The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[[_Riccati, _special]]`

$$\boxed{y' - y^2 = x^2}$$

1.1.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= x^2 + y^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x^2 + y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = x^2$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= x^2 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + x^2 u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \left(\text{BesselJ}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_1 + \text{BesselY}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_2\right) \sqrt{x}$$

The above shows that

$$u'(x) = x^{\frac{3}{2}} \left(\text{BesselJ}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_1 + \text{BesselY}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_2\right)$$

Using the above in (1) gives the solution

$$y = -\frac{x\left(\text{BesselJ}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_1 + \text{BesselY}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_2\right)}{\text{BesselJ}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_1 + \text{BesselY}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{x\left(\text{BesselJ}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3 + \text{BesselY}\left(-\frac{3}{4}, \frac{x^2}{2}\right)\right)}{\text{BesselJ}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_3 + \text{BesselY}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{x\left(\text{BesselJ}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3 + \text{BesselY}\left(-\frac{3}{4}, \frac{x^2}{2}\right)\right)}{\text{BesselJ}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_3 + \text{BesselY}\left(\frac{1}{4}, \frac{x^2}{2}\right)} \tag{1}$$

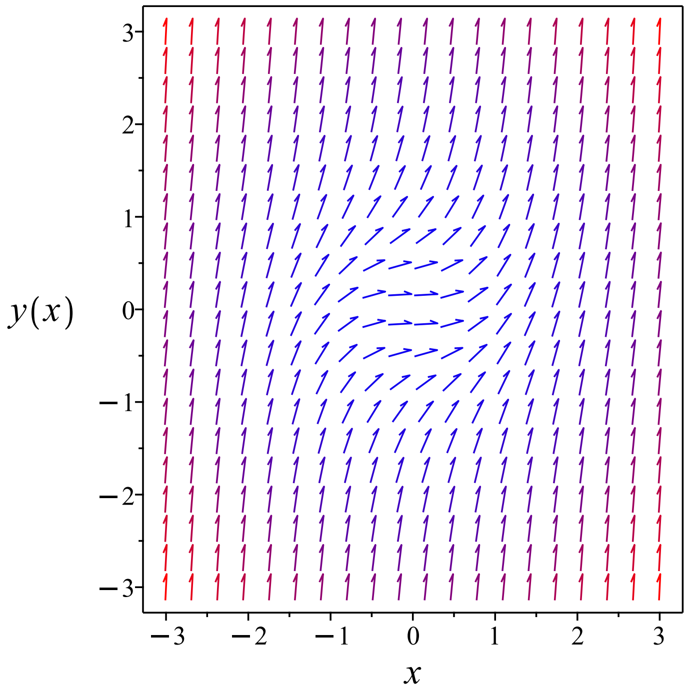

Figure 1: Slope field plot

Verification of solutions

$$y = -\frac{x\left(\operatorname{BesselJ}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3 + \operatorname{BesselY}\left(-\frac{3}{4}, \frac{x^2}{2}\right)\right)}{\operatorname{BesselJ}\left(\frac{1}{4}, \frac{x^2}{2}\right) c_3 + \operatorname{BesselY}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{x}{y} = 0}$$

1.2.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x}{y} \end{aligned}$$

Where $f(x) = x$ and $g(y) = \frac{1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{1}{y}}\, dy = x\, dx$$

$$\int \frac{1}{\frac{1}{y}}\, dy = \int x\, dx$$

$$\frac{y^2}{2} = \frac{x^2}{2} + c_1$$

Which results in

$$y = \sqrt{x^2 + 2c_1}$$

$$y = -\sqrt{x^2 + 2c_1}$$

Summary
The solution(s) found are the following

$$y = \sqrt{x^2 + 2c_1} \tag{1}$$

$$y = -\sqrt{x^2 + 2c_1} \tag{2}$$

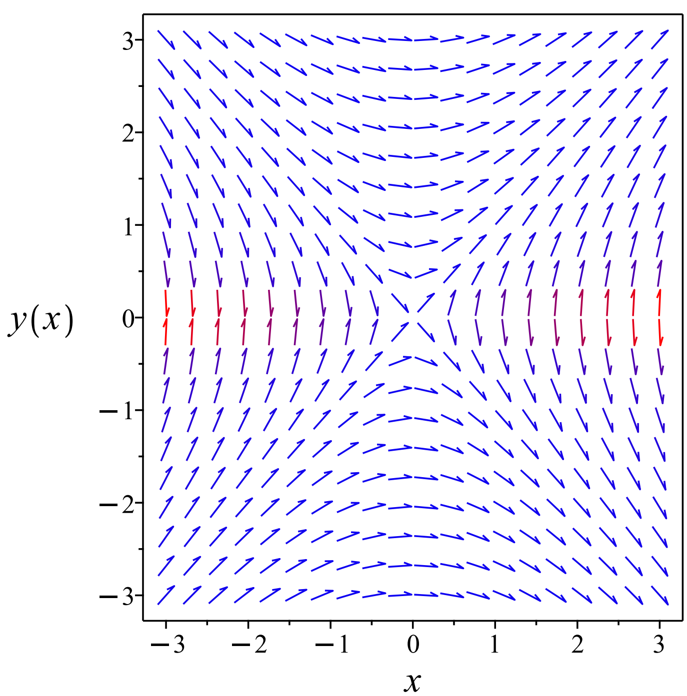

Figure 2: Slope field plot

Verification of solutions

$$y = \sqrt{x^2 + 2c_1}$$

Verified OK.

$$y = -\sqrt{x^2 + 2c_1}$$

Verified OK.

1.2.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{1}{u\,(x)} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^2 - 1}{xu} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2-1}{u}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{u^2-1}{u}}\,du &= -\frac{1}{x}\,dx \\ \int \frac{1}{\frac{u^2-1}{u}}\,du &= \int -\frac{1}{x}\,dx \\ \frac{\ln\,(u-1)}{2} + \frac{\ln\,(u+1)}{2} &= -\ln\,(x) + c_2 \end{aligned}$$

The above can be written as

$$\begin{aligned} \left(\frac{1}{2}\right)(\ln\,(u-1) + \ln\,(u+1)) &= -\ln\,(x) + 2c_2 \\ \ln\,(u-1) + \ln\,(u+1) &= (2)\,(-\ln\,(x) + 2c_2) \\ &= -2\ln\,(x) + 4c_2 \end{aligned}$$

Raising both side to exponential gives

$$e^{\ln(u-1)+\ln(u+1)} = e^{-2\ln(x)+2c_2}$$

Which simplifies to

$$\begin{aligned} u^2 - 1 &= \frac{2c_2}{x^2} \\ &= \frac{c_3}{x^2} \end{aligned}$$

The solution is

$$u(x)^2 - 1 = \frac{c_3}{x^2}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y^2}{x^2} - 1 = \frac{c_3}{x^2}$$
$$\frac{y^2}{x^2} - 1 = \frac{c_3}{x^2}$$

Which simplifies to

$$-(-y + x)(y + x) = c_3$$

Summary

The solution(s) found are the following

$$-(-y + x)(y + x) = c_3 \tag{1}$$

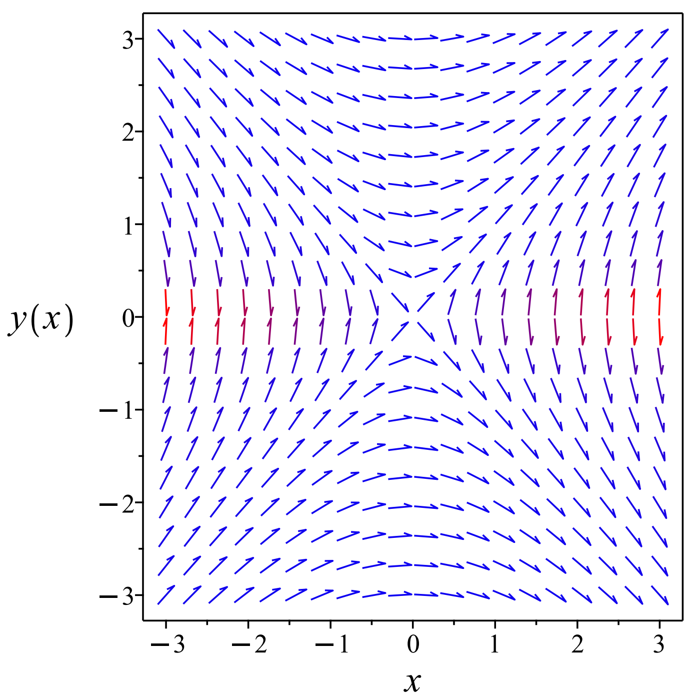

Figure 3: Slope field plot

Verification of solutions

$$-(-y+x)(y+x)=c_3$$

Verified OK.

1.2.3 Solving as differentialType ode

Writing the ode as

$$y'=\frac{x}{y} \tag{1}$$

Which becomes

$$(y)\,dy=(x)\,dx \tag{2}$$

But the RHS is complete differential because

$$(x)\,dx=d\left(\frac{x^2}{2}\right)$$

Hence (2) becomes

$$(y)\,dy=d\left(\frac{x^2}{2}\right)$$

Integrating both sides gives gives these solutions

$$y=\sqrt{x^2+2c_1}+c_1$$
$$y=-\sqrt{x^2+2c_1}+c_1$$

Summary
The solution(s) found are the following

$$y=\sqrt{x^2+2c_1}+c_1 \tag{1}$$
$$y=-\sqrt{x^2+2c_1}+c_1 \tag{2}$$

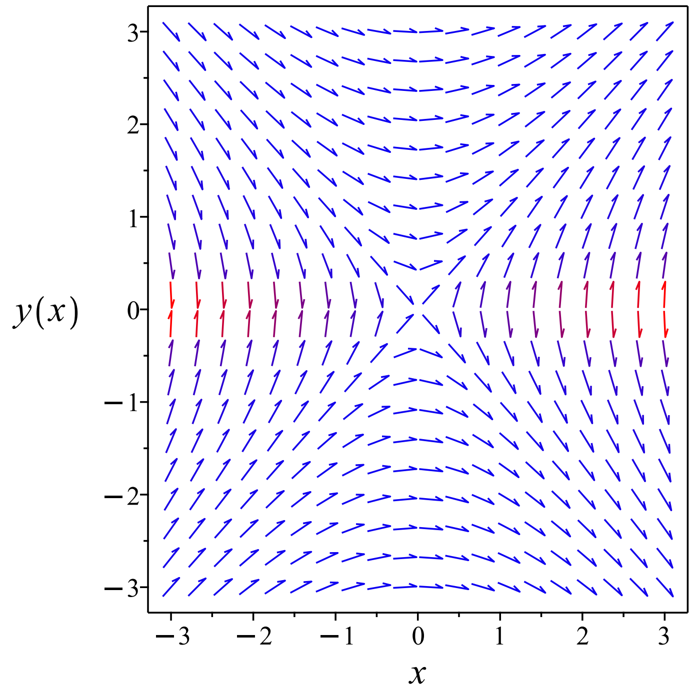

Figure 4: Slope field plot

Verification of solutions

$$y = \sqrt{x^2 + 2c_1} + c_1$$

Verified OK.

$$y = -\sqrt{x^2 + 2c_1} + c_1$$

Verified OK.

1.2.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x}{y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 1: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= \frac{1}{x} \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{\frac{1}{x}} dx \end{aligned}$$

Which results in

$$S = \frac{x^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

Which simplifies to

$$\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x}{y}$ 	$R = y$ $S = \frac{x^2}{2}$	$\frac{dS}{dR} = R$ 
Summary

The solution(s) found are the following

$$\frac{x^2}{2} = \frac{y^2}{2} + c_1 \tag{1}$$

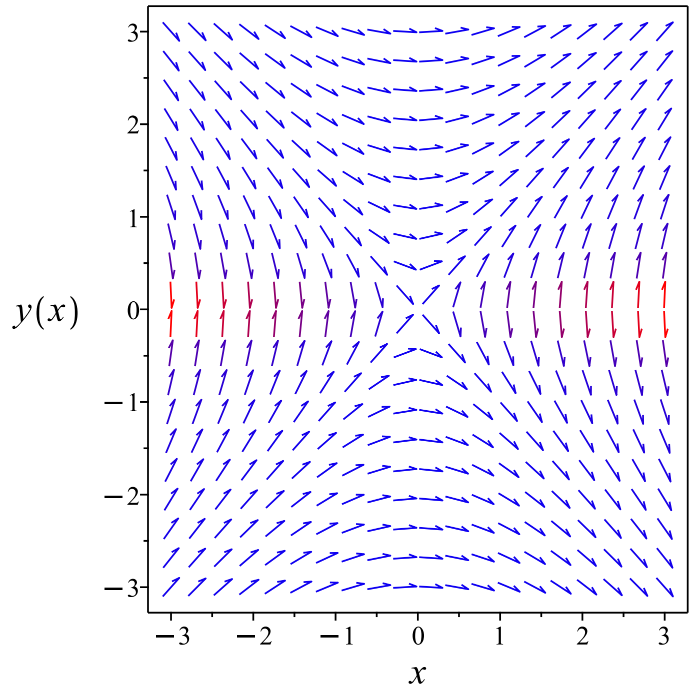

Figure 5: Slope field plot

Verification of solutions

$$\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

Verified OK.

1.2.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(y)\,\mathrm{d}y &= (x)\,\mathrm{d}x \\ (-x)\,\mathrm{d}x + (y)\,\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x \\ N(x, y) &= y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x) \\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int -x \,\mathrm{d}x$$
$$\phi = -\frac{x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y$. Therefore equation (4) becomes

$$y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (y) \,\mathrm{d}y$$
$$f(y) = \frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} + \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x^2}{2} + \frac{y^2}{2} = c_1 \tag{1}$$

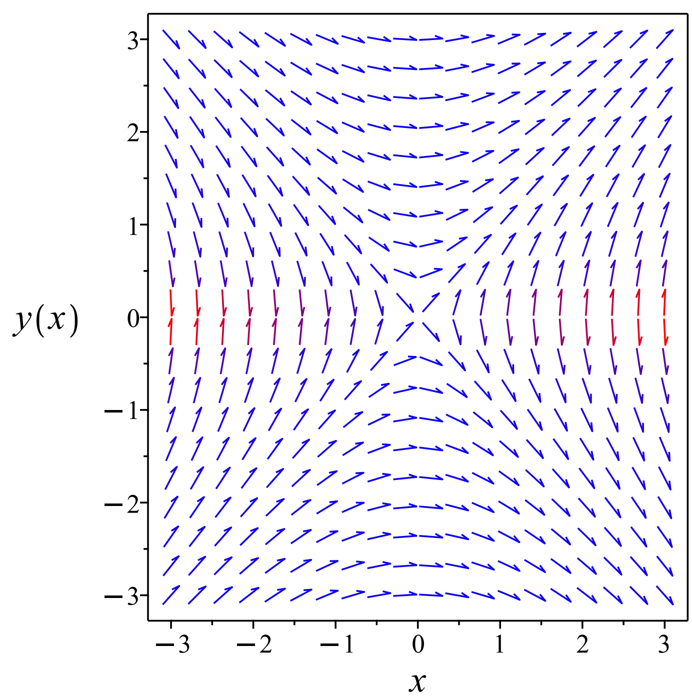

Figure 6: Slope field plot

Verification of solutions

$$-\frac{x^2}{2} + \frac{y^2}{2} = c_1$$

Verified OK.

