$
$$\mathrm{d}\left(\mathrm{e}^{8x} y\right) = \left(\left(4x^2 + c_1\right)\mathrm{e}^{8x}\right)\,\mathrm{d}x$$

Integrating gives

$$e^{8x}y = \int \left(4x^2 + c_1\right) e^{8x}\, dx$$

$$e^{8x}y = \frac{(32x^2 + 8c_1 - 8x + 1)\, e^{8x}}{64} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{8x}$ results in

$$y = \frac{e^{-8x}(32x^2 + 8c_1 - 8x + 1)\, e^{8x}}{64} + c_2 e^{-8x}$$

which simplifies to

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x} \tag{1}$$

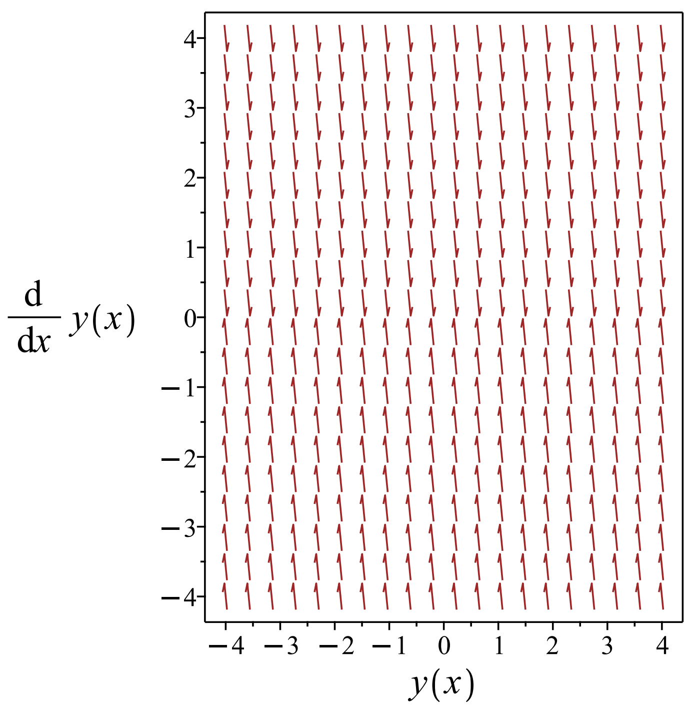

Figure 563: Slope field plot

Verification of solutions

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x}$$

Verified OK.

16.46.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 8y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 8 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{16}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 16 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 16 z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 445: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 16$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-4x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{8}{1}\,dx} \\
&= z_1 e^{-4x} \\
&= z_1 \left(\mathrm{e}^{-4x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-8x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{8}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-8x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\mathrm{e}^{8x}}{8}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-8x}\right) + c_2 \left(\mathrm{e}^{-8x} \left(\frac{\mathrm{e}^{8x}}{8}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 8y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-8x} + \frac{c_2}{8}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^{-8x} \\ y_2 &= \frac{1}{8} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-8x} & \frac{1}{8} \\ \frac{d}{dx}(\mathrm{e}^{-8x}) & \frac{d}{dx}\left(\frac{1}{8}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-8x} & \frac{1}{8} \\ -8\,e^{-8x} & 0 \end{vmatrix}$$

Therefore

$$W = \left(e^{-8x}\right)(0) - \left(\frac{1}{8}\right)\left(-8\,e^{-8x}\right)$$

Which simplifies to

$$W = e^{-8x}$$

Which simplifies to

$$W = e^{-8x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x}{e^{-8x}}\,dx$$

Which simplifies to

$$u_1 = -\int x\,e^{8x} dx$$

Hence

$$u_1 = -\frac{(8x-1)\,e^{8x}}{64}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,e^{-8x}x}{e^{-8x}}\,dx$$

Which simplifies to

$$u_2 = \int 8x dx$$

Hence

$$u_2 = 4x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{e^{-8x}(8x-1)\,e^{8x}}{64} + \frac{x^2}{2}$$

Which simplifies to

$$y_p(x) = -\frac{1}{8}x + \frac{1}{64} + \frac{1}{2}x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-8x} + \frac{c_2}{8}\right) + \left(-\frac{1}{8}x + \frac{1}{64} + \frac{1}{2}x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-8x} + \frac{c_2}{8} - \frac{x}{8} + \frac{1}{64} + \frac{x^2}{2} \tag{1}$$

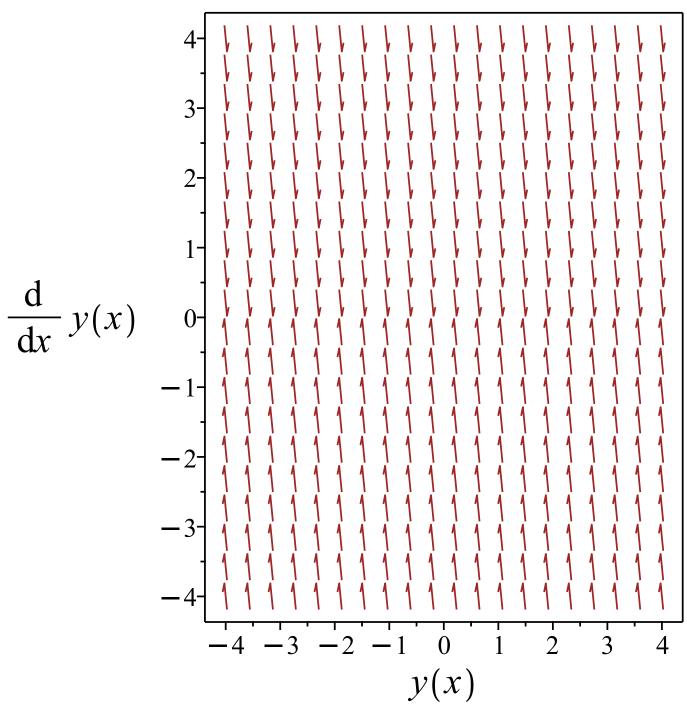

Figure 564: Slope field plot

Verification of solutions

$$y = c_1 e^{-8x} + \frac{c_2}{8} - \frac{x}{8} + \frac{1}{64} + \frac{x^2}{2}$$

Verified OK.

16.46.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 8 \\ r(x) &= 0 \\ s(x) &= 8x \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$8y + y' = \int 8x\, dx$$

We now have a first order ode to solve which is

$$8y + y' = 4x^2 + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 8 \\ q(x) &= 4x^2 + c_1 \end{aligned}$$

Hence the ode is

$$8y + y' = 4x^2 + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 8dx} \\ &= \mathrm{e}^{8x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(4x^2 + c_1\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{8x} y\right) &= \left(\mathrm{e}^{8x}\right)\left(4x^2 + c_1\right) \\ \mathrm{d}\left(\mathrm{e}^{8x} y\right) &= \left(\left(4x^2 + c_1\right)\mathrm{e}^{8x}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{8x} y &= \int \left(4x^2 + c_1\right)\mathrm{e}^{8x}\,\mathrm{d}x \\ \mathrm{e}^{8x} y &= \frac{\left(32x^2 + 8c_1 - 8x + 1\right)\mathrm{e}^{8x}}{64} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{8x}$ results in

$$y = \frac{\mathrm{e}^{-8x}\left(32x^2 + 8c_1 - 8x + 1\right)\mathrm{e}^{8x}}{64} + c_2\mathrm{e}^{-8x}$$

which simplifies to

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2\mathrm{e}^{-8x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x} \tag{1}$$

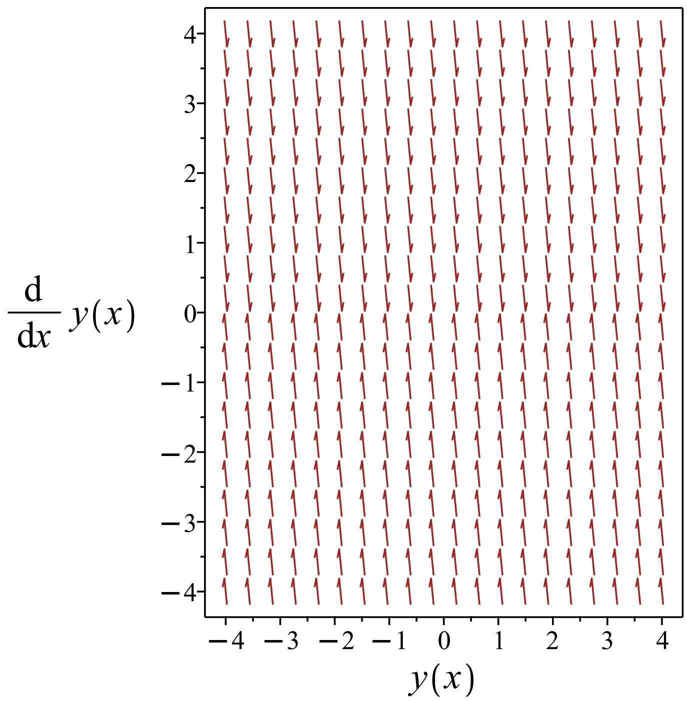

Figure 565: Slope field plot

Verification of solutions

$$y = \frac{x^2}{2} + \frac{c_1}{8} - \frac{x}{8} + \frac{1}{64} + c_2 e^{-8x}$$

Verified OK.

16.46.7 Maple step by step solution

Let's solve

$y'' + 8y' = 8x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 8r = 0$

- Factor the characteristic polynomial

  $r(r+8) = 0$

- Roots of the characteristic polynomial

  $r = (-8, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-8x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-8x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 8x\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-8x} & 1 \\ -8\,e^{-8x} & 0 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 8\,e^{-8x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -e^{-8x}\left(\int x\,e^{8x}dx\right) + \int x dx$

  - Compute integrals

    $y_p(x) = -\frac{1}{8}x + \frac{1}{64} + \frac{1}{2}x^2$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-8x} + c_2 - \frac{x}{8} + \frac{1}{64} + \frac{x^2}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 2y'k + k^2y = e^x}$$

16.47.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2k, C = k^2, f(x) = e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y'k + k^2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2k, C = k^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2k\lambda\, e^{\lambda x} + k^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$k^2 - 2k\lambda + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2k, C = k^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2k}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-2k)^2 - (4)\,(1)\,(k^2)}\\ &= k\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -k$. Therefore the solution is

$$y = c_1 e^{kx} + c_2 x\, e^{kx} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{kx} + c_2 x\, e^{kx}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{kx}, e^{kx}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \mathrm{e}^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 \mathrm{e}^x - 2A_1 \mathrm{e}^x k + k^2 A_1 \mathrm{e}^x = \mathrm{e}^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{(k-1)^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\mathrm{e}^x}{(k-1)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{kx} + c_2 x\, \mathrm{e}^{kx}\right) + \left(\frac{\mathrm{e}^x}{(k-1)^2}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{kx}(c_2 x + c_1) + \frac{\mathrm{e}^x}{(k-1)^2}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{kx}(c_2 x + c_1) + \frac{\mathrm{e}^x}{(k-1)^2} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{kx}(c_2 x + c_1) + \frac{\mathrm{e}^x}{(k-1)^2}$$

Verified OK.

16.47.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2k$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2k\, dx} \\ &= \mathrm{e}^{-kx} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \mathrm{e}^{-kx}\mathrm{e}^{x} \\ \left(\mathrm{e}^{-kx}y\right)'' &= \mathrm{e}^{-kx}\mathrm{e}^{x} \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-kx}y\right)' = -\frac{\mathrm{e}^{-x(k-1)}}{k-1} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-kx}y\right) = \frac{\mathrm{e}^{-x(k-1)} + x(k^2 - 2k + 1)\, c_1}{(k-1)^2} + c_2$$

Hence the solution is

$$y = \frac{\frac{\mathrm{e}^{-x(k-1)} + x(k^2-2k+1)c_1}{(k-1)^2} + c_2}{\mathrm{e}^{-kx}}$$

Or

$$y = c_2\mathrm{e}^{kx} + \left(\frac{k^2 x\, \mathrm{e}^{kx}}{(k-1)^2} - \frac{2kx\, \mathrm{e}^{kx}}{(k-1)^2} + \frac{x\, \mathrm{e}^{kx}}{(k-1)^2}\right) c_1 + \frac{\mathrm{e}^{x}}{(k-1)^2}$$

Summary

The solution(s) found are the following

$$y = c_2\mathrm{e}^{kx} + \left(\frac{k^2 x\, \mathrm{e}^{kx}}{(k-1)^2} - \frac{2kx\, \mathrm{e}^{kx}}{(k-1)^2} + \frac{x\, \mathrm{e}^{kx}}{(k-1)^2}\right) c_1 + \frac{\mathrm{e}^{x}}{(k-1)^2} \tag{1}$$

Verification of solutions

$$y = c_2 e^{kx} + \left(\frac{k^2 x\, e^{kx}}{(k-1)^2} - \frac{2kx\, e^{kx}}{(k-1)^2} + \frac{x\, e^{kx}}{(k-1)^2}\right) c_1 + \frac{e^x}{(k-1)^2}$$

Verified OK.

16.47.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y'k + k^2 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2k \\ C &= k^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 447: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2k}{1}\,dx} \\
&= z_1 e^{kx} \\
&= z_1 \left(\mathrm{e}^{kx}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{kx}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2k}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2kx}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{kx}\right) + c_2 \left(\mathrm{e}^{kx}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y'k + k^2 y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{kx} + c_2 x\, e^{kx}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{kx}, e^{kx}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{x} - 2A_1 e^{x} k + k^2 A_1 e^{x} = e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{(k-1)^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{x}}{(k-1)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{kx} + c_2 x\, e^{kx}\right) + \left(\frac{e^{x}}{(k-1)^2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{kx}(c_2x + c_1) + \frac{e^x}{(k-1)^2}$$

Summary
The solution(s) found are the following

$$y = e^{kx}(c_2x + c_1) + \frac{e^x}{(k-1)^2} \tag{1}$$

Verification of solutions

$$y = e^{kx}(c_2x + c_1) + \frac{e^x}{(k-1)^2}$$

Verified OK.

16.47.4 Maple step by step solution

Let's solve

$y'' - 2y'k + k^2y = e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $k^2 - 2rk + r^2 = 0$

- Factor the characteristic polynomial

  $(k-r)^2 = 0$

- Root of the characteristic polynomial

  $r = k$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{kx}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{kx}$

- General solution of the ODE

  $y = c_1y_1(x) + c_2y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$$y = c_1 e^{kx} + c_2 x\,e^{kx} + y_p(x)$$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))}dx\right), f(x) = e^x\right]$$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{kx} & x\,e^{kx} \\ k\,e^{kx} & e^{kx} + kx\,e^{kx} \end{bmatrix}$$

- Compute Wronskian

$$W(y_1(x), y_2(x)) = e^{2kx}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = e^{kx}\left(-\left(\int x\,e^{-x(k-1)}dx\right) + \left(\int e^{-x(k-1)}dx\right)x\right)$$

- Compute integrals

$$y_p(x) = \frac{e^x}{(k-1)^2}$$

• Substitute particular solution into general solution to ODE

$$y = c_1 e^{kx} + c_2 x\,e^{kx} + \frac{e^x}{(k-1)^2}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + 4y' + 4y = 8\,\mathrm{e}^{-2x}}$$

16.48.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 4, f(x) = 8\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(4)^2 - (4)(1)(4)} \\ &= -2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 2$. Therefore the solution is

$$y = c_1 e^{-2x} + c_2 x\, e^{-2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-2x} + c_2 x\, e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\, e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{-2x}, e^{-2x}\}$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-2x}\}]$$

Since $x\,e^{-2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-2x}x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{-2x} x^2$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{-2x} = 8\,e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 4\,e^{-2x} x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + c_2 x\,e^{-2x}\right) + \left(4\,e^{-2x} x^2\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_2 x + c_1) + 4\,e^{-2x} x^2$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_2 x + c_1) + 4\,e^{-2x} x^2 \tag{1}$$

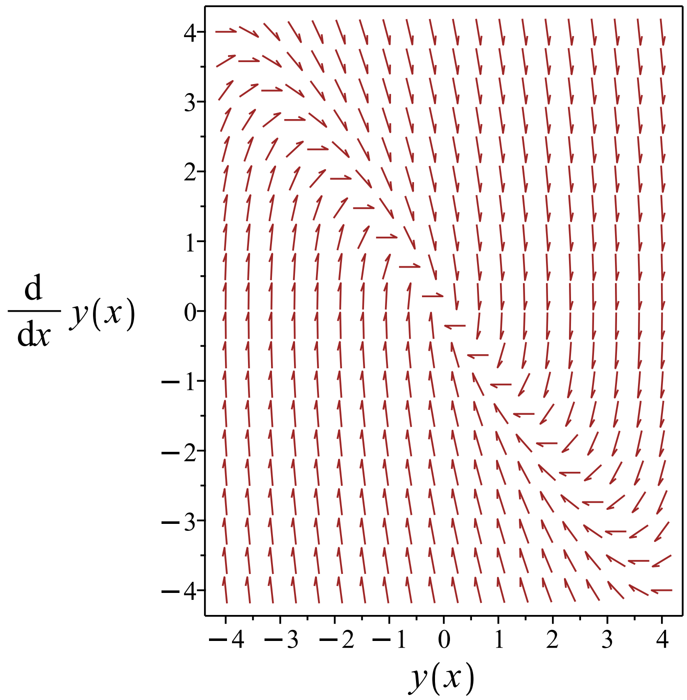

Figure 566: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_2x + c_1) + 4\,e^{-2x}x^2$$

Verified OK.

16.48.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = 4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 4\,dx} \\ &= e^{2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 8\,e^{2x}e^{-2x}$$
$$\left(e^{2x}y\right)'' = 8\,e^{2x}e^{-2x}$$

Integrating once gives

$$\left(e^{2x}y\right)' = 8x + c_1$$

Integrating again gives

$$\left(e^{2x}y\right) = x(c_1 + 4x) + c_2$$

Hence the solution is

$$y = \frac{x(c_1 + 4x) + c_2}{e^{2x}}$$

Or

$$y = c_1 x\,e^{-2x} + 4\,e^{-2x}x^2 + e^{-2x}c_2$$

Summary

The solution(s) found are the following

$$y = c_1 x\,e^{-2x} + 4\,e^{-2x}x^2 + e^{-2x}c_2 \tag{1}$$

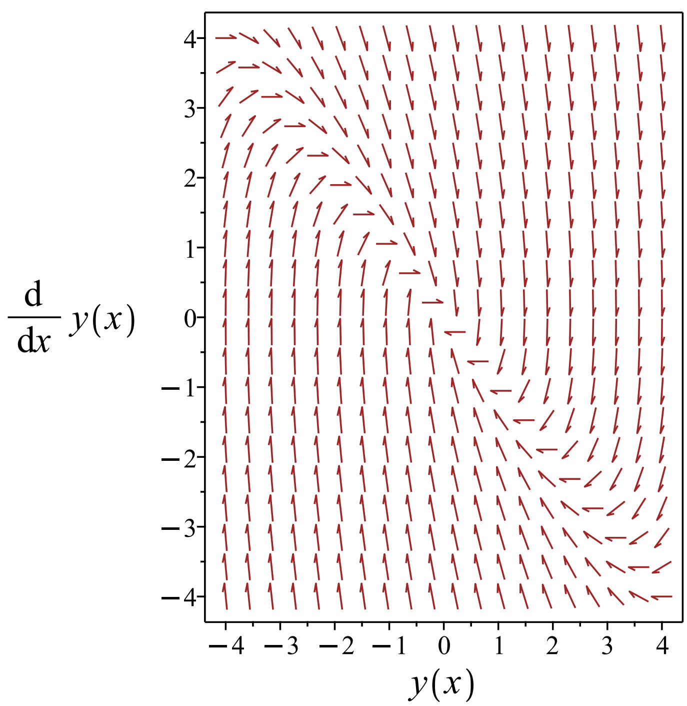

Figure 567: Slope field plot

Verification of solutions

$$y = c_1 x \,\mathrm{e}^{-2x} + 4\,\mathrm{e}^{-2x} x^2 + \mathrm{e}^{-2x} c_2$$

Verified OK.

16.48.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 449: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\
&= z_1 e^{-2x} \\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} + c_2 x \, e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8 \, e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x \, e^{-2x}, e^{-2x}\}$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x \, e^{-2x}\}]$$

Since $x \, e^{-2x}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^{-2x} x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^{-2x} x^2$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{-2x} = 8 \, e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 4]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 4 \, e^{-2x} x^2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} + c_2 x\, \mathrm{e}^{-2x}\right) + \left(4\, \mathrm{e}^{-2x} x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y = \mathrm{e}^{-2x}(c_2 x + c_1) + 4\, \mathrm{e}^{-2x} x^2
$$

Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{-2x}(c_2 x + c_1) + 4\, \mathrm{e}^{-2x} x^2 \tag{1}
$$

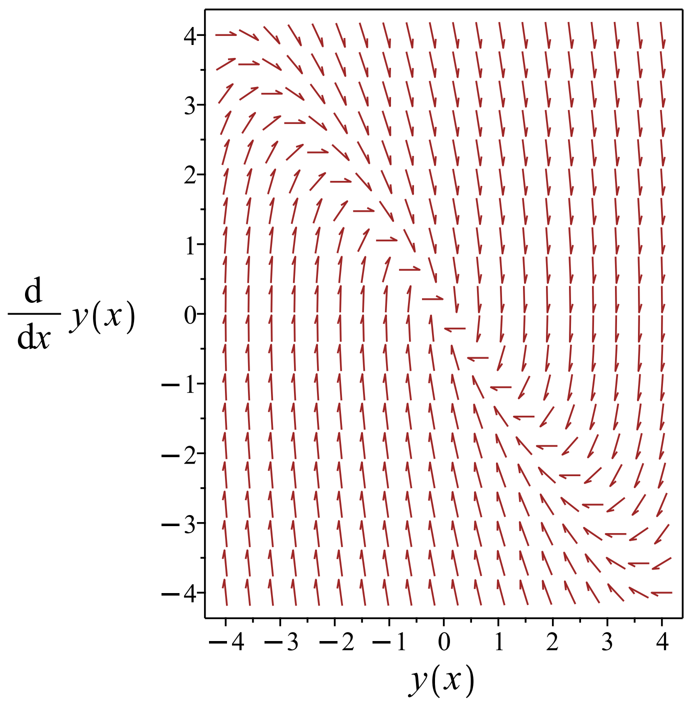

Figure 568: Slope field plot

Verification of solutions

$$
y = \mathrm{e}^{-2x}(c_2 x + c_1) + 4\, \mathrm{e}^{-2x} x^2
$$

Verified OK.

16.48.4 Maple step by step solution

Let's solve

$y'' + 4y' + 4y = 8\,\mathrm{e}^{-2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r+2)^2 = 0$

- Root of the characteristic polynomial

  $r = -2$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 8\,\mathrm{e}^{-2x}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & x\,\mathrm{e}^{-2x} \\ -2\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x} - 2x\,\mathrm{e}^{-2x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-4x}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -8\,\mathrm{e}^{-2x}\left(\int x dx - \left(\int 1 dx\right) x\right)$

- Compute integrals

  $y_p(x) = 4\,e^{-2x}x^2$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,e^{-2x} + 4\,e^{-2x}x^2 + c_1 e^{-2x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 4y' + 3y = 9\,\mathrm{e}^{-3x}}$$

16.49.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 3, f(x) = 9\,\mathrm{e}^{-3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 3y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 3\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{4^2 - (4)\,(1)\,(3)} \\ &= -2 \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + 1 \\ \lambda_2 &= -2 - 1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 \\ \lambda_2 &= -3\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-1)x} + c_2 e^{(-3)x}\end{aligned}$$

Or

$$y = c_1 e^{-x} + c_2 e^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-x} + c_2 e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$9\,\mathrm{e}^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-3x}, \mathrm{e}^{-x}\}$$

Since e^{-3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-3x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\mathrm{e}^{-3x} = 9\,\mathrm{e}^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{9}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{9x\,\mathrm{e}^{-3x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{-3x}\right) + \left(-\frac{9x\,\mathrm{e}^{-3x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{-3x} - \frac{9x\,e^{-3x}}{2} \tag{1}$$

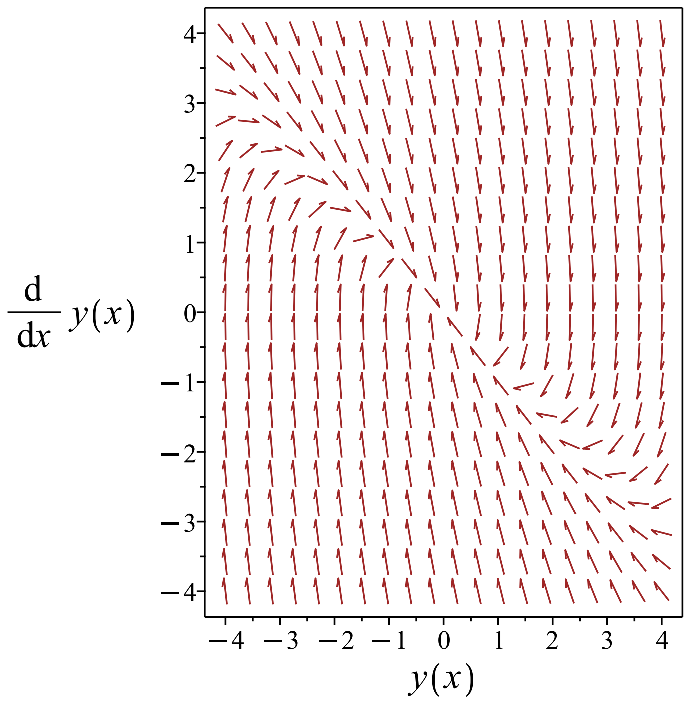

Figure 569: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-3x} - \frac{9x\,e^{-3x}}{2}$$

Verified OK.

16.49.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 4 \\
C &= 3
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 1 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 451: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\
&= z_1 e^{-2x} \\
&= z_1\left(\mathrm{e}^{-2x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-4x}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 3y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} + \frac{\mathrm{e}^{-x} c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$9\,\mathrm{e}^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{-x}}{2}, \mathrm{e}^{-3x}\right\}$$

Since e^{-3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-3x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\mathrm{e}^{-3x} = 9\,\mathrm{e}^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{9}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{9x\,\mathrm{e}^{-3x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-3x} + \frac{\mathrm{e}^{-x}c_2}{2}\right) + \left(-\frac{9x\,\mathrm{e}^{-3x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-3x} + \frac{\mathrm{e}^{-x} c_2}{2} - \frac{9x \, \mathrm{e}^{-3x}}{2} \tag{1}$$

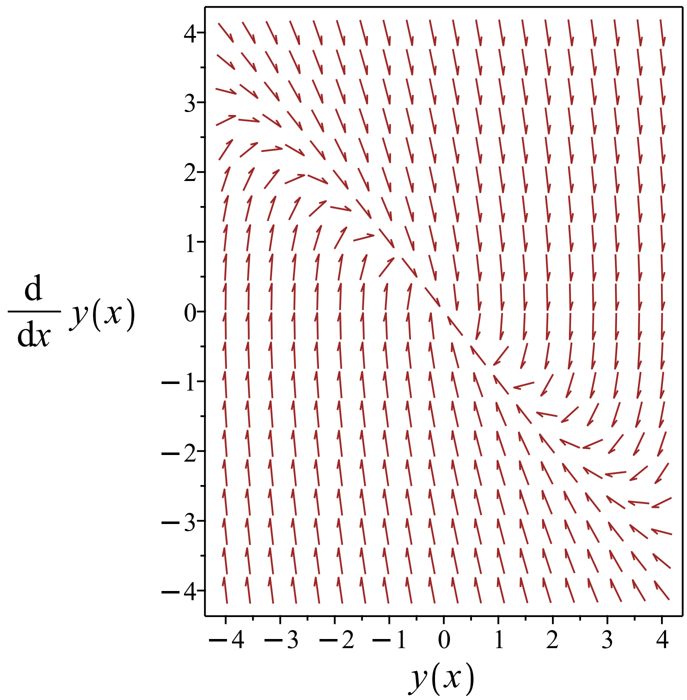

Figure 570: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-3x} + \frac{\mathrm{e}^{-x} c_2}{2} - \frac{9x \, \mathrm{e}^{-3x}}{2}$$

Verified OK.

16.49.3 Maple step by step solution

Let's solve

$y'' + 4y' + 3y = 9 \, \mathrm{e}^{-3x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 + 4r + 3 = 0$

- Factor the characteristic polynomial

  $(r+3)(r+1) = 0$
- Roots of the characteristic polynomial

  $r = (-3, -1)$
- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + \mathrm{e}^{-x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 9\,\mathrm{e}^{-3x}\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & \mathrm{e}^{-x} \\ -3\,\mathrm{e}^{-3x} & -\mathrm{e}^{-x} \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-4x}$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{9\,\mathrm{e}^{-3x}\left(\int 1 dx\right)}{2} + \frac{9\,\mathrm{e}^{-x}\left(\int \mathrm{e}^{-2x} dx\right)}{2}$
  - Compute integrals

    $y_p(x) = -\frac{9\,\mathrm{e}^{-3x}(1+2x)}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3x} + \mathrm{e}^{-x} c_2 - \frac{9\,\mathrm{e}^{-3x}(1+2x)}{4}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{7y'' - y' = 14x}$$

16.50.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 7, B = -1, C = 0, f(x) = 14x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$7y''-y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=7, B=-1, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$7\lambda^2 e^{\lambda x}-\lambda e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$7\lambda^2-\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=7, B=-1, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{1}{(2)(7)}\pm\frac{1}{(2)(7)}\sqrt{-1^2-(4)(7)(0)}\\&=\frac{1}{14}\pm\frac{1}{14}\end{aligned}$$

Hence

$$\lambda_1=\frac{1}{14}+\frac{1}{14}$$
$$\lambda_2=\frac{1}{14}-\frac{1}{14}$$

Which simplifies to

$$\lambda_1=\frac{1}{7}$$
$$\lambda_2=0$$

Since roots are real and distinct, then the solution is

$$y=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}$$
$$y=c_1e^{\left(\frac{1}{7}\right)x}+c_2e^{(0)x}$$

Or

$$y = c_1 e^{\frac{x}{7}} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\frac{x}{7}} + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, e^{\frac{x}{7}}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2 x^2 + A_1 x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2xA_2 - A_1 + 14A_2 = 14x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -98, A_2 = -7]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -7x^2 - 98x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{\frac{x}{7}} + c_2\right) + \left(-7x^2 - 98x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{x}{7}} + c_2 - 7x^2 - 98x \tag{1}$$

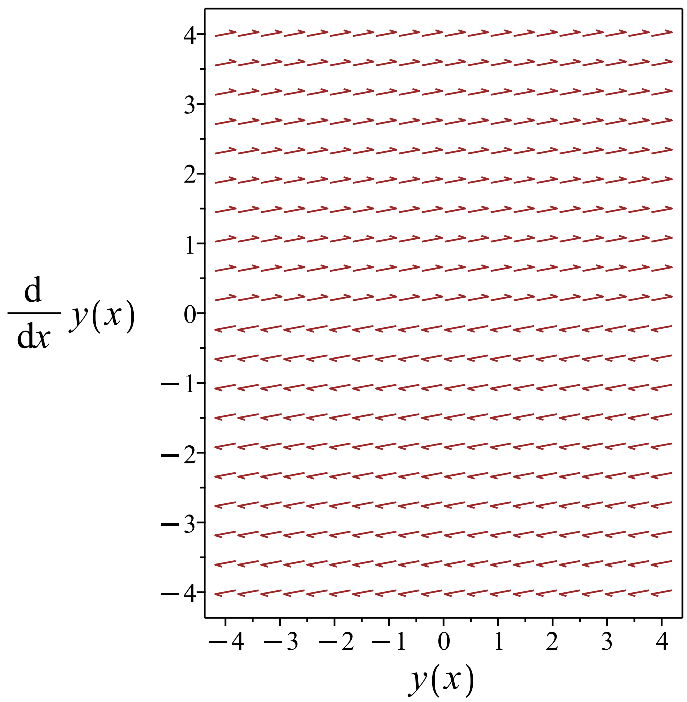

Figure 571: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{\frac{x}{7}} + c_2 - 7x^2 - 98x$$

Verified OK.

16.50.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (7y'' - y')\,dx = \int 14x dx$$
$$7y' - y = 7x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{7}$$
$$q(x) = x^2 + \frac{c_1}{7}$$

Hence the ode is

$$y' - \frac{y}{7} = x^2 + \frac{c_1}{7}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{7}dx}$$
$$= e^{-\frac{x}{7}}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(x^2 + \frac{c_1}{7}\right)$$
$$\frac{d}{dx}\left(e^{-\frac{x}{7}} y\right) = \left(e^{-\frac{x}{7}}\right)\left(x^2 + \frac{c_1}{7}\right)$$
$$d\left(e^{-\frac{x}{7}} y\right) = \left(\frac{(7x^2 + c_1)\,e^{-\frac{x}{7}}}{7}\right) dx$$

Integrating gives

$$e^{-\frac{x}{7}} y = \int \frac{(7x^2 + c_1)\,e^{-\frac{x}{7}}}{7}\, dx$$
$$e^{-\frac{x}{7}} y = -\left(7x^2 + c_1 + 98x + 686\right) e^{-\frac{x}{7}} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{x}{7}}$ results in

$$y = -e^{\frac{x}{7}} \left(7x^2 + c_1 + 98x + 686\right) e^{-\frac{x}{7}} + c_2 e^{\frac{x}{7}}$$

which simplifies to

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}}$$

Summary

The solution(s) found are the following

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}} \tag{1}$$

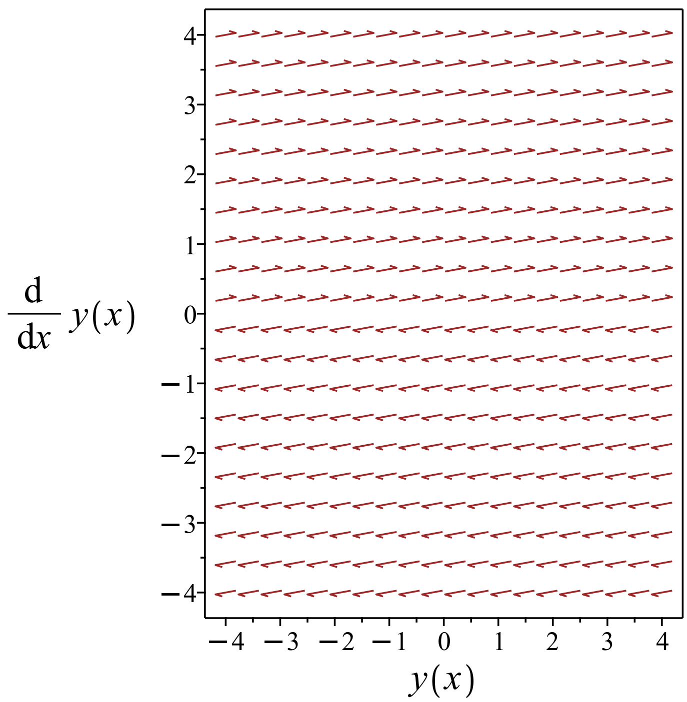

Figure 572: Slope field plot

Verification of solutions

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}}$$

Verified OK.