1.2.6 Maple step by step solution

Let's solve

$y' - \frac{x}{y} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $yy' = x$

- Integrate both sides with respect to x

  $\int yy'dx = \int xdx + c_1$

- Evaluate integral

  $\frac{y^2}{2} = \frac{x^2}{2} + c_1$

- Solve for y

  $\left\{y = \sqrt{x^2 + 2c_1}, y = -\sqrt{x^2 + 2c_1}\right\}$

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{y' - y - 3y^{\frac{1}{3}} = 0}$$

1.3.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{1}{y + 3y^{\frac{1}{3}}} dy = \int dx$$

$$\frac{\ln(y^2 + 27)}{2} - \frac{\ln\left(y^{\frac{4}{3}} - 3y^{\frac{2}{3}} + 9\right)}{2} + \ln\left(y^{\frac{2}{3}} + 3\right) = x + c_1$$

Raising both side to exponential gives

$$e^{\frac{\ln(y^2+27)}{2} - \frac{\ln\left(y^{\frac{4}{3}} - 3y^{\frac{2}{3}} + 9\right)}{2} + \ln\left(y^{\frac{2}{3}} + 3\right)} = e^{x + c_1}$$

Which simplifies to

$$\frac{\sqrt{y^2 + 27}\left(y^{\frac{2}{3}} + 3\right)}{\sqrt{y^{\frac{4}{3}} - 3y^{\frac{2}{3}} + 9}} = c_2 e^x$$

Summary

The solution(s) found are the following

$$y = \left(\left(e^{2x} c_2^2\right)^{\frac{1}{3}} - 3\right)^{\frac{3}{2}} \tag{1}$$

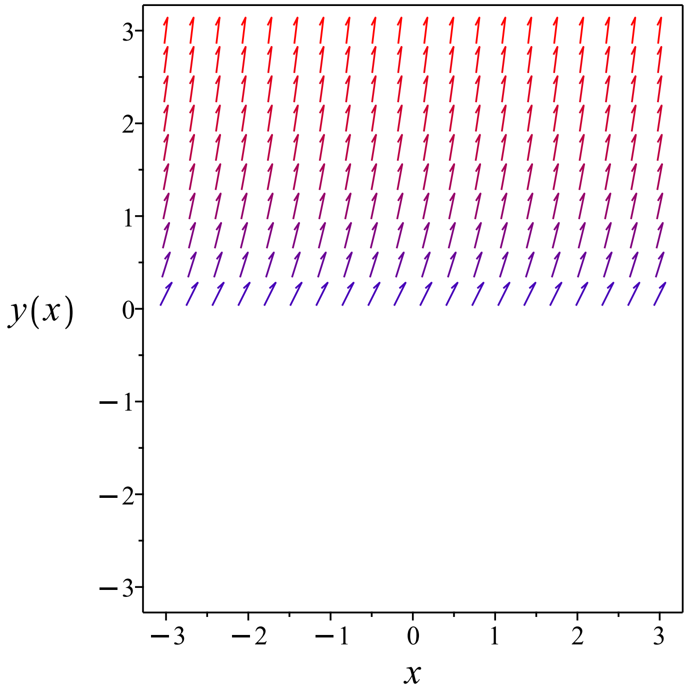

Figure 7: Slope field plot

Verification of solutions

$$y = \left(\left(e^{2x} c_2^2\right)^{\frac{1}{3}} - 3\right)^{\frac{3}{2}}$$

$$\boxed{y' - \sqrt{-y + x} = 0}$$

1.4.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \sqrt{-y + x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \sqrt{-y+x}\,(b_3 - a_2) - (-y+x)\,a_3 - \frac{xa_2 + ya_3 + a_1}{2\sqrt{-y+x}} + \frac{xb_2 + yb_3 + b_1}{2\sqrt{-y+x}} = 0 \quad (5E)$$

Putting the above in normal form gives

$$-\frac{2a_3\sqrt{-y+x}\,x - 2a_3\sqrt{-y+x}\,y - 2b_2\sqrt{-y+x} + 3xa_2 - xb_2 - 2b_3x - 2a_2y + ya_3 + yb_3 + a_1 - b_1}{2\sqrt{-y+x}} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-2a_3\sqrt{-y+x}\,x + 2a_3\sqrt{-y+x}\,y + 2b_2\sqrt{-y+x} \\ &- 3xa_2 + xb_2 + 2b_3x + 2a_2y - ya_3 - yb_3 - a_1 + b_1 = 0 \end{aligned} \quad (6E)$$

Simplifying the above gives

$$\begin{aligned} &-2(-y+x)\,a_2 + 2(-y+x)\,b_3 - 2a_3\sqrt{-y+x}\,x + 2a_3\sqrt{-y+x}\,y \\ &+ 2b_2\sqrt{-y+x} - xa_2 + xb_2 - ya_3 + yb_3 - a_1 + b_1 = 0 \end{aligned} \quad (6E)$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned} &-2a_3\sqrt{-y+x}\,x + 2a_3\sqrt{-y+x}\,y + 2b_2\sqrt{-y+x} \\ &- 3xa_2 + xb_2 + 2b_3x + 2a_2y - ya_3 - yb_3 - a_1 + b_1 = 0 \end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{-y+x}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{-y+x} = v_3\right\}$$

The above PDE (6E) now becomes

$$-2a_3v_3v_1 + 2a_3v_3v_2 - 3v_1a_2 + 2a_2v_2 - v_2a_3 + v_1b_2 + 2b_2v_3 + 2b_3v_1 - v_2b_3 - a_1 + b_1 = 0 \quad (7E)$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$-2a_3v_3v_1 + (-3a_2 + b_2 + 2b_3)\, v_1 + 2a_3v_3v_2 + (2a_2 - a_3 - b_3)\, v_2 + 2b_2v_3 - a_1 + b_1 = 0 \quad \text{(8E)}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -2a_3 &= 0 \\ 2a_3 &= 0 \\ 2b_2 &= 0 \\ -a_1 + b_1 &= 0 \\ -3a_2 + b_2 + 2b_3 &= 0 \\ 2a_2 - a_3 - b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= b_1 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= b_1 \\ b_2 &= 0 \\ b_3 &= 0 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 1 \\ \eta &= 1 \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x, y)\, \xi \\ &= 1 - \left(\sqrt{-y + x}\right)(1) \\ &= 1 - \sqrt{-y + x} \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{1 - \sqrt{-y + x}} dy \end{aligned}$$

Which results in

$$S = \ln (x - y - 1) + 2\sqrt{-y + x} + \ln \left(\sqrt{-y + x} - 1\right) - \ln \left(1 + \sqrt{-y + x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \sqrt{-y + x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{\sqrt{-y + x} - 1} \\ S_y &= \frac{1}{1 - \sqrt{-y + x}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(x-y-1) + 2\sqrt{-y+x} + \ln\left(\sqrt{-y+x}-1\right) - \ln\left(1+\sqrt{-y+x}\right) = -x + c_1$$

Which simplifies to

$$\ln(x-y-1) + 2\sqrt{-y+x} + \ln\left(\sqrt{-y+x}-1\right) - \ln\left(1+\sqrt{-y+x}\right) = -x + c_1$$

Which gives

$$y = -\mathrm{e}^{-2\,\mathrm{LambertW}\left(\mathrm{e}^{-1-\frac{x}{2}+\frac{c_1}{2}}\right)-2-x+c_1} - 2\,\mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-1-\frac{x}{2}+\frac{c_1}{2}}\right)-1-\frac{x}{2}+\frac{c_1}{2}} + x - 1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \sqrt{-y+x}$ 	$R = x$ $S = \ln(x-y-1) + 2\sqrt{-}$	$\frac{dS}{dR} = -1$  $(1+\sqrt{}$

Summary

The solution(s) found are the following

$$y = -\mathrm{e}^{-2\,\mathrm{LambertW}\left(\mathrm{e}^{-1-\frac{x}{2}+\frac{c_1}{2}}\right)-2-x+c_1} - 2\,\mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-1-\frac{x}{2}+\frac{c_1}{2}}\right)-1-\frac{x}{2}+\frac{c_1}{2}} + x - 1 \quad (1)$$

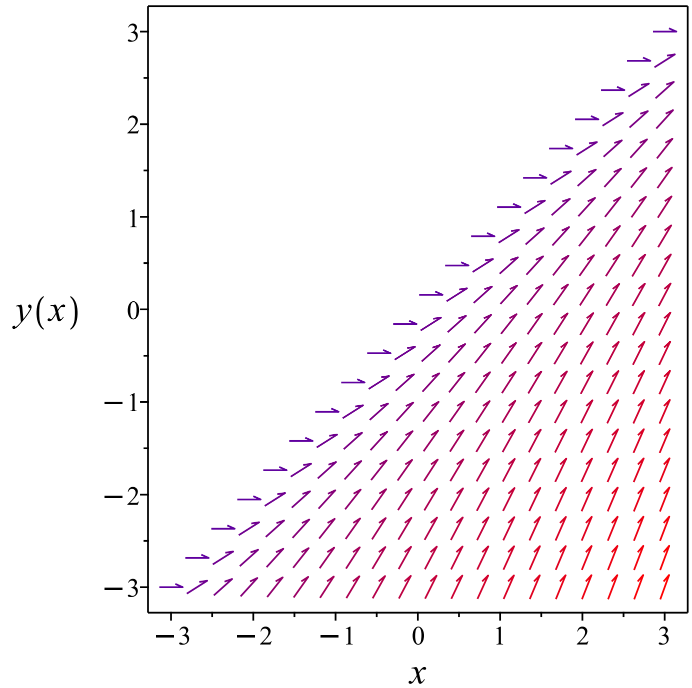

Figure 8: Slope field plot

Verification of solutions

$$y = -\mathrm{e}^{-2\,\mathrm{LambertW}\left(\mathrm{e}^{-1-\frac{x}{2}+\frac{c_1}{2}}\right)-2-x+c_1} - 2\,\mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-1-\frac{x}{2}+\frac{c_1}{2}}\right)-1-\frac{x}{2}+\frac{c_1}{2}} + x - 1$$

Verified OK.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{y' - \sqrt{x^2 - y} = -x}$$

1.5.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \sqrt{x^2 - y} - x \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 + \left(\sqrt{x^2-y}-x\right)(b_3-a_2) - \left(\sqrt{x^2-y}-x\right)^2 a_3 \\
&- \left(\frac{x}{\sqrt{x^2-y}}-1\right)(xa_2+ya_3+a_1) + \frac{xb_2+yb_3+b_1}{2\sqrt{x^2-y}} = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{2(x^2-y)^{\frac{3}{2}} a_3 + 2\sqrt{x^2-y}\,x^2a_3 - 4x^3a_3 - 4\sqrt{x^2-y}\,xa_2 + 2\sqrt{x^2-y}\,xb_3 - 2\sqrt{x^2-y}\,ya_3 + 4x^2a_2 - 2x^2}{2\sqrt{x^2-y}}
$$

$$= 0$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-2\left(x^2-y\right)^{\frac{3}{2}} a_3 - 2\sqrt{x^2-y}\,x^2a_3 + 4x^3a_3 + 4\sqrt{x^2-y}\,xa_2 \\
&- 2\sqrt{x^2-y}\,xb_3 + 2\sqrt{x^2-y}\,ya_3 - 4x^2a_2 + 2x^2b_3 - 6xya_3 \\
&+ 2\sqrt{x^2-y}\,a_1 + 2b_2\sqrt{x^2-y} - 2xa_1 + xb_2 + 2ya_2 - yb_3 + b_1 = 0
\end{aligned} \tag{6E}
$$

Simplifying the above gives

$$
\begin{aligned}
&-2\left(x^2-y\right)^{\frac{3}{2}} a_3 + 4\left(x^2-y\right)xa_3 - 2\sqrt{x^2-y}\,x^2a_3 - 2\left(x^2-y\right)a_2 \\
&+ 2\left(x^2-y\right)b_3 + 4\sqrt{x^2-y}\,xa_2 - 2\sqrt{x^2-y}\,xb_3 + 2\sqrt{x^2-y}\,ya_3 - 2x^2a_2 \\
&- 2xya_3 + 2\sqrt{x^2-y}\,a_1 + 2b_2\sqrt{x^2-y} - 2xa_1 + xb_2 + yb_3 + b_1 = 0
\end{aligned} \tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&-4\sqrt{x^2-y}\,x^2a_3 + 4x^3a_3 + 4\sqrt{x^2-y}\,xa_2 - 2\sqrt{x^2-y}\,xb_3 + 4\sqrt{x^2-y}\,ya_3 - 4x^2a_2 \\
&+ 2x^2b_3 - 6xya_3 + 2\sqrt{x^2-y}\,a_1 + 2b_2\sqrt{x^2-y} - 2xa_1 + xb_2 + 2ya_2 - yb_3 + b_1 = 0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$\left\{x, y, \sqrt{x^2-y}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x,y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{x^2-y} = v_3\right\}$$

The above PDE (6E) now becomes

$$4v_1^3a_3 - 4v_3v_1^2a_3 - 4v_1^2a_2 + 4v_3v_1a_2 - 6v_1v_2a_3 + 4v_3v_2a_3 + 2v_1^2b_3 \\ - 2v_3v_1b_3 - 2v_1a_1 + 2v_3a_1 + 2v_2a_2 + v_1b_2 + 2b_2v_3 - v_2b_3 + b_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$4v_1^3a_3 - 4v_3v_1^2a_3 + (-4a_2 + 2b_3)\, v_1^2 - 6v_1v_2a_3 + (4a_2 - 2b_3)\, v_1v_3 \\ + (-2a_1 + b_2)\, v_1 + 4v_3v_2a_3 + (2a_2 - b_3)\, v_2 + (2a_1 + 2b_2)\, v_3 + b_1 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} b_1 &= 0 \\ -6a_3 &= 0 \\ -4a_3 &= 0 \\ 4a_3 &= 0 \\ -2a_1 + b_2 &= 0 \\ 2a_1 + 2b_2 &= 0 \\ -4a_2 + 2b_3 &= 0 \\ 2a_2 - b_3 &= 0 \\ 4a_2 - 2b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= a_2 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= 2a_2 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= 2y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi \\ &= 2y - \left(\sqrt{x^2-y}-x\right)(x) \\ &= x^2 - x\sqrt{x^2-y}+2y \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta}dy \\ &= \int \frac{1}{x^2 - x\sqrt{x^2-y}+2y}dy\end{aligned}$$

Which results in

$$S = \frac{3\ln(5x^2+4y)}{10} + \frac{\ln(y)}{5} - \frac{\ln\left(\sqrt{x^2-y}+x\right)}{5} - \frac{3\ln\left(2\sqrt{x^2-y}-3x\right)}{10} + \frac{\ln\left(\sqrt{x^2-y}-x\right)}{5} + \frac{3\ln\left(2\sqrt{\right.}}{}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \sqrt{x^2-y} - x$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{2\sqrt{x^2-y}+3x} \\
S_y &= \frac{x\sqrt{x^2-y}+x^2+2y}{5x^2y+4y^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{3\ln(5x^2+4y)}{10}+\frac{\ln(y)}{5}-\frac{\ln\left(\sqrt{x^2-y}+x\right)}{5}-\frac{3\ln\left(2\sqrt{x^2-y}-3x\right)}{10}+\frac{\ln\left(\sqrt{x^2-y}-x\right)}{5}+\frac{3\ln\left(2\sqrt{x^2-\right.}}{10}$$

Which simplifies to

$$\frac{3\ln(5x^2+4y)}{10}+\frac{\ln(y)}{5}-\frac{\ln\left(\sqrt{x^2-y}+x\right)}{5}-\frac{3\ln\left(2\sqrt{x^2-y}-3x\right)}{10}+\frac{\ln\left(\sqrt{x^2-y}-x\right)}{5}+\frac{3\ln\left(2\sqrt{x^2-\right.}}{10}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \sqrt{x^2 - y} - x$ 	$R = x$ $S = \frac{3\ln(5x^2+4y)}{10} + \frac{\ln(\ldots}{5} \ldots 2\sqrt{x^2 - \ldots}{10}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{3\ln(5x^2+4y)}{10} + \frac{\ln(y)}{5} - \frac{\ln\left(\sqrt{x^2-y}+x\right)}{5} - \frac{3\ln\left(2\sqrt{x^2-y}-3x\right)}{10} + \frac{\ln\left(\sqrt{x^2-y}-x\right)}{5} + \frac{3\ln\left(2\sqrt{x^2-y}+3x\right)}{10} = c_1 \tag{1}$$

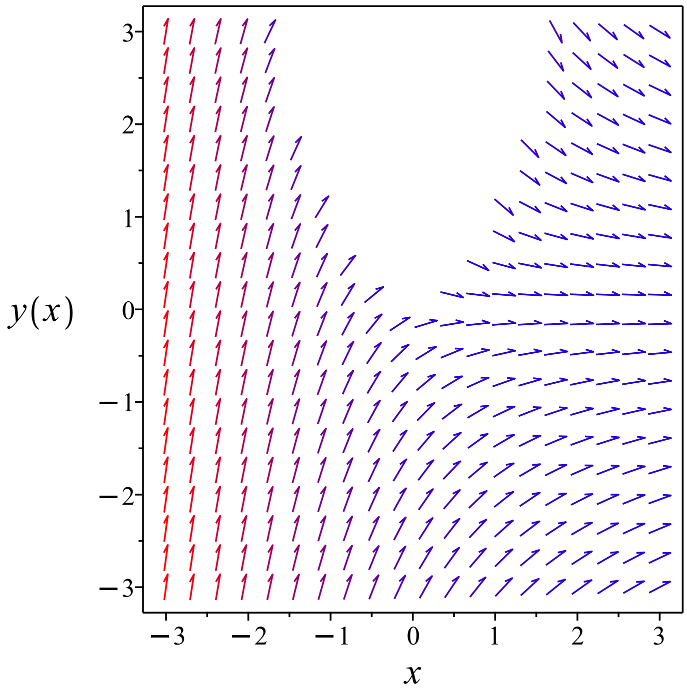

Figure 9: Slope field plot

Verification of solutions

$$\frac{3\ln\left(5x^{2}+4y\right)}{10}+\frac{\ln\left(y\right)}{5}-\frac{\ln\left(\sqrt{x^{2}-y}+x\right)}{5}-\frac{3\ln\left(2\sqrt{x^{2}-y}-3x\right)}{10}+\frac{\ln\left(\sqrt{x^{2}-y}-x\right)}{5}+\frac{3\ln\left(2\sqrt{x^{2}-y}+3x\right)}{10}=c_{1}$$

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - \sqrt{1-y^2} = 0}$$

1.6.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{1}{\sqrt{-y^2+1}} dy = x + c_1$$
$$\arcsin(y) = x + c_1$$

Solving for y gives these solutions

$$y_1 = \sin(x + c_1)$$

Summary
The solution(s) found are the following

$$y = \sin(x + c_1) \tag{1}$$

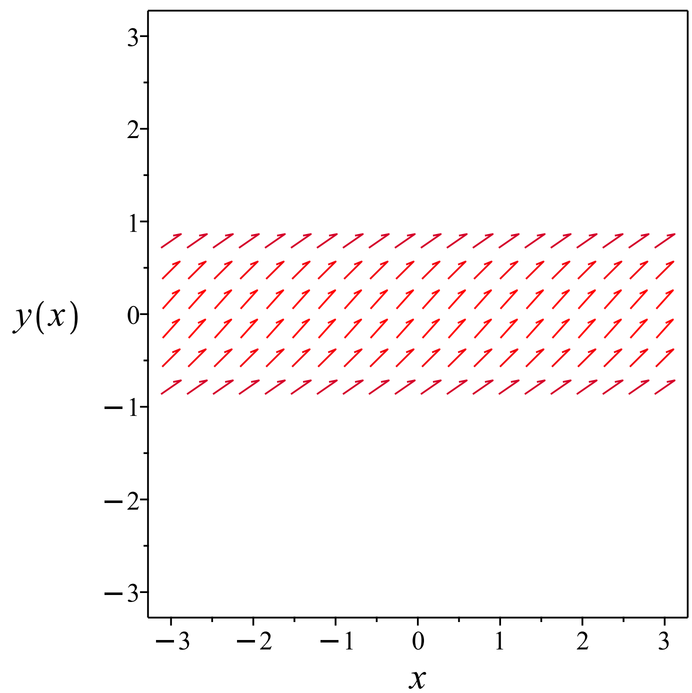

Figure 10: Slope field plot

Verification of solutions

$$y = \sin(x + c_1)$$

Verified OK.

1.6.2 Maple step by step solution

Let's solve

$y' - \sqrt{1 - y^2} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\sqrt{1-y^2}} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{\sqrt{1-y^2}} dx = \int 1 dx + c_1$

- Evaluate integral

$$\arcsin(y) = x + c_1$$

- Solve for y

$$y = \sin(x + c_1)$$

Section: Section 1. Basic concepts and definitions. Exercises page 18
Problem number: 8.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeMapleC", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{y+1}{-y+x} = 0}$$

1.7.1 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = -\frac{Y(X) + y_0 + 1}{Y(X) + y_0 - X - x_0}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = -1$$
$$y_0 = -1$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = -\frac{Y(X)}{Y(X) - X}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X, Y) \\ &= -\frac{Y}{Y - X} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X, Y)$$

In this case, it can be seen that both $M = Y$ and $N = -Y + X$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X} X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X} X + u &= -\frac{u}{u - 1} \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{-\frac{u(X)}{u(X)-1} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX} u(X) - \frac{-\frac{u(X)}{u(X)-1} - u(X)}{X} = 0$$

Or

$$\left(\frac{d}{dX} u(X)\right) X u(X) - \left(\frac{d}{dX} u(X)\right) X + u(X)^2 = 0$$

Or

$$X(u(X) - 1) \left(\frac{d}{dX} u(X)\right) + u(X)^2 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X, u) \\ &= f(X) g(u) \\ &= -\frac{u^2}{X (u - 1)} \end{aligned}$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u^2}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2}{u-1}}\,du = -\frac{1}{X}\,dX$$

$$\int \frac{1}{\frac{u^2}{u-1}}\,du = \int -\frac{1}{X}\,dX$$

$$\frac{1}{u} + \ln(u) = -\ln(X) + c_2$$

The solution is

$$\frac{1}{u(X)} + \ln(u(X)) + \ln(X) - c_2 = 0$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\frac{X}{Y(X)} + \ln\left(\frac{Y(X)}{X}\right) + \ln(X) - c_2 = 0$$

Using the solution for $Y(X)$

$$\frac{X}{Y(X)} + \ln\left(\frac{Y(X)}{X}\right) + \ln(X) - c_2 = 0$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y - 1$$
$$X = x - 1$$

Then the solution in y becomes

$$\frac{x+1}{y+1} + \ln\left(\frac{y+1}{x+1}\right) + \ln(x+1) - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{x+1}{y+1} + \ln\left(\frac{y+1}{x+1}\right) + \ln(x+1) - c_2 = 0 \tag{1}$$

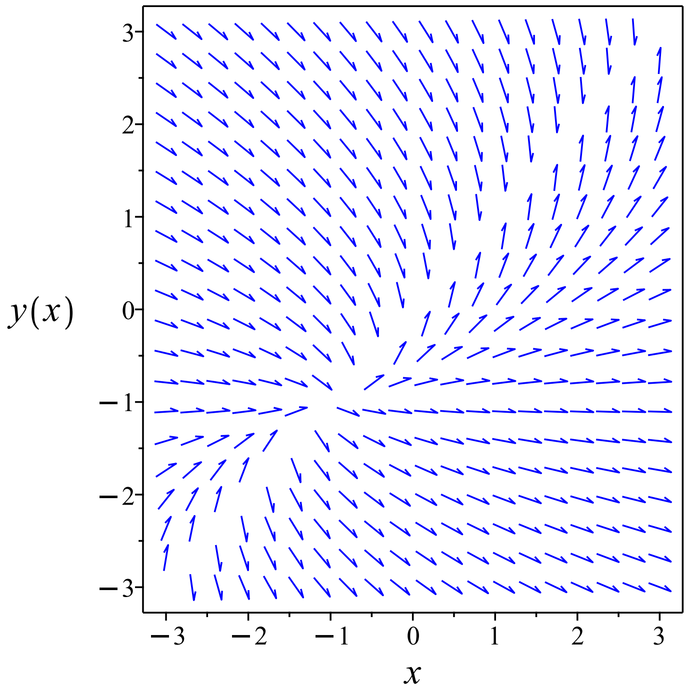

Figure 11: Slope field plot

Verification of solutions

$$\frac{x+1}{y+1}+\ln\left(\frac{y+1}{x+1}\right)+\ln(x+1)-c_2=0$$

Verified OK.

1.7.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{y+1}{y-x}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(y+1)(b_3-a_2)}{y-x} - \frac{(y+1)^2 a_3}{(y-x)^2} + \frac{(y+1)(xa_2+ya_3+a_1)}{(y-x)^2} - \left(-\frac{1}{y-x} + \frac{y+1}{(y-x)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{2xyb_2 - y^2a_2 - y^2b_2 + y^2b_3 + xb_1 + xb_2 - xb_3 - ya_1 - ya_2 + ya_3 + 2yb_3 - a_1 + a_3 + b_1}{(-y+x)^2} = 0$$

Setting the numerator to zero gives

$$-2xyb_2 + y^2a_2 + y^2b_2 - y^2b_3 - xb_1 - xb_2 + xb_3 + ya_1 + ya_2 - ya_3 - 2yb_3 + a_1 - a_3 - b_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$a_2v_2^2 - 2b_2v_1v_2 + b_2v_2^2 - b_3v_2^2 + a_1v_2 + a_2v_2 - a_3v_2 - b_1v_1 - b_2v_1 + b_3v_1 - 2b_3v_2 + a_1 - a_3 - b_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&-2b_2v_1v_2 + (-b_1 - b_2 + b_3)\, v_1 + (a_2 + b_2 - b_3)\, v_2^2 \\
&+ (a_1 + a_2 - a_3 - 2b_3)\, v_2 + a_1 - a_3 - b_1 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-2b_2 &= 0 \\
a_1 - a_3 - b_1 &= 0 \\
a_2 + b_2 - b_3 &= 0 \\
-b_1 - b_2 + b_3 &= 0 \\
a_1 + a_2 - a_3 - 2b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= b_3 + a_3 \\
a_2 &= b_3 \\
a_3 &= a_3 \\
b_1 &= b_3 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x + 1 \\
\eta &= y + 1
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y + 1 - \left(-\frac{y+1}{y-x}\right)(x + 1) \\
&= \frac{-y^2 - 2y - 1}{-y + x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-y^2-2y-1}{-y+x}} dy \end{aligned}$$

Which results in

$$S = \ln (y+1) - \frac{-x-1}{y+1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y+1}{y-x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{y+1} \\ S_y &= \frac{y-x}{(y+1)^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{(y+1)\ln(y+1)+x+1}{y+1} = c_1$$

Which simplifies to

$$\frac{(y+1)\ln(y+1)+x+1}{y+1} = c_1$$

Which gives

$$y = \mathrm{e}^{\mathrm{LambertW}\left(-(x+1)\mathrm{e}^{-c_1}\right)+c_1} - 1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y+1}{y-x}$ 	$R = x$ $S = \frac{(y+1)\ln(y+1)+x}{y+1}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$y = e^{\operatorname{LambertW}\left(-(x+1)e^{-c_1}\right)+c_1} - 1 \tag{1}$$

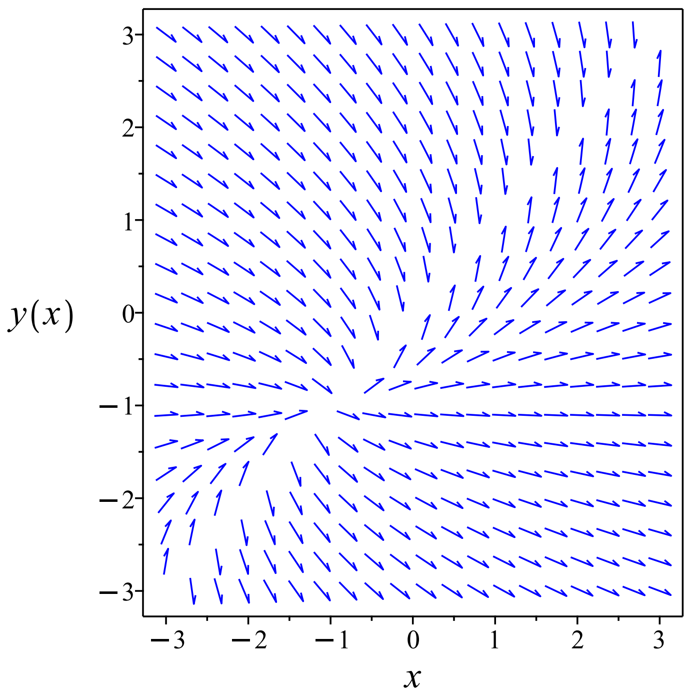

Figure 12: Slope field plot

Verification of solutions

$$y = e^{\operatorname{LambertW}\left(-(x+1)e^{-c_1}\right)+c_1} - 1$$

Verified OK.

1.7.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(y-x)\,\mathrm{d}y &= (-y-1)\,\mathrm{d}x\\ (y+1)\,\mathrm{d}x + (y-x)\,\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= y+1\\ N(x,y) &= y-x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y+1)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y-x)\\ &= -1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{y-x}((1)-(-1))\\ &= -\frac{2}{-y+x}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\\ &= \frac{1}{y+1}((-1)-(1))\\ &= -\frac{2}{y+1}\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}\mu &= e^{\int B \, \mathrm{d}y}\\ &= e^{\int -\frac{2}{y+1} \, \mathrm{d}y}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(y+1)}\\ &= \frac{1}{(y+1)^2}\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{(y+1)^2}(y+1)\\ &= \frac{1}{y+1}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{(y+1)^2}(y-x) \\
&= \frac{y-x}{(y+1)^2}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{1}{y+1}\right) + \left(\frac{y-x}{(y+1)^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{1}{y+1}\,\mathrm{d}x \\
\phi &= \frac{x}{y+1} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -\frac{x}{(y+1)^2} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y-x}{(y+1)^2}$. Therefore equation (4) becomes

$$
\frac{y-x}{(y+1)^2} = -\frac{x}{(y+1)^2} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y}{(y+1)^2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int \left(\frac{y}{(y+1)^2}\right) \mathrm{d}y$$

$$f(y) = \ln(y+1) + \frac{1}{y+1} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x}{y+1} + \ln(y+1) + \frac{1}{y+1} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x}{y+1} + \ln(y+1) + \frac{1}{y+1}$$

The solution becomes

$$y = \mathrm{e}^{\mathrm{LambertW}\left(-(x+1)\mathrm{e}^{-c_1}\right)+c_1} - 1$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\mathrm{LambertW}\left(-(x+1)\mathrm{e}^{-c_1}\right)+c_1} - 1 \tag{1}$$

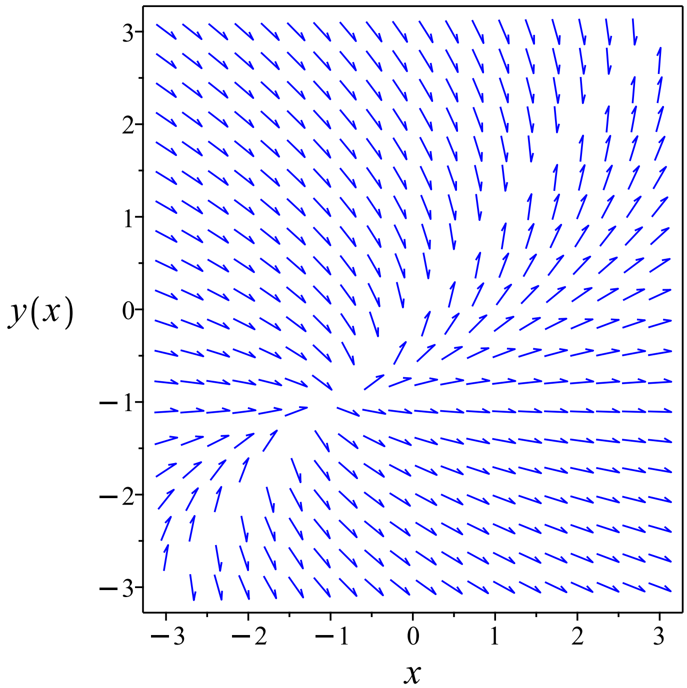

Figure 13: Slope field plot

Verification of solutions

$$y = e^{\text{LambertW}\left(-(x+1)e^{-c_1}\right)+c_1} - 1$$

Verified OK.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' + \cot(y) = 1}$$

1.9.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{1}{1-\cot(y)} dy = \int dx$$
$$\int^{y} \frac{1}{1-\cot(\_a)} d\_a = x + c_1$$

Summary
The solution(s) found are the following

$$\int^{y} \frac{1}{1-\cot(\_a)} d\_a = x + c_1 \tag{1}$$

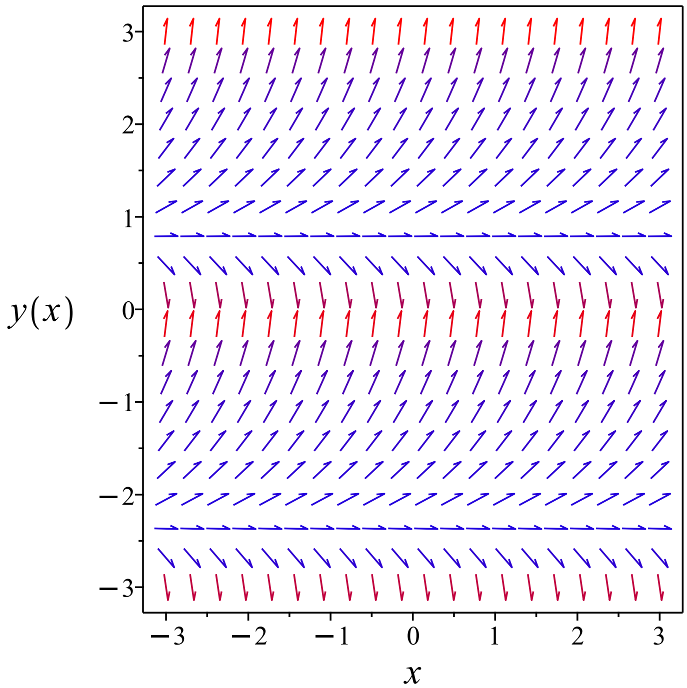

Figure 14: Slope field plot

Verification of solutions

$$\int^{y} \frac{1}{1-\cot(\_a)}d\_a = x + c_1$$

Verified OK.