16.50.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$7p'(x) - p(x) - 14x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{7} \\ q(x) &= 2x \end{aligned}$$

Hence the ode is

$$p'(x) - \frac{p(x)}{7} = 2x$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{7}dx} \\ &= e^{-\frac{x}{7}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)(2x) \\ \frac{d}{dx}\left(e^{-\frac{x}{7}} p\right) &= \left(e^{-\frac{x}{7}}\right)(2x) \\ d\left(e^{-\frac{x}{7}} p\right) &= \left(2x\, e^{-\frac{x}{7}}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-\frac{x}{7}} p &= \int 2x\, e^{-\frac{x}{7}}\, dx \\ e^{-\frac{x}{7}} p &= -14(x+7)\, e^{-\frac{x}{7}} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{x}{7}}$ results in

$$p(x) = -14\, e^{\frac{x}{7}} (x+7)\, e^{-\frac{x}{7}} + c_1 e^{\frac{x}{7}}$$

which simplifies to

$$p(x) = -14x - 98 + c_1 e^{\frac{x}{7}}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -14x - 98 + c_1 e^{\frac{x}{7}}$$

Integrating both sides gives

$$\begin{aligned} y &= \int -14x - 98 + c_1 e^{\frac{x}{7}}\, dx \\ &= -98x + 7c_1 e^{\frac{x}{7}} - 7x^2 + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -98x + 7c_1 e^{\frac{x}{7}} - 7x^2 + c_2 \tag{1}$$

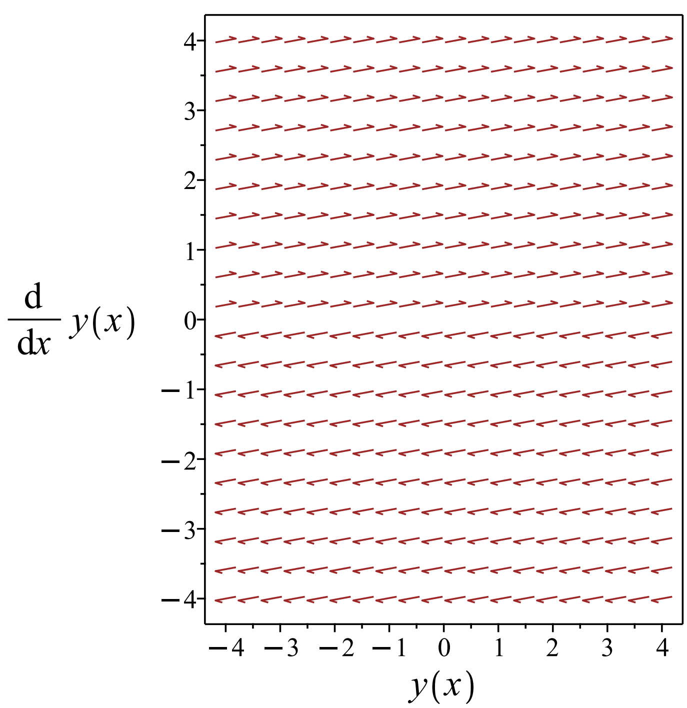

Figure 573: Slope field plot

Verification of solutions

$$y = -98x + 7c_1 e^{\frac{x}{7}} - 7x^2 + c_2$$

Verified OK.

16.50.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$7y'' - y' = 14x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (7y'' - y')\, dx = \int 14x dx$$
$$7y' - y = 7x^2 + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{7}$$
$$q(x) = x^2 + \frac{c_1}{7}$$

Hence the ode is

$$y' - \frac{y}{7} = x^2 + \frac{c_1}{7}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{7} dx}$$
$$= e^{-\frac{x}{7}}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(x^2 + \frac{c_1}{7}\right)$$
$$\frac{d}{dx}\left(e^{-\frac{x}{7}} y\right) = \left(e^{-\frac{x}{7}}\right)\left(x^2 + \frac{c_1}{7}\right)$$
$$d\left(e^{-\frac{x}{7}} y\right) = \left(\frac{(7x^2 + c_1)\, e^{-\frac{x}{7}}}{7}\right) dx$$

Integrating gives

$$e^{-\frac{x}{7}} y = \int \frac{(7x^2 + c_1) e^{-\frac{x}{7}}}{7} dx$$
$$e^{-\frac{x}{7}} y = -(7x^2 + c_1 + 98x + 686) e^{-\frac{x}{7}} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{x}{7}}$ results in

$$y = -e^{\frac{x}{7}} (7x^2 + c_1 + 98x + 686) e^{-\frac{x}{7}} + c_2 e^{\frac{x}{7}}$$

which simplifies to

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}}$$

Summary

The solution(s) found are the following

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}} \tag{1}$$

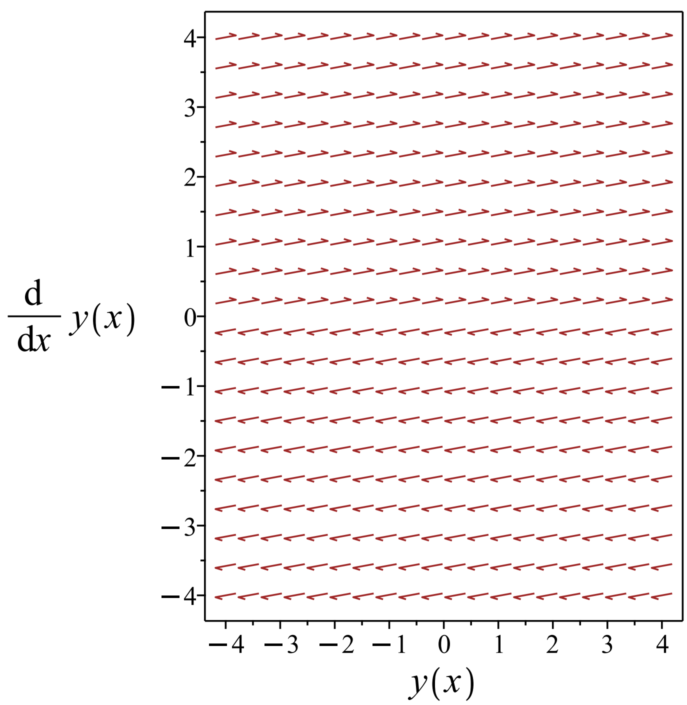

Figure 574: Slope field plot

Verification of solutions

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}}$$

Verified OK.

16.50.5 Solving using Kovacic algorithm

Writing the ode as

$$7y'' - y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 7 \\ B &= -1 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{196} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 196 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{196} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 453: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{196}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{14}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{7}\,dx}
\end{aligned}$$

$$
\begin{aligned}
&= z_1 e^{\frac{x}{14}} \\
&= z_1 \left(\mathrm{e}^{\frac{x}{14}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{7}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{x}{7}}}{(y_1)^2}\, dx \\
&= y_1 \left(7\, \mathrm{e}^{\frac{x}{7}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (1) + c_2 \left(1 \left(7\, \mathrm{e}^{\frac{x}{7}}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
7y'' - y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 + 7 c_2 \mathrm{e}^{\frac{x}{7}}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{1, 7\,\mathrm{e}^{\frac{x}{7}}\right\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_2x^2 + A_1x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2xA_2 - A_1 + 14A_2 = 14x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -98, A_2 = -7]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -7x^2 - 98x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + 7c_2\mathrm{e}^{\frac{x}{7}}\right) + \left(-7x^2 - 98x\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + 7c_2 e^{\frac{x}{7}} - 7x^2 - 98x \tag{1}$$

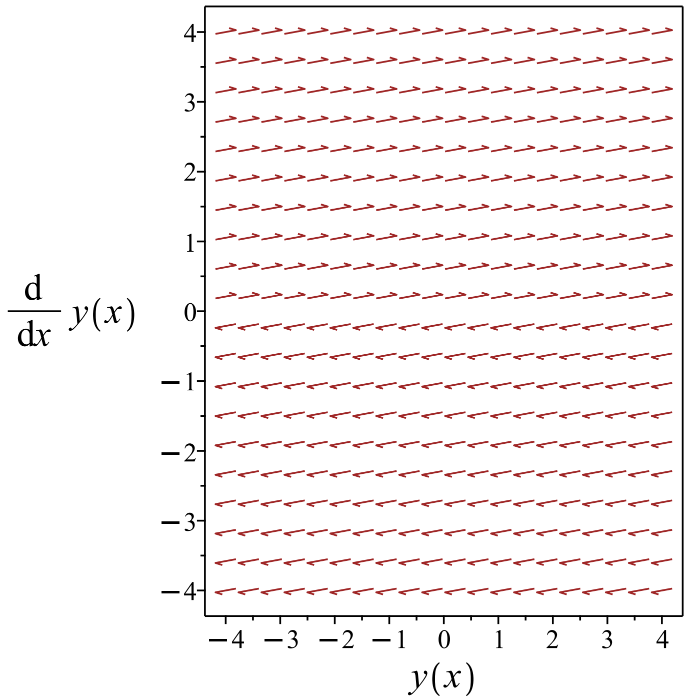

Figure 575: Slope field plot

Verification of solutions

$$y = c_1 + 7c_2 e^{\frac{x}{7}} - 7x^2 - 98x$$

Verified OK.

16.50.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x) y'' + q(x) y' + r(x) y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$
\begin{aligned}
p(x) &= 7 \\
q(x) &= -1 \\
r(x) &= 0 \\
s(x) &= 14x
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0-(0)+(0)=0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)
$$

Integrating gives

$$
p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\; dx
$$

Substituting the above values for p, q, r, s gives

$$
7y' - y = \int 14x\, dx
$$

We now have a first order ode to solve which is

$$
7y' - y = 7x^2 + c_1
$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{7} \\
q(x) &= x^2 + \frac{c_1}{7}
\end{aligned}
$$

Hence the ode is

$$y' - \frac{y}{7} = x^2 + \frac{c_1}{7}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{7}dx} \\ &= e^{-\frac{x}{7}}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(x^2 + \frac{c_1}{7}\right) \\ \frac{d}{dx}\left(e^{-\frac{x}{7}} y\right) &= \left(e^{-\frac{x}{7}}\right)\left(x^2 + \frac{c_1}{7}\right) \\ d\left(e^{-\frac{x}{7}} y\right) &= \left(\frac{(7x^2 + c_1)\, e^{-\frac{x}{7}}}{7}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-\frac{x}{7}} y &= \int \frac{(7x^2 + c_1)\, e^{-\frac{x}{7}}}{7}\, dx \\ e^{-\frac{x}{7}} y &= -\left(7x^2 + c_1 + 98x + 686\right) e^{-\frac{x}{7}} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-\frac{x}{7}}$ results in

$$y = -e^{\frac{x}{7}}\left(7x^2 + c_1 + 98x + 686\right) e^{-\frac{x}{7}} + c_2 e^{\frac{x}{7}}$$

which simplifies to

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}}$$

Summary

The solution(s) found are the following

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}} \tag{1}$$

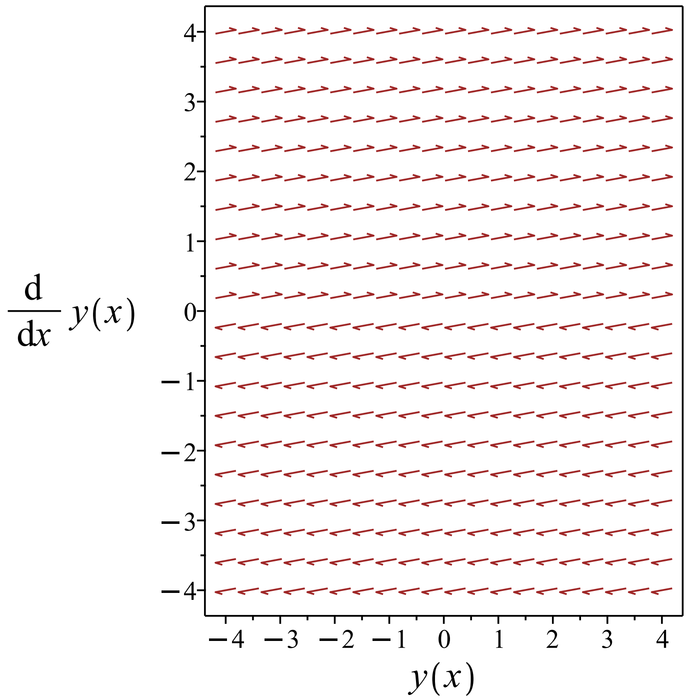

Figure 576: Slope field plot

Verification of solutions

$$y = -7x^2 - c_1 - 98x - 686 + c_2 e^{\frac{x}{7}}$$

Verified OK.

16.50.7 Maple step by step solution

Let's solve

$7y'' - y' = 14x$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{7} + 2x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{7} = 2x$

- Characteristic polynomial of homogeneous ODE

$r^2 - \frac{1}{7}r = 0$

- Factor the characteristic polynomial

  $\frac{r(7r-1)}{7} = 0$

- Roots of the characteristic polynomial

  $r = \left(0, \frac{1}{7}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{\frac{x}{7}}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 \mathrm{e}^{\frac{x}{7}} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2x\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & \mathrm{e}^{\frac{x}{7}} \\ 0 & \frac{\mathrm{e}^{\frac{x}{7}}}{7} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \frac{\mathrm{e}^{\frac{x}{7}}}{7}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -14\left(\int x dx\right) + 14\,\mathrm{e}^{\frac{x}{7}}\left(\int x\,\mathrm{e}^{-\frac{x}{7}}dx\right)$

  - Compute integrals

    $y_p(x) = -7x^2 - 98x - 686$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 \mathrm{e}^{\frac{x}{7}} - 7x^2 - 98x - 686$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 3y' = 3x\,\mathrm{e}^{-3x}}$$

16.51.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 0, f(x) = 3x\,\mathrm{e}^{-3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 3\lambda \,e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 0$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(0)} \\ &= -\frac{3}{2} \pm \frac{3}{2} \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= -\frac{3}{2} + \frac{3}{2} \\ \lambda_2 &= -\frac{3}{2} - \frac{3}{2} \end{aligned}$$

Which simplifies to

$$\begin{aligned} \lambda_1 &= 0 \\ \lambda_2 &= -3 \end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned} y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(0)x} + c_2 e^{(-3)x} \end{aligned}$$

Or

$$y = c_1 + c_2 e^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + c_2 e^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x\, e^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\, e^{-3x}, e^{-3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-3x}\}$$

Since e^{-3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^{-3x}, x^2 e^{-3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\, e^{-3x} + A_2 x^2 e^{-3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-3A_1 e^{-3x} + 2A_2 e^{-3x} - 6A_2 x\, e^{-3x} = 3x\, e^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{3}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\, e^{-3x}}{3} - \frac{x^2 e^{-3x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 + c_2 e^{-3x}) + \left(-\frac{x\,e^{-3x}}{3} - \frac{x^2 e^{-3x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2 e^{-3x} - \frac{x\,e^{-3x}}{3} - \frac{x^2 e^{-3x}}{2} \tag{1}$$

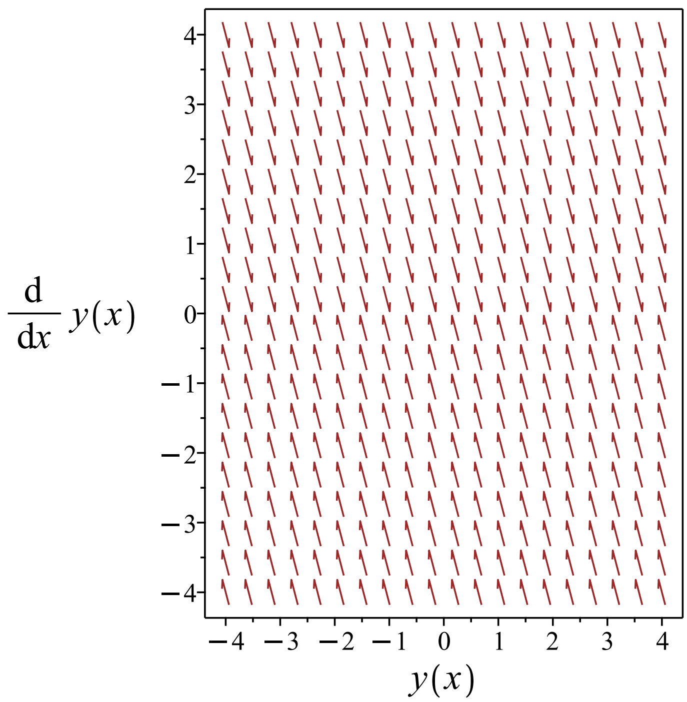

Figure 577: Slope field plot

Verification of solutions

$$y = c_1 + c_2 e^{-3x} - \frac{x\,e^{-3x}}{3} - \frac{x^2 e^{-3x}}{2}$$

Verified OK.

16.51.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 3y')\, dx = \int 3x\,\mathrm{e}^{-3x} dx$$
$$3y + y' = -\frac{(3x+1)\,\mathrm{e}^{-3x}}{3} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 3$$
$$q(x) = -x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1$$

Hence the ode is

$$3y + y' = -x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int 3dx}$$
$$= \mathrm{e}^{3x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(-x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{3x} y\right) = \left(\mathrm{e}^{3x}\right)\left(-x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1\right)$$
$$\mathrm{d}\left(\mathrm{e}^{3x} y\right) = \left(c_1 \mathrm{e}^{3x} - x - \frac{1}{3}\right)\,\mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{3x} y = \int c_1 \mathrm{e}^{3x} - x - \frac{1}{3}\,\mathrm{d}x$$
$$\mathrm{e}^{3x} y = -\frac{x}{3} - \frac{x^2}{2} + \frac{c_1 \mathrm{e}^{3x}}{3} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$y = e^{-3x}\left(-\frac{x}{3} - \frac{x^2}{2} + \frac{c_1 e^{3x}}{3}\right) + c_2 e^{-3x}$$

which simplifies to

$$y = \frac{(-3x^2 + 6c_2 - 2x)\, e^{-3x}}{6} + \frac{c_1}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{(-3x^2 + 6c_2 - 2x)\, e^{-3x}}{6} + \frac{c_1}{3} \tag{1}$$

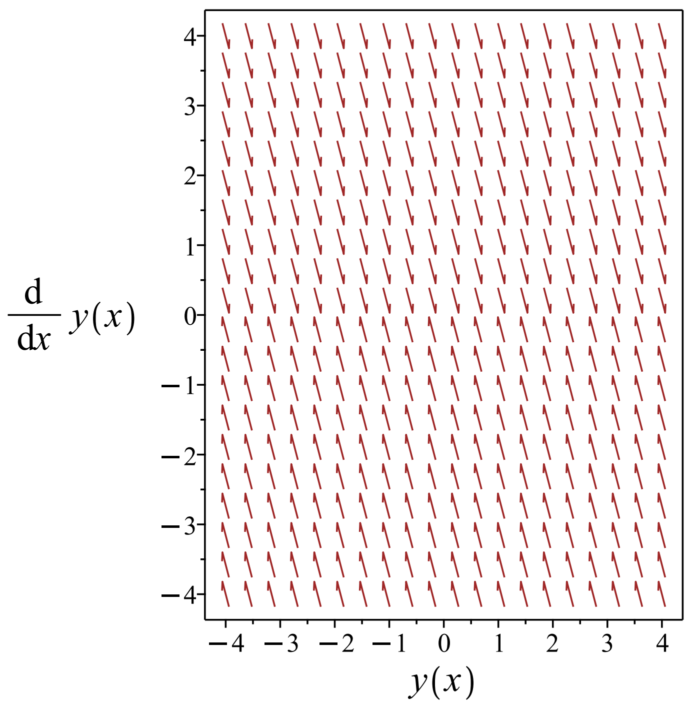

Figure 578: Slope field plot

Verification of solutions

$$y = \frac{(-3x^2 + 6c_2 - 2x)\, e^{-3x}}{6} + \frac{c_1}{3}$$

Verified OK.

16.51.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 3p(x) - 3x\,\mathrm{e}^{-3x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 3 \\ q(x) &= 3x\,\mathrm{e}^{-3x} \end{aligned}$$

Hence the ode is

$$p'(x) + 3p(x) = 3x\,\mathrm{e}^{-3x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 3dx} \\ &= \mathrm{e}^{3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)\left(3x\,\mathrm{e}^{-3x}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{3x} p\right) &= \left(\mathrm{e}^{3x}\right)\left(3x\,\mathrm{e}^{-3x}\right) \\ \mathrm{d}\left(\mathrm{e}^{3x} p\right) &= (3x)\;\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{3x} p &= \int 3x\,\mathrm{d}x \\ \mathrm{e}^{3x} p &= \frac{3x^2}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$p(x) = \frac{3x^2 e^{-3x}}{2} + c_1 e^{-3x}$$

which simplifies to

$$p(x) = e^{-3x}\left(\frac{3x^2}{2} + c_1\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{-3x}\left(\frac{3x^2}{2} + c_1\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{e^{-3x}(3x^2 + 2c_1)}{2}\, dx \\ &= -\frac{(9x^2 + 6c_1 + 6x + 2)\, e^{-3x}}{18} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{(9x^2 + 6c_1 + 6x + 2)\, e^{-3x}}{18} + c_2 \tag{1}$$

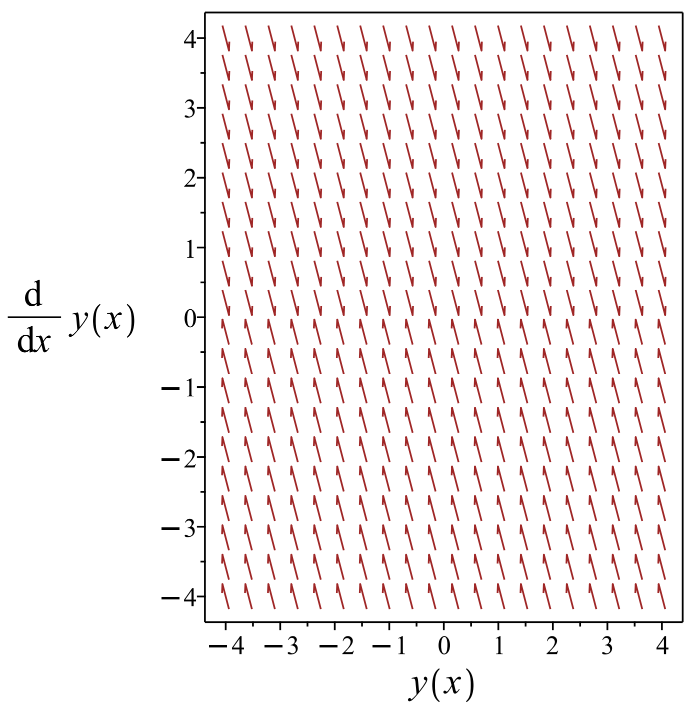

Figure 579: Slope field plot

Verification of solutions

$$y = -\frac{(9x^2 + 6c_1 + 6x + 2)\, e^{-3x}}{18} + c_2$$

Verified OK.

16.51.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 3y' = 3x\, e^{-3x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 3y')\, dx = \int 3x\, e^{-3x} dx$$

$$3y + y' = -\frac{(3x + 1)\, e^{-3x}}{3} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 3 \\ q(x) &= -x\, e^{-3x} - \frac{e^{-3x}}{3} + c_1 \end{aligned}$$

Hence the ode is

$$3y + y' = -x\, e^{-3x} - \frac{e^{-3x}}{3} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 3dx} \\ &= e^{3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu) \left(-x\, e^{-3x} - \frac{e^{-3x}}{3} + c_1\right) \\ \frac{d}{dx}\left(e^{3x} y\right) &= \left(e^{3x}\right) \left(-x\, e^{-3x} - \frac{e^{-3x}}{3} + c_1\right) \\ d\left(e^{3x} y\right) &= \left(c_1 e^{3x} - x - \frac{1}{3}\right) dx \end{aligned}$$

Integrating gives

$$
\begin{aligned}
e^{3x}y &= \int c_1 e^{3x} - x - \frac{1}{3}\, dx \\
e^{3x}y &= -\frac{x}{3} - \frac{x^2}{2} + \frac{c_1 e^{3x}}{3} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{3x}$ results in

$$
y = e^{-3x}\left(-\frac{x}{3} - \frac{x^2}{2} + \frac{c_1 e^{3x}}{3}\right) + c_2 e^{-3x}
$$

which simplifies to

$$
y = \frac{(-3x^2 + 6c_2 - 2x)\, e^{-3x}}{6} + \frac{c_1}{3}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(-3x^2 + 6c_2 - 2x)\, e^{-3x}}{6} + \frac{c_1}{3} \tag{1}
$$

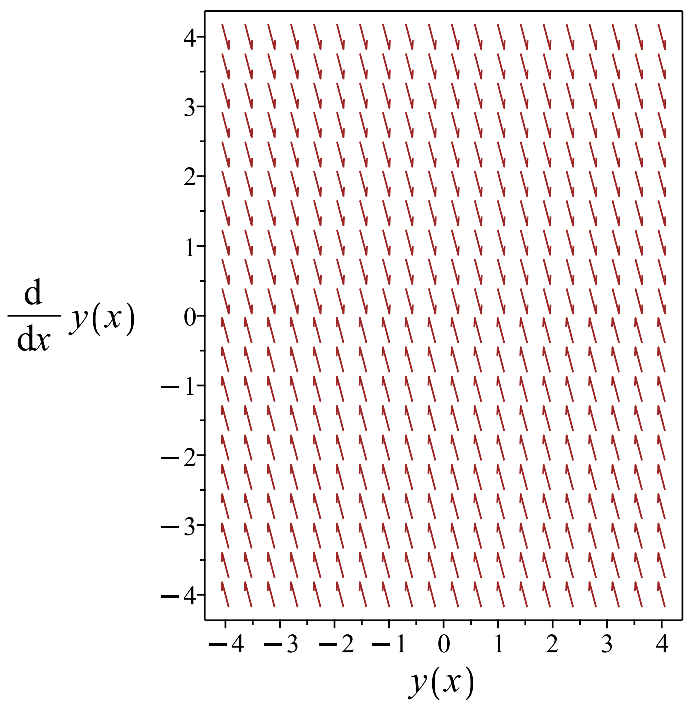

Figure 580: Slope field plot

Verification of solutions

$$y = \frac{(-3x^2 + 6c_2 - 2x)\,\mathrm{e}^{-3x}}{6} + \frac{c_1}{3}$$

Verified OK.

16.51.5 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 455: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\ &= z_1 e^{-\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-3x}\right) + c_2 \left(\mathrm{e}^{-3x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} + \frac{c_2}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$3x\,\mathrm{e}^{-3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-3x}, \mathrm{e}^{-3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{1}{3}, \mathrm{e}^{-3x}\right\}$$

Since e^{-3x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-3x}, x^2\mathrm{e}^{-3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-3x} + A_2 x^2 \mathrm{e}^{-3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-3A_1\mathrm{e}^{-3x} + 2A_2\mathrm{e}^{-3x} - 6A_2 x\,\mathrm{e}^{-3x} = 3x\,\mathrm{e}^{-3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{3}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,\mathrm{e}^{-3x}}{3} - \frac{x^2 \mathrm{e}^{-3x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-3x} + \frac{c_2}{3}\right) + \left(-\frac{x\,\mathrm{e}^{-3x}}{3} - \frac{x^2 \mathrm{e}^{-3x}}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-3x} + \frac{c_2}{3} - \frac{x\,\mathrm{e}^{-3x}}{3} - \frac{x^2 \mathrm{e}^{-3x}}{2} \tag{1}$$

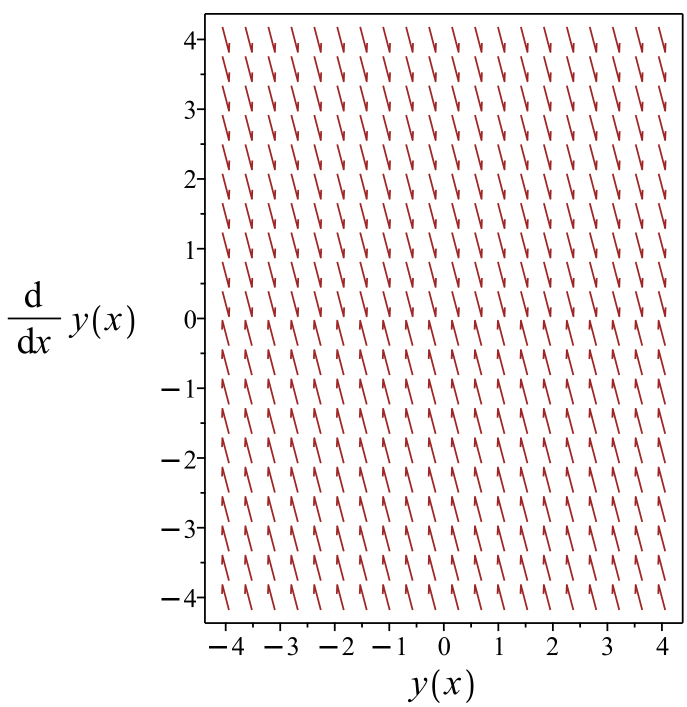

Figure 581: Slope field plot

Verification of solutions

$$y = c_1 e^{-3x} + \frac{c_2}{3} - \frac{x\,e^{-3x}}{3} - \frac{x^2 e^{-3x}}{2}$$

Verified OK.

16.51.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 3 \\ r(x) &= 0 \\ s(x) &= 3x\,e^{-3x} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$3y + y' = \int 3x\,e^{-3x}\,dx$$

We now have a first order ode to solve which is

$$3y + y' = -\frac{(3x+1)\,\mathrm{e}^{-3x}}{3} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 3 \\ q(x) &= -x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1 \end{aligned}$$

Hence the ode is

$$3y + y' = -x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 3dx} \\ &= \mathrm{e}^{3x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(-x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{3x} y\right) &= \left(\mathrm{e}^{3x}\right)\left(-x\,\mathrm{e}^{-3x} - \frac{\mathrm{e}^{-3x}}{3} + c_1\right) \\ \mathrm{d}\left(\mathrm{e}^{3x} y\right) &= \left(c_1 \mathrm{e}^{3x} - x - \frac{1}{3}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{3x} y &= \int c_1 \mathrm{e}^{3x} - x - \frac{1}{3}\,\mathrm{d}x \\ \mathrm{e}^{3x} y &= -\frac{x}{3} - \frac{x^2}{2} + \frac{c_1 \mathrm{e}^{3x}}{3} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{3x}$ results in

$$y = \mathrm{e}^{-3x}\left(-\frac{x}{3} - \frac{x^2}{2} + \frac{c_1 \mathrm{e}^{3x}}{3}\right) + c_2 \mathrm{e}^{-3x}$$

which simplifies to

$$y = \frac{(-3x^2 + 6c_2 - 2x)\,e^{-3x}}{6} + \frac{c_1}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{(-3x^2 + 6c_2 - 2x)\,e^{-3x}}{6} + \frac{c_1}{3} \tag{1}$$

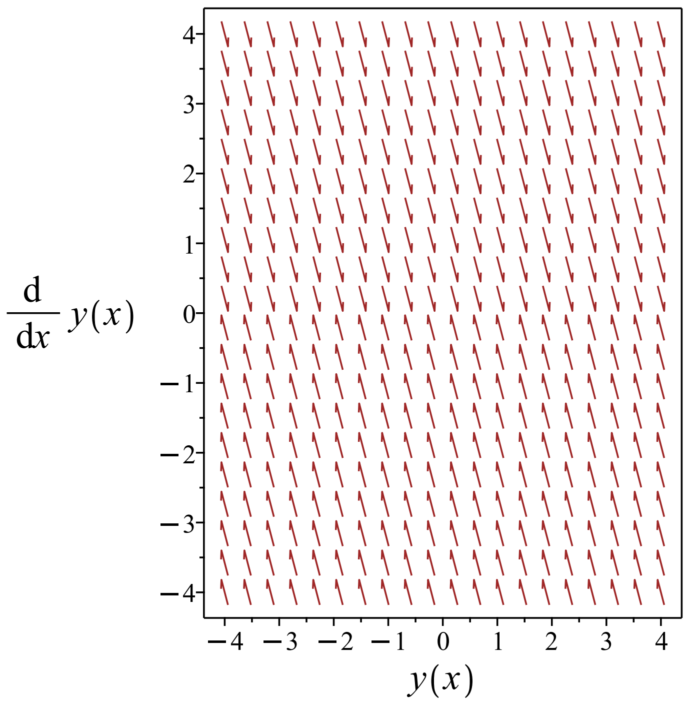

Figure 582: Slope field plot

Verification of solutions

$$y = \frac{(-3x^2 + 6c_2 - 2x)\,e^{-3x}}{6} + \frac{c_1}{3}$$

Verified OK.

16.51.7 Maple step by step solution

Let's solve

$y'' + 3y' = 3x\,e^{-3x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r = 0$

- Factor the characteristic polynomial

  $r(r+3) = 0$

- Roots of the characteristic polynomial

  $r = (-3, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-3x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))}dx\right), f(x) = 3x\,e^{-3x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-3x} & 1 \\ -3\,e^{-3x} & 0 \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 3\,e^{-3x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -e^{-3x}\left(\int x dx\right) + \int x\,e^{-3x}dx$

- Compute integrals

  $y_p(x) = -\frac{e^{-3x}(9x^2+6x+2)}{18}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-3x} + c_2 - \frac{e^{-3x}(9x^2+6x+2)}{18}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 5y' + 6y = 10(1 - x)\,\mathrm{e}^{-2x}}$$

16.52.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 5, C = 6, f(x) = -10(x - 1)\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 5y' + 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 5, C = 6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 5\lambda\,\mathrm{e}^{\lambda x} + 6\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 5\lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 5, C = 6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-5}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{5^2 - (4)\,(1)\,(6)} \\ &= -\frac{5}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{5}{2} + \frac{1}{2} \\ \lambda_2 &= -\frac{5}{2} - \frac{1}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -2 \\ \lambda_2 &= -3\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(-2)x} + c_2 e^{(-3)x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-3x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-3x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-10(x-1)\,\mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-3x}, \mathrm{e}^{-2x}\}$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-2x}, \mathrm{e}^{-2x}x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-2x} + A_2 \mathrm{e}^{-2x} x^2$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 \mathrm{e}^{-2x} + 2A_2 \mathrm{e}^{-2x} x + 2A_2 \mathrm{e}^{-2x} = -10(x-1)\,\mathrm{e}^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 20, A_2 = -5]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 20x\,\mathrm{e}^{-2x} - 5\,\mathrm{e}^{-2x} x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-3x}\right) + \left(20x\,\mathrm{e}^{-2x} - 5\,\mathrm{e}^{-2x} x^2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-3x} + 20x\,\mathrm{e}^{-2x} - 5\,\mathrm{e}^{-2x} x^2 \tag{1}$$

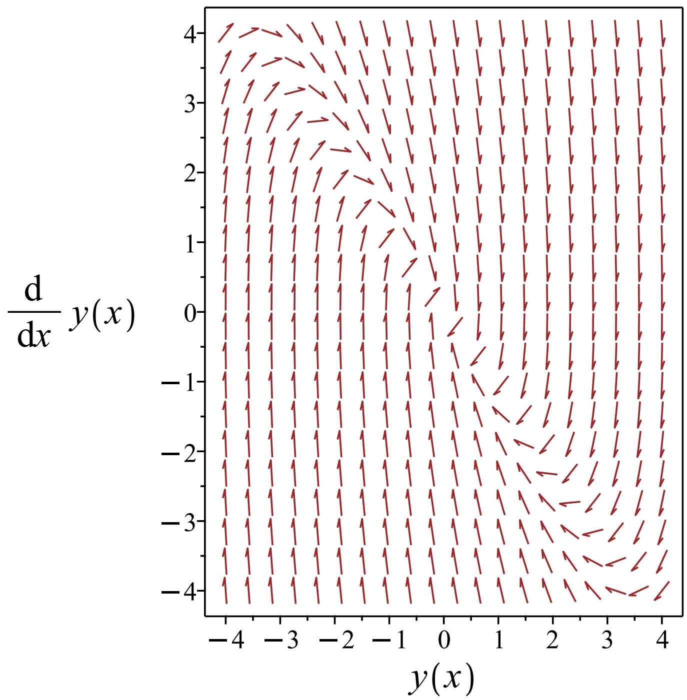

Figure 583: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-3x} + 20x\,\mathrm{e}^{-2x} - 5\,\mathrm{e}^{-2x} x^2$$

Verified OK.

16.52.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 5y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 5 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 457: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{5}{1}\,dx} \\ &= z_1 e^{-\frac{5x}{2}} \\ &= z_1 \left(e^{-\frac{5x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{5}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-5x}}{(y_1)^2}\, dx \\ &= y_1(\mathrm{e}^{x}) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-3x}\right) + c_2\left(\mathrm{e}^{-3x}(\mathrm{e}^{x})\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 5y' + 6y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-3x} + \mathrm{e}^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-10(x-1)\,\mathrm{e}^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{-2x}, e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-3x}, e^{-2x}\}$$

Since e^{-2x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-2x}, e^{-2x}x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{-2x} + A_2 e^{-2x} x^2$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{-2x} + 2A_2 e^{-2x} x + 2A_2 e^{-2x} = -10(x-1)\,e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 20, A_2 = -5]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 20x\,e^{-2x} - 5\,e^{-2x} x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-3x} + e^{-2x} c_2\right) + \left(20x\,e^{-2x} - 5\,e^{-2x} x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-3x} + e^{-2x} c_2 + 20x\,e^{-2x} - 5\,e^{-2x} x^2 \tag{1}$$

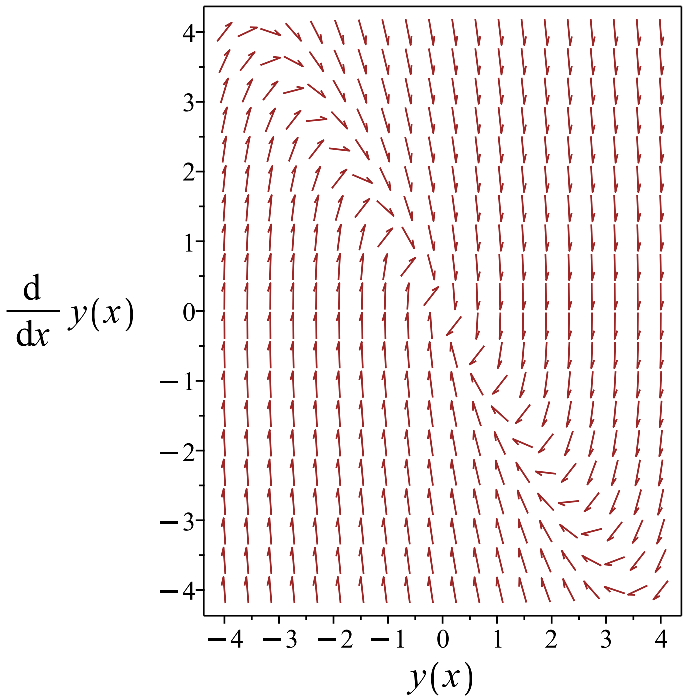

Figure 584: Slope field plot

Verification of solutions

$$y = c_1 e^{-3x} + e^{-2x} c_2 + 20x\, e^{-2x} - 5\, e^{-2x} x^2$$

Verified OK.

16.52.3 Maple step by step solution

Let's solve

$y'' + 5y' + 6y = -10(x-1)\, e^{-2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r+3)(r+2) = 0$

- Roots of the characteristic polynomial

$r = (-3, -2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-3x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3x} + \mathrm{e}^{-2x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = -10(x-1)\,\mathrm{e}^{-2x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-3x} & \mathrm{e}^{-2x} \\ -3\,\mathrm{e}^{-3x} & -2\,\mathrm{e}^{-2x} \end{bmatrix}$$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{-5x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = 10\,\mathrm{e}^{-3x}\left(\int (x-1)\,\mathrm{e}^{x} dx\right) - 10\,\mathrm{e}^{-2x}\left(\int (x-1)\,dx\right)$

  ◦ Compute integrals

  $y_p(x) = -5\,\mathrm{e}^{-2x}(x-2)^2$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3x} + \mathrm{e}^{-2x} c_2 - 5\,\mathrm{e}^{-2x}(x-2)^2$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 2y' + 2y = x + 1}$$

16.53.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 2, f(x) = x + 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(2)}\\ &= -1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + i\\ \lambda_2 &= -1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + i\\ \lambda_2 &= -1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x+1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}\cos(x), e^{-x}\sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_2 x + 2A_1 + 2A_2 = x + 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}(c_1\cos(x) + c_2\sin(x))\right) + \left(\frac{x}{2}\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = e^{-x}(c_1\cos(x) + c_2\sin(x)) + \frac{x}{2} \tag{1}$$

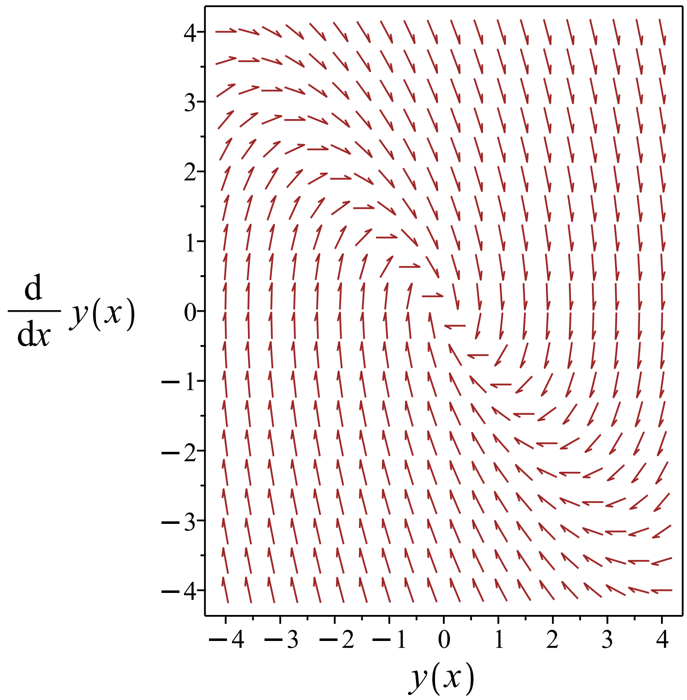

Figure 585: Slope field plot

<u>Verification of solutions</u>

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{x}{2}$$

Verified OK.

16.53.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 459: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x} \cos(x)\right) + c_2 \left(\mathrm{e}^{-x} \cos(x) (\tan(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-x} \cos(x) c_1 + \mathrm{e}^{-x} \sin(x) c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x + 1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-x} \cos(x), \mathrm{e}^{-x} \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_2 x + 2A_1 + 2A_2 = x + 1$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x} \cos(x) c_1 + e^{-x} \sin(x) c_2\right) + \left(\frac{x}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{x}{2}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{x}{2} \tag{1}$$

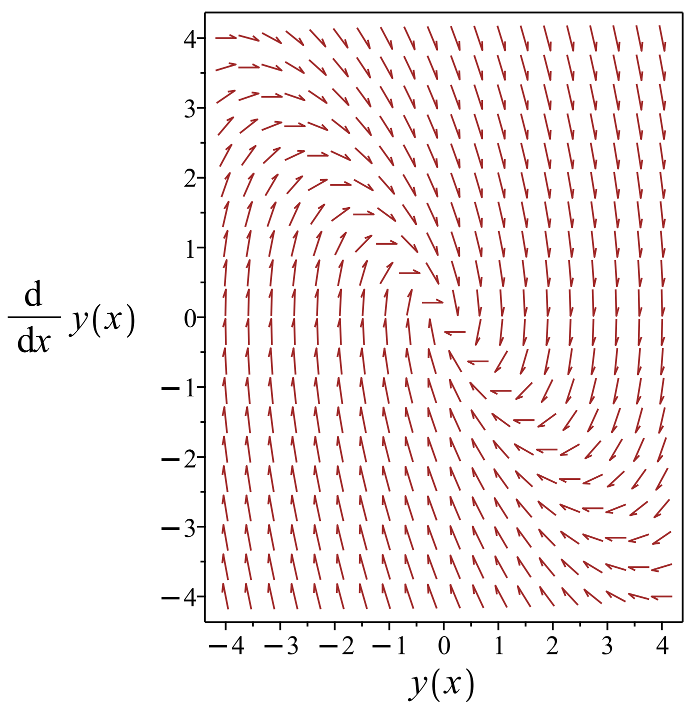

Figure 586: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(x) + c_2 \sin(x)) + \frac{x}{2}$$

Verified OK.

16.53.3 Maple step by step solution

Let's solve

$y'' + 2y' + 2y = x + 1$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2) \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-1 - \mathrm{I}, -1 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x} \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-x} \cos(x) c_1 + e^{-x} \sin(x) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x + 1\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} \cos(x) & e^{-x} \sin(x) \\ -e^{-x} \cos(x) - e^{-x} \sin(x) & -e^{-x} \sin(x) + e^{-x} \cos(x) \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-2x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -e^{-x}\left(\cos(x)\left(\int(x+1)\sin(x)e^x dx\right) - \sin(x)\left(\int(x+1)\cos(x)e^x dx\right)\right)$
- Compute integrals

  $y_p(x) = \frac{x}{2}$

- Substitute particular solution into general solution to ODE

  $y = e^{-x}\cos(x)c_1 + e^{-x}\sin(x)c_2 + \frac{x}{2}$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' + y = (x^2 + x)\,\mathrm{e}^x}$$

16.54.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 1, f(x) = x(x+1)\,\mathrm{e}^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \lambda \,\mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{1^2 - (4)\,(1)\,(1)}\\ &= -\frac{1}{2} \pm \frac{i\sqrt{3}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + \frac{i\sqrt{3}}{2}\\ \lambda_2 &= -\frac{1}{2} - \frac{i\sqrt{3}}{2}\end{aligned}$$

Which simplifies to

$$\lambda_1 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{1}{2}$ and $\beta = \frac{\sqrt{3}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x(x+1)\,\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}x^2, \mathrm{e}^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right), \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,\mathrm{e}^{x} + A_2 \mathrm{e}^{x} x^2 + A_3 \mathrm{e}^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1\mathrm{e}^{x} + 3A_1 x\,\mathrm{e}^{x} + 3A_2\mathrm{e}^{x}x^2 + 6A_2\mathrm{e}^{x}x + 2A_2\mathrm{e}^{x} + 3A_3\mathrm{e}^{x} = x(x+1)\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{3}, A_2 = \frac{1}{3}, A_3 = \frac{1}{9}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,\mathrm{e}^x}{3} + \frac{\mathrm{e}^x x^2}{3} + \frac{\mathrm{e}^x}{9}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-\frac{x}{2}}\left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right)\right) + \left(-\frac{x\,\mathrm{e}^x}{3} + \frac{\mathrm{e}^x x^2}{3} + \frac{\mathrm{e}^x}{9}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{x}{2}}\left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right) - \frac{x\,\mathrm{e}^x}{3} + \frac{\mathrm{e}^x x^2}{3} + \frac{\mathrm{e}^x}{9} \tag{1}$$

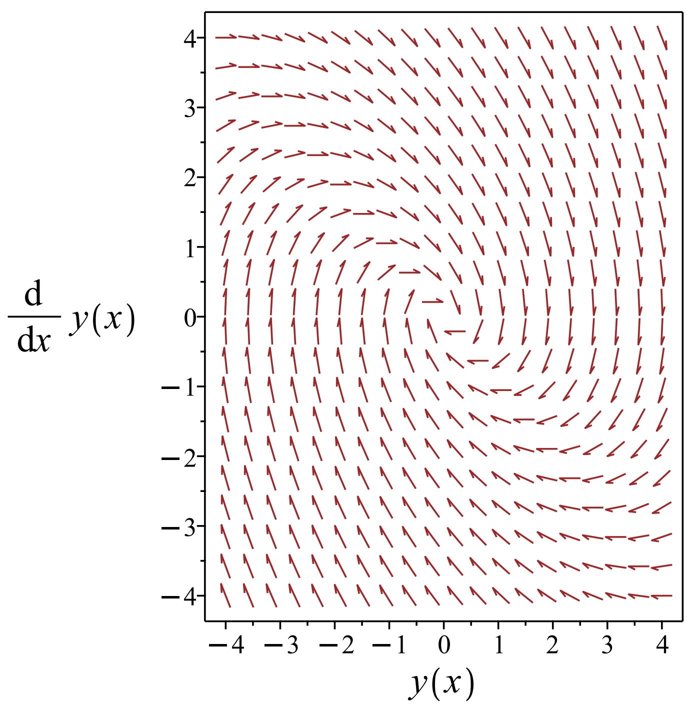

Figure 587: Slope field plot

Verification of solutions

$$y = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{x\sqrt{3}}{2}\right) + c_2 \sin\left(\frac{x\sqrt{3}}{2}\right)\right) - \frac{x\,e^x}{3} + \frac{e^x x^2}{3} + \frac{e^x}{9}$$

Verified OK.

16.54.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{3z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 461: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{3}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{x\sqrt{3}}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2\sqrt{3}\,\tan\left(\frac{x\sqrt{3}}{2}\right)}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)\right) + c_2\left(\mathrm{e}^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)\left(\frac{2\sqrt{3}\,\tan\left(\frac{x\sqrt{3}}{2}\right)}{3}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x(x+1)\,e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{x}, e^{x}x^{2}, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right), \frac{2\,e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x\,e^{x} + A_2 e^{x} x^{2} + A_3 e^{x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 e^{x} + 3A_1 x\,e^{x} + 3A_2 e^{x} x^{2} + 6A_2 e^{x} x + 2A_2 e^{x} + 3A_3 e^{x} = x(x+1)\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{3}, A_2 = \frac{1}{3}, A_3 = \frac{1}{9}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^x}{3} + \frac{e^x x^2}{3} + \frac{e^x}{9}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3}\right) + \left(-\frac{x\,e^x}{3} + \frac{e^x x^2}{3} + \frac{e^x}{9}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \frac{x\,e^x}{3} + \frac{e^x x^2}{3} + \frac{e^x}{9} \tag{1}$$

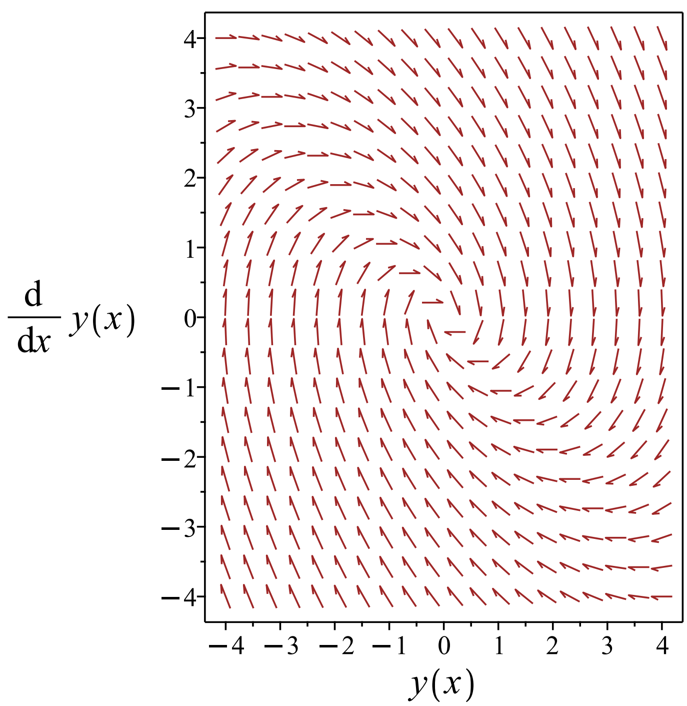

Figure 588: Slope field plot

Verification of solutions

$$y = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} - \frac{x\,e^x}{3} + \frac{e^x x^2}{3} + \frac{e^x}{9}$$

Verified OK.

16.54.3 Maple step by step solution

Let's solve

$y'' + y' + y = x(x+1)\,e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1)\pm(\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - \frac{I\sqrt{3}}{2}, -\frac{1}{2} + \frac{I\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \sin\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))} dx\right), f(x) = x(x+1)\,e^x\right]$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right) & e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right) \\ -\frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} & -\frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = \frac{\sqrt{3}\, e^{-x}}{2}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{2\, e^{-\frac{x}{2}} \sqrt{3} \left(\cos\left(\frac{x\sqrt{3}}{2}\right)\left(\int x(x+1) e^{\frac{3x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right) dx\right) - \sin\left(\frac{x\sqrt{3}}{2}\right)\left(\int x(x+1) e^{\frac{3x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right) dx\right)\right)}{3}$

- Compute integrals

  $y_p(x) = \frac{(3x^2-3x+1)e^x}{9}$

- Substitute particular solution into general solution to ODE

  $y = \cos\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_1 + \sin\left(\frac{x\sqrt{3}}{2}\right) e^{-\frac{x}{2}} c_2 + \frac{(3x^2-3x+1)e^x}{9}$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 528.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y' - 2y = 8\sin(2x)}$$

16.55.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = -2, f(x) = 8\sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=4, C=-2$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+4\lambda\,\mathrm{e}^{\lambda x}-2\,\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+4\lambda-2=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=4, C=-2$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-4}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{4^2-(4)(1)(-2)}\\&=-2\pm\sqrt{6}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=-2+\sqrt{6}\\\lambda_2&=-2-\sqrt{6}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=-2+\sqrt{6}\\\lambda_2&=-2-\sqrt{6}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y&=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}\\y&=c_1e^{\left(-2+\sqrt{6}\right)x}+c_2e^{\left(-2-\sqrt{6}\right)x}\end{aligned}$$

Or

$$y=c_1\mathrm{e}^{\left(-2+\sqrt{6}\right)x}+c_2\mathrm{e}^{\left(-2-\sqrt{6}\right)x}$$

Therefore the homogeneous solution y_h is

$$y_h=c_1\mathrm{e}^{\left(-2+\sqrt{6}\right)x}+c_2\mathrm{e}^{\left(-2-\sqrt{6}\right)x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8 \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{ e^{\left(-2-\sqrt{6}\right)x}, e^{\left(-2+\sqrt{6}\right)x} \right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(2x) + A_2 \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1 \cos(2x) - 6A_2 \sin(2x) - 8A_1 \sin(2x) + 8A_2 \cos(2x) = 8 \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{16}{25}, A_2 = -\frac{12}{25}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\left(-2+\sqrt{6}\right)x} + c_2 e^{\left(-2-\sqrt{6}\right)x}\right) + \left(-\frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 e^{\left(-2+\sqrt{6}\right)x} + c_2 e^{-\left(2+\sqrt{6}\right)x} - \frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{\left(-2+\sqrt{6}\right)x} + c_2 e^{-\left(2+\sqrt{6}\right)x} - \frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25} \tag{1}$$

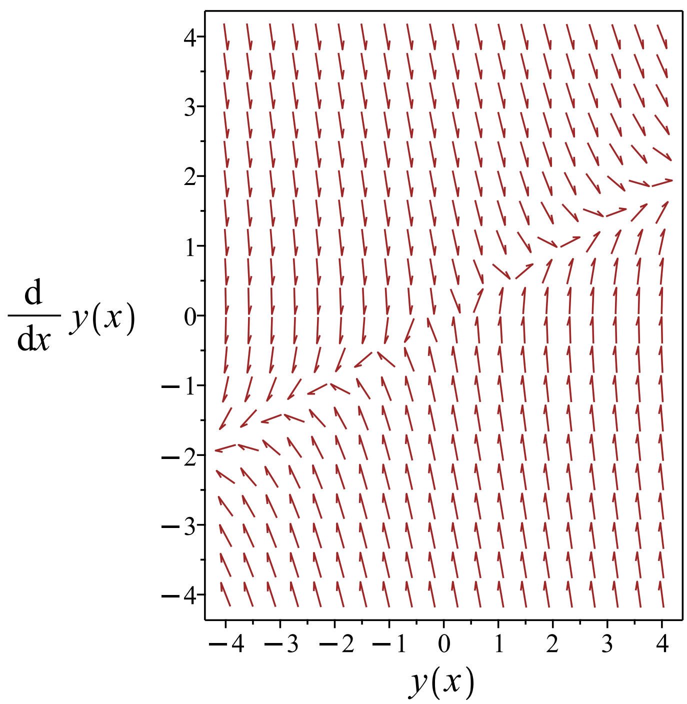

Figure 589: Slope field plot

Verification of solutions

$$y = c_1 e^{\left(-2+\sqrt{6}\right)x} + c_2 e^{-\left(2+\sqrt{6}\right)x} - \frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}$$

Verified OK.

16.55.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{6}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 6 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 6z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 463: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 6$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x\sqrt{6}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-2x} \\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\left(2+\sqrt{6}\right)x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-4x}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\sqrt{6}\, \mathrm{e}^{2x\sqrt{6}}}{12}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\left(2+\sqrt{6}\right)x}\right) + c_2 \left(\mathrm{e}^{-\left(2+\sqrt{6}\right)x} \left(\frac{\sqrt{6}\, \mathrm{e}^{2x\sqrt{6}}}{12}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 4y' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-\left(2+\sqrt{6}\right)x} + \frac{c_2\sqrt{6}\, e^{\left(-2+\sqrt{6}\right)x}}{12}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$8\sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{6}\, e^{\left(-2+\sqrt{6}\right)x}}{12}, e^{-\left(2+\sqrt{6}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(2x) + A_2\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-6A_1\cos(2x) - 6A_2\sin(2x) - 8A_1\sin(2x) + 8A_2\cos(2x) = 8\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{16}{25}, A_2 = -\frac{12}{25}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-\left(2+\sqrt{6}\right)x} + \frac{c_2\sqrt{6}\,\mathrm{e}^{\left(-2+\sqrt{6}\right)x}}{12}\right) + \left(-\frac{16\cos\left(2x\right)}{25} - \frac{12\sin\left(2x\right)}{25}\right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\left(2+\sqrt{6}\right)x} + \frac{c_2\sqrt{6}\,\mathrm{e}^{\left(-2+\sqrt{6}\right)x}}{12} - \frac{16\cos\left(2x\right)}{25} - \frac{12\sin\left(2x\right)}{25} \tag{1}
$$

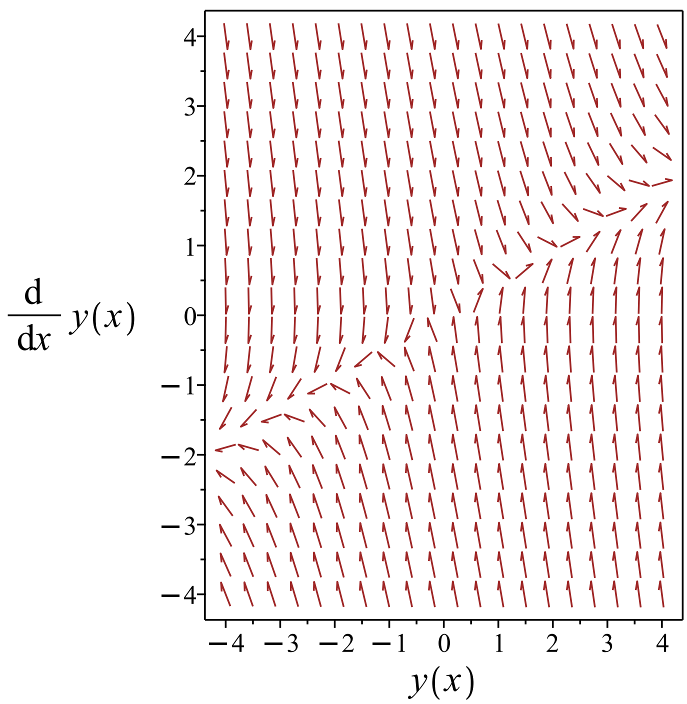

Figure 590: Slope field plot

<u>Verification of solutions</u>

$$
y = c_1 \mathrm{e}^{-\left(2+\sqrt{6}\right)x} + \frac{c_2\sqrt{6}\,\mathrm{e}^{\left(-2+\sqrt{6}\right)x}}{12} - \frac{16\cos\left(2x\right)}{25} - \frac{12\sin\left(2x\right)}{25}
$$

Verified OK.

16.55.3 Maple step by step solution

Let's solve

$y'' + 4y' - 2y = 8\sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r - 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-4)\pm\left(\sqrt{24}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-2-\sqrt{6}, -2+\sqrt{6}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{\left(-2-\sqrt{6}\right)x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{\left(-2+\sqrt{6}\right)x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{\left(-2-\sqrt{6}\right)x} + c_2 \mathrm{e}^{\left(-2+\sqrt{6}\right)x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 8\sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{\left(-2-\sqrt{6}\right)x} & \mathrm{e}^{\left(-2+\sqrt{6}\right)x} \\ \left(-2-\sqrt{6}\right)\mathrm{e}^{\left(-2-\sqrt{6}\right)x} & \left(-2+\sqrt{6}\right)\mathrm{e}^{\left(-2+\sqrt{6}\right)x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\sqrt{6}\,\mathrm{e}^{-4x}$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = \frac{2\sqrt{6}\left(e^{\left(-2+\sqrt{6}\right)x}\left(\int e^{-\left(-2+\sqrt{6}\right)x}\sin(2x)dx\right)-e^{-\left(2+\sqrt{6}\right)x}\left(\int e^{\left(2+\sqrt{6}\right)x}\sin(2x)dx\right)\right)}{3}$$

- Compute integrals

$$y_p(x) = -\frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{\left(-2-\sqrt{6}\right)x} + c_2 e^{\left(-2+\sqrt{6}\right)x} - \frac{16\cos(2x)}{25} - \frac{12\sin(2x)}{25}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = 4\cos(x)\, x}$$

16.56.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = 4\cos(x)\, x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4 \cos(x) x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x) x, \sin(x) x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 \cos(x), x^2 \sin(x), \cos(x) x, \sin(x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 \cos(x) + A_2 x^2 \sin(x) + A_3 \cos(x) x + A_4 \sin(x) x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 \cos(x) - 4A_1 x \sin(x) + 2A_2 \sin(x) + 4A_2 x \cos(x) - 2A_3 \sin(x) + 2A_4 \cos(x) = 4 \cos(x) x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1, A_3 = 1, A_4 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2 \sin(x) + \cos(x) x$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(x^2 \sin(x) + \cos(x)\, x\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x)\, x \tag{1}
$$

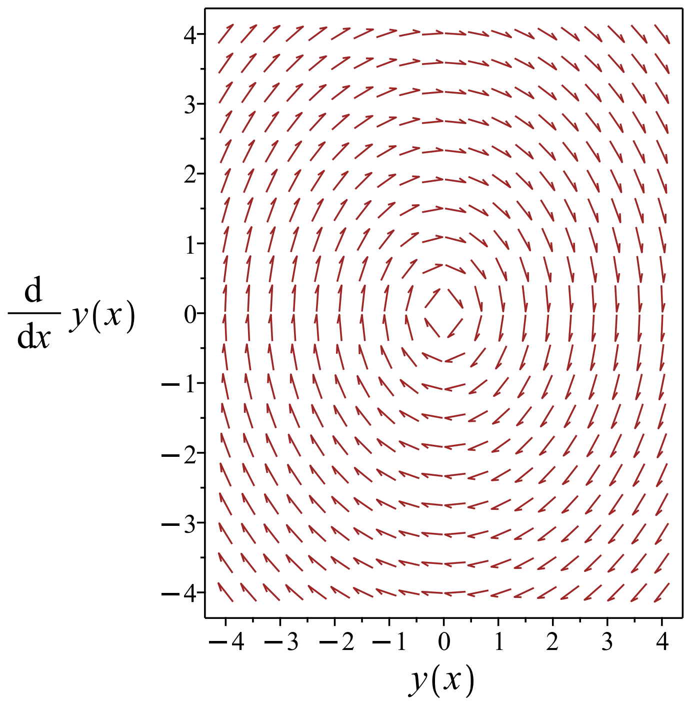

Figure 591: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x)\, x
$$

Verified OK.

16.56.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 465: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4 \cos(x) x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x) x, \sin(x) x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 \cos(x), x^2 \sin(x), \cos(x) x, \sin(x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 \cos(x) + A_2 x^2 \sin(x) + A_3 \cos(x) x + A_4 \sin(x) x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} &2A_1 \cos(x) - 4A_1 x \sin(x) + 2A_2 \sin(x) + 4A_2 x \cos(x) - 2A_3 \sin(x) + 2A_4 \cos(x) \\ &= 4 \cos(x) x \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 1, A_3 = 1, A_4 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^2 \sin(x) + \cos(x) x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (x^2 \sin(x) + \cos(x) x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x)\, x \tag{1}$$

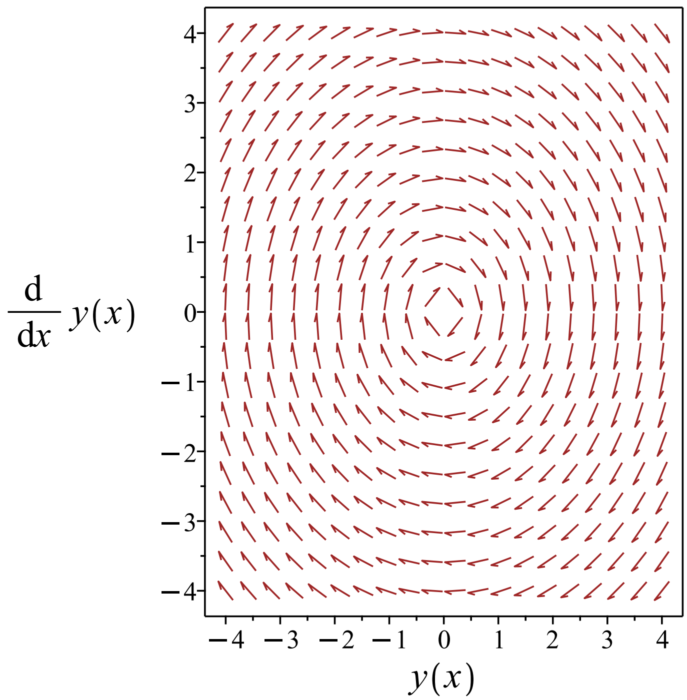

Figure 592: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x)\, x$$

Verified OK.

16.56.3 Maple step by step solution

Let's solve

$y'' + y = 4\cos(x)\, x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 4\cos(x)\, x\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -2\cos(x) \left(\int x \sin(2x)\, dx\right) + 4\sin(x) \left(\int \cos(x)^2 x dx\right)$
  - Compute integrals

    $y_p(x) = x^2 \sin(x) + \cos(x)\, x - \sin(x)$
- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + x^2 \sin(x) + \cos(x)\, x - \sin(x)$

Problem number: 530.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 2my' + m^2y = \sin(nx)}$$

16.57.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2m, C = m^2, f(x) = \sin(nx)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2my' + m^2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2m, C = m^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2m\lambda\, e^{\lambda x} + m^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2m\lambda + m^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2m, C = m^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2m}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2m)^2 - (4)(1)(m^2)}\\ &= m\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -m$. Therefore the solution is

$$y = c_1 e^{mx} + c_2 x\, e^{mx} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{mx} + c_2 x\, e^{mx}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(nx)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(nx), \sin(nx)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{mx}, e^{mx}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(nx) + A_2 \sin(nx)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 n^2 \cos(nx) - A_2 n^2 \sin(nx) - 2m(-A_1 n \sin(nx) + A_2 n \cos(nx)) \\ + m^2(A_1 \cos(nx) + A_2 \sin(nx)) = \sin(nx)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{2mn}{(m^2+n^2)^2}, A_2 = \frac{m^2-n^2}{(m^2+n^2)^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{mx} + c_2 x\, e^{mx}) + \left(\frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{mx}(c_2 x + c_1) + \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}$$

Summary

The solution(s) found are the following

$$y = e^{mx}(c_2 x + c_1) + \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2} \tag{1}$$

Verification of solutions

$$y = e^{mx}(c_2 x + c_1) + \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}$$

Verified OK.