1.9.2 Maple step by step solution

Let's solve

$y' + \cot(y) = 1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{1-\cot(y)} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{1-\cot(y)}dx = \int 1dx + c_1$

- Evaluate integral

$$\frac{\ln(-1+\cot(y))}{2} - \frac{\ln\left(\cot(y)^2+1\right)}{4} - \frac{\pi}{4} + \frac{y}{2} = x + c_1$$

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _dAlembert]
```

$$\boxed{y' - (3x - y)^{\frac{1}{3}} = -1}$$

1.10.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= (3x - y)^{\frac{1}{3}} - 1 \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 + \left((3x-y)^{\frac{1}{3}}-1\right)(b_3-a_2) - \left((3x-y)^{\frac{1}{3}}-1\right)^2 a_3 \\ &- \frac{xa_2+ya_3+a_1}{(3x-y)^{\frac{2}{3}}} + \frac{xb_2+yb_3+b_1}{3\,(3x-y)^{\frac{2}{3}}} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{3(3x-y)^{\frac{4}{3}}\,a_3 - 3(3x-y)^{\frac{2}{3}}\,a_2 + 3a_3(3x-y)^{\frac{2}{3}} - 3b_2(3x-y)^{\frac{2}{3}} + 3(3x-y)^{\frac{2}{3}}\,b_3 + 12xa_2 - 18a_3x - xb_2 -}{3\,(3x-y)^{\frac{2}{3}}}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-3(3x-y)^{\frac{4}{3}}\,a_3 + 3(3x-y)^{\frac{2}{3}}\,a_2 - 3a_3(3x-y)^{\frac{2}{3}} + 3b_2(3x-y)^{\frac{2}{3}} - 3(3x-y)^{\frac{2}{3}}\,b_3 \\ &- 12xa_2 + 18a_3x + xb_2 + 9b_3x + 3a_2y - 9ya_3 - 2yb_3 - 3a_1 + b_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &-3(3x-y)^{\frac{4}{3}}\,a_3 - 3(3x-y)\,a_2 + 6(3x-y)\,a_3 + 3(3x-y)\,b_3 \\ &+ 3(3x-y)^{\frac{2}{3}}\,a_2 - 3a_3(3x-y)^{\frac{2}{3}} + 3b_2(3x-y)^{\frac{2}{3}} \\ &- 3(3x-y)^{\frac{2}{3}}\,b_3 - 3xa_2 + xb_2 - 3ya_3 + yb_3 - 3a_1 + b_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned} &3(3x-y)^{\frac{2}{3}}\,a_2 - 3a_3(3x-y)^{\frac{2}{3}} + 3b_2(3x-y)^{\frac{2}{3}} - 3(3x-y)^{\frac{2}{3}}\,b_3 - 9(3x-y)^{\frac{1}{3}}\,a_3x \\ &+ 3(3x-y)^{\frac{1}{3}}\,a_3y - 12xa_2 + 18a_3x + xb_2 + 9b_3x + 3a_2y - 9ya_3 - 2yb_3 - 3a_1 + b_1 = 0 \end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, (3x-y)^{\frac{1}{3}}, (3x-y)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, (3x-y)^{\frac{1}{3}} = v_3, (3x-y)^{\frac{2}{3}} = v_4\right\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-9v_3a_3v_1 + 3v_3a_3v_2 - 12v_1a_2 + 3a_2v_2 + 3v_4a_2 + 18a_3v_1 - 9v_2a_3 \\
&- 3a_3v_4 + v_1b_2 + 3b_2v_4 + 9b_3v_1 - 2v_2b_3 - 3v_4b_3 - 3a_1 + b_1 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&-9v_3a_3v_1 + (-12a_2 + 18a_3 + b_2 + 9b_3)\, v_1 + 3v_3a_3v_2 \\
&+ (3a_2 - 9a_3 - 2b_3)\, v_2 + (3a_2 - 3a_3 + 3b_2 - 3b_3)\, v_4 - 3a_1 + b_1 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-9a_3 &= 0 \\
3a_3 &= 0 \\
-3a_1 + b_1 &= 0 \\
3a_2 - 9a_3 - 2b_3 &= 0 \\
-12a_2 + 18a_3 + b_2 + 9b_3 &= 0 \\
3a_2 - 3a_3 + 3b_2 - 3b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= a_1 \\
a_2 &= 0 \\
a_3 &= 0 \\
b_1 &= 3a_1 \\
b_2 &= 0 \\
b_3 &= 0
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 1 \\
\eta &= 3
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 3 - \left((3x-y)^{\frac{1}{3}} - 1\right)(1) \\
&= 4 - (3x-y)^{\frac{1}{3}} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{4 - (3x-y)^{\frac{1}{3}}} dy
\end{aligned}$$

Which results in

$$S = \frac{3(3x-y)^{\frac{2}{3}}}{2} + 32\ln\left(-4 + (3x-y)^{\frac{1}{3}}\right) - 16\ln\left((3x-y)^{\frac{2}{3}} + 4(3x-y)^{\frac{1}{3}} + 16\right) + 16\ln\left(-64 + 3x - y\right.$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = (3x-y)^{\frac{1}{3}} - 1$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{3}{-4 + (3x - y)^{\frac{1}{3}}} \\
S_y &= \frac{1}{4 - (3x - y)^{\frac{1}{3}}}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{3(3x - y)^{\frac{2}{3}}}{2} + 32\ln\left(-4 + (3x - y)^{\frac{1}{3}}\right) - 16\ln\left((3x - y)^{\frac{2}{3}} + 4(3x - y)^{\frac{1}{3}} + 16\right) + 16\ln(-64 + 3x - y) + 1$$

Which simplifies to

$$\frac{3(3x - y)^{\frac{2}{3}}}{2} + 32\ln\left(-4 + (3x - y)^{\frac{1}{3}}\right) - 16\ln\left((3x - y)^{\frac{2}{3}} + 4(3x - y)^{\frac{1}{3}} + 16\right) + 16\ln(-64 + 3x - y) + 1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = (3x-y)^{\frac{1}{3}} - 1$ 	$R = x$ $S = \frac{3(3x-y)^{\frac{2}{3}}}{2} + 32\ln\Big($ ... $y)^{\frac{2}{3}} + 4$	$\frac{dS}{dR} = -1$ 
Summary

The solution(s) found are the following

$$
\frac{3(3x-y)^{\frac{2}{3}}}{2} + 32\ln\left(-4+(3x-y)^{\frac{1}{3}}\right) - 16\ln\left((3x-y)^{\frac{2}{3}} + 4(3x-y)^{\frac{1}{3}} + 16\right) + 16\ln(-64+3x-y) + 12(3x-y)^{\frac{1}{3}} = -x + c_1 \tag{1}
$$

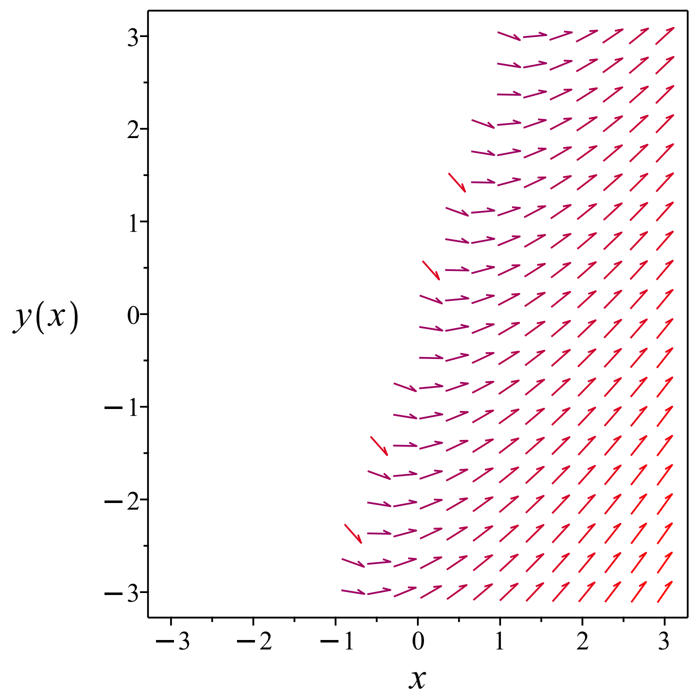

Figure 15: Slope field plot

Verification of solutions

$$\frac{3(3x-y)^{\frac{2}{3}}}{2}+32\ln\left(-4+(3x-y)^{\frac{1}{3}}\right)-16\ln\left((3x-y)^{\frac{2}{3}}+4(3x-y)^{\frac{1}{3}}+16\right)+16\ln\left(-64+3x-y\right)+12(3x-y)^{\frac{1}{3}}=-x+c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{y'x + y = \cos(x)}$$

1.12.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{\cos(x)}{x}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{\cos(x)}{x}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{1}{x}dx} \\
&= x
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{\cos(x)}{x}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}(xy) &= (x)\left(\frac{\cos(x)}{x}\right) \\
\mathrm{d}(xy) &= \cos(x)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
xy &= \int \cos(x)\,\mathrm{d}x \\
xy &= \sin(x) + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$
y = \frac{\sin(x)}{x} + \frac{c_1}{x}
$$

which simplifies to

$$
y = \frac{\sin(x) + c_1}{x}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = \frac{\sin(x) + c_1}{x} \tag{1}
$$

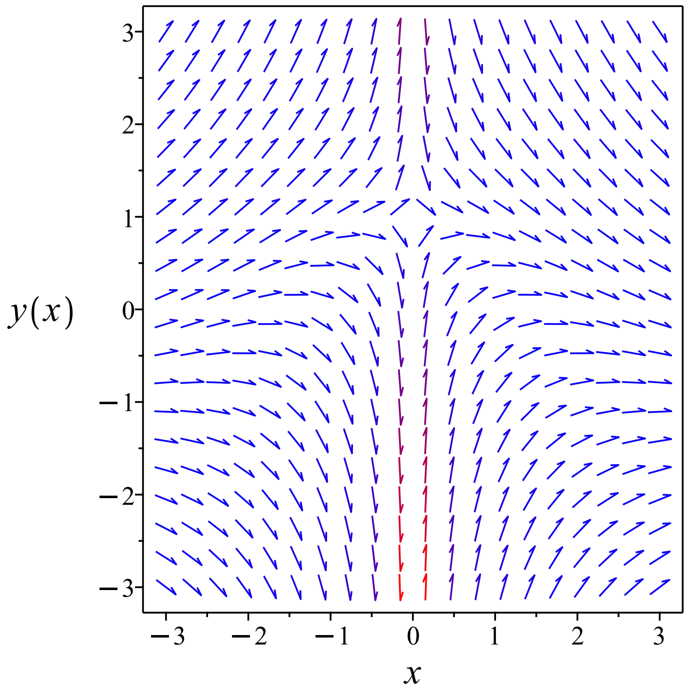

Figure 16: Slope field plot

Verification of solutions

$$y = \frac{\sin(x) + c_1}{x}$$

Verified OK.

1.12.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{\cos(x) - y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 6: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\cos(x) - y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cos(x) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cos(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \sin(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = \sin(x) + c_1$$

Which simplifies to

$$yx = \sin(x) + c_1$$

Which gives

$$y = \frac{\sin(x) + c_1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\cos(x)-y}{x}$ 	$R = x$ $S = xy$	$\frac{dS}{dR} = \cos(R)$ 
Summary

The solution(s) found are the following

$$y = \frac{\sin(x) + c_1}{x} \tag{1}$$

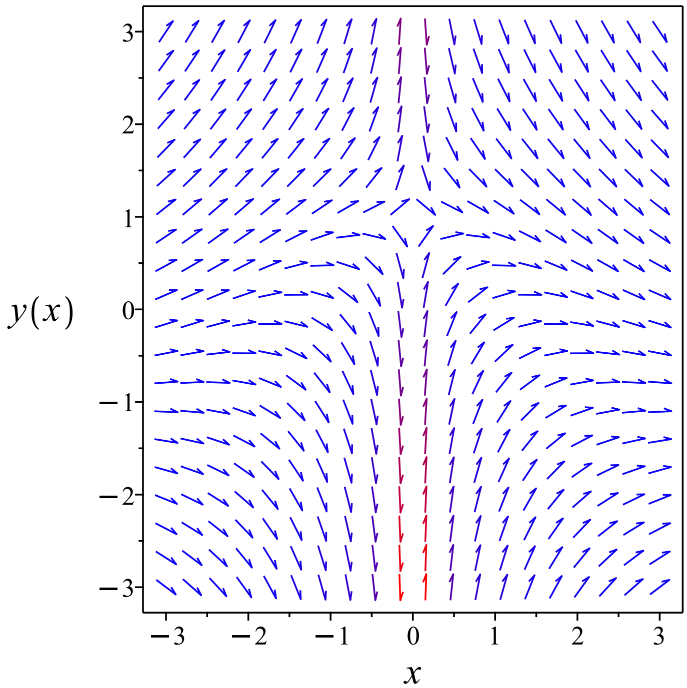

Figure 17: Slope field plot

Verification of solutions

$$y = \frac{\sin(x) + c_1}{x}$$

Verified OK.

1.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\, \mathrm{d}y &= (\cos(x) - y)\, \mathrm{d}x \\ (-\cos(x) + y)\, \mathrm{d}x + (x)\, \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -\cos(x) + y \\ N(x, y) &= x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cos(x) + y) \\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x) \\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\cos(x) + y \, \mathrm{d}x$$

$$\phi = xy - \sin(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x$. Therefore equation (4) becomes

$$x = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = xy - \sin(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = xy - \sin(x)$$

The solution becomes

$$y = \frac{\sin(x) + c_1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\sin(x) + c_1}{x} \tag{1}$$

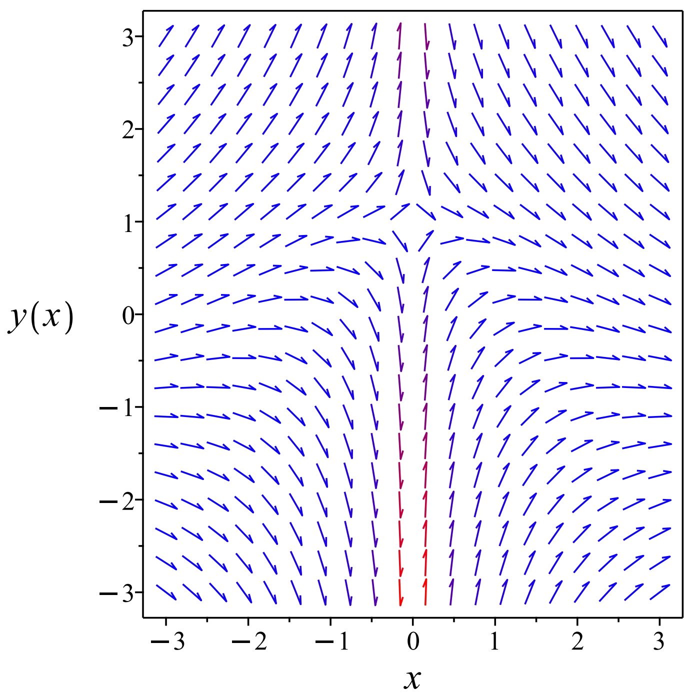

Figure 18: Slope field plot

Verification of solutions

$$y = \frac{\sin(x) + c_1}{x}$$

Verified OK.

1.12.4 Maple step by step solution

Let's solve

$y'x + y = \cos(x)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{x} + \frac{\cos(x)}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{x} = \frac{\cos(x)}{x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \frac{\mu(x)\cos(x)}{x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = x$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)\cos(x)}{x} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)\cos(x)}{x} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)\cos(x)}{x} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = x$

  $y = \frac{\int \cos(x) dx + c_1}{x}$

- Evaluate the integrals on the rhs

  $y = \frac{\sin(x) + c_1}{x}$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' + 2y = e^x}$$

1.13.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = e^x$$

Hence the ode is

$$y' + 2y = e^x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 2dx} \\ &= e^{2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(e^{x}\right) \\ \frac{d}{dx}\left(y\,e^{2x}\right) &= \left(e^{2x}\right)\left(e^{x}\right) \\ d\left(y\,e^{2x}\right) &= e^{3x}\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}y\,e^{2x} &= \int e^{3x}\,dx \\ y\,e^{2x} &= \frac{e^{3x}}{3} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = \frac{e^{3x}e^{-2x}}{3} + c_1 e^{-2x}$$

which simplifies to

$$y = \frac{\left(e^{3x} + 3c_1\right)e^{-2x}}{3}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{\left(e^{3x} + 3c_1\right)e^{-2x}}{3} \tag{1}$$

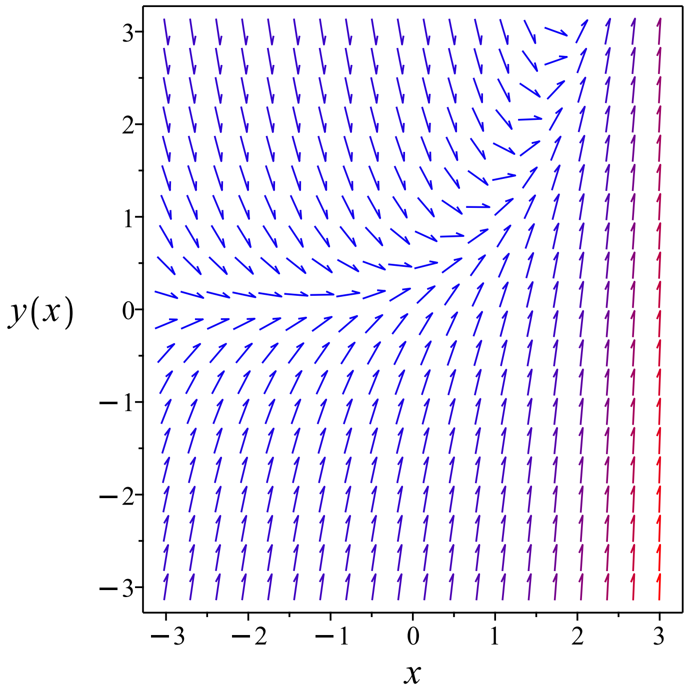

Figure 19: Slope field plot

Verification of solutions

$$y = \frac{(e^{3x} + 3c_1) e^{-2x}}{3}$$

Verified OK.

1.13.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -2y + e^x$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 9: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= 0 \\ \eta(x, y) &= \mathrm{e}^{-2x} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-2x}} dy \end{aligned}$$

Which results in