16.57.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2m$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -2m\,dx} \\ &= \mathrm{e}^{-mx} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \mathrm{e}^{-mx} \sin(nx) \\ \left(\mathrm{e}^{-mx} y\right)'' &= \mathrm{e}^{-mx} \sin(nx) \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-mx} y\right)' = -\frac{\mathrm{e}^{-mx}(\sin(nx)\,m + n\cos(nx))}{m^2 + n^2} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-mx} y\right) = \frac{\left((m^2 - n^2)\sin(nx) + 2mn\cos(nx)\right)\mathrm{e}^{-mx} + c_1 x (m^2 + n^2)^2}{(m^2 + n^2)^2} + c_2$$

Hence the solution is

$$y = \frac{\frac{\left((m^2 - n^2)\sin(nx) + 2mn\cos(nx)\right)\mathrm{e}^{-mx} + c_1 x (m^2 + n^2)^2}{(m^2 + n^2)^2} + c_2}{\mathrm{e}^{-mx}}$$

Or

$$\begin{aligned} y = {} & \frac{m^2 \sin(nx)}{(m^2 + n^2)^2} + \frac{2mn\cos(nx)}{(m^2 + n^2)^2} - \frac{n^2 \sin(nx)}{(m^2 + n^2)^2} + c_2 \mathrm{e}^{mx} \\ & + \left(\frac{m^4 x\,\mathrm{e}^{mx}}{(m^2 + n^2)^2} + \frac{2m^2 n^2 x\,\mathrm{e}^{mx}}{(m^2 + n^2)^2} + \frac{n^4 x\,\mathrm{e}^{mx}}{(m^2 + n^2)^2}\right) c_1 \end{aligned}$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \frac{m^2 \sin(nx)}{(m^2+n^2)^2} + \frac{2mn\cos(nx)}{(m^2+n^2)^2} - \frac{n^2 \sin(nx)}{(m^2+n^2)^2} + c_2 e^{mx} \\
& + \left(\frac{m^4 x\, e^{mx}}{(m^2+n^2)^2} + \frac{2m^2 n^2 x\, e^{mx}}{(m^2+n^2)^2} + \frac{n^4 x\, e^{mx}}{(m^2+n^2)^2}\right) c_1
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \frac{m^2 \sin(nx)}{(m^2+n^2)^2} + \frac{2mn\cos(nx)}{(m^2+n^2)^2} - \frac{n^2 \sin(nx)}{(m^2+n^2)^2} + c_2 e^{mx} \\
& + \left(\frac{m^4 x\, e^{mx}}{(m^2+n^2)^2} + \frac{2m^2 n^2 x\, e^{mx}}{(m^2+n^2)^2} + \frac{n^4 x\, e^{mx}}{(m^2+n^2)^2}\right) c_1
\end{aligned}
$$

Verified OK.

16.57.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2my' + m^2 y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= -2m \\
C &= m^2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 467: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2m}{1}\,dx} \\ &= z_1 e^{mx} \\ &= z_1(\mathrm{e}^{mx}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{mx}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2m}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2mx}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\mathrm{e}^{mx}) + c_2(\mathrm{e}^{mx}(x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2my' + m^2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{mx} + c_2 x\, e^{mx}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(nx)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(nx), \sin(nx)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{mx}, e^{mx}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(nx) + A_2 \sin(nx)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1n^2 \cos(nx) - A_2n^2 \sin(nx) - 2m(-A_1n \sin(nx) + A_2n \cos(nx)) \\ + m^2(A_1 \cos(nx) + A_2 \sin(nx)) = \sin(nx)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{2mn}{(m^2+n^2)^2}, A_2 = \frac{m^2-n^2}{(m^2+n^2)^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^{mx} + c_2 x\, e^{mx}) + \left(\frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}\right) \end{aligned}$$

Which simplifies to

$$y = e^{mx}(c_2 x + c_1) + \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}$$

Summary

The solution(s) found are the following

$$y = e^{mx}(c_2 x + c_1) + \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2} \tag{1}$$

Verification of solutions

$$y = e^{mx}(c_2 x + c_1) + \frac{2mn\cos(nx)}{(m^2+n^2)^2} + \frac{(m^2-n^2)\sin(nx)}{(m^2+n^2)^2}$$

Verified OK.

16.57.4 Maple step by step solution

Let's solve

$y'' - 2my' + m^2 y = \sin(nx)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $m^2 - 2mr + r^2 = 0$

- Factor the characteristic polynomial

$(m-r)^2=0$

- Root of the characteristic polynomial

  $r=m$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{mx}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x)=x\,\mathrm{e}^{mx}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\mathrm{e}^{mx}+c_2x\,\mathrm{e}^{mx}+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x)=\sin(nx)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x),y_2(x))=\begin{bmatrix} \mathrm{e}^{mx} & x\,\mathrm{e}^{mx} \\ m\,\mathrm{e}^{mx} & \mathrm{e}^{mx}+xm\,\mathrm{e}^{mx} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x),y_2(x))=\mathrm{e}^{2mx}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x)=\mathrm{e}^{mx}\left(-\left(\int \sin(nx)\,x\,\mathrm{e}^{-mx}dx\right)+x\left(\int \mathrm{e}^{-mx}\sin(nx)\,dx\right)\right)$

  - Compute integrals

    $y_p(x)=\frac{(m^2-n^2)\sin(nx)+2mn\cos(nx)}{(m^2+n^2)^2}$

- Substitute particular solution into general solution to ODE

  $y=c_1\mathrm{e}^{mx}+c_2x\,\mathrm{e}^{mx}+\frac{(m^2-n^2)\sin(nx)+2mn\cos(nx)}{(m^2+n^2)^2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' + 5y = \mathrm{e}^{-x} \sin(2x)}$$

16.58.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 5, f(x) = \mathrm{e}^{-x} \sin(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{2^2 - (4)\,(1)\,(5)}\\ &= -1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x} \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x} \cos(2x), e^{-x} \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x} \cos(2x), e^{-x} \sin(2x)\}$$

Since $e^{-x} \cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^{-x} \cos(2x), x e^{-x} \sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x e^{-x} \cos(2x) + A_2 x e^{-x} \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-x} \sin(2x) + 4A_2 e^{-x} \cos(2x) = e^{-x} \sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x e^{-x} \cos(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))\right) + \left(-\frac{x e^{-x} \cos(2x)}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{x e^{-x} \cos(2x)}{4} \tag{1}$$

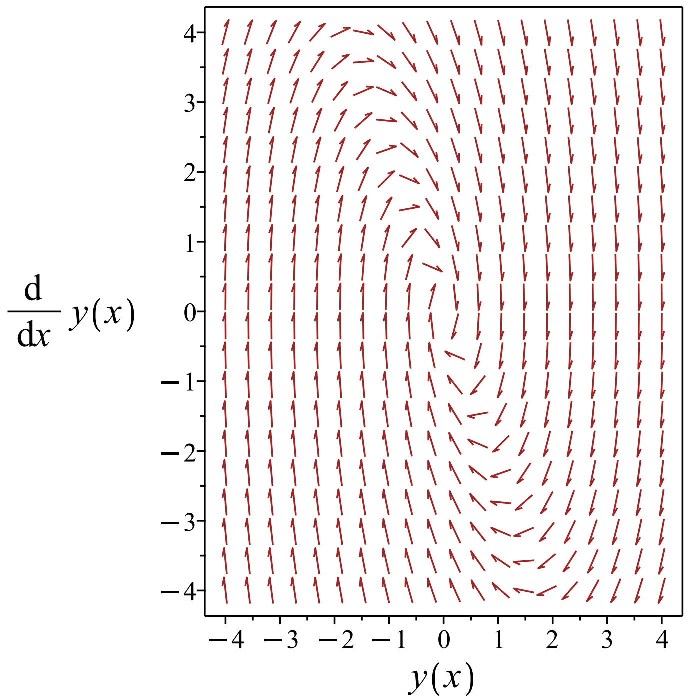

Figure 593: Slope field plot

Verification of solutions

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) - \frac{x e^{-x} \cos(2x)}{4}$$

Verified OK.

16.58.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 2 \\
C &= 5
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-4}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -4 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -4z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 469: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\
&= z_1 e^{-x} \\
&= z_1\left(\mathrm{e}^{-x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x} \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\, dx \\ &= y_1 \left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x} \cos(2x)\right) + c_2 \left(\mathrm{e}^{-x} \cos(2x) \left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-x} \cos(2x)\, c_1 + \frac{\mathrm{e}^{-x} \sin(2x)\, c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{-x} \sin(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\cos(2x), e^{-x}\sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-x}\cos(2x), \frac{e^{-x}\sin(2x)}{2}\right\}$$

Since $e^{-x}\cos(2x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-x}\cos(2x), x\,e^{-x}\sin(2x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{-x}\cos(2x) + A_2 x\,e^{-x}\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-x}\sin(2x) + 4A_2 e^{-x}\cos(2x) = e^{-x}\sin(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{-x}\cos(2x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}\cos(2x)\,c_1 + \frac{e^{-x}\sin(2x)\,c_2}{2}\right) + \left(-\frac{x\,e^{-x}\cos(2x)}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-x} \cos(2x) c_1 + \frac{e^{-x} \sin(2x) c_2}{2} - \frac{x e^{-x} \cos(2x)}{4} \tag{1}$$

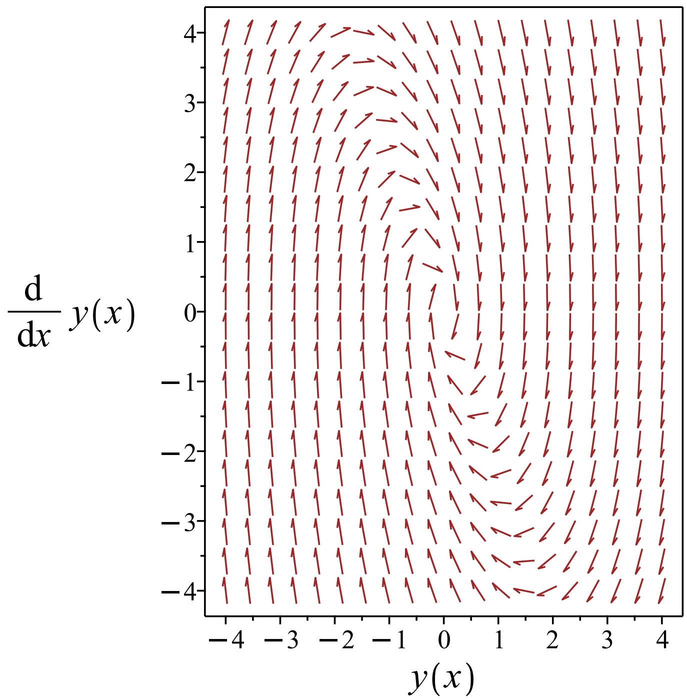

Figure 594: Slope field plot

Verification of solutions

$$y = e^{-x} \cos(2x) c_1 + \frac{e^{-x} \sin(2x) c_2}{2} - \frac{x e^{-x} \cos(2x)}{4}$$

Verified OK.

16.58.3 Maple step by step solution

Let's solve

$y'' + 2y' + 5y = e^{-x} \sin(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2+2r+5=0$

- Use quadratic formula to solve for r

  $r=\frac{(-2)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r=(-1-2\,\mathrm{I},-1+2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{-x}\cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\mathrm{e}^{-x}\sin(2x)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=\mathrm{e}^{-x}\cos(2x)\,c_1+\mathrm{e}^{-x}\sin(2x)\,c_2+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=\mathrm{e}^{-x}\sin(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x),y_2(x))=\begin{bmatrix}\mathrm{e}^{-x}\cos(2x) & \mathrm{e}^{-x}\sin(2x)\\ -\mathrm{e}^{-x}\cos(2x)-2\,\mathrm{e}^{-x}\sin(2x) & -\mathrm{e}^{-x}\sin(2x)+2\,\mathrm{e}^{-x}\cos(2x)\end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x),y_2(x))=2\,\mathrm{e}^{-2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x)=\frac{\mathrm{e}^{-x}\left(\sin(2x)\left(\int\sin(4x)dx\right)-2\cos(2x)\left(\int\sin(2x)^2dx\right)\right)}{4}$

  - Compute integrals

    $y_p(x)=\frac{(\sin(2x)-4x\cos(2x))\mathrm{e}^{-x}}{16}$

- Substitute particular solution into general solution to ODE

  $y=\mathrm{e}^{-x}\cos(2x)\,c_1+\mathrm{e}^{-x}\sin(2x)\,c_2+\frac{(\sin(2x)-4x\cos(2x))\mathrm{e}^{-x}}{16}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + a^2 y = 2\cos(mx) + 3\sin(mx)}$$

16.59.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = a^2, f(x) = 2\cos(mx) + 3\sin(mx)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + a^2 y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = a^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + a^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$a^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = a^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(a^2)} \\ &= \pm\sqrt{-a^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-a^2} \\ \lambda_2 &= -\sqrt{-a^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-a^2} \\ \lambda_2 &= -\sqrt{-a^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\sqrt{-a^2}\right)x} + c_2 e^{\left(-\sqrt{-a^2}\right)x}\end{aligned}$$

Or

$$y = c_1 e^{\sqrt{-a^2}\, x} + c_2 e^{-\sqrt{-a^2}\, x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\sqrt{-a^2}\, x} + c_2 e^{-\sqrt{-a^2}\, x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2\cos(mx)+3\sin(mx)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(mx),\sin(mx)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{\sqrt{-a^2}\,x},\mathrm{e}^{-\sqrt{-a^2}\,x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(mx)+A_2\sin(mx)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-A_1m^2\cos(mx)-A_2m^2\sin(mx)+a^2(A_1\cos(mx)+A_2\sin(mx))\\&=2\cos(mx)+3\sin(mx)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=\frac{2}{a^2-m^2},A_2=\frac{3}{a^2-m^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p=\frac{2\cos(mx)}{a^2-m^2}+\frac{3\sin(mx)}{a^2-m^2}$$

Therefore the general solution is

$$\begin{aligned}y&=y_h+y_p\\&=\left(c_1\mathrm{e}^{\sqrt{-a^2}\,x}+c_2\mathrm{e}^{-\sqrt{-a^2}\,x}\right)+\left(\frac{2\cos(mx)}{a^2-m^2}+\frac{3\sin(mx)}{a^2-m^2}\right)\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{\sqrt{-a^2}\, x} + c_2 e^{-\sqrt{-a^2}\, x} + \frac{2\cos(mx)}{a^2 - m^2} + \frac{3\sin(mx)}{a^2 - m^2} \tag{1}$$

Verification of solutions

$$y = c_1 e^{\sqrt{-a^2}\, x} + c_2 e^{-\sqrt{-a^2}\, x} + \frac{2\cos(mx)}{a^2 - m^2} + \frac{3\sin(mx)}{a^2 - m^2}$$

Verified OK.

16.59.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + a^2 y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -a^2$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = \left(-a^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 471: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r=-a^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z''=rz$ as one solution is

$$z_1(x)=\mathrm{e}^{\sqrt{-a^2}\,x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B=0$ then the above reduces to

$$\begin{aligned}y_1&=z_1\\&=\mathrm{e}^{\sqrt{-a^2}\,x}\end{aligned}$$

Which simplifies to

$$y_1=\mathrm{e}^{\sqrt{-a^2}\,x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2=y_1\int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B=0$ then the above becomes

$$\begin{aligned}y_2&=y_1\int \frac{1}{y_1^2}\,dx\\&=\mathrm{e}^{\sqrt{-a^2}\,x}\int \frac{1}{\mathrm{e}^{2\sqrt{-a^2}\,x}}\,dx\\&=\mathrm{e}^{\sqrt{-a^2}\,x}\left(\frac{\sqrt{-a^2}\,\mathrm{e}^{-2\sqrt{-a^2}\,x}}{2a^2}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y&=c_1y_1+c_2y_2\\&=c_1\left(\mathrm{e}^{\sqrt{-a^2}\,x}\right)+c_2\left(\mathrm{e}^{\sqrt{-a^2}\,x}\left(\frac{\sqrt{-a^2}\,\mathrm{e}^{-2\sqrt{-a^2}\,x}}{2a^2}\right)\right)\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + a^2 y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{\sqrt{-a^2}\, x} + \frac{c_2 \sqrt{-a^2}\, \mathrm{e}^{-\sqrt{-a^2}\, x}}{2a^2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$2 \cos (mx) + 3 \sin (mx)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos (mx) , \sin (mx)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{-a^2}\, \mathrm{e}^{-\sqrt{-a^2}\, x}}{2a^2}, \mathrm{e}^{\sqrt{-a^2}\, x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos (mx) + A_2 \sin (mx)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-A_1 m^2 \cos (mx) - A_2 m^2 \sin (mx) + a^2 (A_1 \cos (mx) + A_2 \sin (mx)) \\ &= 2 \cos (mx) + 3 \sin (mx)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{2}{a^2 - m^2}, A_2 = \frac{3}{a^2 - m^2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{2\cos(mx)}{a^2 - m^2} + \frac{3\sin(mx)}{a^2 - m^2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{\sqrt{-a^2}\, x} + \frac{c_2\sqrt{-a^2}\, \mathrm{e}^{-\sqrt{-a^2}\, x}}{2a^2}\right) + \left(\frac{2\cos(mx)}{a^2 - m^2} + \frac{3\sin(mx)}{a^2 - m^2}\right)
\end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\sqrt{-a^2}\, x} + \frac{c_2\sqrt{-a^2}\, \mathrm{e}^{-\sqrt{-a^2}\, x}}{2a^2} + \frac{2\cos(mx)}{a^2 - m^2} + \frac{3\sin(mx)}{a^2 - m^2} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 \mathrm{e}^{\sqrt{-a^2}\, x} + \frac{c_2\sqrt{-a^2}\, \mathrm{e}^{-\sqrt{-a^2}\, x}}{2a^2} + \frac{2\cos(mx)}{a^2 - m^2} + \frac{3\sin(mx)}{a^2 - m^2}$$

Verified OK.

16.59.3 Maple step by step solution

Let's solve

$y'' + a^2 y = 2\cos(mx) + 3\sin(mx)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $a^2 + r^2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm \left(\sqrt{-4a^2}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(\sqrt{-a^2}, -\sqrt{-a^2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{\sqrt{-a^2}\, x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\sqrt{-a^2}\, x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{\sqrt{-a^2}\, x} + c_2 e^{-\sqrt{-a^2}\, x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 2\cos(mx) + 3\sin(mx)\right.$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\sqrt{-a^2}\, x} & e^{-\sqrt{-a^2}\, x} \\ \sqrt{-a^2}\, e^{\sqrt{-a^2}\, x} & -\sqrt{-a^2}\, e^{-\sqrt{-a^2}\, x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = -2\sqrt{-a^2}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \frac{e^{\sqrt{-a^2}\, x}\left(\int (2\cos(mx)+3\sin(mx)) e^{-\sqrt{-a^2}\, x} dx\right) - e^{-\sqrt{-a^2}\, x}\left(\int (2\cos(mx)+3\sin(mx)) e^{\sqrt{-a^2}\, x} dx\right)}{2\sqrt{-a^2}}$

  - Compute integrals

    $y_p(x) = \frac{2\cos(mx)+3\sin(mx)}{a^2-m^2}$

- Substitute particular solution into general solution to ODE

  $y = \frac{2\cos(mx)+3\sin(mx)}{a^2-m^2} + c_1 e^{\sqrt{-a^2}\, x} + c_2 e^{-\sqrt{-a^2}\, x}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - y' = e^{x} \sin (x)}$$

16.60.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$A y''(x) + B y'(x) + C y(x) = f(x)$$

Where $A = 1, B = -1, C = 0, f(x) = e^{x} \sin (x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(0)}\\ &= \frac{1}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{1}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = 0$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(1)x} + c_2 e^{(0)x}$$

Or

$$y = e^x c_1 + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = e^x c_1 + c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x \cos(x) + A_2 e^x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^x \sin(x) + A_2 e^x \cos(x) - A_1 e^x \cos(x) - A_2 e^x \sin(x) = e^x \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (e^x c_1 + c_2) + \left(-\frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2}\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = e^x c_1 + c_2 - \frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2} \tag{1}
$$

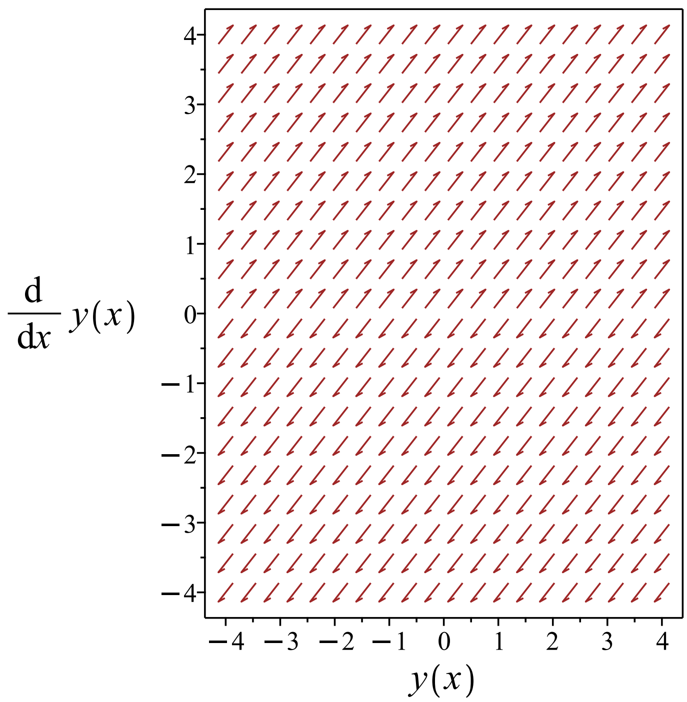

Figure 595: Slope field plot

<u>Verification of solutions</u>

$$
y = e^x c_1 + c_2 - \frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2}
$$

Verified OK.

16.60.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - y')\, dx = \int e^x \sin(x)\, dx$$

$$-y + y' = -\frac{e^x \cos(x)}{2} + \frac{e^x \sin(x)}{2} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2} \end{aligned}$$

Hence the ode is

$$-y + y' = c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-1)dx} \\ &= e^{-x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2}\right) \\ \frac{d}{dx}\left(e^{-x} y\right) &= \left(e^{-x}\right)\left(c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2}\right) \\ d\left(e^{-x} y\right) &= \left(\frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_1 e^{-x}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-x} y &= \int \frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_1 e^{-x}\, dx \\ e^{-x} y &= -c_1 e^{-x} - \frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = e^{x}\left(-c_1 e^{-x} - \frac{\sin(x)}{2} - \frac{\cos(x)}{2}\right) + e^{x} c_2$$

which simplifies to

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\, e^{x}}{2} - c_1$$

Summary

The solution(s) found are the following

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\, e^{x}}{2} - c_1 \tag{1}$$

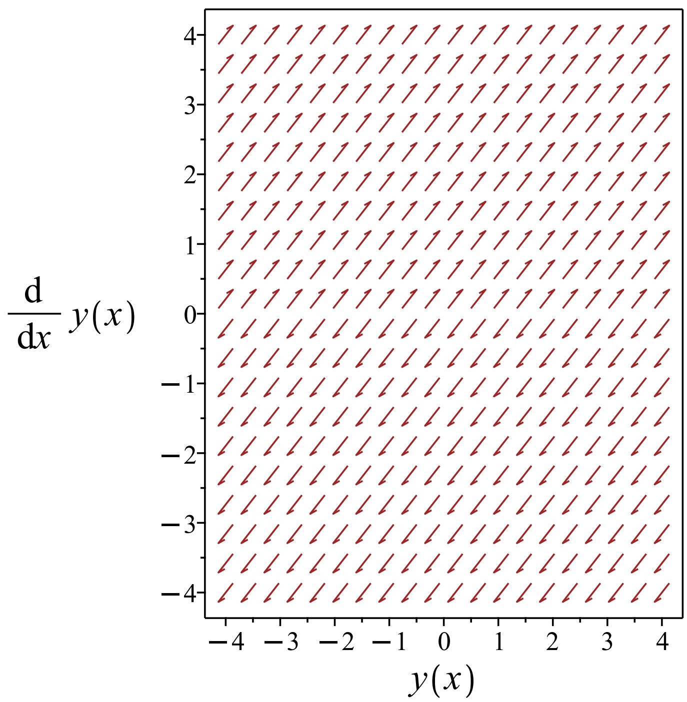

Figure 596: Slope field plot

Verification of solutions

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\, e^{x}}{2} - c_1$$

Verified OK.

16.60.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - p(x) - e^x \sin(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= e^x \sin(x) \end{aligned}$$

Hence the ode is

$$p'(x) - p(x) = e^x \sin(x)$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-1)dx} \\ &= e^{-x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(e^x \sin(x)\right) \\ \frac{d}{dx}\left(e^{-x} p\right) &= \left(e^{-x}\right)\left(e^x \sin(x)\right) \\ d\left(e^{-x} p\right) &= \sin(x)\, dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-x} p &= \int \sin(x)\, dx \\ e^{-x} p &= -\cos(x) + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$p(x) = -e^{x} \cos(x) + e^{x} c_1$$

which simplifies to

$$p(x) = e^{x}(-\cos(x) + c_1)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{x}(-\cos(x) + c_1)$$

Integrating both sides gives

$$\begin{aligned} y &= \int -e^{x}(\cos(x) - c_1)\, dx \\ &= e^{x} c_1 + c_2 - \frac{e^{x}\cos(x)}{2} - \frac{e^{x}\sin(x)}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{x} c_1 + c_2 - \frac{e^{x}\cos(x)}{2} - \frac{e^{x}\sin(x)}{2} \tag{1}$$

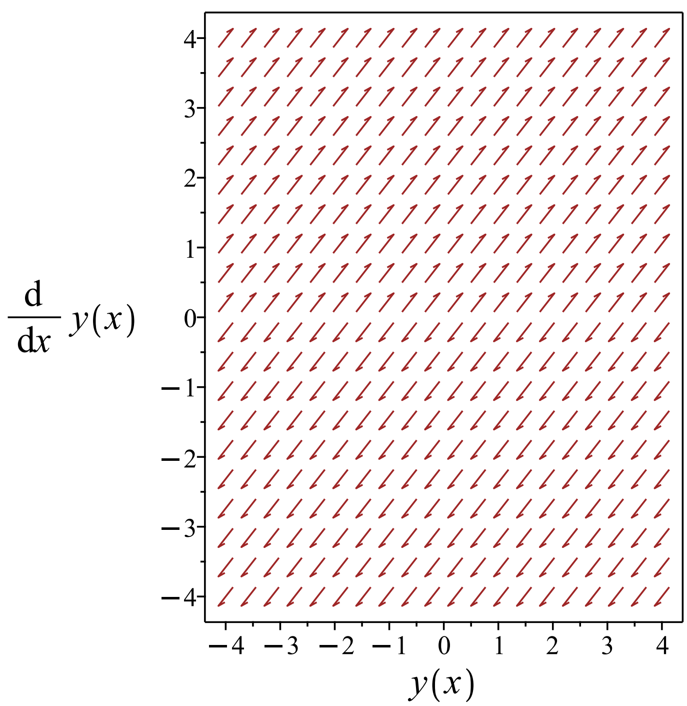

Figure 597: Slope field plot

Verification of solutions

$$y = e^{x} c_1 + c_2 - \frac{e^{x} \cos(x)}{2} - \frac{e^{x} \sin(x)}{2}$$

Verified OK.

16.60.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - y' = e^{x} \sin(x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - y')\, dx = \int e^{x} \sin(x)\, dx$$

$$-y + y' = -\frac{e^{x} \cos(x)}{2} + \frac{e^{x} \sin(x)}{2} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x) y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= c_1 + \frac{e^{x}(-\cos(x) + \sin(x))}{2} \end{aligned}$$

Hence the ode is

$$-y + y' = c_1 + \frac{e^{x}(-\cos(x) + \sin(x))}{2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-1) dx} \\ &= e^{-x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu) \left(c_1 + \frac{e^{x}(-\cos(x) + \sin(x))}{2}\right) \\ \frac{d}{dx}(e^{-x} y) &= (e^{-x}) \left(c_1 + \frac{e^{x}(-\cos(x) + \sin(x))}{2}\right) \\ d(e^{-x} y) &= \left(\frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_1 e^{-x}\right) dx \end{aligned}$$

Integrating gives

$$e^{-x}y = \int \frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_1 e^{-x}\, dx$$
$$e^{-x}y = -c_1 e^{-x} - \frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = e^{x}\left(-c_1 e^{-x} - \frac{\sin(x)}{2} - \frac{\cos(x)}{2}\right) + e^{x} c_2$$

which simplifies to

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\, e^{x}}{2} - c_1$$

Summary

The solution(s) found are the following

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\, e^{x}}{2} - c_1 \tag{1}$$

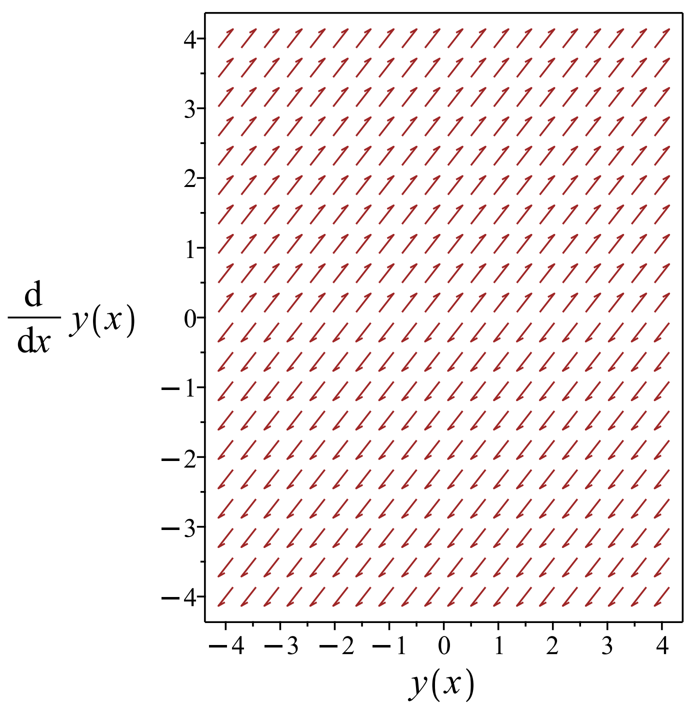

Figure 598: Slope field plot

Verification of solutions

$$
y = \frac{(2c_2 - \cos(x) - \sin(x))\,\mathrm{e}^{x}}{2} - c_1
$$

Verified OK.

16.60.5 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y'' - y' &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 1 \\
B &= -1 \tag{3} \\
C &= 0
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{1}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= 1 \\
t &= 4
\end{align*}
$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 473: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^x}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2(1(\mathrm{e}^x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 + e^x c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x \cos(x), e^x \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x \cos(x) + A_2 e^x \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^x \sin(x) + A_2 e^x \cos(x) - A_1 e^x \cos(x) - A_2 e^x \sin(x) = e^x \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 + e^x c_2) + \left(-\frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + e^x c_2 - \frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2} \tag{1}
$$

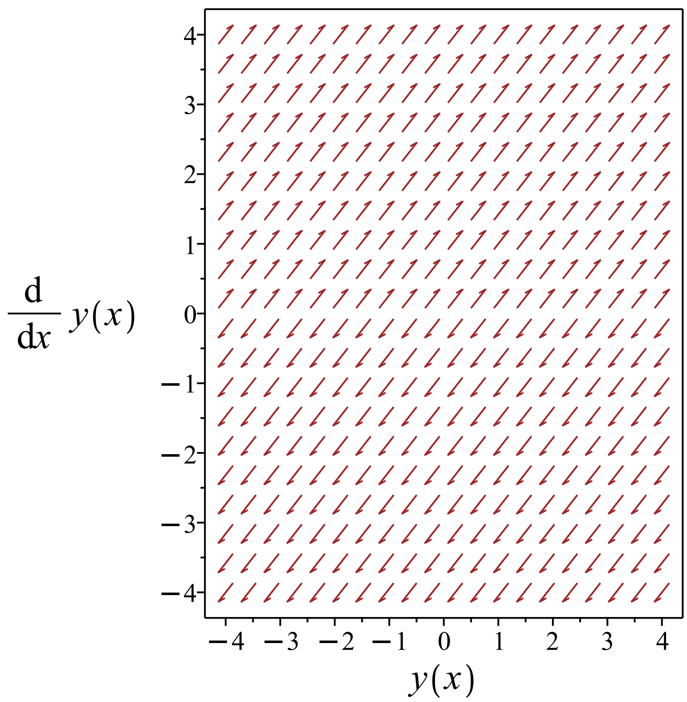

Figure 599: Slope field plot

Verification of solutions

$$
y = c_1 + e^x c_2 - \frac{e^x \cos(x)}{2} - \frac{e^x \sin(x)}{2}
$$

Verified OK.

16.60.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1 \\
q(x) &= -1 \\
r(x) &= 0 \\
s(x) &= \mathrm{e}^{x} \sin(x)
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + (q(x) - p'(x))\, y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$-y + y' = \int \mathrm{e}^{x} \sin(x)\, dx$$

We now have a first order ode to solve which is

$$-y + y' = -\frac{\mathrm{e}^{x} \cos(x)}{2} + \frac{\mathrm{e}^{x} \sin(x)}{2} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2} \end{aligned}$$

Hence the ode is

$$-y + y' = c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int (-1)dx} \\ &= e^{-x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2}\right) \\ \frac{d}{dx}\left(e^{-x} y\right) &= \left(e^{-x}\right)\left(c_1 + \frac{e^x(-\cos(x) + \sin(x))}{2}\right) \\ d\left(e^{-x} y\right) &= \left(\frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_1 e^{-x}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{-x} y &= \int \frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_1 e^{-x} \, dx \\ e^{-x} y &= -c_1 e^{-x} - \frac{\sin(x)}{2} - \frac{\cos(x)}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = e^x\left(-c_1 e^{-x} - \frac{\sin(x)}{2} - \frac{\cos(x)}{2}\right) + e^x c_2$$

which simplifies to

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\, e^x}{2} - c_1$$

Summary

The solution(s) found are the following

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\,e^x}{2} - c_1 \tag{1}$$

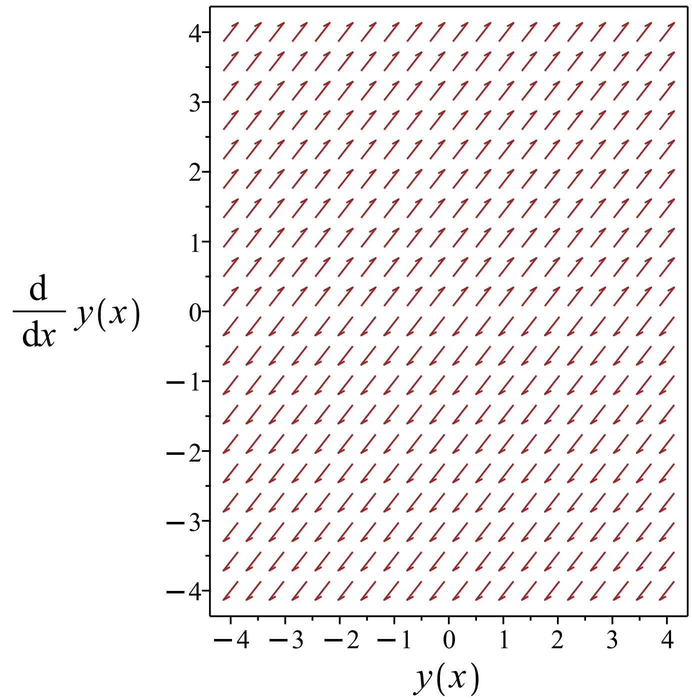

Figure 600: Slope field plot

Verification of solutions

$$y = \frac{(2c_2 - \cos(x) - \sin(x))\,e^x}{2} - c_1$$

Verified OK.

16.60.7 Maple step by step solution

Let's solve

$y'' - y' = e^x \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - r = 0$

- Factor the characteristic polynomial

  $r(r-1) = 0$

- Roots of the characteristic polynomial

  $r = (0, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + e^x c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^x \sin(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^x \\ 0 & e^x \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^x$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\left(\int e^x \sin(x)\, dx\right) + e^x\left(\int \sin(x)\, dx\right)$

  - Compute integrals

    $y_p(x) = -\frac{e^x(\sin(x) + \cos(x))}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + e^x c_2 - \frac{e^x(\sin(x) + \cos(x))}{2}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + 2y' = 4\,\mathrm{e}^{x}(\sin(x) + \cos(x))}$$

16.61.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 0, f(x) = (4\sin(x) + 4\cos(x))\,\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 2\lambda \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{2^2 - (4)(1)(0)}\\ &= -1 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = -1 + 1$$
$$\lambda_2 = -1 - 1$$

Which simplifies to

$$\lambda_1 = 0$$
$$\lambda_2 = -2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(0)x} + c_2 e^{(-2)x}$$

Or

$$y = c_1 + e^{-2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4\,e^{x}(\sin(x) + \cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x} \cos(x), e^{x} \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} \cos(x) + A_2 e^{x} \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{x} \sin(x) + 4A_2 e^{x} \cos(x) + 2A_1 e^{x} \cos(x) + 2A_2 e^{x} \sin(x) = (4\sin(x) + 4\cos(x))\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{2}{5}, A_2 = \frac{6}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{2\,e^{x} \cos(x)}{5} + \frac{6\,e^{x} \sin(x)}{5}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 + e^{-2x} c_2\right) + \left(-\frac{2 e^{x} \cos(x)}{5} + \frac{6 e^{x} \sin(x)}{5}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 + e^{-2x} c_2 - \frac{2 e^{x} \cos(x)}{5} + \frac{6 e^{x} \sin(x)}{5} \tag{1}
$$

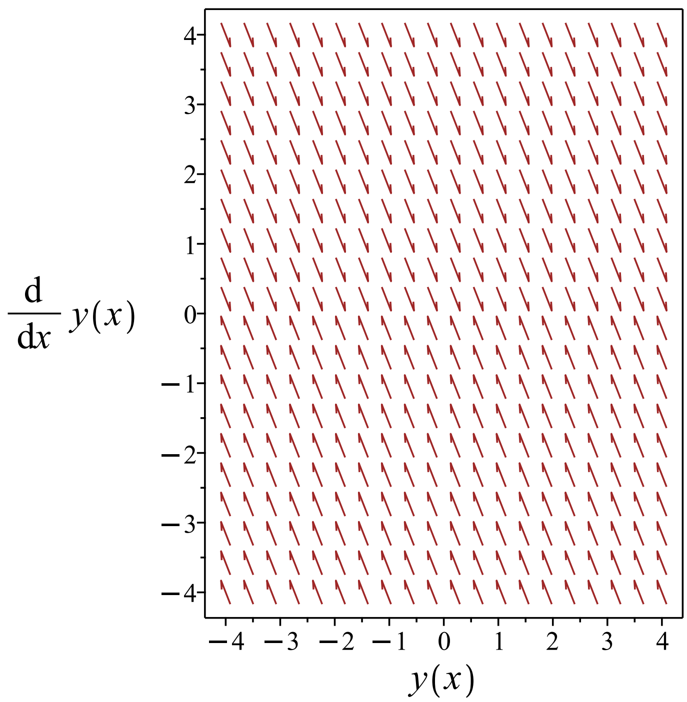

Figure 601: Slope field plot

Verification of solutions

$$
y = c_1 + e^{-2x} c_2 - \frac{2 e^{x} \cos(x)}{5} + \frac{6 e^{x} \sin(x)}{5}
$$

Verified OK.

16.61.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\,dx = \int (4\sin(x) + 4\cos(x))\,e^{x}dx$$
$$2y + y' = 4\,e^{x}\sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= 4\,e^{x}\sin(x) + c_1 \end{aligned}$$

Hence the ode is

$$2y + y' = 4\,e^{x}\sin(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 2dx} \\ &= e^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(4\,e^{x}\sin(x) + c_1\right) \\ \frac{d}{dx}\left(e^{2x}y\right) &= \left(e^{2x}\right)\left(4\,e^{x}\sin(x) + c_1\right) \\ d\left(e^{2x}y\right) &= \left(\left(4\,e^{x}\sin(x) + c_1\right)e^{2x}\right)\,dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{2x}y &= \int \left(4\,e^{x}\sin(x) + c_1\right)e^{2x}\,dx \\ e^{2x}y &= -\frac{2\,e^{3x}\cos(x)}{5} + \frac{6\,e^{3x}\sin(x)}{5} + \frac{e^{2x}c_1}{2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{2\,e^{3x}\cos(x)}{5} + \frac{6\,e^{3x}\sin(x)}{5} + \frac{e^{2x}c_1}{2}\right) + e^{-2x}c_2$$

which simplifies to

$$y = \frac{e^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5} + e^{2x}c_1 + 2c_2\right)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5} + e^{2x}c_1 + 2c_2\right)}{2} \tag{1}$$

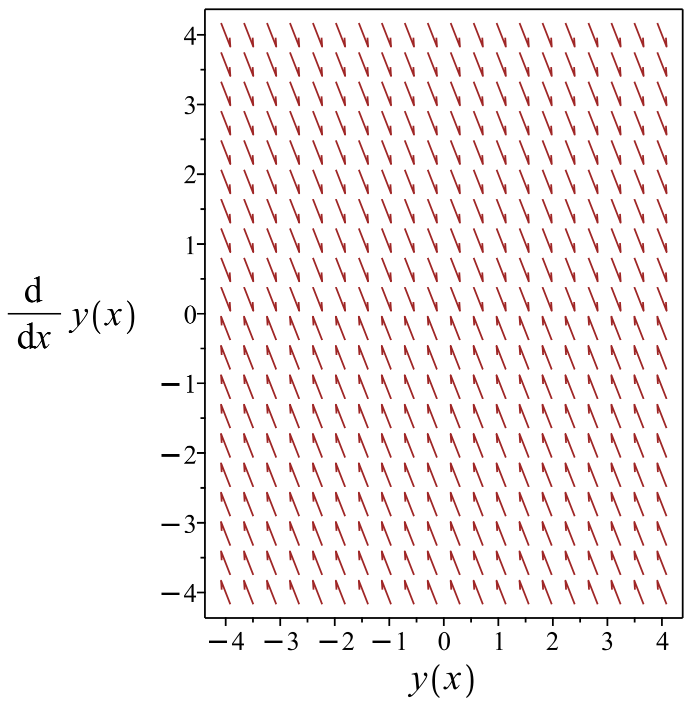

Figure 602: Slope field plot

Verification of solutions

$$y = \frac{e^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5} + e^{2x}c_1 + 2c_2\right)}{2}$$

Verified OK.

16.61.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + 2p(x) - (4\sin(x) + 4\cos(x))\,\mathrm{e}^{x} = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= 4\,\mathrm{e}^{x}(\sin(x) + \cos(x)) \end{aligned}$$

Hence the ode is

$$p'(x) + 2p(x) = 4\,\mathrm{e}^{x}(\sin(x) + \cos(x))$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 2dx} \\ &= \mathrm{e}^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu p) &= (\mu)\left(4\,\mathrm{e}^{x}(\sin(x) + \cos(x))\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{2x}p\right) &= \left(\mathrm{e}^{2x}\right)\left(4\,\mathrm{e}^{x}(\sin(x) + \cos(x))\right) \\ \mathrm{d}\left(\mathrm{e}^{2x}p\right) &= \left(4(\sin(x) + \cos(x))\,\mathrm{e}^{3x}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{2x}p &= \int 4(\sin(x) + \cos(x))\,\mathrm{e}^{3x}\,\mathrm{d}x \\ \mathrm{e}^{2x}p &= \frac{4\,\mathrm{e}^{3x}\cos(x)}{5} + \frac{8\,\mathrm{e}^{3x}\sin(x)}{5} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$p(x) = e^{-2x}\left(\frac{4\,e^{3x}\cos(x)}{5} + \frac{8\,e^{3x}\sin(x)}{5}\right) + c_1 e^{-2x}$$

which simplifies to

$$p(x) = e^{-2x}\left(\frac{4\,e^{3x}(\cos(x) + 2\sin(x))}{5} + c_1\right)$$

Since $p = y'$ then the new first order ode to solve is

$$y' = e^{-2x}\left(\frac{4\,e^{3x}(\cos(x) + 2\sin(x))}{5} + c_1\right)$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{e^{-2x}(8\,e^{3x}\sin(x) + 4\,e^{3x}\cos(x) + 5c_1)}{5}\, dx \\ &= -\frac{2\,e^{x}\cos(x)}{5} + \frac{6\,e^{x}\sin(x)}{5} - \frac{c_1 e^{-2x}}{2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{2\,e^{x}\cos(x)}{5} + \frac{6\,e^{x}\sin(x)}{5} - \frac{c_1 e^{-2x}}{2} + c_2 \tag{1}$$

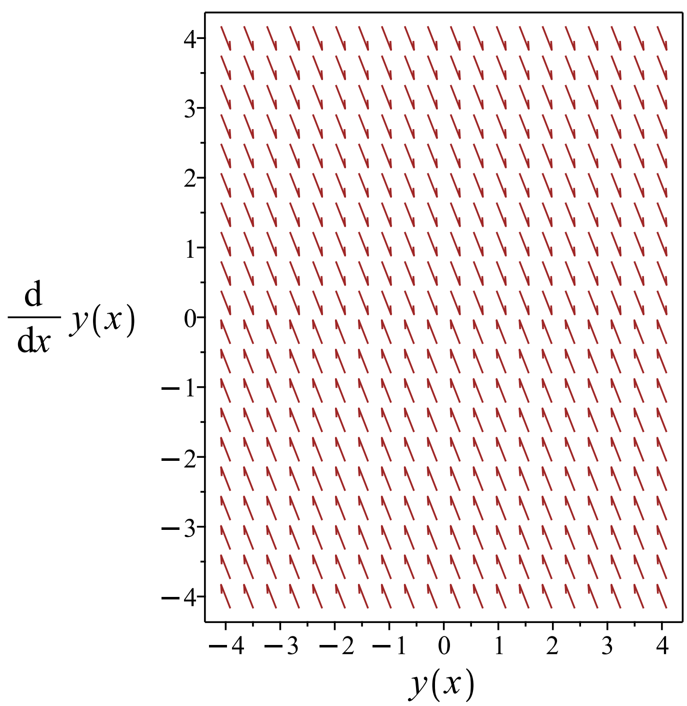

Figure 603: Slope field plot

Verification of solutions

$$y = -\frac{2\,\mathrm{e}^{x} \cos(x)}{5} + \frac{6\,\mathrm{e}^{x} \sin(x)}{5} - \frac{c_1 \mathrm{e}^{-2x}}{2} + c_2$$

Verified OK.

16.61.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + 2y' = (4\sin(x) + 4\cos(x))\,\mathrm{e}^{x}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + 2y')\,dx = \int (4\sin(x) + 4\cos(x))\,\mathrm{e}^{x}\,dx$$

$$2y + y' = 4\,\mathrm{e}^{x} \sin(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= 4\,\mathrm{e}^{x} \sin(x) + c_1 \end{aligned}$$

Hence the ode is

$$2y + y' = 4\,\mathrm{e}^{x} \sin(x) + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int 2dx} \\ &= \mathrm{e}^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(4\,\mathrm{e}^{x} \sin(x) + c_1\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{2x} y\right) &= \left(\mathrm{e}^{2x}\right)\left(4\,\mathrm{e}^{x} \sin(x) + c_1\right) \\ \mathrm{d}\left(\mathrm{e}^{2x} y\right) &= \left(\left(4\,\mathrm{e}^{x} \sin(x) + c_1\right) \mathrm{e}^{2x}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$e^{2x}y = \int (4\,e^{x}\sin(x) + c_1)\,e^{2x}\,dx$$

$$e^{2x}y = -\frac{2\,e^{3x}\cos(x)}{5} + \frac{6\,e^{3x}\sin(x)}{5} + \frac{e^{2x}c_1}{2} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{2\,e^{3x}\cos(x)}{5} + \frac{6\,e^{3x}\sin(x)}{5} + \frac{e^{2x}c_1}{2}\right) + e^{-2x}c_2$$

which simplifies to

$$y = \frac{e^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5} + e^{2x}c_1 + 2c_2\right)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5} + e^{2x}c_1 + 2c_2\right)}{2} \tag{1}$$

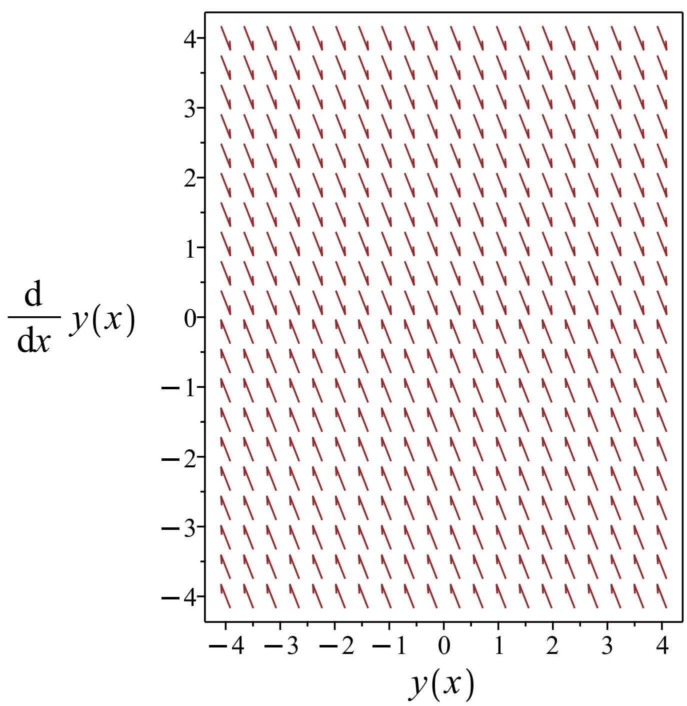

Figure 604: Slope field plot

Verification of solutions

$$y = \frac{e^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5}+e^{2x}c_1+2c_2\right)}{2}$$

Verified OK.

16.61.5 Solving using Kovacic algorithm

Writing the ode as

$$y''+2y'=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1\\ B &= 2\\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t}\\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1\\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 475: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\, dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-2x}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x}\left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{-2x} + \frac{c_2}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$4 e^{x} (\sin(x) + \cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x} \cos(x), e^{x} \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{1}{2}, e^{-2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} \cos(x) + A_2 e^{x} \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{x} \sin(x) + 4A_2 e^{x} \cos(x) + 2A_1 e^{x} \cos(x) + 2A_2 e^{x} \sin(x) = (4\sin(x) + 4\cos(x)) e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{2}{5}, A_2 = \frac{6}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{2 e^{x} \cos(x)}{5} + \frac{6 e^{x} \sin(x)}{5}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} + \frac{c_2}{2}\right) + \left(-\frac{2\,\mathrm{e}^{x} \cos(x)}{5} + \frac{6\,\mathrm{e}^{x} \sin(x)}{5}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2} - \frac{2\,\mathrm{e}^{x} \cos(x)}{5} + \frac{6\,\mathrm{e}^{x} \sin(x)}{5} \tag{1}
$$

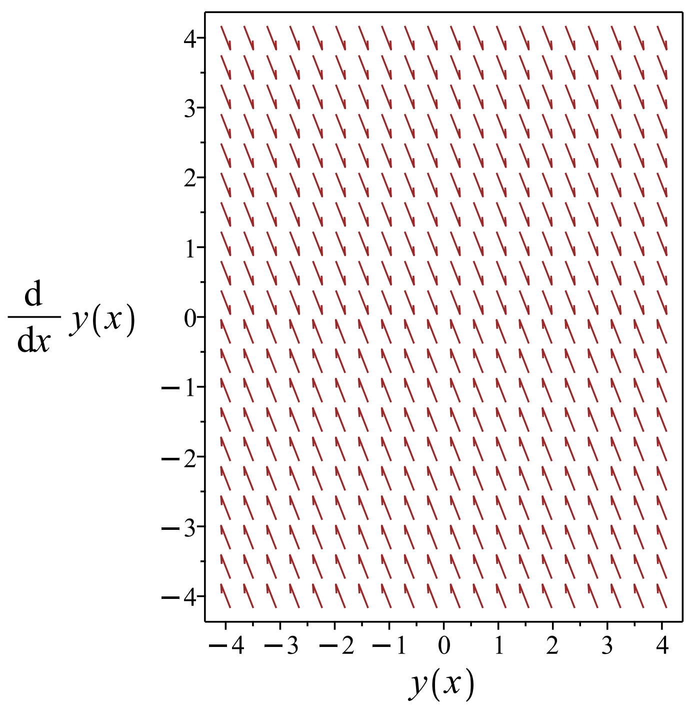

Figure 605: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2} - \frac{2\,\mathrm{e}^{x} \cos(x)}{5} + \frac{6\,\mathrm{e}^{x} \sin(x)}{5}
$$

Verified OK.

16.61.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 2 \\ r(x) &= 0 \\ s(x) &= (4\sin(x) + 4\cos(x))\, e^{x} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$2y + y' = \int (4\sin(x) + 4\cos(x))\, e^{x}\, dx$$

We now have a first order ode to solve which is

$$2y + y' = 4\, e^{x} \sin(x) + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= 2\\ q(x) &= 4\,\mathrm{e}^{x} \sin(x) + c_1\end{aligned}$$

Hence the ode is

$$2y + y' = 4\,\mathrm{e}^{x} \sin(x) + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int 2dx}\\ &= \mathrm{e}^{2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(4\,\mathrm{e}^{x} \sin(x) + c_1\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{2x} y\right) &= \left(\mathrm{e}^{2x}\right)\left(4\,\mathrm{e}^{x} \sin(x) + c_1\right)\\ \mathrm{d}\left(\mathrm{e}^{2x} y\right) &= \left(\left(4\,\mathrm{e}^{x} \sin(x) + c_1\right)\mathrm{e}^{2x}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{2x} y &= \int \left(4\,\mathrm{e}^{x} \sin(x) + c_1\right)\mathrm{e}^{2x}\,\mathrm{d}x\\ \mathrm{e}^{2x} y &= -\frac{2\,\mathrm{e}^{3x} \cos(x)}{5} + \frac{6\,\mathrm{e}^{3x} \sin(x)}{5} + \frac{\mathrm{e}^{2x} c_1}{2} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{2x}$ results in

$$y = \mathrm{e}^{-2x}\left(-\frac{2\,\mathrm{e}^{3x} \cos(x)}{5} + \frac{6\,\mathrm{e}^{3x} \sin(x)}{5} + \frac{\mathrm{e}^{2x} c_1}{2}\right) + \mathrm{e}^{-2x} c_2$$

which simplifies to

$$y = \frac{\mathrm{e}^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))\mathrm{e}^{3x}}{5} + \mathrm{e}^{2x} c_1 + 2c_2\right)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-2x}\left(\frac{4(-\cos(x)+3\sin(x))\mathrm{e}^{3x}}{5} + \mathrm{e}^{2x} c_1 + 2c_2\right)}{2} \tag{1}$$

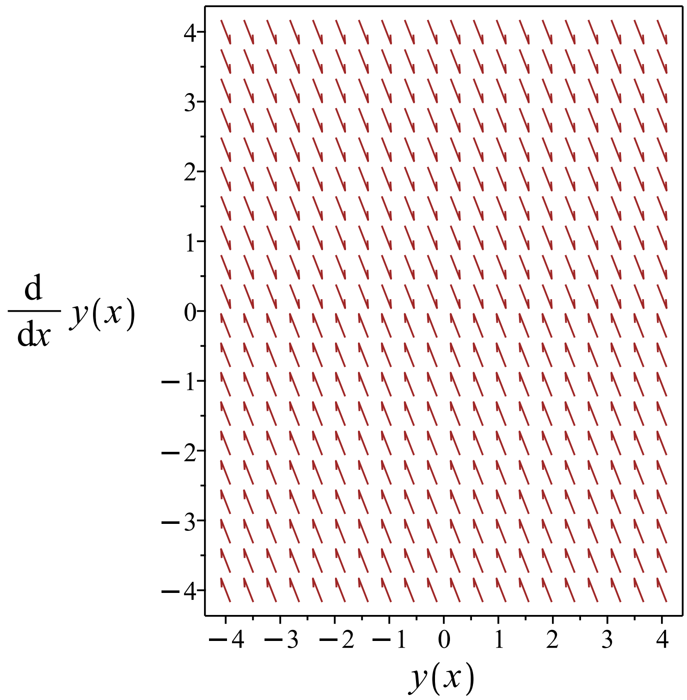

Figure 606: Slope field plot

Verification of solutions

$$y = \frac{e^{-2x} \left(\frac{4(-\cos(x)+3\sin(x))e^{3x}}{5} + e^{2x}c_1 + 2c_2\right)}{2}$$

Verified OK.

16.61.7 Maple step by step solution

Let's solve

$y'' + 2y' = (4\sin(x) + 4\cos(x))\,e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = 4\,e^x \sin(x) + 4\,e^x \cos(x) - 2y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + 2y' = 4\,e^x(\sin(x) + \cos(x))$

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r = 0$
- Factor the characteristic polynomial

  $r(r+2) = 0$
- Roots of the characteristic polynomial

  $r = (-2, 0)$
- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + c_2 + y_p(x)$
- ☐ Find a particular solution $y_p(x)$ of the ODE
  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 4\,e^x(\sin(x) + \cos(x))\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & 1 \\ -2\,e^{-2x} & 0 \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,e^{-2x}$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -2\,e^{-2x}\left(\int (\sin(x) + \cos(x))\,e^{3x}dx\right) + 2\left(\int e^x(\sin(x) + \cos(x))\,dx\right)$
  - Compute integrals

    $y_p(x) = -\frac{2\,e^x(\cos(x) - 3\sin(x))}{5}$
- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + c_2 - \frac{2\,e^x(\cos(x) - 3\sin(x))}{5}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y' + 5y = 10\,\mathrm{e}^{-2x} \cos(x)}$$

16.62.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 5, f(x) = 10\,\mathrm{e}^{-2x} \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{4^2 - (4)\,(1)\,(5)}\\ &= -2 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -2 + i\\ \lambda_2 &= -2 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -2 + i\\ \lambda_2 &= -2 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10\,\mathrm{e}^{-2x}\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\mathrm{e}^{-2x}\cos(x), \mathrm{e}^{-2x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{-2x}\cos(x), \mathrm{e}^{-2x}\sin(x)\}$$

Since $\mathrm{e}^{-2x}\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{-2x}\cos(x), x\,\mathrm{e}^{-2x}\sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{-2x}\cos(x) + A_2 x\,\mathrm{e}^{-2x}\sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1\mathrm{e}^{-2x}\sin(x) + 2A_2\mathrm{e}^{-2x}\cos(x) = 10\,\mathrm{e}^{-2x}\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 5]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 5x\,\mathrm{e}^{-2x}\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{-2x}(c_1\cos(x) + c_2\sin(x))\right) + \left(5x\,\mathrm{e}^{-2x}\sin(x)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + 5x e^{-2x} \sin(x) \tag{1}$$

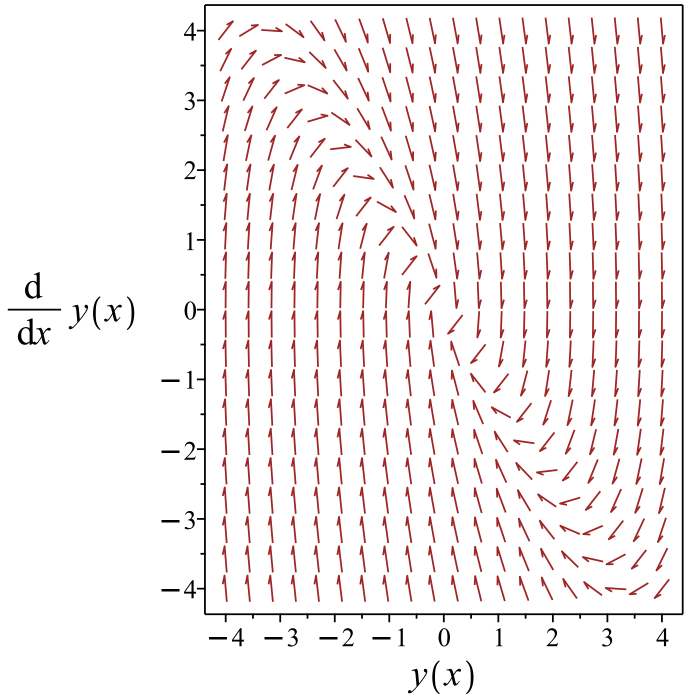

Figure 607: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + 5x e^{-2x} \sin(x)$$

Verified OK.

16.62.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 477: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx} \\
&= z_1 e^{-2x} \\
&= z_1\left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = e^{-2x} \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-4x}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(e^{-2x} \cos(x)\right) + c_2\left(e^{-2x} \cos(x)\,(\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^{-2x} \cos(x)\, c_1 + e^{-2x} \sin(x)\, c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10\, e^{-2x} \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-2x}\cos(x), e^{-2x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}\cos(x), e^{-2x}\sin(x)\}$$

Since $e^{-2x}\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{-2x}\cos(x), x\,e^{-2x}\sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{-2x}\cos(x) + A_2 x\,e^{-2x}\sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{-2x}\sin(x) + 2A_2 e^{-2x}\cos(x) = 10\,e^{-2x}\cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = 5]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 5x\,e^{-2x}\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-2x}\cos(x)\,c_1 + e^{-2x}\sin(x)\,c_2\right) + \left(5x\,e^{-2x}\sin(x)\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_1\cos(x) + c_2\sin(x)) + 5x\,e^{-2x}\sin(x)$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + 5x\,e^{-2x} \sin(x) \tag{1}$$

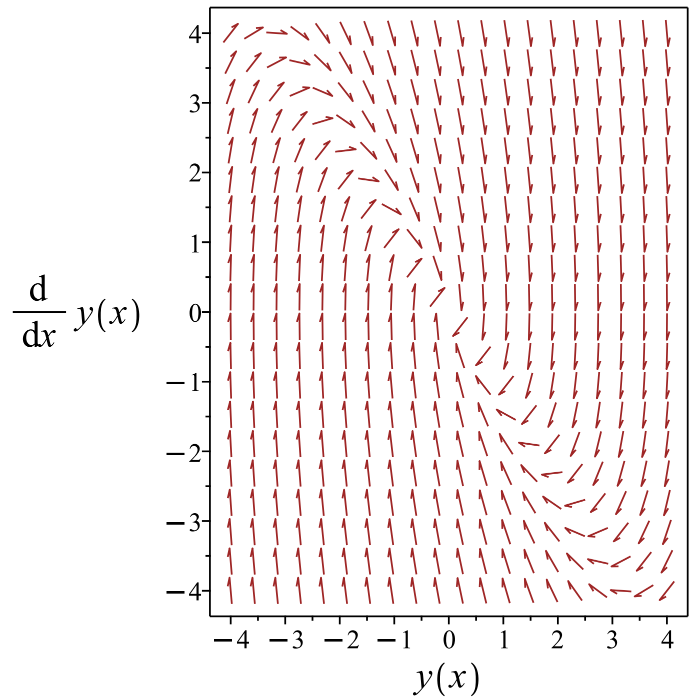

Figure 608: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_1 \cos(x) + c_2 \sin(x)) + 5x\,e^{-2x} \sin(x)$$

Verified OK.

16.62.3 Maple step by step solution

Let's solve

$y'' + 4y' + 5y = 10\,e^{-2x} \cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 5 = 0$

- Use quadratic formula to solve for r
  $r = \frac{(-4)\pm(\sqrt{-4})}{2}$
- Roots of the characteristic polynomial
  $r = (-2-\mathrm{I}, -2+\mathrm{I})$
- 1st solution of the homogeneous ODE
  $y_1(x) = \mathrm{e}^{-2x}\cos(x)$
- 2nd solution of the homogeneous ODE
  $y_2(x) = \mathrm{e}^{-2x}\sin(x)$
- General solution of the ODE
  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE
  $y = \mathrm{e}^{-2x}\cos(x)\, c_1 + \mathrm{e}^{-2x}\sin(x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function
    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 10\,\mathrm{e}^{-2x}\cos(x)\right]$
  - Wronskian of solutions of the homogeneous equation
    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x}\cos(x) & \mathrm{e}^{-2x}\sin(x) \\ -2\,\mathrm{e}^{-2x}\cos(x) - \mathrm{e}^{-2x}\sin(x) & -2\,\mathrm{e}^{-2x}\sin(x) + \mathrm{e}^{-2x}\cos(x) \end{bmatrix}$
  - Compute Wronskian
    $W(y_1(x), y_2(x)) = \mathrm{e}^{-4x}$
  - Substitute functions into equation for $y_p(x)$
    $y_p(x) = -5\,\mathrm{e}^{-2x}\left(\cos(x)\left(\int \sin(2x)\,dx\right) - 2\sin(x)\left(\int \cos(x)^2\,dx\right)\right)$
  - Compute integrals
    $y_p(x) = \frac{5(2\sin(x)x+\cos(x))\mathrm{e}^{-2x}}{2}$

- Substitute particular solution into general solution to ODE
  $y = \mathrm{e}^{-2x}\cos(x)\, c_1 + \mathrm{e}^{-2x}\sin(x)\, c_2 + \frac{5(2\sin(x)x+\cos(x))\mathrm{e}^{-2x}}{2}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{4y'' + 8y' = \sin(x)\, x}$$

16.63.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4, B = 8, C = 0, f(x) = \sin(x)\, x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$4y''+8y'=0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=0$$

Where in the above $A=4, B=8, C=0$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x}+8\lambda\, e^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2+8\lambda=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=4, B=8, C=0$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{-8}{(2)\,(4)}\pm\frac{1}{(2)\,(4)}\sqrt{8^2-(4)\,(4)\,(0)}\\&=-1\pm 1\end{aligned}$$

Hence

$$\lambda_1=-1+1$$
$$\lambda_2=-1-1$$

Which simplifies to

$$\lambda_1=0$$
$$\lambda_2=-2$$

Since roots are real and distinct, then the solution is

$$y=c_1e^{\lambda_1 x}+c_2e^{\lambda_2 x}$$
$$y=c_1e^{(0)x}+c_2e^{(-2)x}$$

Or

$$y = c_1 + e^{-2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 + e^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x) x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x) x, \sin(x) x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) x + A_2 \sin(x) x + A_3 \cos(x) + A_4 \sin(x)$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&-4A_1 \cos(x) x - 8A_1 \sin(x) - 4A_2 \sin(x) x + 8A_2 \cos(x) \\
&- 4A_3 \cos(x) - 4A_4 \sin(x) - 8A_1 \sin(x) x + 8A_1 \cos(x) \\
&+ 8A_2 \cos(x) x + 8A_2 \sin(x) - 8A_3 \sin(x) + 8A_4 \cos(x) = \sin(x) x
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{10}, A_2 = -\frac{1}{20}, A_3 = -\frac{1}{50}, A_4 = \frac{7}{50}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x) x}{10} - \frac{\sin(x) x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 + \mathrm{e}^{-2x} c_2) + \left(-\frac{\cos(x)\, x}{10} - \frac{\sin(x)\, x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 + \mathrm{e}^{-2x} c_2 - \frac{\cos(x)\, x}{10} - \frac{\sin(x)\, x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50} \tag{1}
$$

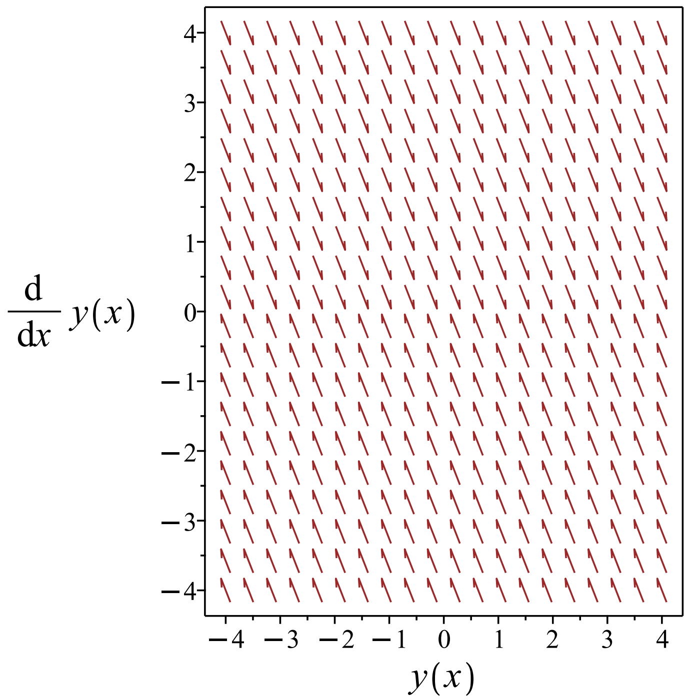

Figure 609: Slope field plot

Verification of solutions

$$
y = c_1 + \mathrm{e}^{-2x} c_2 - \frac{\cos(x)\, x}{10} - \frac{\sin(x)\, x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50}
$$

Verified OK.