$$S = y\,e^{2x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -2y + e^{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= 2y\,e^{2x} \\ S_y &= e^{2x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^{3x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^{3R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{e^{3R}}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,e^{2x} = \frac{e^{3x}}{3} + c_1$$

Which simplifies to

$$y\,e^{2x} = \frac{e^{3x}}{3} + c_1$$

Which gives

$$y = \frac{(e^{3x} + 3c_1)\,e^{-2x}}{3}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -2y + e^x$ 	$R = x$ $S = y\,e^{2x}$	$\frac{dS}{dR} = e^{3R}$ 
Summary
The solution(s) found are the following

$$y = \frac{(e^{3x} + 3c_1)\,e^{-2x}}{3} \tag{1}$$

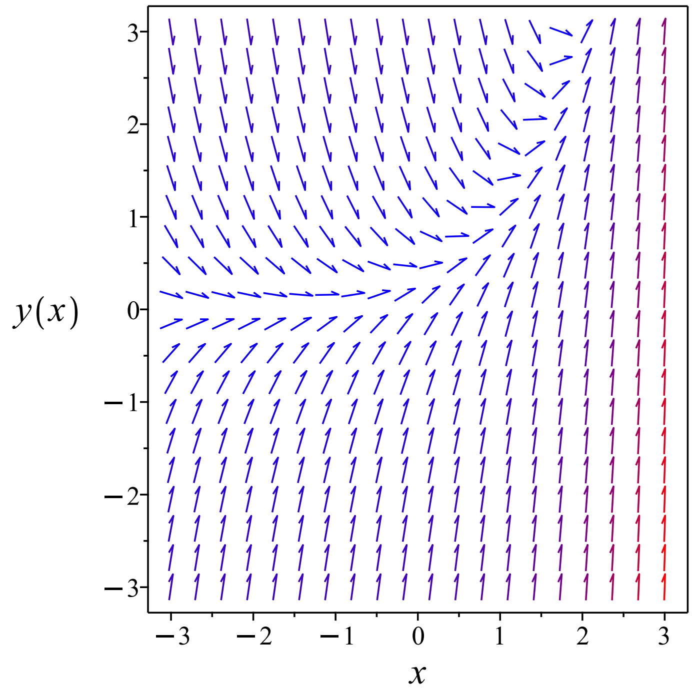

Figure 20: Slope field plot

Verification of solutions

$$y = \frac{(e^{3x} + 3c_1) e^{-2x}}{3}$$

Verified OK.

1.13.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, dx + N(x, y) \, dy = 0 \tag{1A}$$

Therefore

$$\begin{aligned} dy &= (-2y + e^x) \, dx\\ (2y - e^x) \, dx + dy &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= 2y - e^x\\ N(x, y) &= 1 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2y - e^x)\\ &= 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= 1((2) - (0))\\ &= 2\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int 2\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{2x}\\ &= \mathrm{e}^{2x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{2x}(2y - \mathrm{e}^{x})\\ &= (2y - \mathrm{e}^{x})\,\mathrm{e}^{2x}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \mathrm{e}^{2x}(1)\\ &= \mathrm{e}^{2x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left((2y - \mathrm{e}^{x})\,\mathrm{e}^{2x}\right) + \left(\mathrm{e}^{2x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int (2y - \mathrm{e}^{x})\,\mathrm{e}^{2x}\,\mathrm{d}x$$
$$\phi = -\frac{\mathrm{e}^{3x}}{3} + y\,\mathrm{e}^{2x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{2x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{2x}$. Therefore equation (4) becomes

$$\mathrm{e}^{2x} = \mathrm{e}^{2x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\mathrm{e}^{3x}}{3} + y\,\mathrm{e}^{2x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\mathrm{e}^{3x}}{3} + y\,\mathrm{e}^{2x}$$

The solution becomes

$$y = \frac{(\mathrm{e}^{3x} + 3c_1)\,\mathrm{e}^{-2x}}{3}$$

Summary
The solution(s) found are the following

$$y = \frac{(e^{3x} + 3c_1) e^{-2x}}{3} \tag{1}$$

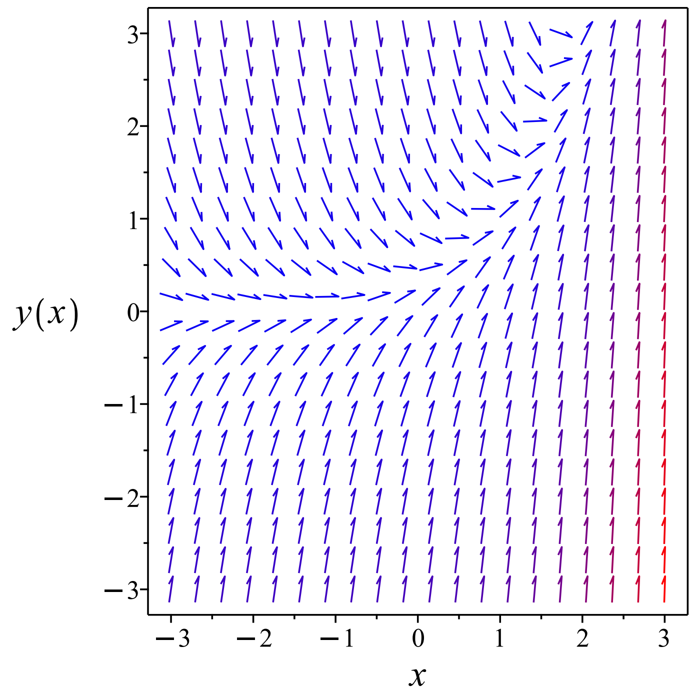

Figure 21: Slope field plot

Verification of solutions

$$y = \frac{(e^{3x} + 3c_1) e^{-2x}}{3}$$

Verified OK.

1.13.4 Maple step by step solution

Let's solve

$y' + 2y = e^x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$y' = -2y + e^{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

$y' + 2y = e^{x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$\mu(x)\left(y' + 2y\right) = \mu(x)\, e^{x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}\left(\mu(x)\, y\right)$

$\mu(x)\left(y' + 2y\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

$\mu'(x) = 2\mu(x)$

- Solve to find the integrating factor

$\mu(x) = e^{2x}$

- Integrate both sides with respect to x

$\int \left(\frac{d}{dx}\left(\mu(x)\, y\right)\right) dx = \int \mu(x)\, e^{x} dx + c_1$

- Evaluate the integral on the lhs

$\mu(x)\, y = \int \mu(x)\, e^{x} dx + c_1$

- Solve for y

$y = \frac{\int \mu(x) e^{x} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = e^{2x}$

$y = \frac{\int e^{x} e^{2x} dx + c_1}{e^{2x}}$

- Evaluate the integrals on the rhs

$y = \frac{\frac{e^{3x}}{3} + c_1}{e^{2x}}$

- Simplify

$y = \frac{\left(e^{3x} + 3c_1\right) e^{-2x}}{3}$

Section: Section 1. Basic concepts and definitions. Exercises page 18
Problem number: 16.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(-x^2+1)\, y' + yx = 2x}$$

1.14.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{x(y-2)}{x^2-1} \end{aligned}$$

Where $f(x) = \frac{x}{x^2-1}$ and $g(y) = y-2$. Integrating both sides gives

$$\frac{1}{y-2}\, dy = \frac{x}{x^2-1}\, dx$$

$$\int \frac{1}{y-2}\, dy = \int \frac{x}{x^2-1}\, dx$$

$$\ln(y-2) = \frac{\ln(x-1)}{2} + \frac{\ln(x+1)}{2} + c_1$$

Raising both side to exponential gives

$$y - 2 = e^{\frac{\ln(x-1)}{2} + \frac{\ln(x+1)}{2} + c_1}$$

Which simplifies to

$$y - 2 = c_2 e^{\frac{\ln(x-1)}{2} + \frac{\ln(x+1)}{2}}$$

Which simplifies to

$$y = c_2 \sqrt{x-1}\,\sqrt{x+1}\,e^{c_1} + 2$$

Summary

The solution(s) found are the following

$$y = c_2 \sqrt{x-1}\,\sqrt{x+1}\,e^{c_1} + 2 \tag{1}$$

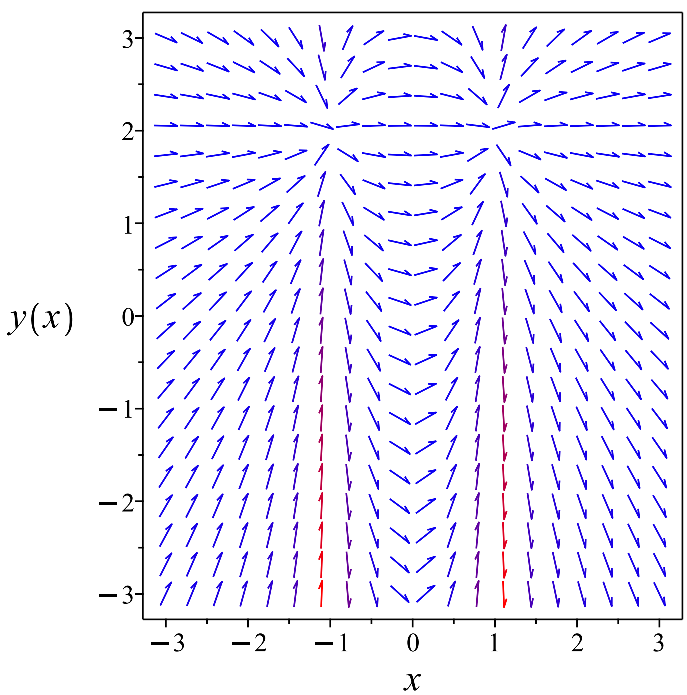

Figure 22: Slope field plot

Verification of solutions

$$y = c_2 \sqrt{x-1}\,\sqrt{x+1}\,e^{c_1} + 2$$

Verified OK.

1.14.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{x}{x^2-1}\\ q(x) &= -\frac{2x}{x^2-1}\end{aligned}$$

Hence the ode is

$$y' - \frac{xy}{x^2-1} = -\frac{2x}{x^2-1}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{x}{x^2-1}dx}\\ &= \mathrm{e}^{-\frac{\ln(x-1)}{2}-\frac{\ln(x+1)}{2}}\end{aligned}$$

Which simplifies to

$$\mu = \frac{1}{\sqrt{x-1}\,\sqrt{x+1}}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(-\frac{2x}{x^2-1}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{\sqrt{x-1}\,\sqrt{x+1}}\right) &= \left(\frac{1}{\sqrt{x-1}\,\sqrt{x+1}}\right)\left(-\frac{2x}{x^2-1}\right)\\ \mathrm{d}\left(\frac{y}{\sqrt{x-1}\,\sqrt{x+1}}\right) &= \left(-\frac{2x}{(x^2-1)\sqrt{x-1}\,\sqrt{x+1}}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{\sqrt{x-1}\,\sqrt{x+1}} &= \int -\frac{2x}{(x^2-1)\sqrt{x-1}\,\sqrt{x+1}}\,\mathrm{d}x\\ \frac{y}{\sqrt{x-1}\,\sqrt{x+1}} &= \frac{2\sqrt{x-1}\,\sqrt{x+1}}{x^2-1} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{\sqrt{x-1}\,\sqrt{x+1}}$ results in

$$y = \frac{2(x-1)(x+1)}{x^2-1} + c_1\sqrt{x-1}\,\sqrt{x+1}$$

which simplifies to

$$y = 2 + c_1\sqrt{x-1}\,\sqrt{x+1}$$

Summary

The solution(s) found are the following

$$y = 2 + c_1\sqrt{x-1}\,\sqrt{x+1} \tag{1}$$

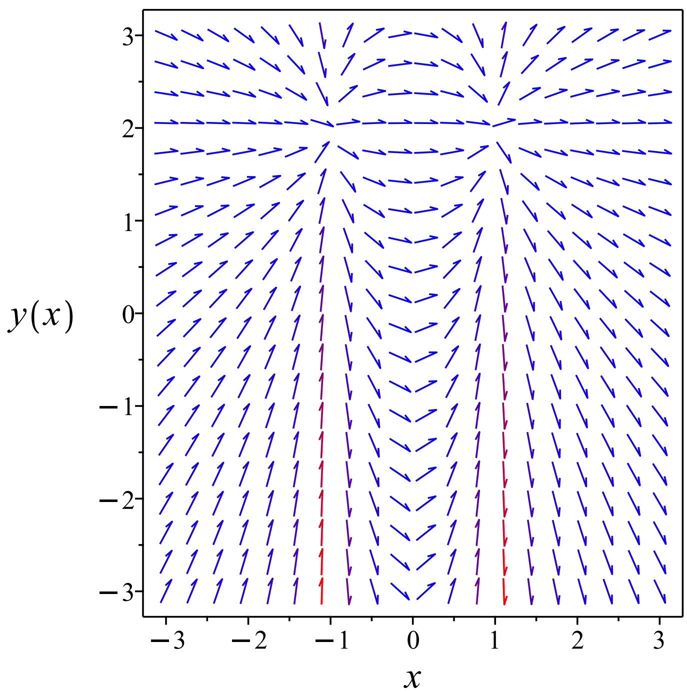

Figure 23: Slope field plot

Verification of solutions

$$y = 2 + c_1\sqrt{x-1}\,\sqrt{x+1}$$

Verified OK.

1.14.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{x(y-2)}{x^2-1} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 12: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x,y) = 0$$
$$\eta(x,y) = \mathrm{e}^{\frac{\ln(x-1)}{2}+\frac{\ln(x+1)}{2}} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{\frac{\ln(x-1)}{2}+\frac{\ln(x+1)}{2}}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{\ln\left(\frac{1}{\sqrt{x-1}}\right)+\ln\left(\frac{1}{\sqrt{x+1}}\right)} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x(y-2)}{x^2-1}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{yx}{(x-1)^{\frac{3}{2}} (x+1)^{\frac{3}{2}}} \\
S_y &= \frac{1}{\sqrt{x-1}\,\sqrt{x+1}}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{2x}{(x-1)^{\frac{3}{2}} (x+1)^{\frac{3}{2}}} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{2R}{(R-1)^{\frac{3}{2}} (R+1)^{\frac{3}{2}}}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{2}{\sqrt{R-1}\,\sqrt{R+1}} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{y}{\sqrt{x-1}\,\sqrt{x+1}} = \frac{2}{\sqrt{x-1}\,\sqrt{x+1}} + c_1
$$

Which simplifies to

$$
\frac{y}{\sqrt{x-1}\,\sqrt{x+1}} = \frac{2}{\sqrt{x-1}\,\sqrt{x+1}} + c_1
$$

Which gives

$$
y = 2 + c_1\sqrt{x-1}\,\sqrt{x+1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x(y-2)}{x^2-1}$ 	$R = x$ $S = \frac{y}{\sqrt{x-1}\,\sqrt{x+1}}$	$\frac{dS}{dR} = -\frac{2R}{(R-1)^{\frac{3}{2}}(R+1)^{\frac{3}{2}}}$ 
Summary

The solution(s) found are the following

$$y = 2 + c_1\sqrt{x-1}\,\sqrt{x+1} \tag{1}$$

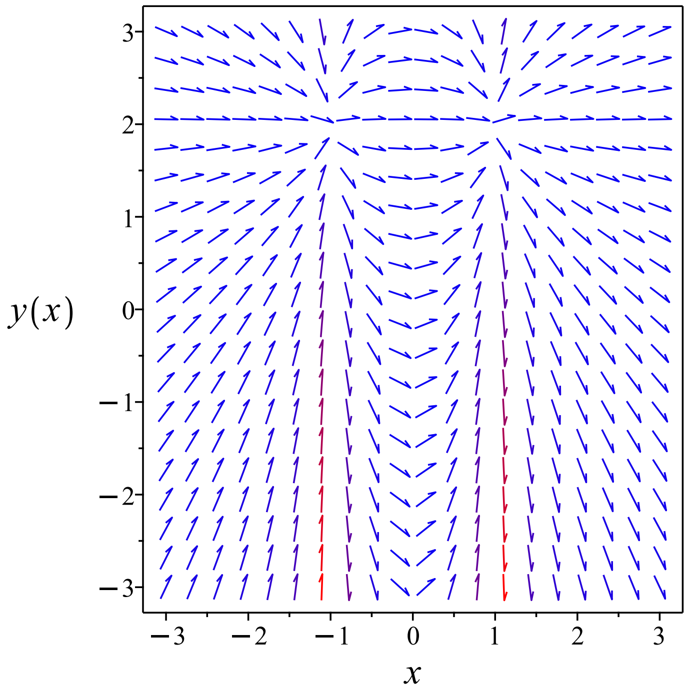

Figure 24: Slope field plot

Verification of solutions

$$y = 2 + c_1\sqrt{x-1}\,\sqrt{x+1}$$

Verified OK.

1.14.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{y-2}\right) \mathrm{d}y &= \left(\frac{x}{x^2-1}\right) \mathrm{d}x \\
\left(-\frac{x}{x^2-1}\right) \mathrm{d}x + \left(\frac{1}{y-2}\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{x}{x^2-1} \\
N(x, y) &= \frac{1}{y-2}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{x^2-1}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y-2}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{x}{x^2-1}\,\mathrm{d}x \\
\phi &= -\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2} + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y-2}$. Therefore equation (4) becomes

$$
\frac{1}{y-2} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y-2}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\,\mathrm{d}y &= \int \left(\frac{1}{y-2}\right)\mathrm{d}y \\
f(y) &= \ln(y-2) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2} + \ln(y-2) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2} + \ln(y-2)$$

Summary
The solution(s) found are the following

$$-\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2} + \ln(y-2) = c_1 \tag{1}$$

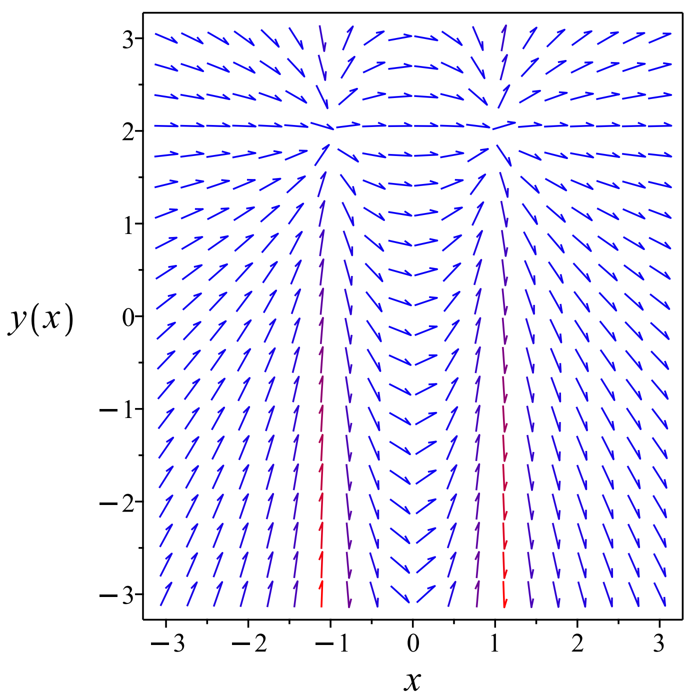

Figure 25: Slope field plot

Verification of solutions

$$-\frac{\ln(x-1)}{2} - \frac{\ln(x+1)}{2} + \ln(y-2) = c_1$$

Verified OK.

1.14.5 Maple step by step solution

Let's solve

$(-x^2+1)\,y' + yx = 2x$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y-2} = \frac{x}{(x-1)(x+1)}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y-2}dx = \int \frac{x}{(x-1)(x+1)}dx + c_1$

- Evaluate integral

  $\ln(y-2) = \frac{\ln((x-1)(x+1))}{2} + c_1$

- Solve for y

  $y = \mathrm{e}^{\frac{\ln((x-1)(x+1))}{2}+c_1} + 2$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = x}$$

2.2.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = x$$

Hence the ode is

$$y' - y = x$$

The integrating factor μ is

$$\mu = e^{\int (-1)dx}$$
$$= e^{-x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(x)$$
$$\frac{d}{dx}(e^{-x} y) = (e^{-x})(x)$$
$$d(e^{-x} y) = (x e^{-x})\, dx$$

Integrating gives

$$e^{-x} y = \int x e^{-x}\, dx$$
$$e^{-x} y = -(x+1) e^{-x} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = -e^{x}(x+1) e^{-x} + e^{x} c_1$$

which simplifies to

$$y = e^{x} c_1 - x - 1$$

Summary

The solution(s) found are the following

$$y = e^{x} c_1 - x - 1 \tag{1}$$

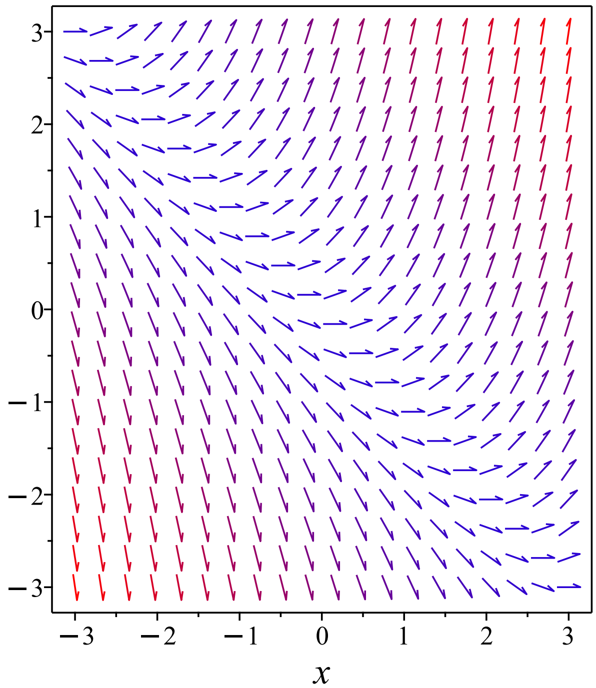

Figure 27: Slope field plot

Verification of solutions

$$y = e^x c_1 - x - 1$$

Verified OK.

2.2.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = y + x$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 16: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= e^x
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^x} dy \end{aligned}$$

Which results in

$$S = e^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = y + x$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -e^{-x} y \\ S_y &= e^{-x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x\,e^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R\,e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -(R+1)\,\mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-x} y = -(x+1)\,\mathrm{e}^{-x} + c_1$$

Which simplifies to

$$(x+y+1)\,\mathrm{e}^{-x} - c_1 = 0$$

Which gives

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = y + x$ 	$R = x$ $S = \mathrm{e}^{-x} y$	$\frac{dS}{dR} = R\,\mathrm{e}^{-R}$ 
Summary
The solution(s) found are the following

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x} \tag{1}$$

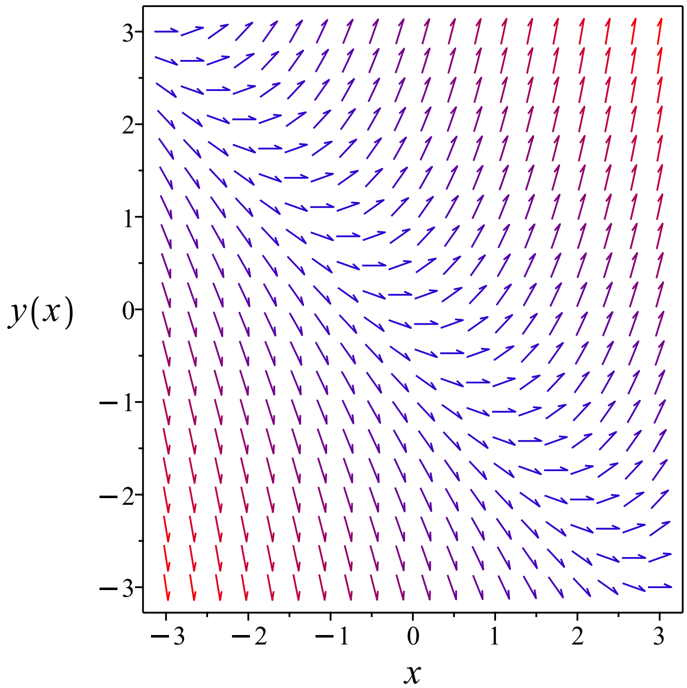

Figure 28: Slope field plot

Verification of solutions

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x}$$

Verified OK.

2.2.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= (y + x)\, \mathrm{d}x\\ (-y - x)\, \mathrm{d}x + \mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -y - x\\ N(x, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y - x)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((-1) - (0)) \\
&= -1
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -1 \, \mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{-x} \\
&= \mathrm{e}^{-x}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-x}(-y - x) \\
&= -\mathrm{e}^{-x}(y + x)
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-x}(1) \\
&= \mathrm{e}^{-x}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{-x}(y + x)\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\mathrm{e}^{-x}(y+x) \mathrm{d}x$$
$$\phi = (x+y+1)\,\mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (x+y+1)\,\mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (x+y+1)\,\mathrm{e}^{-x}$$

The solution becomes

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x} \tag{1}$$

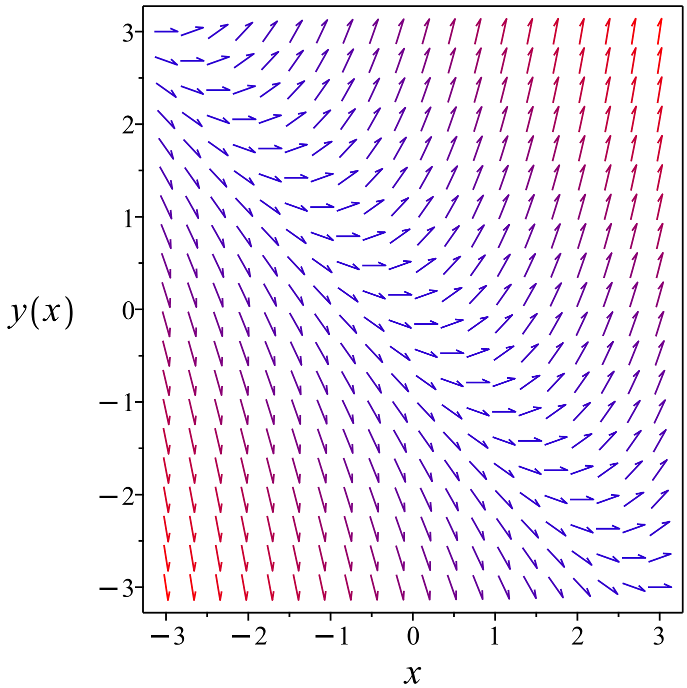

Figure 29: Slope field plot

Verification of solutions

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x}$$

Verified OK.

2.2.4 Maple step by step solution

Let's solve

$y' - y = x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = y + x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - y) = \mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\, (y'-y) = \mu'(x)\, y + \mu(x)\, y'$
- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{-x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x)\, x dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \mu(x)\, x dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x) x dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{-x}$

  $y = \frac{\int x\, \mathrm{e}^{-x} dx + c_1}{\mathrm{e}^{-x}}$
- Evaluate the integrals on the rhs

  $y = \frac{-(x+1)\mathrm{e}^{-x} + c_1}{\mathrm{e}^{-x}}$
- Simplify

  $y = \mathrm{e}^{x} c_1 - x - 1$

Section: Section 2. The method of isoclines. Exercises page 27
Problem number: 23.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = -x}$$

2.3.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = -x$$

Hence the ode is

$$y' - y = -x$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int (-1)dx} \\
&= \mathrm{e}^{-x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(-x) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-x} y\right) &= \left(\mathrm{e}^{-x}\right)(-x) \\
\mathrm{d}\left(\mathrm{e}^{-x} y\right) &= \left(-x\,\mathrm{e}^{-x}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-x} y &= \int -x\,\mathrm{e}^{-x}\,\mathrm{d}x \\
\mathrm{e}^{-x} y &= (x+1)\,\mathrm{e}^{-x} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$
y = \mathrm{e}^{x} (x+1)\,\mathrm{e}^{-x} + \mathrm{e}^{x} c_1
$$

which simplifies to

$$
y = \mathrm{e}^{x} c_1 + x + 1
$$

Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{x} c_1 + x + 1 \tag{1}
$$

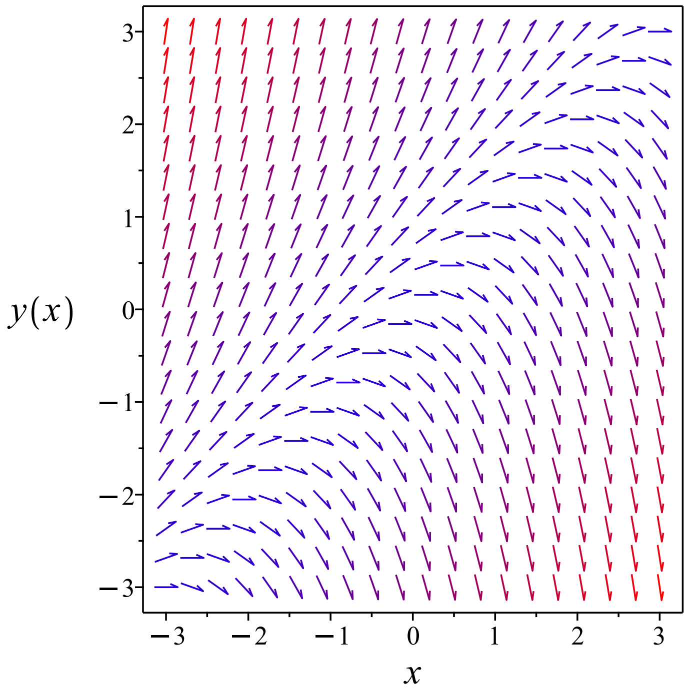

Figure 30: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{x} c_1 + x + 1$$

Verified OK.

2.3.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= y - x \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 19: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{x}} dy \end{aligned}$$

Which results in

$$S = e^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = y - x$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -e^{-x} y \\ S_y &= e^{-x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -x\,e^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -R\,e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = (R+1)\,\mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-x} y = (x+1)\,\mathrm{e}^{-x} + c_1$$

Which simplifies to

$$\mathrm{e}^{-x} y = (x+1)\,\mathrm{e}^{-x} + c_1$$

Which gives

$$y = \left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} + c_1\right) \mathrm{e}^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = y - x$ 	$R = x$ $S = \mathrm{e}^{-x} y$	$\frac{dS}{dR} = -R\,\mathrm{e}^{-R}$ 
Summary

The solution(s) found are the following

$$y = \left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} + c_1\right) \mathrm{e}^{x} \tag{1}$$

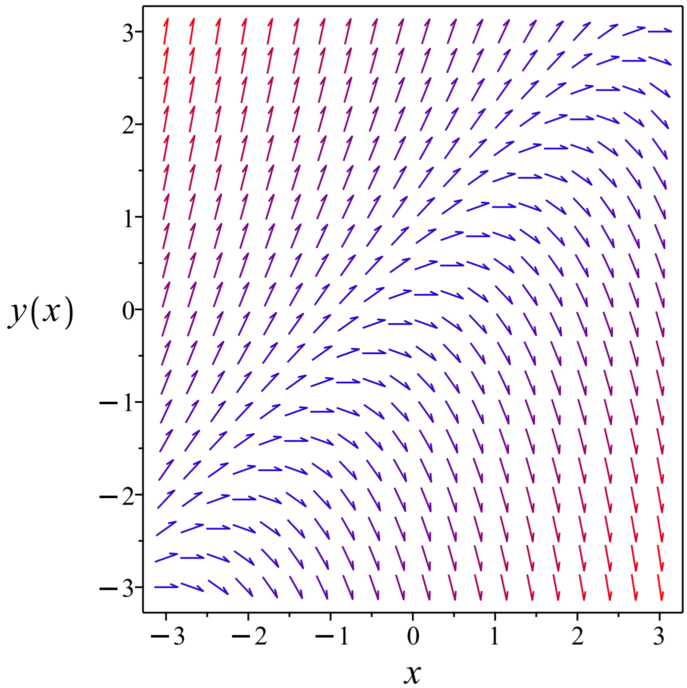

Figure 31: Slope field plot

Verification of solutions

$$y = \left(x\,e^{-x} + e^{-x} + c_1\right) e^{x}$$

Verified OK.

2.3.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = (y - x) \,\mathrm{d}x$$
$$(-y + x) \,\mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -y + x$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y + x) \\ &= -1 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-1) - (0)) \\ &= -1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}x} \\ &= e^{\int -1 \,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-x} \\ &= \mathrm{e}^{-x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{-x}(-y + x) \\ &= (-y + x)\,\mathrm{e}^{-x}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{-x}(1) \\ &= \mathrm{e}^{-x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left((-y + x)\,\mathrm{e}^{-x}\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int (-y+x) \mathrm{e}^{-x} \mathrm{d}x$$
$$\phi = -(-y+1+x) \mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -(-y+1+x) \mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -(-y+1+x) \mathrm{e}^{-x}$$

The solution becomes

$$y = \left(x \mathrm{e}^{-x} + \mathrm{e}^{-x} + c_1\right) \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \left(x \mathrm{e}^{-x} + \mathrm{e}^{-x} + c_1\right) \mathrm{e}^{x} \tag{1}$$

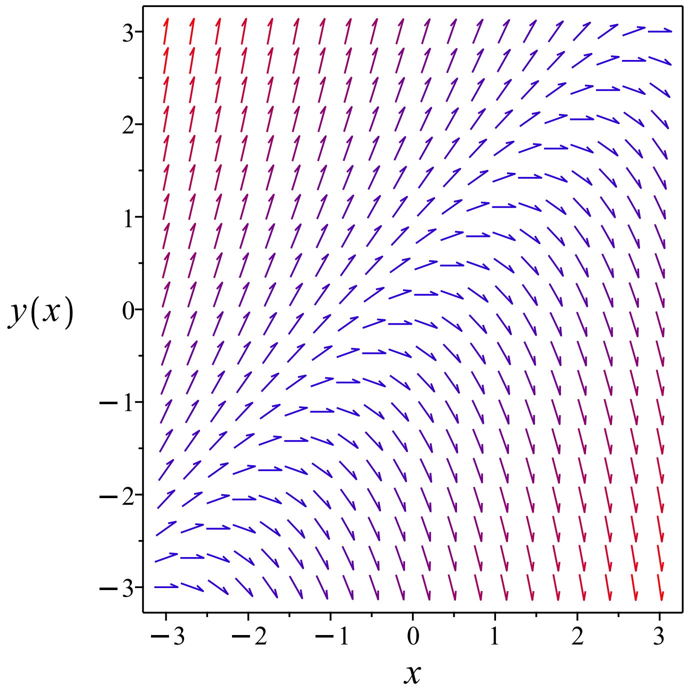

Figure 32: Slope field plot

Verification of solutions

$$y = \left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} + c_1\right)\mathrm{e}^{x}$$

Verified OK.

Problem number: 24.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' + y = \frac{x}{2} + \frac{3}{2}}$$

2.4.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= \frac{x}{2} + \frac{3}{2} \end{aligned}$$

Hence the ode is

$$y' + y = \frac{x}{2} + \frac{3}{2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1dx} \\ &= e^{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{x}{2}+\frac{3}{2}\right) \\ \frac{d}{dx}(e^{x} y) &= (e^{x})\left(\frac{x}{2}+\frac{3}{2}\right) \\ d(e^{x} y) &= \left(\frac{(x+3)\,e^{x}}{2}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{x} y &= \int \frac{(x+3)\,e^{x}}{2}\, dx \\ e^{x} y &= \frac{(x+2)\,e^{x}}{2} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = \frac{e^{-x}(x+2)\,e^{x}}{2} + c_1 e^{-x}$$

which simplifies to

$$y = 1 + \frac{x}{2} + c_1 e^{-x}$$

Summary

The solution(s) found are the following

$$y = 1 + \frac{x}{2} + c_1 e^{-x} \tag{1}$$

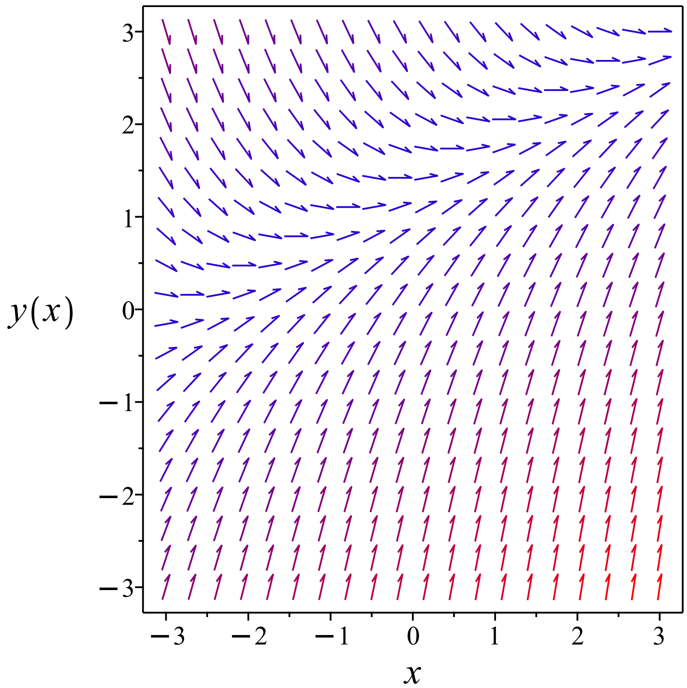

Figure 33: Slope field plot

Verification of solutions

$$y = 1 + \frac{x}{2} + c_1 e^{-x}$$

Verified OK.

2.4.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x}{2} - y + \frac{3}{2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 22: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-x}} dy \end{aligned}$$

Which results in

$$S = e^x y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x}{2} - y + \frac{3}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= e^x y \\ S_y &= e^x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{(x + 3) e^x}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{(R + 3) e^R}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{(R+2)\,e^{R}}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,e^{x} = \frac{(x+2)\,e^{x}}{2} + c_1$$

Which simplifies to

$$y\,e^{x} = \frac{(x+2)\,e^{x}}{2} + c_1$$

Which gives

$$y = \frac{(x\,e^{x} + 2\,e^{x} + 2c_1)\,e^{-x}}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x}{2} - y + \frac{3}{2}$ 	$R = x$ $S = e^{x} y$	$\frac{dS}{dR} = \frac{(R+3)e^{R}}{2}$ 