16.63.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (4y'' + 8y')\, dx = \int \sin(x)\, x dx$$
$$8y + 4y' = \sin(x) - \cos(x)\, x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = \frac{\sin(x)}{4} - \frac{\cos(x)\, x}{4} + \frac{c_1}{4}$$

Hence the ode is

$$2y + y' = \frac{\sin(x)}{4} - \frac{\cos(x)\, x}{4} + \frac{c_1}{4}$$

The integrating factor μ is

$$\mu = e^{\int 2dx}$$
$$= e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{\sin(x)}{4} - \frac{\cos(x)\, x}{4} + \frac{c_1}{4}\right)$$
$$\frac{d}{dx}(e^{2x} y) = (e^{2x})\left(\frac{\sin(x)}{4} - \frac{\cos(x)\, x}{4} + \frac{c_1}{4}\right)$$
$$d(e^{2x} y) = \left(\frac{(\sin(x) - \cos(x)\, x + c_1)\, e^{2x}}{4}\right) dx$$

Integrating gives

$$e^{2x} y = \int \frac{(\sin(x) - \cos(x)\, x + c_1)\, e^{2x}}{4}\, dx$$
$$e^{2x} y = -\frac{e^{2x}\cos(x)}{20} + \frac{e^{2x}\sin(x)}{10} - \frac{\left(\frac{2x}{5} - \frac{3}{25}\right) e^{2x}\cos(x)}{4} + \frac{\left(-\frac{x}{5} + \frac{4}{25}\right) e^{2x}\sin(x)}{4} + \frac{e^{2x} c_1}{8} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x}\left(-\frac{e^{2x}\cos(x)}{20} + \frac{e^{2x}\sin(x)}{10} - \frac{\left(\frac{2x}{5} - \frac{3}{25}\right)e^{2x}\cos(x)}{4} + \frac{\left(-\frac{x}{5} + \frac{4}{25}\right)e^{2x}\sin(x)}{4} + \frac{e^{2x}c_1}{8}\right) + e^{-2x}c_2$$

which simplifies to

$$y = e^{-2x}c_2 + \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100} + \frac{c_1}{8}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}c_2 + \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100} + \frac{c_1}{8} \tag{1}$$

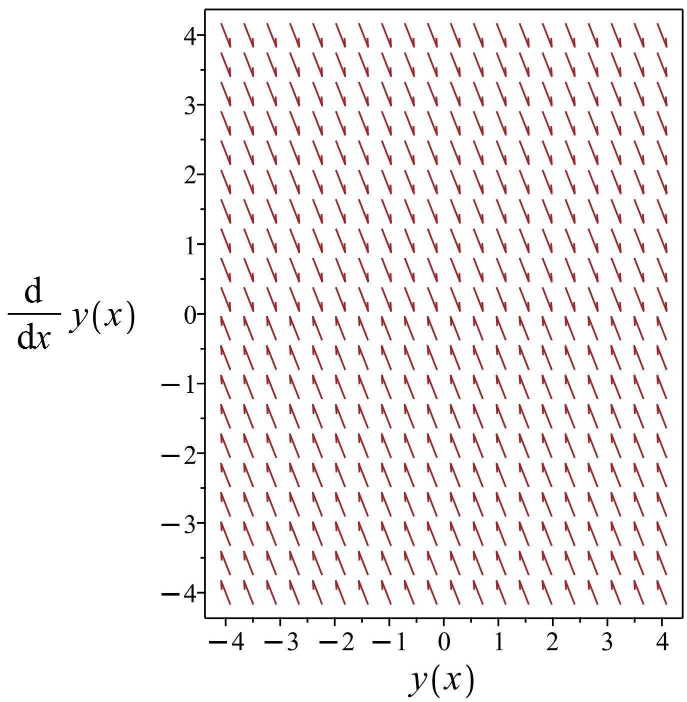

Figure 610: Slope field plot

Verification of solutions

$$y = e^{-2x}c_2 + \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100} + \frac{c_1}{8}$$

Verified OK.

16.63.3 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$4p'(x) + 8p(x) - \sin(x)\, x = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x) + p(x)p(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= \frac{\sin(x)\, x}{4} \end{aligned}$$

Hence the ode is

$$p'(x) + 2p(x) = \frac{\sin(x)\, x}{4}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int 2dx} \\ &= e^{2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu p) &= (\mu)\left(\frac{\sin(x)\, x}{4}\right) \\ \frac{d}{dx}\left(e^{2x} p\right) &= \left(e^{2x}\right)\left(\frac{\sin(x)\, x}{4}\right) \\ d\left(e^{2x} p\right) &= \left(\frac{\sin(x)\, x\, e^{2x}}{4}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} e^{2x}p &= \int \frac{\sin(x)\, x\, e^{2x}}{4}\, dx \\ e^{2x}p &= \frac{\left(-\frac{x}{5}+\frac{4}{25}\right) e^{2x} \cos(x)}{4} + \frac{\left(\frac{2x}{5}-\frac{3}{25}\right) e^{2x} \sin(x)}{4} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$p(x) = e^{-2x}\left(\frac{\left(-\frac{x}{5}+\frac{4}{25}\right) e^{2x} \cos(x)}{4} + \frac{\left(\frac{2x}{5}-\frac{3}{25}\right) e^{2x} \sin(x)}{4}\right) + c_1 e^{-2x}$$

which simplifies to

$$p(x) = c_1 e^{-2x} + \frac{(4-5x)\cos(x)}{100} + \frac{(-3+10x)\sin(x)}{100}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_1 e^{-2x} + \frac{(4-5x)\cos(x)}{100} + \frac{(-3+10x)\sin(x)}{100}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\sin(x)\, x}{10} - \frac{\cos(x)\, x}{20} - \frac{3\sin(x)}{100} + \frac{\cos(x)}{25} + c_1 e^{-2x}\, dx \\ &= -\frac{c_1 e^{-2x}}{2} - \frac{\cos(x)}{50} - \frac{\sin(x)\, x}{20} + \frac{7\sin(x)}{50} - \frac{\cos(x)\, x}{10} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1 e^{-2x}}{2} - \frac{\cos(x)}{50} - \frac{\sin(x)\, x}{20} + \frac{7\sin(x)}{50} - \frac{\cos(x)\, x}{10} + c_2 \tag{1}$$

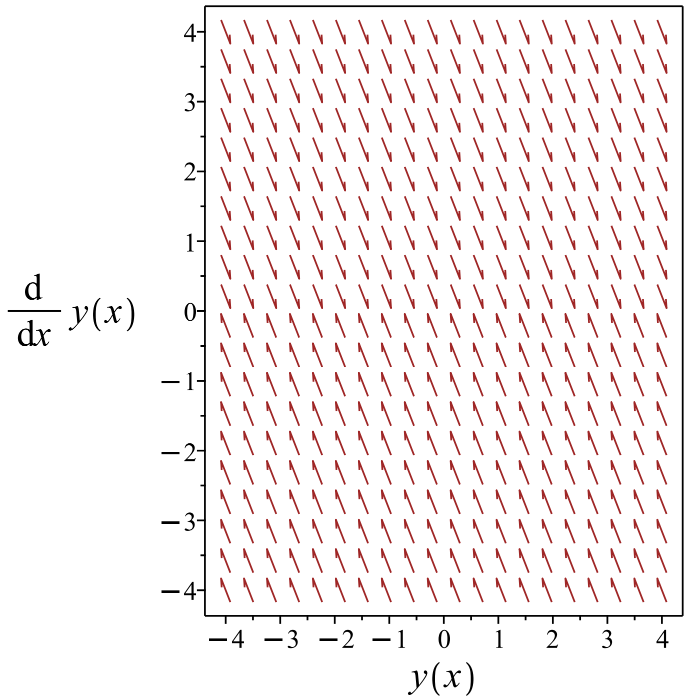

Figure 611: Slope field plot

Verification of solutions

$$y = -\frac{c_1 e^{-2x}}{2} - \frac{\cos(x)}{50} - \frac{\sin(x)\,x}{20} + \frac{7\sin(x)}{50} - \frac{\cos(x)\,x}{10} + c_2$$

Verified OK.

16.63.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$4y'' + 8y' = \sin(x)\,x$$

Integrating both sides of the ODE w.r.t x gives

$$\int (4y'' + 8y')\,dx = \int \sin(x)\,x dx$$

$$8y + 4y' = \sin(x) - \cos(x)\,x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= 2 \\
q(x) &= \frac{\sin(x)}{4} - \frac{\cos(x)\,x}{4} + \frac{c_1}{4}
\end{aligned}
$$

Hence the ode is

$$
2y + y' = \frac{\sin(x)}{4} - \frac{\cos(x)\,x}{4} + \frac{c_1}{4}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 2dx} \\
&= e^{2x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{\sin(x)}{4} - \frac{\cos(x)\,x}{4} + \frac{c_1}{4}\right) \\
\frac{d}{dx}\left(e^{2x} y\right) &= \left(e^{2x}\right)\left(\frac{\sin(x)}{4} - \frac{\cos(x)\,x}{4} + \frac{c_1}{4}\right) \\
d\left(e^{2x} y\right) &= \left(\frac{(\sin(x) - \cos(x)\,x + c_1)\,e^{2x}}{4}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{2x} y &= \int \frac{(\sin(x) - \cos(x)\,x + c_1)\,e^{2x}}{4}\,dx \\
e^{2x} y &= -\frac{e^{2x}\cos(x)}{20} + \frac{e^{2x}\sin(x)}{10} - \frac{\left(\frac{2x}{5} - \frac{3}{25}\right)e^{2x}\cos(x)}{4} + \frac{\left(-\frac{x}{5} + \frac{4}{25}\right)e^{2x}\sin(x)}{4} + \frac{e^{2x} c_1}{8} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$
y = e^{-2x}\left(-\frac{e^{2x}\cos(x)}{20} + \frac{e^{2x}\sin(x)}{10} - \frac{\left(\frac{2x}{5} - \frac{3}{25}\right)e^{2x}\cos(x)}{4} + \frac{\left(-\frac{x}{5} + \frac{4}{25}\right)e^{2x}\sin(x)}{4} + \frac{e^{2x} c_1}{8}\right) + e^{-2x} c_2
$$

which simplifies to

$$
y = e^{-2x} c_2 + \frac{(-1 - 5x)\cos(x)}{50} + \frac{(-5x + 14)\sin(x)}{100} + \frac{c_1}{8}
$$

Summary

The solution(s) found are the following

$$
y = e^{-2x} c_2 + \frac{(-1 - 5x)\cos(x)}{50} + \frac{(-5x + 14)\sin(x)}{100} + \frac{c_1}{8} \tag{1}
$$

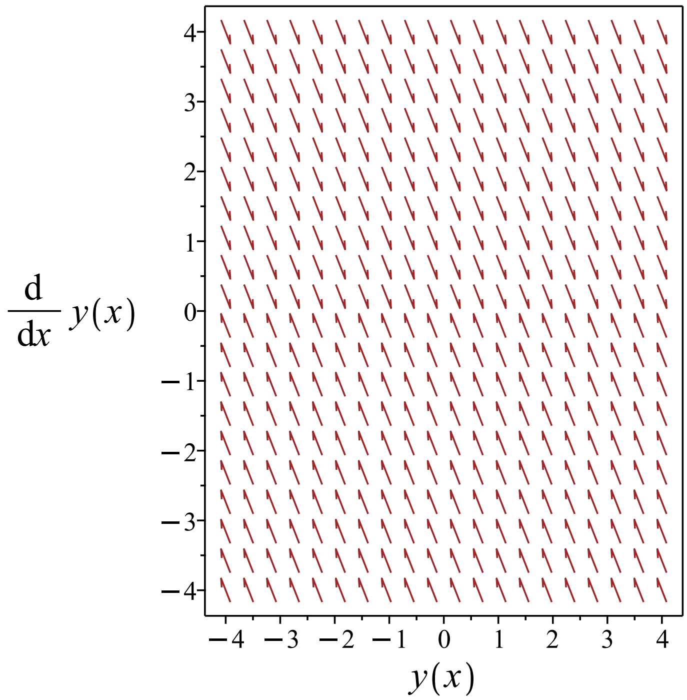

Figure 612: Slope field plot

Verification of solutions

$$y = e^{-2x}c_2 + \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100} + \frac{c_1}{8}$$

Verified OK.

16.63.5 Solving using Kovacic algorithm

Writing the ode as

$$4y'' + 8y' = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4 \\ B &= 8 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 479: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{8}{4}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{8}{4}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{2x}}{2}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-2x}\right) + c_2 \left(e^{-2x} \left(\frac{e^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
4y'' + 8y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{-2x} + \frac{c_2}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\sin(x)\, x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(x)\, x, \sin(x)\, x, \cos(x), \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{1}{2}, e^{-2x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos(x)\, x + A_2 \sin(x)\, x + A_3 \cos(x) + A_4 \sin(x)
$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}
&-4A_1 \cos(x) x - 8A_1 \sin(x) - 4A_2 \sin(x) x + 8A_2 \cos(x) \\
&- 4A_3 \cos(x) - 4A_4 \sin(x) - 8A_1 \sin(x) x + 8A_1 \cos(x) \\
&+ 8A_2 \cos(x) x + 8A_2 \sin(x) - 8A_3 \sin(x) + 8A_4 \cos(x) = \sin(x) x
\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{10}, A_2 = -\frac{1}{20}, A_3 = -\frac{1}{50}, A_4 = \frac{7}{50}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x) x}{10} - \frac{\sin(x) x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-2x} + \frac{c_2}{2}\right) + \left(-\frac{\cos(x) x}{10} - \frac{\sin(x) x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50}\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + \frac{c_2}{2} - \frac{\cos(x) x}{10} - \frac{\sin(x) x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50} \tag{1}$$

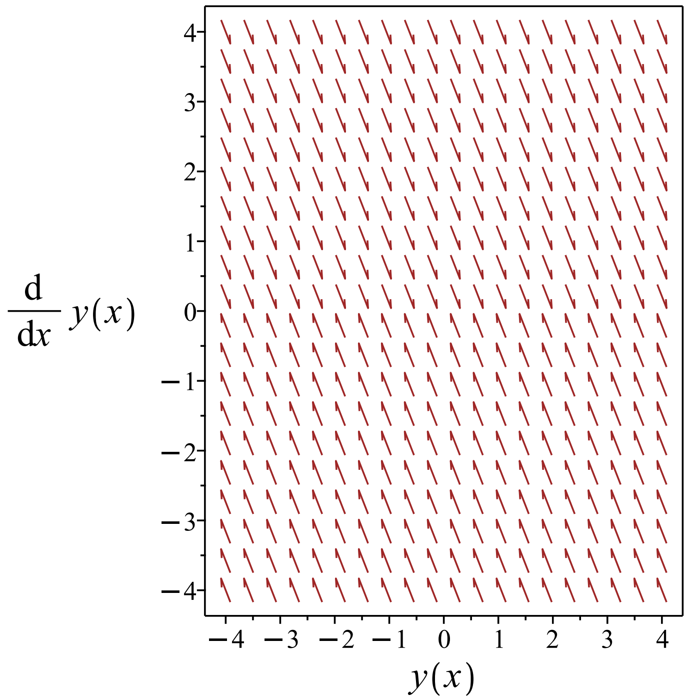

Figure 613: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{c_2}{2} - \frac{\cos(x)\, x}{10} - \frac{\sin(x)\, x}{20} - \frac{\cos(x)}{50} + \frac{7\sin(x)}{50}$$

Verified OK.

16.63.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 4 \\ q(x) &= 8 \\ r(x) &= 0 \\ s(x) &= \sin(x)\, x \end{aligned}$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 0
\end{aligned}
$$

Therefore (1) becomes

$$
0 - (0) + (0) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)
$$

Integrating gives

$$
p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx
$$

Substituting the above values for p, q, r, s gives

$$
8y + 4y' = \int \sin(x)\, x\, dx
$$

We now have a first order ode to solve which is

$$
8y + 4y' = \sin(x) - \cos(x)\, x + c_1
$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= 2 \\
q(x) &= \frac{\sin(x)}{4} - \frac{\cos(x)\, x}{4} + \frac{c_1}{4}
\end{aligned}
$$

Hence the ode is

$$
2y + y' = \frac{\sin(x)}{4} - \frac{\cos(x)\, x}{4} + \frac{c_1}{4}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 2dx} \\
&= e^{2x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{\sin(x)}{4}-\frac{\cos(x)\,x}{4}+\frac{c_1}{4}\right)\\
\frac{d}{dx}\left(e^{2x}y\right) &= \left(e^{2x}\right)\left(\frac{\sin(x)}{4}-\frac{\cos(x)\,x}{4}+\frac{c_1}{4}\right)\\
d\left(e^{2x}y\right) &= \left(\frac{(\sin(x)-\cos(x)\,x+c_1)\,e^{2x}}{4}\right)\,dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{2x}y &= \int \frac{(\sin(x)-\cos(x)\,x+c_1)\,e^{2x}}{4}\,dx\\
e^{2x}y &= -\frac{e^{2x}\cos(x)}{20}+\frac{e^{2x}\sin(x)}{10}-\frac{\left(\frac{2x}{5}-\frac{3}{25}\right)e^{2x}\cos(x)}{4}+\frac{\left(-\frac{x}{5}+\frac{4}{25}\right)e^{2x}\sin(x)}{4}+\frac{e^{2x}c_1}{8}+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$
y = e^{-2x}\left(-\frac{e^{2x}\cos(x)}{20}+\frac{e^{2x}\sin(x)}{10}-\frac{\left(\frac{2x}{5}-\frac{3}{25}\right)e^{2x}\cos(x)}{4}+\frac{\left(-\frac{x}{5}+\frac{4}{25}\right)e^{2x}\sin(x)}{4}+\frac{e^{2x}c_1}{8}\right)+e^{-2x}c_2
$$

which simplifies to

$$
y = e^{-2x}c_2+\frac{(-1-5x)\cos(x)}{50}+\frac{(-5x+14)\sin(x)}{100}+\frac{c_1}{8}
$$

Summary

The solution(s) found are the following

$$
y = e^{-2x}c_2+\frac{(-1-5x)\cos(x)}{50}+\frac{(-5x+14)\sin(x)}{100}+\frac{c_1}{8} \tag{1}
$$

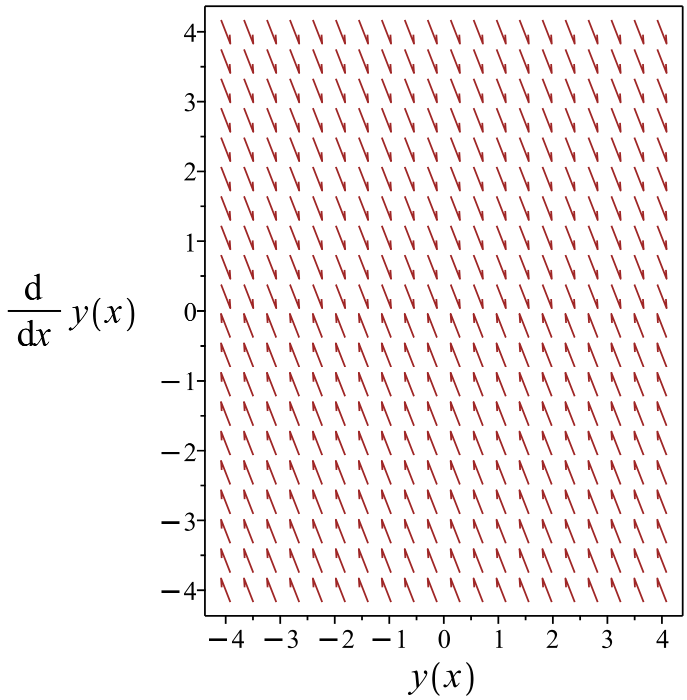

Figure 614: Slope field plot

Verification of solutions

$$y = e^{-2x}c_2 + \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100} + \frac{c_1}{8}$$

Verified OK.

16.63.7 Maple step by step solution

Let's solve

$4y'' + 8y' = \sin(x)\,x$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -2y' + \frac{\sin(x)x}{4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + 2y' = \frac{\sin(x)x}{4}$

- Characteristic polynomial of homogeneous ODE

$r^2 + 2r = 0$

- Factor the characteristic polynomial

  $r(r + 2) = 0$

- Roots of the characteristic polynomial

  $r = (-2, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{\sin(x) x}{4}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-2x} & 1 \\ -2\,\mathrm{e}^{-2x} & 0 \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\,\mathrm{e}^{-2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-2x} \left(\int \sin(x) x\, \mathrm{e}^{2x} dx\right)}{8} + \frac{\left(\int \sin(x) x dx\right)}{8}$

  ◦ Compute integrals

  $y_p(x) = \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-2x} + c_2 + \frac{(-1-5x)\cos(x)}{50} + \frac{(-5x+14)\sin(x)}{100}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 3y' + 2y = x\,\mathrm{e}^{x}}$$

16.64.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = x\,\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda \,\mathrm{e}^{\lambda x} + 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(2)}\\ &= \frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{3}{2} + \frac{1}{2}$$

$$\lambda_2 = \frac{3}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 2$$

$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$y = c_1 e^{(2)x} + c_2 e^{(1)x}$$

Or

$$y = \mathrm{e}^{2x} c_1 + \mathrm{e}^{x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{2x} c_1 + \mathrm{e}^{x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\,e^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,e^{x}, e^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{2x}\}$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{x}, e^{x}x^{2}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{x} + A_2 e^{x} x^{2}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 e^{x} - 2A_2 e^{x} x + 2A_2 e^{x} = x\,e^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -1, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x\,e^{x} - \frac{e^{x}x^{2}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}c_1 + e^{x}c_2\right) + \left(-x\,e^{x} - \frac{e^{x}x^{2}}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{2x} c_1 + e^x c_2 - x\,e^x - \frac{e^x x^2}{2} \tag{1}$$

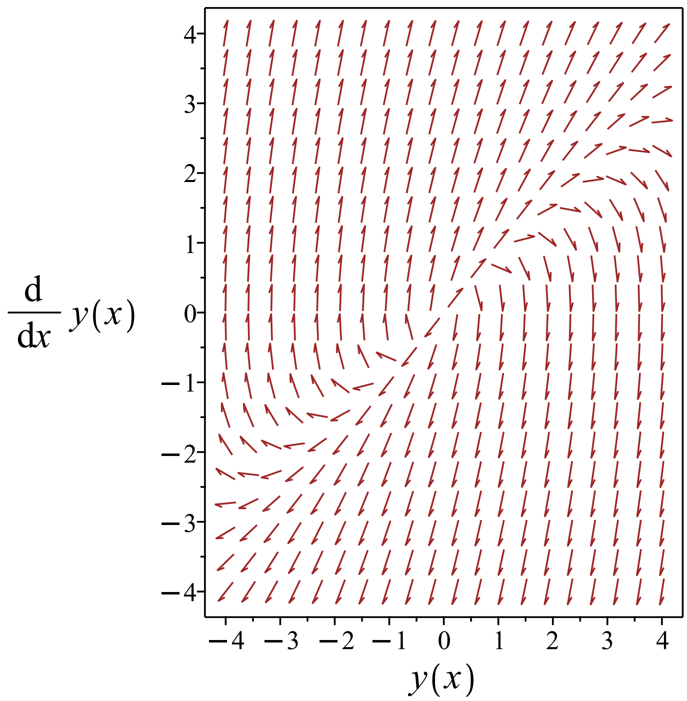

Figure 615: Slope field plot

Verification of solutions

$$y = e^{2x} c_1 + e^x c_2 - x\,e^x - \frac{e^x x^2}{2}$$

Verified OK.

16.64.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 481: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-3}{1} \, dx} \\
&= z_1 e^{\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2}\, dx \\ &= y_1(e^x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(e^x) + c_2(e^x(e^x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^x c_1 + e^{2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x\, e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\mathrm{e}^{x}, \mathrm{e}^{2x}\}$$

Since e^{x} is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}x^{2}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,\mathrm{e}^{x} + A_2 \mathrm{e}^{x} x^{2}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1\mathrm{e}^{x} - 2A_2\mathrm{e}^{x}x + 2A_2\mathrm{e}^{x} = x\,\mathrm{e}^{x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -1, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x\,\mathrm{e}^{x} - \frac{\mathrm{e}^{x}x^{2}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\mathrm{e}^{x}c_1 + \mathrm{e}^{2x}c_2\right) + \left(-x\,\mathrm{e}^{x} - \frac{\mathrm{e}^{x}x^{2}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x}c_1 + \mathrm{e}^{2x}c_2 - x\,\mathrm{e}^{x} - \frac{\mathrm{e}^{x}x^{2}}{2} \tag{1}$$

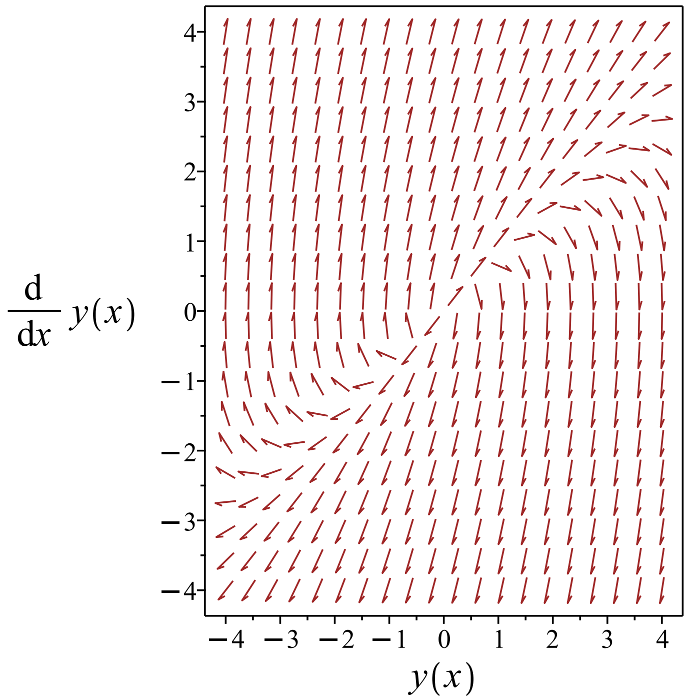

Figure 616: Slope field plot

<u>Verification of solutions</u>

$$y = e^x c_1 + e^{2x} c_2 - x e^x - \frac{e^x x^2}{2}$$

Verified OK.

16.64.3 Maple step by step solution

Let's solve

$y'' - 3y' + 2y = x e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

$r = (1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + e^{2x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x\,e^x\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{2x} \\ e^x & 2\,e^{2x} \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{3x}$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x) = -e^x\left(\int x dx\right) + e^{2x}\left(\int x\,e^{-x} dx\right)$

  ◦ Compute integrals

    $y_p(x) = e^x\left(-1 - \frac{1}{2}x^2 - x\right)$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + e^{2x} c_2 + e^x\left(-1 - \frac{1}{2}x^2 - x\right)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' - 2y = x^2 \mathrm{e}^{4x}}$$

16.65.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = -2, f(x) = x^2 \mathrm{e}^{4x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \lambda\, \mathrm{e}^{\lambda x} - 2\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{1^2 - (4)\,(1)\,(-2)}\\ &= -\frac{1}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2} + \frac{3}{2}\\ \lambda_2 &= -\frac{1}{2} - \frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(1)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = \mathrm{e}^{x} c_1 + \mathrm{e}^{-2x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x} c_1 + \mathrm{e}^{-2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^{4x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x^2 e^{4x}, e^{4x} x, e^{4x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{-2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x^2 e^{4x} + A_2 e^{4x} x + A_3 e^{4x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{4x} + 18A_1 x\, e^{4x} + 18A_1 x^2 e^{4x} + 18A_2 e^{4x} x + 9A_2 e^{4x} + 18A_3 e^{4x} = x^2 e^{4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{18}, A_2 = -\frac{1}{18}, A_3 = \frac{7}{324}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7\, e^{4x}}{324}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + e^{-2x} c_2\right) + \left(\frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7\, e^{4x}}{324}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{x} c_1 + e^{-2x} c_2 + \frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7 e^{4x}}{324} \tag{1}$$

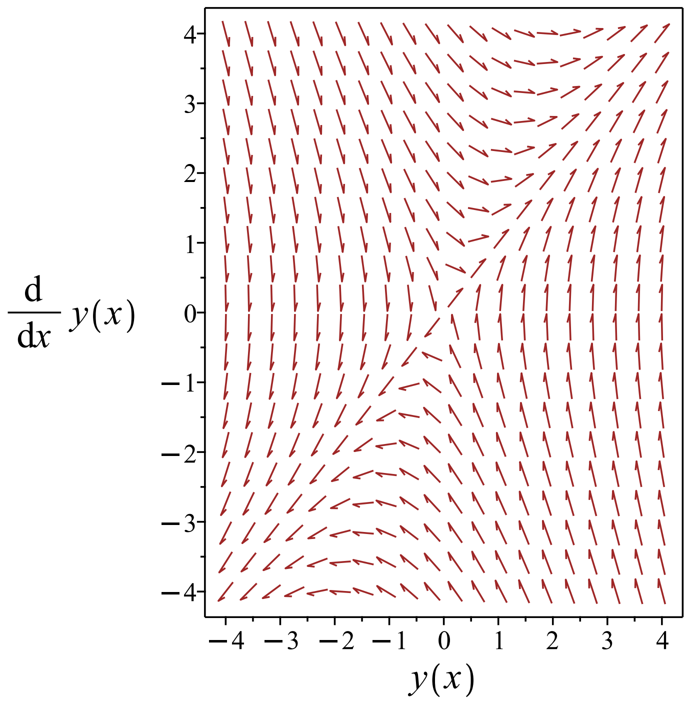

Figure 617: Slope field plot

Verification of solutions

$$y = e^{x} c_1 + e^{-2x} c_2 + \frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7 e^{4x}}{324}$$

Verified OK.

16.65.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' - 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 1 \\
C &= -2
\end{aligned}
\tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{9}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 9 \\
t &= 4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \frac{9z(x)}{4} \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 483: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{3x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{3x}}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' - 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-2x} + \frac{\mathrm{e}^{x} c_2}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \mathrm{e}^{4x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x^2 e^{4x}, e^{4x} x, e^{4x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{e^x}{3}, e^{-2x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x^2 e^{4x} + A_2 e^{4x} x + A_3 e^{4x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{4x} + 18A_1 x\, e^{4x} + 18A_1 x^2 e^{4x} + 18A_2 e^{4x} x + 9A_2 e^{4x} + 18A_3 e^{4x} = x^2 e^{4x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{18}, A_2 = -\frac{1}{18}, A_3 = \frac{7}{324}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7\, e^{4x}}{324}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + \frac{e^x c_2}{3}\right) + \left(\frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7\, e^{4x}}{324}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-2x} + \frac{e^x c_2}{3} + \frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7\, e^{4x}}{324} \tag{1}$$

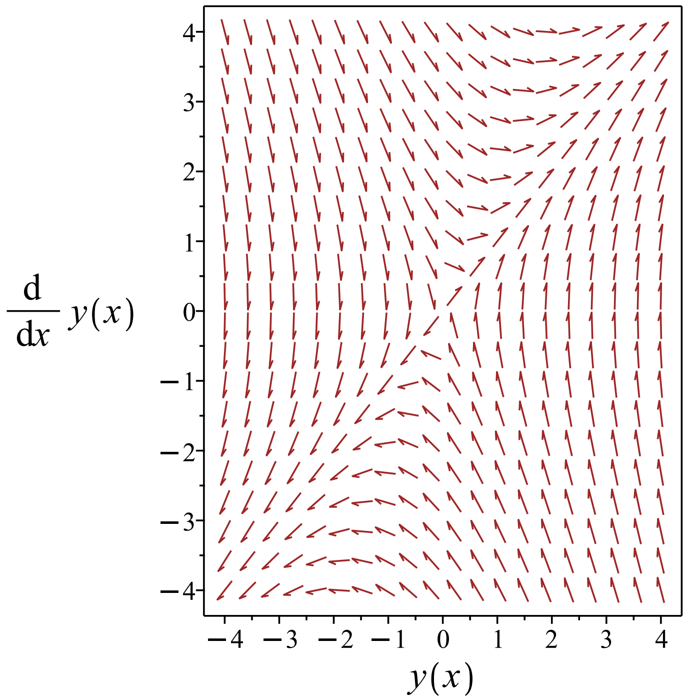

Figure 618: Slope field plot

Verification of solutions

$$y = c_1 e^{-2x} + \frac{e^x c_2}{3} + \frac{x^2 e^{4x}}{18} - \frac{e^{4x} x}{18} + \frac{7 e^{4x}}{324}$$

Verified OK.