Summary

The solution(s) found are the following

$$y = \frac{(x\,e^{x} + 2\,e^{x} + 2c_1)\,e^{-x}}{2} \tag{1}$$

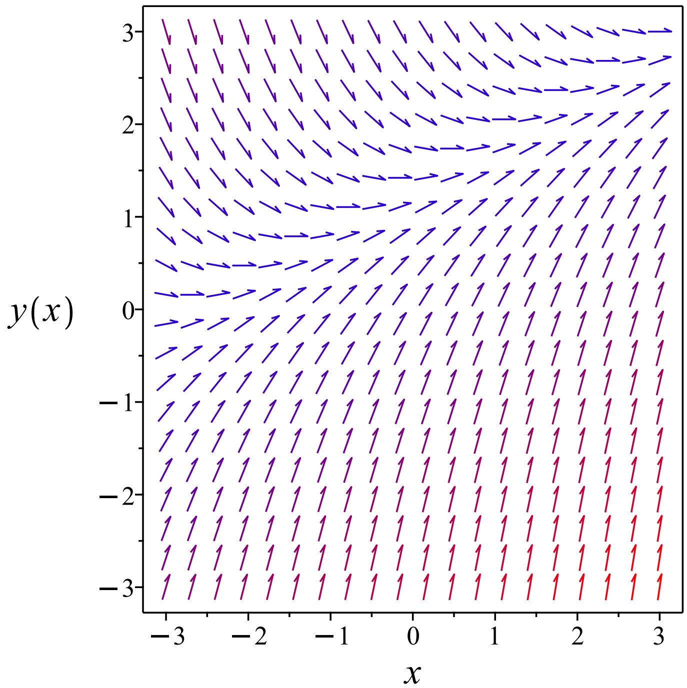

Figure 34: Slope field plot

Verification of solutions

$$y = \frac{(x\,e^{x} + 2\,e^{x} + 2c_1)\,e^{-x}}{2}$$

Verified OK.

2.4.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(\frac{x}{2} - y + \frac{3}{2}\right)\mathrm{d}x$$
$$\left(-\frac{x}{2} + y - \frac{3}{2}\right)\mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{x}{2} + y - \frac{3}{2}$$
$$N(x,y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{x}{2} + y - \frac{3}{2}\right)$$
$$= 1$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= 1((1) - (0))\\ &= 1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}x}\\ &= e^{\int 1 \,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{x}\\ &= \mathrm{e}^{x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{x}\left(-\frac{x}{2} + y - \frac{3}{2}\right)\\ &= -\frac{(x - 2y + 3)\,\mathrm{e}^{x}}{2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \mathrm{e}^{x}(1)\\ &= \mathrm{e}^{x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(-\frac{(x - 2y + 3)\,\mathrm{e}^{x}}{2}\right) + (\mathrm{e}^{x})\,\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x} \, dx = \int \overline{M} \, dx$$
$$\int \frac{\partial\phi}{\partial x} \, dx = \int -\frac{(x - 2y + 3) e^{x}}{2} \, dx$$
$$\phi = -\frac{(x - 2y + 2) e^{x}}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = e^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = e^{x}$. Therefore equation (4) becomes

$$e^{x} = e^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{(x - 2y + 2) e^{x}}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{(x - 2y + 2) e^{x}}{2}$$

The solution becomes

$$y = \frac{(x\,e^{x} + 2\,e^{x} + 2c_1)\,e^{-x}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{(x\,e^{x} + 2\,e^{x} + 2c_1)\,e^{-x}}{2} \tag{1}$$

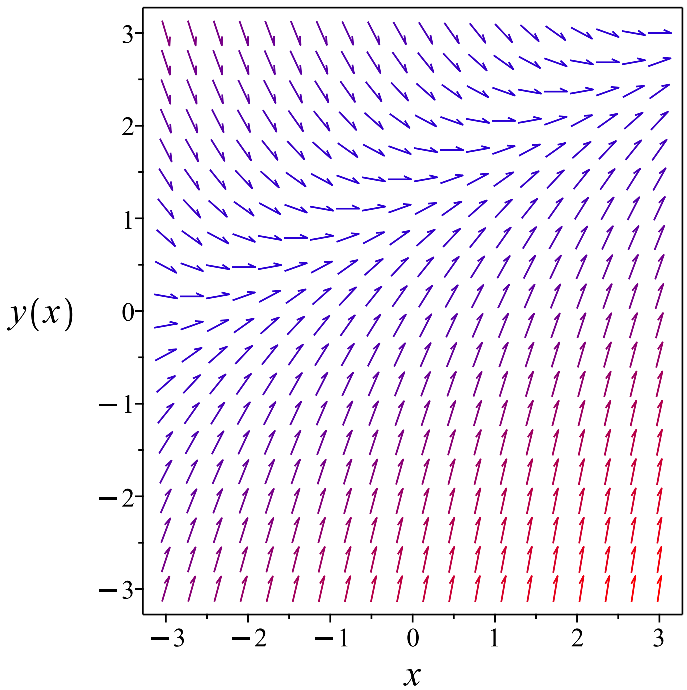

Figure 35: Slope field plot

2.4.4 Maple step by step solution

Let's solve

$y' + y = \frac{x}{2} + \frac{3}{2}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{x}{2} - y + \frac{3}{2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + y = \frac{x}{2} + \frac{3}{2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' + y) = \mu(x)\left(\frac{x}{2} + \frac{3}{2}\right)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' + y) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)$

- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\left(\frac{x}{2} + \frac{3}{2}\right) dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\left(\frac{x}{2} + \frac{3}{2}\right) dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x)\left(\frac{x}{2}+\frac{3}{2}\right)dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \mathrm{e}^{x}$

  $y = \frac{\int \left(\frac{x}{2}+\frac{3}{2}\right)\mathrm{e}^{x}dx + c_1}{\mathrm{e}^{x}}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{(x+2)\,\mathrm{e}^{x}}{2} + c_1}{\mathrm{e}^{x}}$

- Simplify

$$y = 1 + \frac{x}{2} + c_1 e^{-x}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - (y-1)\,x = 0}$$

2.6.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= (y-1)\,x \end{aligned}$$

Where $f(x) = x$ and $g(y) = y - 1$. Integrating both sides gives

$$\frac{1}{y-1}\,dy = x\,dx$$

$$\int \frac{1}{y-1}\,dy = \int x\,dx$$

$$\ln(y-1) = \frac{x^2}{2} + c_1$$

Raising both side to exponential gives

$$y - 1 = e^{\frac{x^2}{2}+c_1}$$

Which simplifies to

$$y - 1 = c_2 e^{\frac{x^2}{2}}$$

Summary

The solution(s) found are the following

$$y = c_2 e^{\frac{x^2}{2}+c_1} + 1 \tag{1}$$

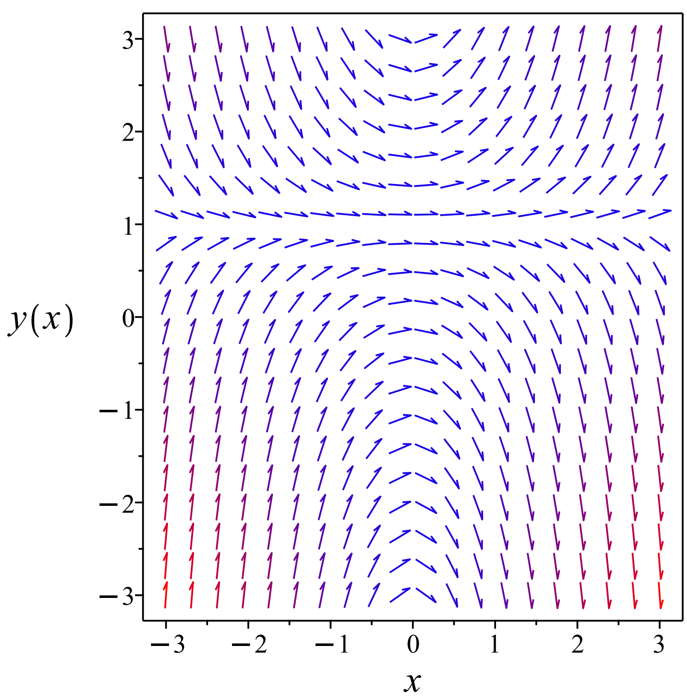

Figure 37: Slope field plot

Verification of solutions

$$y = c_2 e^{\frac{x^2}{2}+c_1} + 1$$

Verified OK.

2.6.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -x \\ q(x) &= -x \end{aligned}$$

Hence the ode is

$$y' - yx = -x$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -x dx} \\ &= \mathrm{e}^{-\frac{x^2}{2}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(-x) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-\frac{x^2}{2}} y\right) &= \left(\mathrm{e}^{-\frac{x^2}{2}}\right)(-x) \\ \mathrm{d}\left(\mathrm{e}^{-\frac{x^2}{2}} y\right) &= \left(-x\,\mathrm{e}^{-\frac{x^2}{2}}\right)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \mathrm{e}^{-\frac{x^2}{2}} y &= \int -x\,\mathrm{e}^{-\frac{x^2}{2}}\,\mathrm{d}x \\ \mathrm{e}^{-\frac{x^2}{2}} y &= \mathrm{e}^{-\frac{x^2}{2}} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-\frac{x^2}{2}}$ results in

$$y = \mathrm{e}^{\frac{x^2}{2}}\mathrm{e}^{-\frac{x^2}{2}} + c_1\mathrm{e}^{\frac{x^2}{2}}$$

which simplifies to

$$y = 1 + c_1\mathrm{e}^{\frac{x^2}{2}}$$

Summary
The solution(s) found are the following

$$y = 1 + c_1\mathrm{e}^{\frac{x^2}{2}} \tag{1}$$

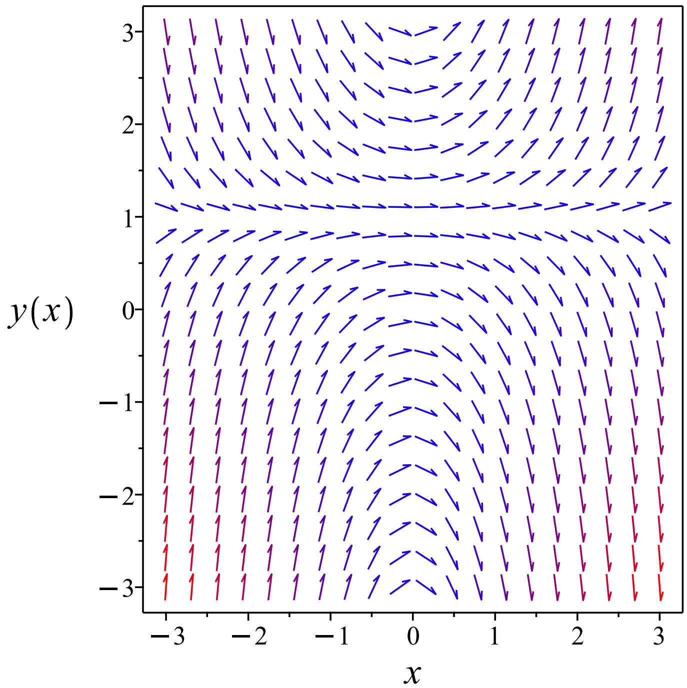

Figure 38: Slope field plot

Verification of solutions

$$y = 1 + c_1 \mathrm{e}^{\frac{x^2}{2}}$$

Verified OK.

2.6.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = (y - 1)\,x$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 26: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \mathrm{e}^{\frac{x^2}{2}}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\frac{x^2}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{-\frac{x^2}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = (y - 1) x$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -x e^{-\frac{x^2}{2}} y \\ S_y &= e^{-\frac{x^2}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -x e^{-\frac{x^2}{2}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -R e^{-\frac{R^2}{2}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \mathrm{e}^{-\frac{R^2}{2}} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-\frac{x^2}{2}} y = \mathrm{e}^{-\frac{x^2}{2}} + c_1$$

Which simplifies to

$$(y-1)\,\mathrm{e}^{-\frac{x^2}{2}} - c_1 = 0$$

Which gives

$$y = \left(\mathrm{e}^{-\frac{x^2}{2}} + c_1\right) \mathrm{e}^{\frac{x^2}{2}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = (y-1)\,x$ 	$R = x$ $S = \mathrm{e}^{-\frac{x^2}{2}} y$	$\frac{dS}{dR} = -R\,\mathrm{e}^{-\frac{R^2}{2}}$ 
Summary

The solution(s) found are the following

$$y = \left(\mathrm{e}^{-\frac{x^2}{2}} + c_1\right) \mathrm{e}^{\frac{x^2}{2}} \tag{1}$$

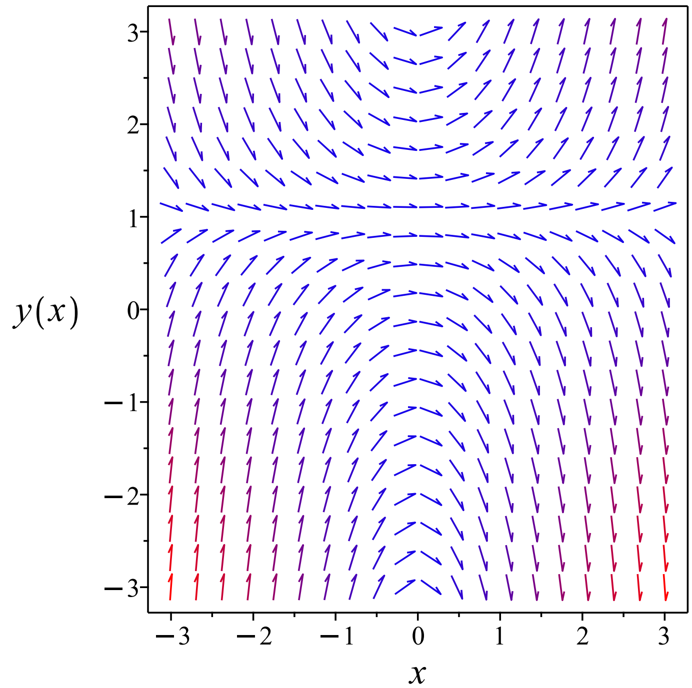

Figure 39: Slope field plot

Verification of solutions

$$y = \left(e^{-\frac{x^2}{2}} + c_1\right) e^{\frac{x^2}{2}}$$

Verified OK.

2.6.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{y-1}\right) \mathrm{d}y &= (x)\, \mathrm{d}x \\
(-x)\, \mathrm{d}x + \left(\frac{1}{y-1}\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -x \\
N(x, y) &= \frac{1}{y-1}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y-1}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -x\, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{x^2}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y-1}$. Therefore equation (4) becomes

$$
\frac{1}{y-1} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y-1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\, \mathrm{d}y &= \int \left(\frac{1}{y-1}\right) \mathrm{d}y\\
f(y) &= \ln(y-1) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} + \ln(y-1) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} + \ln(y-1)$$

The solution becomes

$$y = e^{\frac{x^2}{2}+c_1} + 1$$

Summary

The solution(s) found are the following

$$y = e^{\frac{x^2}{2}+c_1} + 1 \tag{1}$$

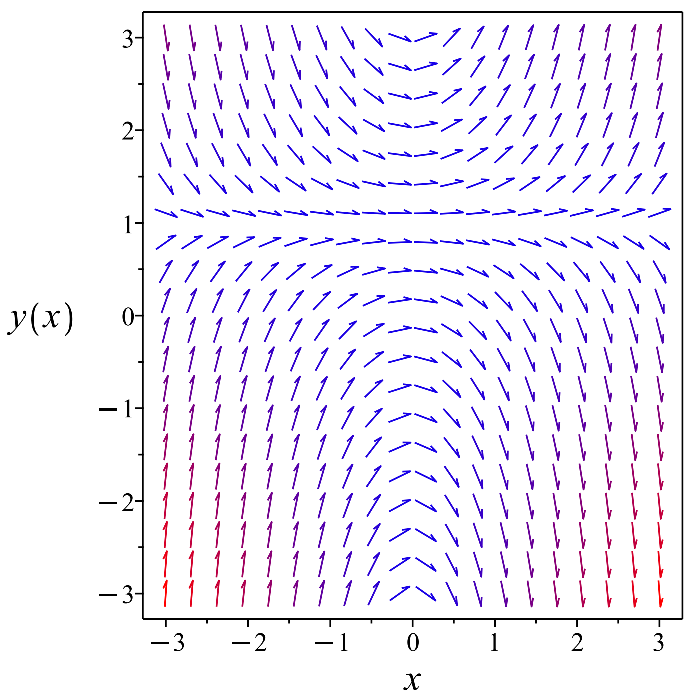

Figure 40: Slope field plot

Verification of solutions

$$y = e^{\frac{x^2}{2}+c_1} + 1$$

Verified OK.

2.6.5 Maple step by step solution

Let's solve

$y' - (y-1)\,x = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y-1} = x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y-1}dx = \int x dx + c_1$

- Evaluate integral

  $\ln(y-1) = \frac{x^2}{2} + c_1$

- Solve for y

  $y = e^{\frac{x^2}{2}+c_1} + 1$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{y' + y^2 = x^2}$$

2.7.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= x^2 - y^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x^2 - y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = x^2$, $f_1(x) = 0$ and $f_2(x) = -1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= x^2 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x) + x^2 u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \sqrt{x}\left(c_1 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + c_2 \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)\right)$$

The above shows that

$$u'(x) = \left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) c_2 + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_1\right) x^{\frac{3}{2}}$$

Using the above in (1) gives the solution

$$y = \frac{\left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) c_2 + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_1\right) x}{c_1 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + c_2 \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3\right) x}{c_3 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3\right) x}{c_3 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)} \tag{1}$$

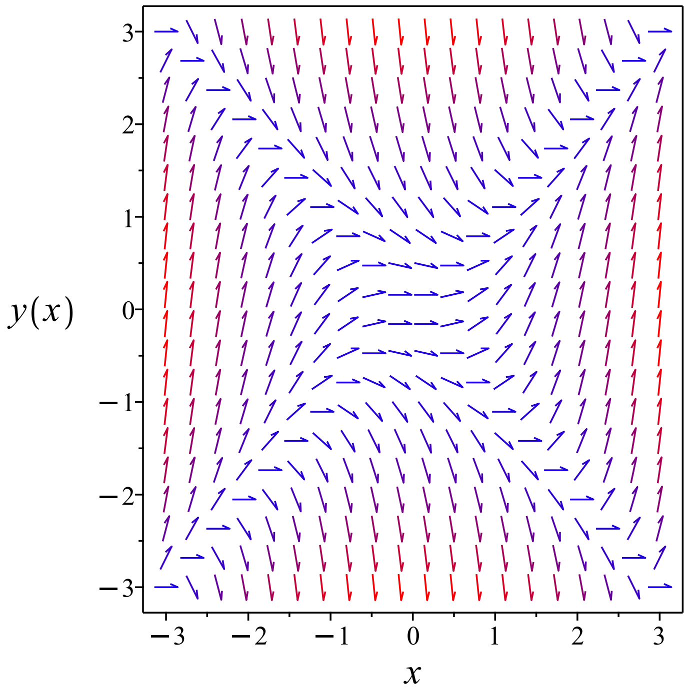

Figure 41: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{\left(-\text{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) + \text{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3\right) x}{c_3 \,\text{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + \text{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Verified OK.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _dAlembert]
```