16.65.3 Maple step by step solution

Let's solve

$y'' + y' - 2y = x^2 e^{4x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r - 2 = 0$

- Factor the characteristic polynomial

  $(r+2)(r-1) = 0$

- Roots of the characteristic polynomial

$r = (-2, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-2x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-2x} + e^{x} c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 e^{4x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & e^{x} \\ -2\,e^{-2x} & e^{x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3\,e^{-x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\left(e^{3x}\left(\int x^2 e^{3x} dx\right) - \left(\int x^2 e^{6x} dx\right)\right) e^{-2x}}{3}$

  ◦ Compute integrals

  $y_p(x) = \frac{e^{4x}(18x^2 - 18x + 7)}{324}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + e^{x} c_2 + \frac{e^{4x}(18x^2 - 18x + 7)}{324}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 3y' + 2y = (x^2 + x)\, e^{3x}}$$

16.66.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = x(x+1)\, e^{3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda \,\mathrm{e}^{\lambda x} + 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(2)}\\ &= \frac{3}{2} \pm \frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{3}{2} + \frac{1}{2}$$
$$\lambda_2 = \frac{3}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 2$$
$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(2)x} + c_2 e^{(1)x}$$

Or

$$y = \mathrm{e}^{2x} c_1 + \mathrm{e}^{x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x}c_1 + e^{x}c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x(x+1)\,e^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x^2 e^{3x}, e^{3x}x, e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x^2 e^{3x} + A_2 e^{3x} x + A_3 e^{3x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{3x} + 6A_1 x\,e^{3x} + 2A_1 x^2 e^{3x} + 2A_2 e^{3x} x + 3A_2 e^{3x} + 2A_3 e^{3x} = x(x+1)\,e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -1, A_3 = 1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{3x}}{2} - e^{3x} x + e^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}c_1 + e^{x}c_2\right) + \left(\frac{x^2 e^{3x}}{2} - e^{3x} x + e^{3x}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{2x}c_1 + e^x c_2 + \frac{x^2 e^{3x}}{2} - e^{3x}x + e^{3x} \tag{1}$$

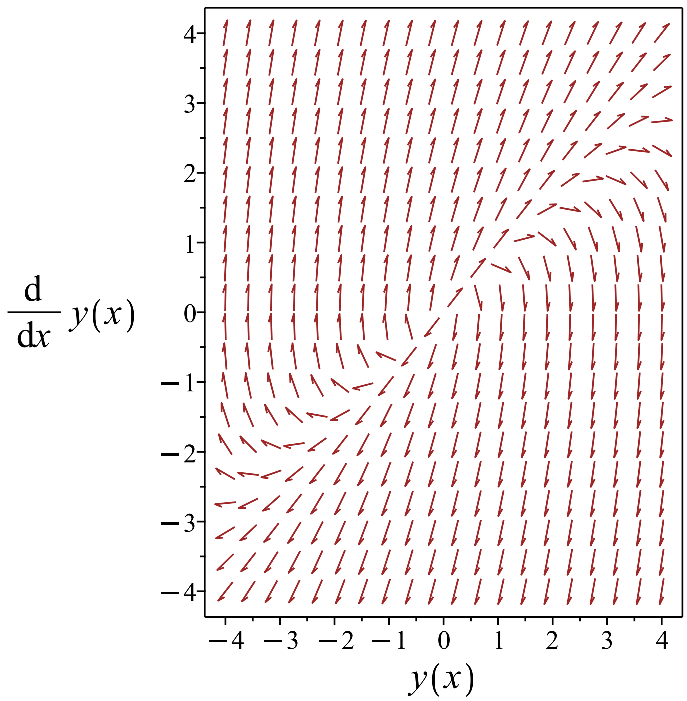

Figure 619: Slope field plot

Verification of solutions

$$y = e^{2x}c_1 + e^x c_2 + \frac{x^2 e^{3x}}{2} - e^{3x}x + e^{3x}$$

Verified OK.

16.66.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 485: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-3}{1} \, dx} \\ &= z_1 e^{\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} dx}}{y_1^2} dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1} dx}}{(y_1)^2} dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2} dx \\ &= y_1(e^x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(e^x) + c_2(e^x(e^x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^x c_1 + e^{2x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x(x + 1) e^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x^2 e^{3x}, e^{3x} x, e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 x^2 e^{3x} + A_2 e^{3x} x + A_3 e^{3x}$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{3x} + 6A_1 x\, e^{3x} + 2A_1 x^2 e^{3x} + 2A_2 e^{3x} x + 3A_2 e^{3x} + 2A_3 e^{3x} = x(x+1)\, e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -1, A_3 = 1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 e^{3x}}{2} - e^{3x} x + e^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + e^{2x} c_2) + \left(\frac{x^2 e^{3x}}{2} - e^{3x} x + e^{3x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x c_1 + e^{2x} c_2 + \frac{x^2 e^{3x}}{2} - e^{3x} x + e^{3x} \tag{1}$$

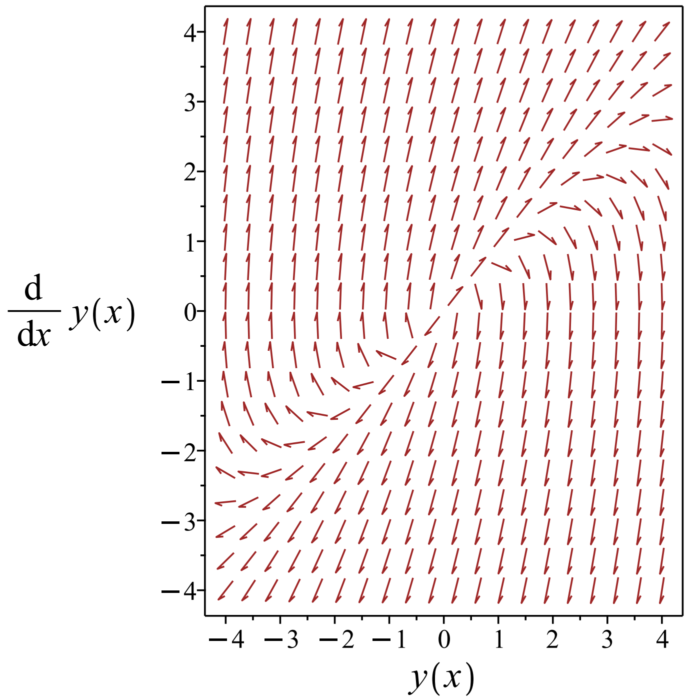

Figure 620: Slope field plot

Verification of solutions

$$y = e^x c_1 + e^{2x} c_2 + \frac{x^2 e^{3x}}{2} - e^{3x} x + e^{3x}$$

Verified OK.

16.66.3 Maple step by step solution

Let's solve

$y'' - 3y' + 2y = x(x+1)\,e^{3x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

$r = (1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^x c_1 + e^{2x} c_2 + y_p(x)$

- □ Find a particular solution $y_p(x)$ of the ODE
  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x(x+1)\,e^{3x}\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{2x} \\ e^x & 2\,e^{2x} \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{3x}$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -e^x\left(\int e^{2x} x(x+1)\,dx\right) + e^{2x}\left(\int x(x+1)\,e^x dx\right)$
  - Compute integrals

    $y_p(x) = e^{3x}\left(\frac{1}{2}x^2 - x + 1\right)$

- Substitute particular solution into general solution to ODE

  $y = e^x c_1 + e^{2x} c_2 + e^{3x}\left(\frac{1}{2}x^2 - x + 1\right)$

Problem number: 540.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{y''' - y'' + y' - y = x^2 + x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y'' + y' - y = 0$$

The characteristic equation is

$$\lambda^3 - \lambda^2 + \lambda - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + e^{ix} c_2 + e^{-ix} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = e^{ix}$$
$$y_3 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y''' - y'' + y' - y = x^2 + x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^x, e^{ix}, e^{-ix}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_3 x^2 + A_2 x + A_1$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_3 x^2 - A_2 x + 2x A_3 - A_1 + A_2 - 2A_3 = x^2 + x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = -3, A_3 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x^2 - 3x - 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + e^{ix} c_2 + e^{-ix} c_3\right) + \left(-x^2 - 3x - 1\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x c_1 + e^{ix} c_2 + e^{-ix} c_3 - x^2 - 3x - 1 \tag{1}$$

Verification of solutions

$$y = e^x c_1 + e^{ix} c_2 + e^{-ix} c_3 - x^2 - 3x - 1$$

Verified OK.

16.67.1 Maple step by step solution

Let's solve

$y''' - y'' + y' - y = x^2 + x$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = x^2 + y_3(x) - y_2(x) + y_1(x) + x$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = x^2 + y_3(x) - y_2(x) + y_1(x) + x]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -1 & 1 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ x^2 + x \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ x^2 + x \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -1 \\ I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\cos(x) + I\sin(x) \\ I(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\overrightarrow{y}_2(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \overrightarrow{y}_3(x) = \begin{bmatrix} \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{y}_p($

$$\overrightarrow{y}(x) = c_1\overrightarrow{y}_1 + c_2\overrightarrow{y}_2(x) + c_3\overrightarrow{y}_3(x) + \overrightarrow{y}_p(x)$$

☐ Fundamental matrix

  - Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x)=\begin{bmatrix} e^{x} & -\cos(x) & \sin(x) \\ e^{x} & \sin(x) & \cos(x) \\ e^{x} & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0)=I$ where I is t
  $\Phi(x)=\phi(x)\cdot\frac{1}{\phi(0)}$
- Substitute the value of $\phi(x)$ and $\phi(0)$
  $$\Phi(x)=\begin{bmatrix} e^{x} & -\cos(x) & \sin(x) \\ e^{x} & \sin(x) & \cos(x) \\ e^{x} & \cos(x) & -\sin(x) \end{bmatrix}\cdot\frac{1}{\begin{bmatrix} 1 & -1 & 0 \\ 1 & 0 & 1 \\ 1 & 1 & 0 \end{bmatrix}}$$
- Evaluate and simplify to get the fundamental matrix
  $$\Phi(x)=\begin{bmatrix} \frac{e^{x}}{2}+\frac{\cos(x)}{2}-\frac{\sin(x)}{2} & \sin(x) & \frac{e^{x}}{2}-\frac{\cos(x)}{2}-\frac{\sin(x)}{2} \\ \frac{e^{x}}{2}-\frac{\cos(x)}{2}-\frac{\sin(x)}{2} & \cos(x) & \frac{e^{x}}{2}+\frac{\sin(x)}{2}-\frac{\cos(x)}{2} \\ \frac{e^{x}}{2}+\frac{\sin(x)}{2}-\frac{\cos(x)}{2} & -\sin(x) & \frac{e^{x}}{2}+\frac{\cos(x)}{2}+\frac{\sin(x)}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$
  $\vec{y}_p(x)=\Phi(x)\cdot\vec{v}(x)$
- Take the derivative of the particular solution
  $\vec{y}'_p(x)=\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs
  $\Phi'(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der
  $A\cdot\Phi(x)\cdot\vec{v}(x)+\Phi(x)\cdot\vec{v}'(x)=A\cdot\Phi(x)\cdot\vec{v}(x)+\vec{f}(x)$
- Cancel like terms
  $\Phi(x)\cdot\vec{v}'(x)=\vec{f}(x)$
- Multiply by the inverse of the fundamental matrix
  $\vec{v}'(x)=\frac{1}{\Phi(x)}\cdot\vec{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$
- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} -x^2 + \frac{3\,\mathrm{e}^x}{2} - 3x - 1 - \frac{\cos(x)}{2} + \frac{3\sin(x)}{2} \\ \frac{3\,\mathrm{e}^x}{2} - 2x - 3 + \frac{3\cos(x)}{2} + \frac{\sin(x)}{2} \\ \frac{3\,\mathrm{e}^x}{2} - 2 + \frac{\cos(x)}{2} - \frac{3\sin(x)}{2} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3(x) + \left[\begin{array}{c} -x^2 + \frac{3\,\mathrm{e}^x}{2} - 3x - 1 - \frac{\cos(x)}{2} + \frac{3\sin(x)}{2} \\ \frac{3\,\mathrm{e}^x}{2} - 2x - 3 + \frac{3\cos(x)}{2} + \frac{\sin(x)}{2} \\ \frac{3\,\mathrm{e}^x}{2} - 2 + \frac{\cos(x)}{2} - \frac{3\sin(x)}{2} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(-2c_2-1)\cos(x)}{2} + \frac{(2c_1+3)\mathrm{e}^x}{2} + \frac{(2c_3+3)\sin(x)}{2} - x^2 - 3x - 1$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 541.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _with_linear_symmetries]]
```

$$\boxed{y'''' - 2y''' + 2y'' - 2y' + y = e^{x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 2y''' + 2y'' - 2y' + y = 0$$

The characteristic equation is

$$\lambda^4 - 2\lambda^3 + 2\lambda^2 - 2\lambda + 1 = 0$$

The roots of the above equation are

$$\begin{aligned}
\lambda_1 &= i \\
\lambda_2 &= -i \\
\lambda_3 &= 1 \\
\lambda_4 &= 1
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + x e^x c_2 + e^{ix} c_3 + e^{-ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = x e^x$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' - 2y''' + 2y'' - 2y' + y = e^x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^x, e^x, e^{ix}, e^{-ix}\}$$

Since e^x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x e^x\}]$$

Since $x e^x$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{e^x x^2\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 e^x x^2$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x x^2}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + x e^x c_2 + e^{ix} c_3 + e^{-ix} c_4\right) + \left(\frac{e^x x^2}{4}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-ix} c_4 + e^{ix} c_3 + e^x (c_2 x + c_1) + \frac{e^x x^2}{4}$$

Summary

The solution(s) found are the following

$$y = e^{-ix} c_4 + e^{ix} c_3 + e^x (c_2 x + c_1) + \frac{e^x x^2}{4} \tag{1}$$

Verification of solutions

$$y = e^{-ix} c_4 + e^{ix} c_3 + e^x (c_2 x + c_1) + \frac{e^x x^2}{4}$$

Verified OK.

16.68.1 Maple step by step solution

Let's solve

$y'''' - 2y''' + 2y'' - 2y' + y = e^{x}$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Define new variable $y_4(x)$

    $y_4(x) = y'''$

  ◦ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = e^{x} + 2y_4(x) - 2y_3(x) + 2y_2(x) - y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = e^{x} + 2y_4(x) - 2y_3(x) + 2y_2(x) - y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 2 & -2 & 2 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 0 \\ e^{x} \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 0 \\ e^{x} \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 2 & -2 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[-I, \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}\right], \left[I, \begin{bmatrix} I \\ -1 \\ -I \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 1

$$\vec{y}_1(x) = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$\vec{y}_2(x) = e^{\lambda x}\left(x\vec{v} + \vec{p}\right)$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

  $\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = \left(e^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$
- Use the fact that $\vec{v}$ is an eigenvector of A

  $\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = e^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$
- Simplify equation

  $\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$
- Make use of the identity matrix I

  $(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$
- Condition $\vec{p}$ must meet for $\vec{y}_2(x)$ to be a solution to the homogeneous system

  $(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$
- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & 2 & -2 & 2 \end{bmatrix} - 1 \cdot \begin{bmatrix} 1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 1

$$\vec{y}_2(x) = e^{x} \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-\mathrm{I}x} \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x) + \vec{y}_p(x)$

□ Fundamental matrix

  ○ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^x & (x-1)e^x & -\sin(x) & -\cos(x) \\ e^x & x e^x & -\cos(x) & \sin(x) \\ e^x & x e^x & \sin(x) & \cos(x) \\ e^x & x e^x & \cos(x) & -\sin(x) \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$
- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^x & (x-1)e^x & -\sin(x) & -\cos(x) \\ e^x & x e^x & -\cos(x) & \sin(x) \\ e^x & x e^x & \sin(x) & \cos(x) \\ e^x & x e^x & \cos(x) & -\sin(x) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & -1 & 0 & -1 \\ 1 & 0 & -1 & 0 \\ 1 & 0 & 0 & 1 \\ 1 & 0 & 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} -(x-1)e^x & x e^x - \frac{e^x}{2} + \frac{\cos(x)}{2} + \frac{\sin(x)}{2} & -x e^x + e^x - \cos(x) & x e^x - \frac{e^x}{2} + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \\ -x e^x & \frac{e^x}{2} + x e^x + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} & -x e^x + \sin(x) & \frac{e^x}{2} + x e^x - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \\ -x e^x & \frac{e^x}{2} + x e^x - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} & -x e^x + \cos(x) & \frac{e^x}{2} + x e^x + \frac{\sin(x)}{2} - \frac{\cos(x)}{2} \\ -x e^x & \frac{e^x}{2} + x e^x + \frac{\sin(x)}{2} - \frac{\cos(x)}{2} & -x e^x - \sin(x) & \frac{e^x}{2} + x e^x + \frac{\cos(x)}{2} + \frac{\sin(x)}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$
- Take the derivative of the particular solution

  $\vec{y}'_p(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

$\Phi(x) \cdot \overrightarrow{v}'(x) = \overrightarrow{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(x) = \frac{1}{\Phi(x)} \cdot \overrightarrow{f}(x)$

- Integrate to solve for $\overrightarrow{v}(x)$

  $\overrightarrow{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds$

- Plug $\overrightarrow{v}(x)$ into the equation for the particular solution

  $\overrightarrow{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \overrightarrow{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{y}_p(x) = \left[\begin{array}{c} \frac{(x^2-x)\mathrm{e}^x}{2} + \frac{\sin(x)}{2} \\ \frac{(x^2+x-1)\mathrm{e}^x}{2} + \frac{\cos(x)}{2} \\ \frac{(x^2+x)\mathrm{e}^x}{2} - \frac{\sin(x)}{2} \\ \frac{(x^2+x+1)\mathrm{e}^x}{2} - \frac{\cos(x)}{2} \end{array}\right]$$

- Plug particular solution back into general solution

$$\overrightarrow{y}(x) = c_1 \overrightarrow{y}_1(x) + c_2 \overrightarrow{y}_2(x) + c_3 \overrightarrow{y}_3(x) + c_4 \overrightarrow{y}_4(x) + \left[\begin{array}{c} \frac{(x^2-x)\mathrm{e}^x}{2} + \frac{\sin(x)}{2} \\ \frac{(x^2+x-1)\mathrm{e}^x}{2} + \frac{\cos(x)}{2} \\ \frac{(x^2+x)\mathrm{e}^x}{2} - \frac{\sin(x)}{2} \\ \frac{(x^2+x+1)\mathrm{e}^x}{2} - \frac{\cos(x)}{2} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = \frac{(x^2+(2c_2-1)x+2c_1-2c_2)\mathrm{e}^x}{2} + \frac{(-2c_3+1)\sin(x)}{2} - \cos(x)\, c_4$$

Problem number: 542.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = x^3}$$

16.69.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)}\\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^{x} + c_2 x e^{x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{x} c_1 + x e^{x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^3$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2, x^3\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^{x}, e^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_4x^3 + A_3x^2 + A_2x + A_1$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_4x^3 + A_3x^2 - 6x^2A_4 + A_2x - 4xA_3 + 6xA_4 + A_1 - 2A_2 + 2A_3 = x^3$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 24, A_2 = 18, A_3 = 6, A_4 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^3 + 6x^2 + 18x + 24$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + x e^x c_2) + \left(x^3 + 6x^2 + 18x + 24\right) \end{aligned}$$

Which simplifies to

$$y = e^x(c_2x + c_1) + x^3 + 6x^2 + 18x + 24$$

Summary

The solution(s) found are the following

$$y = e^x(c_2x + c_1) + x^3 + 6x^2 + 18x + 24 \tag{1}$$

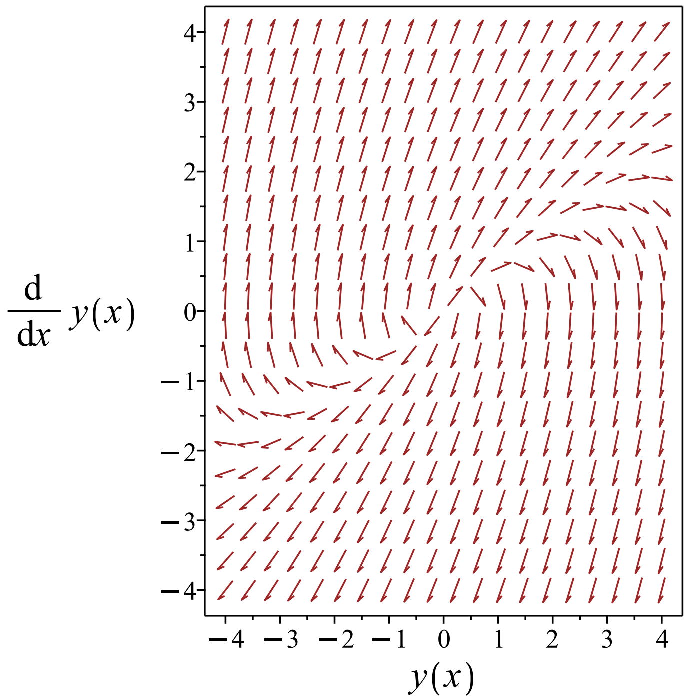

Figure 621: Slope field plot

Verification of solutions

$$y = e^x(c_2x + c_1) + x^3 + 6x^2 + 18x + 24$$

Verified OK.

16.69.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2\, dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= e^{-x}x^3 \\
(e^{-x}y)'' &= e^{-x}x^3
\end{aligned}
$$

Integrating once gives

$$
(e^{-x}y)' = -(x^3 + 3x^2 + 6x + 6)\,e^{-x} + c_1
$$

Integrating again gives

$$
(e^{-x}y) = (x^3 + 6x^2 + 18x + 24)\,e^{-x} + c_1x + c_2
$$

Hence the solution is

$$
y = \frac{(x^3 + 6x^2 + 18x + 24)\,e^{-x} + c_1x + c_2}{e^{-x}}
$$

Or

$$
y = c_1x\,e^{x} + x^3 + e^{x}c_2 + 6x^2 + 18x + 24
$$

Summary

The solution(s) found are the following

$$
y = c_1x\,e^{x} + x^3 + e^{x}c_2 + 6x^2 + 18x + 24 \tag{1}
$$

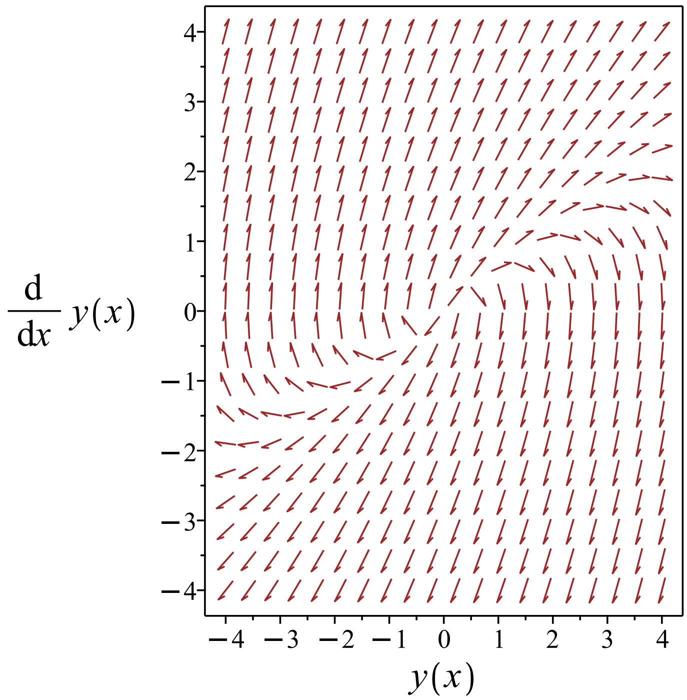

Figure 622: Slope field plot

Verification of solutions

$$y = c_1 x\,\mathrm{e}^x + x^3 + \mathrm{e}^x c_2 + 6x^2 + 18x + 24$$

Verified OK.

16.69.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 489: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \mathrm{e}^x c_1 + x\,\mathrm{e}^x c_2
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x^3
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x, x^2, x^3\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^x, \mathrm{e}^x\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_4 x^3 + A_3 x^2 + A_2 x + A_1
$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
A_4 x^3 + A_3 x^2 - 6x^2 A_4 + A_2 x - 4x A_3 + 6x A_4 + A_1 - 2A_2 + 2A_3 = x^3
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 24, A_2 = 18, A_3 = 6, A_4 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^3 + 6x^2 + 18x + 24$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + x\,e^x c_2) + \left(x^3 + 6x^2 + 18x + 24\right) \end{aligned}$$

Which simplifies to

$$y = e^x(c_2 x + c_1) + x^3 + 6x^2 + 18x + 24$$

Summary
The solution(s) found are the following

$$y = e^x(c_2 x + c_1) + x^3 + 6x^2 + 18x + 24 \tag{1}$$

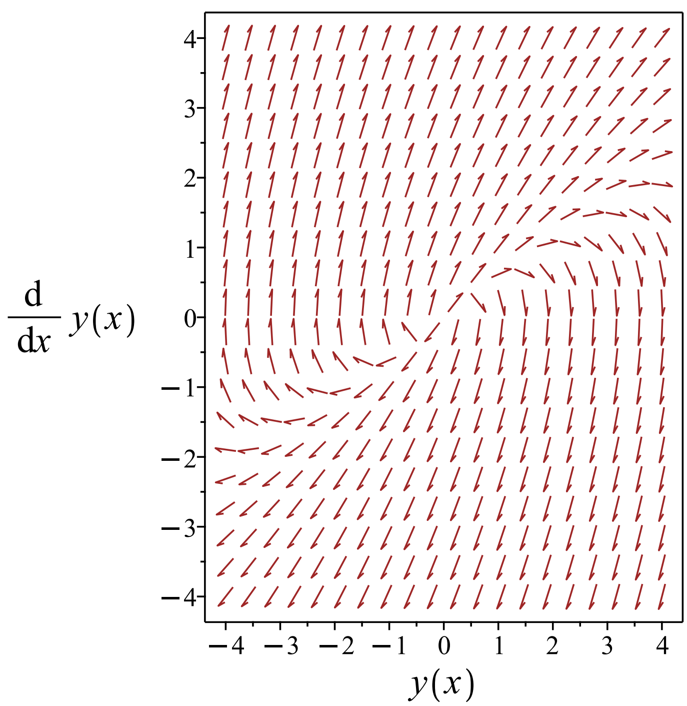

Figure 623: Slope field plot

Verification of solutions

$$y = e^{x}(c_2 x + c_1) + x^3 + 6x^2 + 18x + 24$$

Verified OK.

16.69.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = x^3$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

  $r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{x} c_1 + x\,e^{x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x^3\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{x} & x\,e^{x} \\ e^{x} & x\,e^{x} + e^{x} \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{2x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^x \left(-\left(\int x^4 e^{-x} dx\right) + \left(\int e^{-x} x^3 dx\right) x\right)$
- Compute integrals

  $y_p(x) = x^3 + 6x^2 + 18x + 24$

- Substitute particular solution into general solution to ODE

  $y = x\, e^x c_2 + x^3 + e^x c_1 + 6x^2 + 18x + 24$

Problem number: 543.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{y'''' + y'' = x^2 + x}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' + y'' = 0$$

The characteristic equation is

$$\lambda^4 + \lambda^2 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = i$$
$$\lambda_4 = -i$$

Therefore the homogeneous solution is

$$y_h(x) = c_2x + c_1 + e^{ix}c_3 + e^{-ix}c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = e^{ix}$$
$$y_4 = e^{-ix}$$

Now the particular solution to the given ODE is found

$$y'''' + y'' = x^2 + x$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 + x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x, x^2\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, e^{ix}, e^{-ix}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x, x^2, x^3\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2, x^3, x^4\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_3x^4 + A_2x^3 + A_1x^2$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$12x^2A_3 + 6xA_2 + 2A_1 + 24A_3 = x^2 + x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -1, A_2 = \frac{1}{6}, A_3 = \frac{1}{12}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{1}{12}x^4 + \frac{1}{6}x^3 - x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2x + c_1 + e^{ix}c_3 + e^{-ix}c_4) + \left(\frac{1}{12}x^4 + \frac{1}{6}x^3 - x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2x + c_1 + e^{ix}c_3 + e^{-ix}c_4 + \frac{x^4}{12} + \frac{x^3}{6} - x^2 \tag{1}$$

Verification of solutions

$$y = c_2x + c_1 + e^{ix}c_3 + e^{-ix}c_4 + \frac{x^4}{12} + \frac{x^3}{6} - x^2$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = x^2 \sin(x)}$$

16.71.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = x^2 \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$y = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x^2 \cos(x), x^2 \sin(x), \cos(x) x, \sin(x) x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 \cos(x), x^2 \sin(x), x^3 \cos(x), x^3 \sin(x), \cos(x) x, \sin(x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 \cos(x) + A_2 x^2 \sin(x) + A_3 x^3 \cos(x) + A_4 x^3 \sin(x) + A_5 \cos(x) x + A_6 \sin(x) x$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} &2A_1 \cos(x) - 4A_1 x \sin(x) + 2A_2 \sin(x) + 4A_2 x \cos(x) + 6A_3 x \cos(x) - 6A_3 x^2 \sin(x) \\ &+ 6A_4 x \sin(x) + 6A_4 x^2 \cos(x) - 2A_5 \sin(x) + 2A_6 \cos(x) = x^2 \sin(x) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}, A_3 = -\frac{1}{6}, A_4 = 0, A_5 = \frac{1}{4}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x) x}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x) x}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x) x}{4} \tag{1}$$

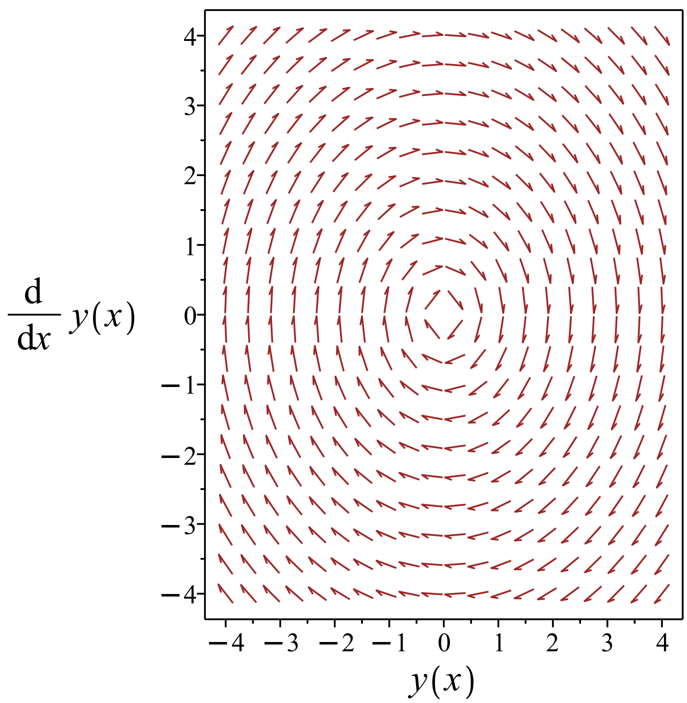

Figure 624: Slope field plot

Verification of solutions

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x) x}{4}$$

Verified OK.

16.71.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 491: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}
$$

Since $B=0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B=0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)\,(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)\,(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 \sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{x^2 \cos(x), x^2 \sin(x), \cos(x) x, \sin(x) x, \cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2 \cos(x), x^2 \sin(x), x^3 \cos(x), x^3 \sin(x), \cos(x) x, \sin(x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x^2 \cos(x) + A_2 x^2 \sin(x) + A_3 x^3 \cos(x) + A_4 x^3 \sin(x) + A_5 \cos(x) x + A_6 \sin(x) x$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned} &2A_1 \cos(x) - 4A_1 x \sin(x) + 2A_2 \sin(x) + 4A_2 x \cos(x) + 6A_3 x \cos(x) - 6A_3 x^2 \sin(x) \\ &+ 6A_4 x \sin(x) + 6A_4 x^2 \cos(x) - 2A_5 \sin(x) + 2A_6 \cos(x) = x^2 \sin(x) \end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}, A_3 = -\frac{1}{6}, A_4 = 0, A_5 = \frac{1}{4}, A_6 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x) x}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x)\, x}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x)\, x}{4} \tag{1}
$$

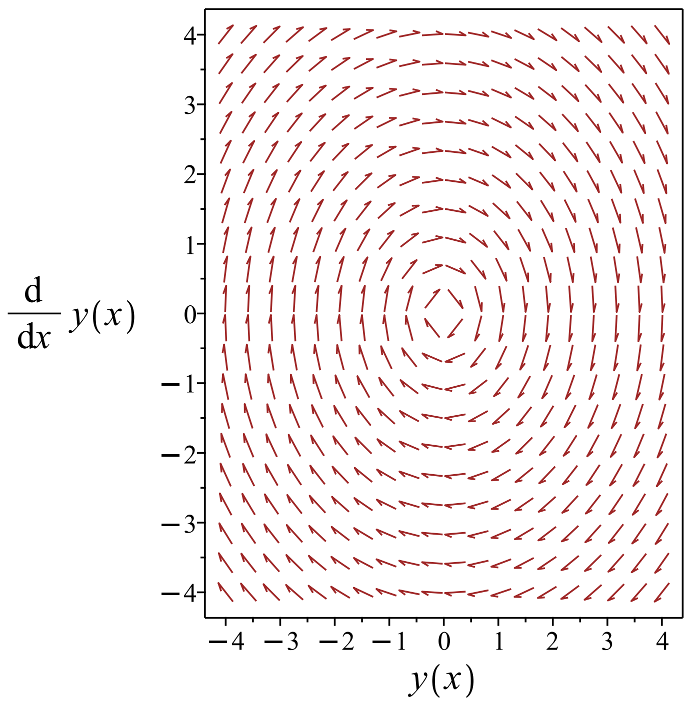

Figure 625: Slope field plot

Verification of solutions

$$
y = c_1 \cos(x) + c_2 \sin(x) + \frac{x^2 \sin(x)}{4} - \frac{x^3 \cos(x)}{6} + \frac{\cos(x)\, x}{4}
$$

Verified OK.

16.71.3 Maple step by step solution

Let's solve

$y'' + y = x^2 \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''
- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$
- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(x) + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x^2 \sin(x)\right]$
- Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
- Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$
- Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\cos(x)\left(\int \sin(x)^2 x^2 dx\right) + \frac{\sin(x)\left(\int \sin(2x) x^2 dx\right)}{2}$$

- Compute integrals

$$y_p(x) = \frac{(-2x^3+3x)\cos(x)}{12} + \frac{\sin(x)(2x^2-1)}{8}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 \cos(x) + c_2 \sin(x) + \frac{(-2x^3+3x)\cos(x)}{12} + \frac{\sin(x)(2x^2-1)}{8}$$

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 2y' + y = x^2 e^{-x} \cos(x)}$$

16.72.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 1, f(x) = x^2 e^{-x} \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(2)^2 - (4)\,(1)\,(1)}\\ &= -1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 1$. Therefore the solution is

$$y = c_1 e^{-x} + c_2 x\, e^{-x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{-x} + c_2 x\, e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x^2 e^{-x} \cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x} \cos(x), e^{-x} \sin(x), x \cos(x) e^{-x}, x \sin(x) e^{-x}, x^2 e^{-x} \cos(x), x^2 \sin(x) e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\, e^{-x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
\begin{aligned}
y_p = {} & A_1 \mathrm{e}^{-x} \cos(x) + A_2 \mathrm{e}^{-x} \sin(x) + A_3 x \cos(x) \mathrm{e}^{-x} \\
& + A_4 x \sin(x) \mathrm{e}^{-x} + A_5 x^2 \mathrm{e}^{-x} \cos(x) + A_6 x^2 \sin(x) \mathrm{e}^{-x}
\end{aligned}
$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
\begin{aligned}
& -A_4 x \sin(x) \mathrm{e}^{-x} - A_5 x^2 \mathrm{e}^{-x} \cos(x) - A_6 x^2 \sin(x) \mathrm{e}^{-x} - A_3 x \cos(x) \mathrm{e}^{-x} \\
& - 2A_3 \sin(x) \mathrm{e}^{-x} + 2A_4 \cos(x) \mathrm{e}^{-x} + 2A_5 \mathrm{e}^{-x} \cos(x) - 4A_5 x \mathrm{e}^{-x} \sin(x) \\
& + 2A_6 \sin(x) \mathrm{e}^{-x} + 4A_6 x \cos(x) \mathrm{e}^{-x} - A_1 \mathrm{e}^{-x} \cos(x) - A_2 \mathrm{e}^{-x} \sin(x) = x^2 \mathrm{e}^{-x} \cos(x)
\end{aligned}
$$

Solving for the unknowns by comparing coefficients results in

$$
[A_1 = 6, A_2 = 0, A_3 = 0, A_4 = 4, A_5 = -1, A_6 = 0]
$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$
y_p = 6\,\mathrm{e}^{-x} \cos(x) + 4x \sin(x) \mathrm{e}^{-x} - x^2 \mathrm{e}^{-x} \cos(x)
$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x}\right) + \left(6\,\mathrm{e}^{-x} \cos(x) + 4x \sin(x) \mathrm{e}^{-x} - x^2 \mathrm{e}^{-x} \cos(x)\right)
\end{aligned}
$$

Which simplifies to

$$
y = \mathrm{e}^{-x}(c_2 x + c_1) + 6\,\mathrm{e}^{-x} \cos(x) + 4x \sin(x) \mathrm{e}^{-x} - x^2 \mathrm{e}^{-x} \cos(x)
$$

Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{-x}(c_2 x + c_1) + 6\,\mathrm{e}^{-x} \cos(x) + 4x \sin(x) \mathrm{e}^{-x} - x^2 \mathrm{e}^{-x} \cos(x) \tag{1}
$$

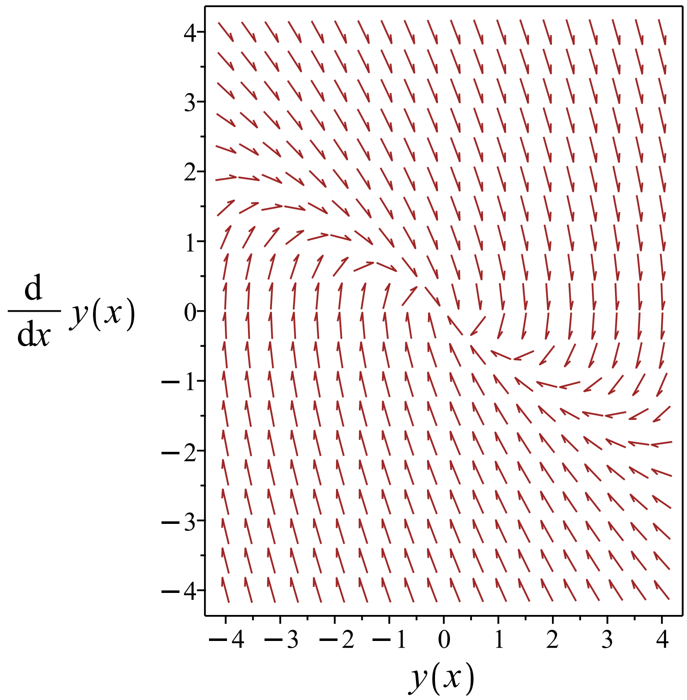

Figure 626: Slope field plot

Verification of solutions

$$y = e^{-x}(c_2x + c_1) + 6\,e^{-x}\cos(x) + 4x\sin(x)\,e^{-x} - x^2e^{-x}\cos(x)$$

Verified OK.

16.72.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{(p(x)^2 + p'(x))\,y}{2} = f(x)$$

Where $p(x) = 2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 2\,dx} \\ &= e^{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= e^{x}x^{2}e^{-x}\cos(x)\\
(e^{x}y)'' &= e^{x}x^{2}e^{-x}\cos(x)
\end{aligned}
$$

Integrating once gives

$$(e^{x}y)' = x^{2}\sin(x) - 2\sin(x) + 2\cos(x)\,x + c_1$$

Integrating again gives

$$(e^{x}y) = \left(-x^{2}+6\right)\cos(x) + x(c_1 + 4\sin(x)) + c_2$$

Hence the solution is

$$y = \frac{(-x^{2}+6)\cos(x) + x(c_1 + 4\sin(x)) + c_2}{e^{x}}$$

Or

$$y = -x^{2}e^{-x}\cos(x) + c_1 x\,e^{-x} + 4x\sin(x)\,e^{-x} + e^{-x}c_2 + 6\,e^{-x}\cos(x)$$

Summary

The solution(s) found are the following

$$y = -x^{2}e^{-x}\cos(x) + c_1 x\,e^{-x} + 4x\sin(x)\,e^{-x} + e^{-x}c_2 + 6\,e^{-x}\cos(x) \tag{1}$$

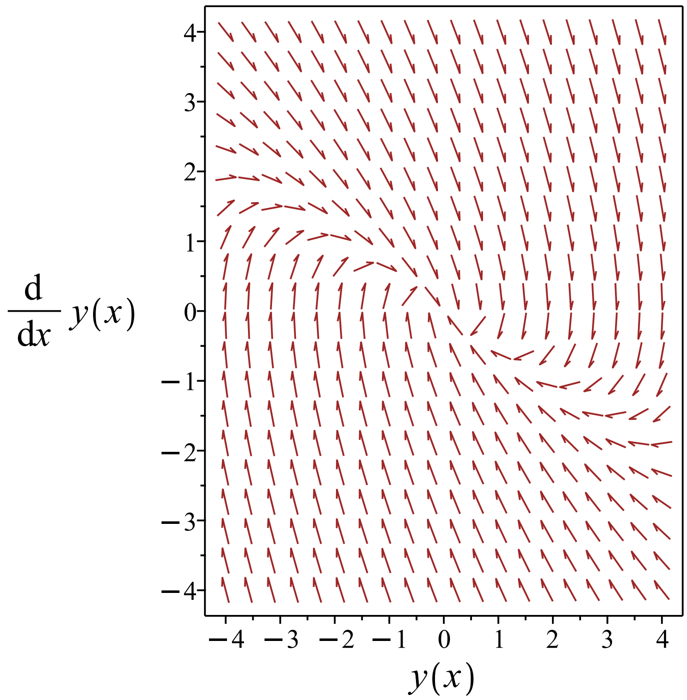

Figure 627: Slope field plot

Verification of solutions

$$y = -x^2 e^{-x} \cos(x) + c_1 x e^{-x} + 4x \sin(x) e^{-x} + e^{-x} c_2 + 6 e^{-x} \cos(x)$$

Verified OK.

16.72.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 493: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx} \\ &= z_1 e^{-x} \\ &= z_1\left(\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-2x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{-x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x^2 \mathrm{e}^{-x} \cos(x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-x}\cos(x), \mathrm{e}^{-x}\sin(x), x\cos(x)\,\mathrm{e}^{-x}, x\sin(x)\,\mathrm{e}^{-x}, x^2\mathrm{e}^{-x}\cos(x), x^2\sin(x)\,\mathrm{e}^{-x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^{-x}, \mathrm{e}^{-x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
\begin{aligned}
y_p = {} & A_1\mathrm{e}^{-x}\cos(x) + A_2\mathrm{e}^{-x}\sin(x) + A_3 x\cos(x)\,\mathrm{e}^{-x} \\
& + A_4 x\sin(x)\,\mathrm{e}^{-x} + A_5 x^2\mathrm{e}^{-x}\cos(x) + A_6 x^2\sin(x)\,\mathrm{e}^{-x}
\end{aligned}
$$

The unknowns $\{A_1, A_2, A_3, A_4, A_5, A_6\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-A_4 x \sin\left(x\right) {\mathrm e}^{-x}-A_5 x^{2} {\mathrm e}^{-x} \cos\left(x\right)-A_6 x^{2} \sin\left(x\right) {\mathrm e}^{-x}+2 A_5 {\mathrm e}^{-x} \cos\left(x\right)\\ &-4 A_5 x \,{\mathrm e}^{-x} \sin\left(x\right)+2 A_6 \sin\left(x\right) {\mathrm e}^{-x}+4 A_6 x \cos\left(x\right) {\mathrm e}^{-x}-A_3 x \cos\left(x\right) {\mathrm e}^{-x}\\ &-2 A_3 \sin\left(x\right) {\mathrm e}^{-x}+2 A_4 \cos\left(x\right) {\mathrm e}^{-x}-A_1 {\mathrm e}^{-x} \cos\left(x\right)-A_2 {\mathrm e}^{-x} \sin\left(x\right) = x^{2} {\mathrm e}^{-x} \cos\left(x\right)\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 6, A_2 = 0, A_3 = 0, A_4 = 4, A_5 = -1, A_6 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 6\,{\mathrm e}^{-x} \cos\left(x\right)+4 x \sin\left(x\right) {\mathrm e}^{-x}-x^{2} {\mathrm e}^{-x} \cos\left(x\right)$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(c_1 {\mathrm e}^{-x}+c_2 x \,{\mathrm e}^{-x}\right) + \left(6\,{\mathrm e}^{-x} \cos\left(x\right)+4 x \sin\left(x\right) {\mathrm e}^{-x}-x^{2} {\mathrm e}^{-x} \cos\left(x\right)\right)\end{aligned}$$

Which simplifies to

$$y = {\mathrm e}^{-x} \left(c_2 x +c_1 \right)+6\,{\mathrm e}^{-x} \cos\left(x\right)+4 x \sin\left(x\right) {\mathrm e}^{-x}-x^{2} {\mathrm e}^{-x} \cos\left(x\right)$$

<u>Summary</u>
The solution(s) found are the following

$$y = {\mathrm e}^{-x} \left(c_2 x +c_1 \right)+6\,{\mathrm e}^{-x} \cos\left(x\right)+4 x \sin\left(x\right) {\mathrm e}^{-x}-x^{2} {\mathrm e}^{-x} \cos\left(x\right) \tag{1}$$

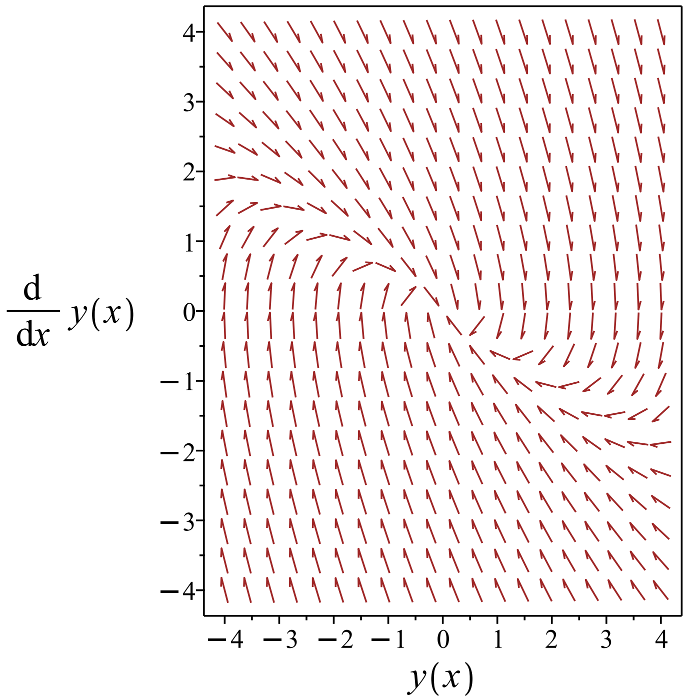

Figure 628: Slope field plot

Verification of solutions

$$y = e^{-x}(c_2 x + c_1) + 6\,e^{-x}\cos(x) + 4x\sin(x)\,e^{-x} - x^2 e^{-x}\cos(x)$$

Verified OK.

16.72.4 Maple step by step solution

Let's solve

$y'' + 2y' + y = x^2 e^{-x}\cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r+1)^2 = 0$

- Root of the characteristic polynomial

$r = -1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\, e^{-x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 x\, e^{-x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x^2 e^{-x}\cos(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & x\, e^{-x} \\ -e^{-x} & e^{-x} - x\, e^{-x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{-x}\left(-\left(\int x^3 \cos(x)\, dx\right) + x\left(\int x^2 \cos(x)\, dx\right)\right)$

  ◦ Compute integrals

  $y_p(x) = -(x^2 \cos(x) - 4\sin(x)\, x - 6\cos(x))\, e^{-x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 x\, e^{-x} - (x^2 \cos(x) - 4\sin(x)\, x - 6\cos(x))\, e^{-x}$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 546.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''' - y = \sin(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y = 0$$

The characteristic equation is

$$\lambda^3 - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = -\frac{1}{2} - \frac{i\sqrt{3}}{2}$$
$$\lambda_3 = -\frac{1}{2} + \frac{i\sqrt{3}}{2}$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$

$$y_2 = e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}$$

$$y_3 = e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}$$

Now the particular solution to the given ODE is found

$$y''' - y = \sin(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^x, e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x}, e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 \sin(x) - A_2 \cos(x) - A_1 \cos(x) - A_2 \sin(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}, A_2 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(x)}{2} - \frac{\sin(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^x c_1 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3\right) + \left(\frac{\cos(x)}{2} - \frac{\sin(x)}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^x c_1 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3 + \frac{\cos(x)}{2} - \frac{\sin(x)}{2} \tag{1}$$

Verification of solutions

$$y = e^x c_1 + e^{\left(-\frac{1}{2}-\frac{i\sqrt{3}}{2}\right)x} c_2 + e^{\left(-\frac{1}{2}+\frac{i\sqrt{3}}{2}\right)x} c_3 + \frac{\cos(x)}{2} - \frac{\sin(x)}{2}$$

Verified OK.

16.73.1 Maple step by step solution

Let's solve

$y''' - y = \sin(x)$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Isolate for $y_3'(x)$ using original ODE

$y_3'(x) = \sin(x) + y_1(x)$

Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = \sin(x) + y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ \sin(x) \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ \sin(x) \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\frac{1}{2} - \frac{I\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right], \left[-\frac{1}{2} + \frac{I\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}+\frac{I\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}+\frac{I\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{1}{2} - \frac{I\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)x} \cdot \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-\frac{x}{2}} \cdot \left(\cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right)\right) \cdot \begin{bmatrix} \frac{1}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2} \\ \frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-\frac{x}{2}} \cdot \begin{bmatrix} \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)-I\sin\left(\frac{x\sqrt{3}}{2}\right)}{\left(-\frac{1}{2}-\frac{I\sqrt{3}}{2}\right)^2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)-I\sin\left(\frac{x\sqrt{3}}{2}\right)}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) - I\sin\left(\frac{x\sqrt{3}}{2}\right) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{-\frac{x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} \\ \cos\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right], \vec{y}_3(x) = e^{-\frac{x}{2}} \cdot \left[\begin{array}{c} -\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ \frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} \\ -\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

  $\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + \vec{y}_p(x)$

☐ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \left[\begin{array}{ccc} e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right]$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \left[\begin{array}{ccc} e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\left(-\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2}\right) & e^{-\frac{x}{2}}\left(\frac{\cos\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{2} + \frac{\sin\left(\frac{x\sqrt{3}}{2}\right)}{2}\right) \\ e^{x} & e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right) & -e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right) \end{array}\right] \cdot \frac{1}{\left[\begin{array}{ccc} 1 & -\frac{1}{2} & -\frac{\sqrt{3}}{2} \\ 1 & -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ 1 & 1 & 0 \end{array}\right.}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \left[\begin{array}{ccc} \frac{e^{x}}{3} + \frac{2\,e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} + \frac{2\,e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} + \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} - \frac{e^{-\frac{x}{2}}\cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{e^{-\frac{x}{2}}\sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} & \frac{e^{x}}{3} + \frac{2\,e}{} \end{array}\right.$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \left[\begin{array}{c} \frac{\cos(x)}{2} - \frac{\sin(x)}{2} + \frac{e^x}{6} - \frac{2\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} + \frac{e^x}{6} \\ -\frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{\cos(x)}{2} + \frac{\sin(x)}{2} + \frac{e^x}{6} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2(x) + c_3 \vec{y}_3(x) + \left[\begin{array}{c} \frac{\cos(x)}{2} - \frac{\sin(x)}{2} + \frac{e^x}{6} - \frac{2\,e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} \\ \frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{\cos(x)}{2} - \frac{\sin(x)}{2} + \frac{e^x}{6} \\ -\frac{e^{-\frac{x}{2}} \sin\left(\frac{x\sqrt{3}}{2}\right)\sqrt{3}}{3} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{x\sqrt{3}}{2}\right)}{3} - \frac{\cos(x)}{2} + \frac{\sin(x)}{2} + \frac{e^x}{6} \end{array}\right]$$

- First component of the vector is the solution to the ODE

$$y = -\frac{e^{-\frac{x}{2}}\left(\sqrt{3}\,c_3 + c_2 + \frac{4}{3}\right)\cos\left(\frac{x\sqrt{3}}{2}\right)}{2} - \frac{e^{-\frac{x}{2}}\left(\sqrt{3}\,c_2 - c_3\right)\sin\left(\frac{x\sqrt{3}}{2}\right)}{2} + \frac{(6c_1+1)e^x}{6} + \frac{\cos(x)}{2} - \frac{\sin(x)}{2}$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Trial and error method. Exercises page 132
Problem number: 547.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'''' - 2y'' + y = \cos(x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' - 2y'' + y = 0$$

The characteristic equation is

$$\lambda^4 - 2\lambda^2 + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 1$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 x e^{-x} + e^x c_3 + x e^x c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = x e^{-x}$$
$$y_3 = e^x$$
$$y_4 = x e^x$$

Now the particular solution to the given ODE is found

$$y'''' - 2y'' + y = \cos(x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^x, x e^{-x}, e^x, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_1 \cos(x) + 4A_2 \sin(x) = \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{\cos(x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 x \,\mathrm{e}^{-x} + \mathrm{e}^{x} c_3 + x \,\mathrm{e}^{x} c_4\right) + \left(\frac{\cos(x)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x}(c_2 x + c_1) + \mathrm{e}^{x}(c_4 x + c_3) + \frac{\cos(x)}{4}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}(c_2 x + c_1) + \mathrm{e}^{x}(c_4 x + c_3) + \frac{\cos(x)}{4} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-x}(c_2 x + c_1) + \mathrm{e}^{x}(c_4 x + c_3) + \frac{\cos(x)}{4}$$

Verified OK.

Problem number: 548.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

`[[_3rd_order, _linear, _nonhomogeneous]]`

$$\boxed{y''' - 3y'' + 3y' - y = e^{x} \cos(2x)}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 3y'' + 3y' - y = 0$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 3\lambda - 1 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 1$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = e^x c_1 + x e^x c_2 + x^2 e^x c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = x e^x$$
$$y_3 = e^x x^2$$

Now the particular solution to the given ODE is found

$$y''' - 3y'' + 3y' - y = e^x \cos(2x)$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x \cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x \cos(2x), e^x \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x e^x, e^x x^2, e^x\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x \cos(2x) + A_2 e^x \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 e^x \sin(2x) - 8A_2 e^x \cos(2x) = e^x \cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = -\frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^x \sin(2x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x c_1 + x e^x c_2 + x^2 e^x c_3) + \left(-\frac{e^x \sin(2x)}{8}\right) \end{aligned}$$

Which simplifies to

$$y = e^x(c_3 x^2 + c_2 x + c_1) - \frac{e^x \sin(2x)}{8}$$

Summary

The solution(s) found are the following

$$y = e^x(c_3 x^2 + c_2 x + c_1) - \frac{e^x \sin(2x)}{8} \tag{1}$$

Verification of solutions

$$y = e^x(c_3 x^2 + c_2 x + c_1) - \frac{e^x \sin(2x)}{8}$$

Verified OK.

Problem number: 549.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - 4y' + 5y = e^{2x}(\sin(x) + 2\cos(x))}$$

16.76.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -4, C = 5, f(x) = e^{2x}(\sin(x) + 2\cos(x))$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -4, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 4\lambda\, e^{\lambda x} + 5\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -4, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-4^2 - (4)\,(1)\,(5)}\\ &= 2 \pm i\end{aligned}$$

Hence

$$\lambda_1 = 2 + i$$
$$\lambda_2 = 2 - i$$

Which simplifies to

$$\lambda_1 = 2 + i$$
$$\lambda_2 = 2 - i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 2$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x}(c_1 \cos(x) + c_2 \sin(x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{2x}(\sin(x) + 2\cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x}\cos(x), e^{2x}\sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x}\cos(x), e^{2x}\sin(x)\}$$

Since $e^{2x}\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\,e^{2x}\cos(x), \sin(x)\,x\,e^{2x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\,e^{2x}\cos(x) + A_2\sin(x)\,x\,e^{2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1e^{2x}\sin(x) + 2A_2\cos(x)\,e^{2x} = e^{2x}(\sin(x) + 2\cos(x))$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = 1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\,e^{2x}\cos(x)}{2} + \sin(x)\,x\,e^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x}(c_1\cos(x) + c_2\sin(x))\right) + \left(-\frac{x\,e^{2x}\cos(x)}{2} + \sin(x)\,x\,e^{2x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{x e^{2x} \cos(x)}{2} + \sin(x) x e^{2x} \tag{1}$$

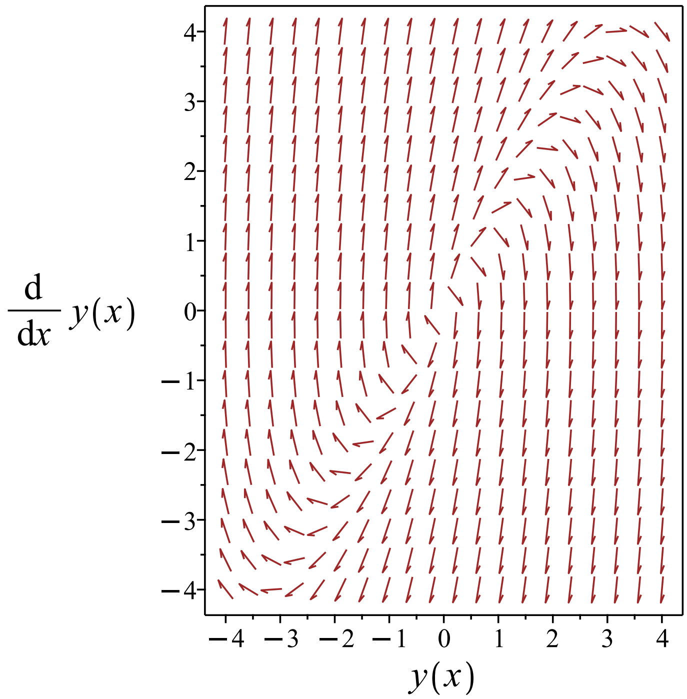

Figure 629: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{x e^{2x} \cos(x)}{2} + \sin(x) x e^{2x}$$

Verified OK.

16.76.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 4y' + 5y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -4 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 496: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-4}{1} \, dx} \\ &= z_1 e^{2x} \\ &= z_1 \left(\mathrm{e}^{2x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x} \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4x}}{(y_1)^2}\,dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{2x}\cos(x)\right) + c_2\left(\mathrm{e}^{2x}\cos(x)(\tan(x))\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 4y' + 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{2x}\cos(x)\,c_1 + \mathrm{e}^{2x}\sin(x)\,c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{2x}(\sin(x) + 2\cos(x))$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{2x} \cos(x), e^{2x} \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{2x} \cos(x), e^{2x} \sin(x)\}$$

Since $e^{2x} \cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\, e^{2x} \cos(x), \sin(x)\, x\, e^{2x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x\, e^{2x} \cos(x) + A_2 \sin(x)\, x\, e^{2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{2x} \sin(x) + 2A_2 \cos(x)\, e^{2x} = e^{2x}(\sin(x) + 2\cos(x))$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = 1\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x\, e^{2x} \cos(x)}{2} + \sin(x)\, x\, e^{2x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{2x} \cos(x)\, c_1 + e^{2x} \sin(x)\, c_2\right) + \left(-\frac{x\, e^{2x} \cos(x)}{2} + \sin(x)\, x\, e^{2x}\right) \end{aligned}$$

Which simplifies to

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{x\, e^{2x} \cos(x)}{2} + \sin(x)\, x\, e^{2x}$$

Summary
The solution(s) found are the following

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{x e^{2x} \cos(x)}{2} + \sin(x) x e^{2x} \tag{1}$$

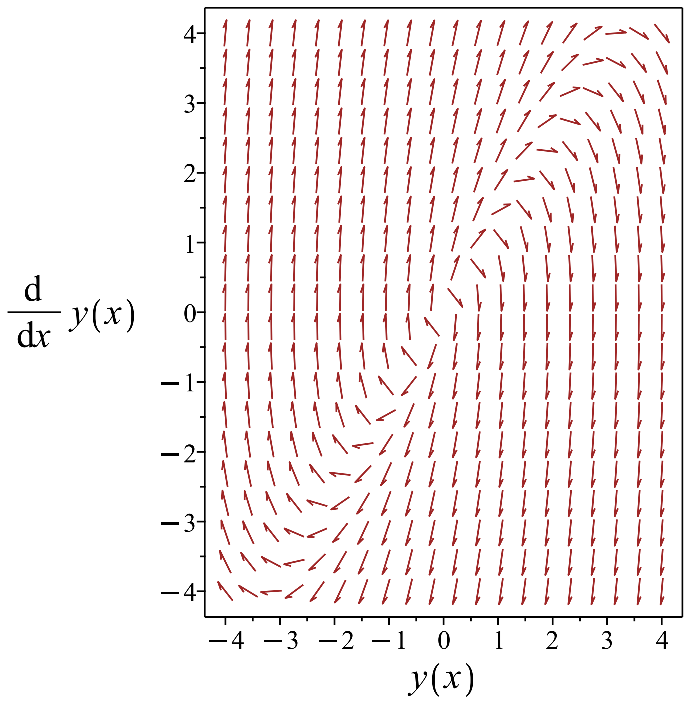

Figure 630: Slope field plot

Verification of solutions

$$y = e^{2x}(c_1 \cos(x) + c_2 \sin(x)) - \frac{x e^{2x} \cos(x)}{2} + \sin(x) x e^{2x}$$

Verified OK.

16.76.3 Maple step by step solution

Let's solve

$y'' - 4y' + 5y = e^{2x}(\sin(x) + 2\cos(x))$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 4r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{4 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (2 - \mathrm{I}, 2 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{2x} \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{2x} \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{2x} \cos(x) c_1 + \mathrm{e}^{2x} \sin(x) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \mathrm{e}^{2x}(\sin(x) + 2\cos(x))\right.$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{2x} \cos(x) & \mathrm{e}^{2x} \sin(x) \\ 2\,\mathrm{e}^{2x} \cos(x) - \mathrm{e}^{2x} \sin(x) & 2\,\mathrm{e}^{2x} \sin(x) + \mathrm{e}^{2x} \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{4x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = \mathrm{e}^{2x}\left(-\cos(x) \left(\int \sin(x) (\sin(x) + 2\cos(x)) dx\right) + \sin(x) \left(\int \cos(x) (\sin(x) + 2\cos(x)) d\right.\right.$

  - Compute integrals

    $y_p(x) = -\frac{\mathrm{e}^{2x}((x-2)\cos(x) - 2\sin(x) x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{2x} \cos(x) c_1 + \mathrm{e}^{2x} \sin(x) c_2 - \frac{\mathrm{e}^{2x}((x-2)\cos(x) - 2\sin(x) x)}{2}$

Section: Chapter 2 (Higher order ODE's). Section 15.3 Nonhomogeneous linear equations with constant coefficients. Superposition principle. Exercises page 137
Problem number: 551.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y' - 2y = \mathrm{e}^{x} + \mathrm{e}^{-2x}}$$

17.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -2, f(x) = (\mathrm{e}^{3x} + 1)\,\mathrm{e}^{-2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \lambda e^{\lambda x} - 2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-1^2 - (4)(1)(-2)}\\ &= \frac{1}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{1}{2} + \frac{3}{2}\\ \lambda_2 &= \frac{1}{2} - \frac{3}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(2)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = e^{2x} c_1 + e^{-x} c_2$$

Therefore the homogeneous solution y_h is

$$y_h = e^{2x} c_1 + e^{-x} c_2$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$(e^{3x}+1)\,e^{-2x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{x}\},\{e^{-2x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{x} + A_2 e^{-2x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 e^{x} + 4A_2 e^{-2x} = (e^{3x}+1)\,e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^{x}}{2} + \frac{e^{-2x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^{2x}c_1 + e^{-x}c_2) + \left(-\frac{e^{x}}{2} + \frac{e^{-2x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{2x}c_1 + e^{-x}c_2 - \frac{e^{x}}{2} + \frac{e^{-2x}}{4} \tag{1}$$

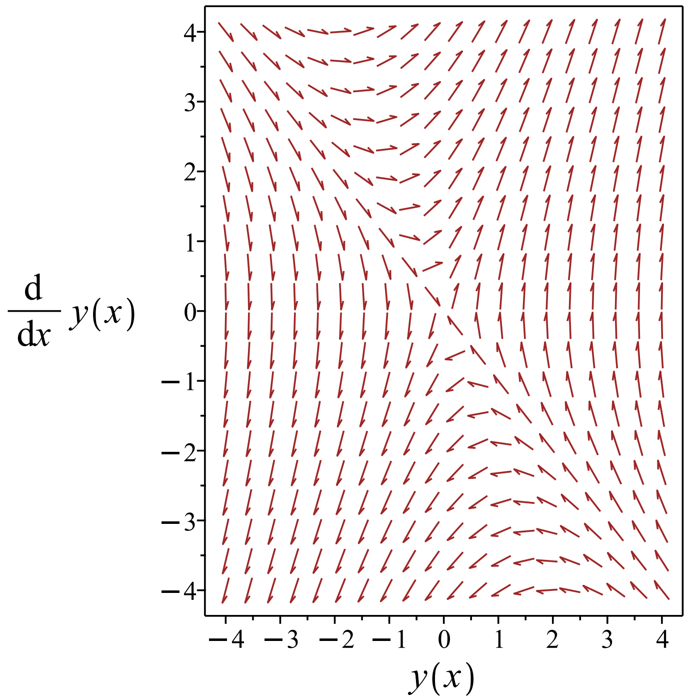

Figure 631: Slope field plot

Verification of solutions

$$y = e^{2x}c_1 + e^{-x}c_2 - \frac{e^x}{2} + \frac{e^{-2x}}{4}$$

Verified OK.

17.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 9 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 498: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1\left(e^{\frac{x}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{e^{3x}}{3}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\right) + c_2\left(\mathrm{e}^{-x}\left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + \frac{\mathrm{e}^{2x} c_2}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\left(\mathrm{e}^{3x} + 1\right) \mathrm{e}^{-2x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{x}\}, \{\mathrm{e}^{-2x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{2x}}{3}, \mathrm{e}^{-x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{x} + A_2 \mathrm{e}^{-2x}
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1e^x + 4A_2e^{-2x} = (e^{3x} + 1) e^{-2x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^x}{2} + \frac{e^{-2x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1e^{-x} + \frac{e^{2x}c_2}{3}\right) + \left(-\frac{e^x}{2} + \frac{e^{-2x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1e^{-x} + \frac{e^{2x}c_2}{3} - \frac{e^x}{2} + \frac{e^{-2x}}{4} \tag{1}$$

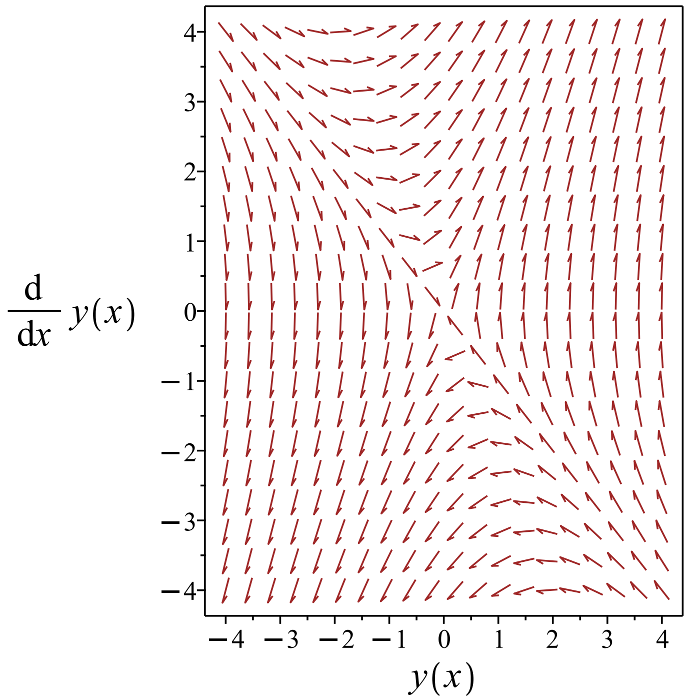

Figure 632: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{e^{2x} c_2}{3} - \frac{e^{x}}{2} + \frac{e^{-2x}}{4}$$

Verified OK.

17.1.3 Maple step by step solution

Let's solve

$y'' - y' - 2y = (e^{3x} + 1) e^{-2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r - 2 = 0$

- Factor the characteristic polynomial

  $(r + 1)(r - 2) = 0$

- Roots of the characteristic polynomial

$r = (-1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + e^{2x} c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = (e^{3x} + 1) e^{-2x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{2x} \\ -e^{-x} & 2 e^{2x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3 e^{x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{e^{-x} \left(\int (e^{2x} + e^{-x}) dx\right)}{3} + \frac{e^{2x} \left(\int (e^{3x} + 1) e^{-4x} dx\right)}{3}$

  ◦ Compute integrals

  $y_p(x) = -\frac{(2 e^{3x} - 1) e^{-2x}}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + e^{2x} c_2 - \frac{(2 e^{3x} - 1) e^{-2x}}{4}$