$$\boxed{y' - \cos(-y + x) = 0}$$

2.8.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \cos(-y + x) \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 + \cos(-y+x)(b_3 - a_2) - \cos(-y+x)^2 a_3 \\
& + \sin(-y+x)(x a_2 + y a_3 + a_1) - \sin(-y+x)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
\begin{aligned}
& \sin(-y+x) x a_2 - \sin(-y+x) x b_2 + \sin(-y+x) y a_3 \\
& - \sin(-y+x) y b_3 - \cos(-y+x)^2 a_3 + \sin(-y+x) a_1 \\
& - \sin(-y+x) b_1 - \cos(-y+x) a_2 + \cos(-y+x) b_3 + b_2 = 0
\end{aligned}
$$

Setting the numerator to zero gives

$$
\begin{aligned}
& \sin(-y+x) x a_2 - \sin(-y+x) x b_2 + \sin(-y+x) y a_3 \\
& - \sin(-y+x) y b_3 - \cos(-y+x)^2 a_3 + \sin(-y+x) a_1 \\
& - \sin(-y+x) b_1 - \cos(-y+x) a_2 + \cos(-y+x) b_3 + b_2 = 0
\end{aligned} \tag{6E}
$$

Simplifying the above gives

$$
\begin{aligned}
& b_2 - \frac{a_3}{2} + \sin(-y+x) x a_2 - \sin(-y+x) x b_2 + \sin(-y+x) y a_3 \\
& - \sin(-y+x) y b_3 - \frac{a_3 \cos(-2y+2x)}{2} + \sin(-y+x) a_1 \\
& - \sin(-y+x) b_1 - \cos(-y+x) a_2 + \cos(-y+x) b_3 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\{x, y, \cos(-2y+2x), \cos(-y+x), \sin(-y+x)\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\{x = v_1, y = v_2, \cos(-2y+2x) = v_3, \cos(-y+x) = v_4, \sin(-y+x) = v_5\}
$$

The above PDE (6E) now becomes

$$
b_2 - \frac{1}{2} a_3 + v_5 v_1 a_2 - v_5 v_1 b_2 + v_5 v_2 a_3 - v_5 v_2 b_3 - \frac{1}{2} a_3 v_3 + v_5 a_1 - v_5 b_1 - v_4 a_2 + v_4 b_3 = 0 \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5\}$$

Equation (7E) now becomes

$$b_2 - \frac{a_3}{2} + (a_2 - b_2)\, v_1 v_5 + (a_3 - b_3)\, v_2 v_5 - \frac{a_3 v_3}{2} + (b_3 - a_2)\, v_4 + (a_1 - b_1)\, v_5 = 0 \quad (8E)$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -\frac{a_3}{2} &= 0 \\ a_1 - b_1 &= 0 \\ a_2 - b_2 &= 0 \\ a_3 - b_3 &= 0 \\ b_2 - \frac{a_3}{2} &= 0 \\ b_3 - a_2 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= b_1 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= b_1 \\ b_2 &= 0 \\ b_3 &= 0 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 1 \\ \eta &= 1 \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x, y)\, \xi \\ &= 1 - (\cos(-y + x))\, (1) \\ &= 1 - \cos(y) \cos(x) - \sin(y) \sin(x) \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{1 - \cos(y)\cos(x) - \sin(y)\sin(x)} dy \end{aligned}$$

Which results in

$$S = \frac{1}{\tan\left(-\frac{y}{2} + \frac{x}{2}\right)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \cos(-y + x)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{\csc\left(-\frac{y}{2} + \frac{x}{2}\right)^2}{2} \\ S_y &= \frac{\csc\left(-\frac{y}{2} + \frac{x}{2}\right)^2}{2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\csc\left(-\frac{y}{2}+\frac{x}{2}\right)^{2}\left(\cos\left(-y+x\right)-1\right)}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\cot\left(-\frac{y}{2}+\frac{x}{2}\right) = -x + c_1$$

Which simplifies to

$$\cot\left(-\frac{y}{2}+\frac{x}{2}\right) = -x + c_1$$

Which gives

$$y = x - 2\operatorname{arccot}\left(-x + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \cos(-y + x)$ 	$R = x$ $S = \cot\left(-\frac{y}{2} + \frac{x}{2}\right)$	$\frac{dS}{dR} = -1$ 
Summary

The solution(s) found are the following

$$y = x - 2 \operatorname{arccot}(-x + c_1) \tag{1}$$

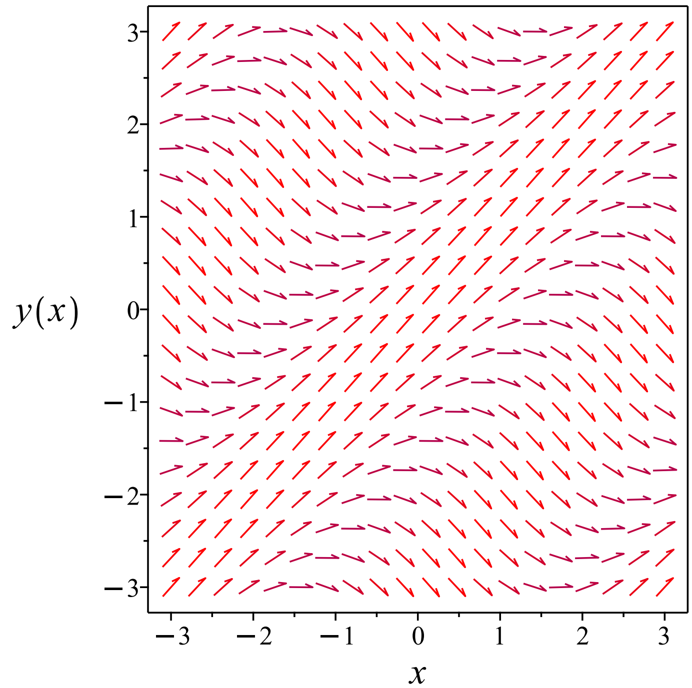

Figure 42: Slope field plot

Verification of solutions

$$y = x - 2 \operatorname{arccot}(-x + c_1)$$

Problem number: 29.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first__order__ode__lie__symmetry__lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = -x^2}$$

2.9.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= -x^2 \end{aligned}$$

Hence the ode is

$$y' - y = -x^2$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int (-1)dx} \\
&= \mathrm{e}^{-x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(-x^2\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{-x} y\right) &= \left(\mathrm{e}^{-x}\right)\left(-x^2\right) \\
\mathrm{d}\left(\mathrm{e}^{-x} y\right) &= \left(-x^2 \mathrm{e}^{-x}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{-x} y &= \int -x^2 \mathrm{e}^{-x}\,\mathrm{d}x \\
\mathrm{e}^{-x} y &= \left(x^2 + 2x + 2\right)\mathrm{e}^{-x} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-x}$ results in

$$
y = \mathrm{e}^{x}\left(x^2 + 2x + 2\right)\mathrm{e}^{-x} + \mathrm{e}^{x} c_1
$$

which simplifies to

$$
y = x^2 + 2x + 2 + \mathrm{e}^{x} c_1
$$

Summary

The solution(s) found are the following

$$
y = x^2 + 2x + 2 + \mathrm{e}^{x} c_1 \tag{1}
$$

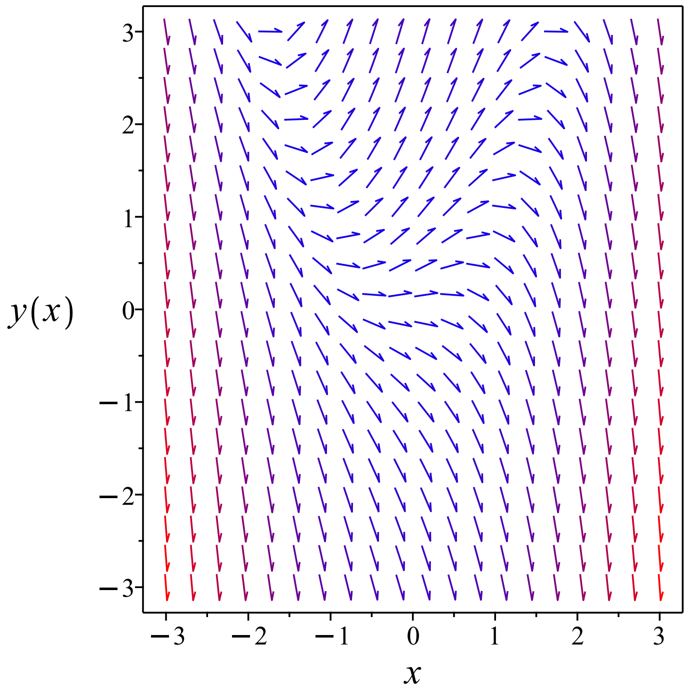

Figure 43: Slope field plot

Verification of solutions

$$y = x^2 + 2x + 2 + e^x c_1$$

Verified OK.

2.9.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -x^2 + y \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 29: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \mathrm{e}^{x} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^x} dy\end{aligned}$$

Which results in

$$S = \mathrm{e}^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -x^2 + y$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1 \\ R_y &= 0 \\ S_x &= -\mathrm{e}^{-x} y \\ S_y &= \mathrm{e}^{-x}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -x^2 \mathrm{e}^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -R^2 \mathrm{e}^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = (R^2 + 2R + 2)\,e^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-x}y = (x^2 + 2x + 2)\,e^{-x} + c_1$$

Which simplifies to

$$e^{-x}y = (x^2 + 2x + 2)\,e^{-x} + c_1$$

Which gives

$$y = (x^2 e^{-x} + 2x\,e^{-x} + 2\,e^{-x} + c_1)\,e^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -x^2 + y$ 	$R = x$ $S = e^{-x}y$	$\frac{dS}{dR} = -R^2 e^{-R}$ 
Summary

The solution(s) found are the following

$$y = (x^2 e^{-x} + 2x\,e^{-x} + 2\,e^{-x} + c_1)\,e^{x} \tag{1}$$

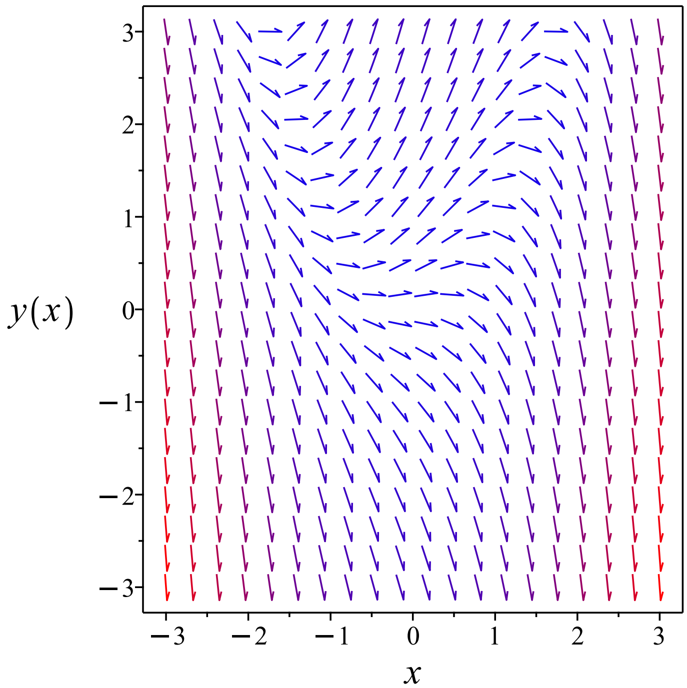

Figure 44: Slope field plot

Verification of solutions

$$y = \left(x^2 e^{-x} + 2x\, e^{-x} + 2\, e^{-x} + c_1\right) e^{x}$$

Verified OK.

2.9.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-x^2 + y\right) \mathrm{d}x$$
$$\left(x^2 - y\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = x^2 - y$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(x^2 - y\right)$$
$$= -1$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(1)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-1) - (0)) \\ &= -1 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -1 \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-x} \\ &= \mathrm{e}^{-x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-x}\left(x^2 - y\right) \\ &= \left(x^2 - y\right) \mathrm{e}^{-x} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-x}(1) \\ &= \mathrm{e}^{-x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\left(x^2 - y\right) \mathrm{e}^{-x}\right) + \left(\mathrm{e}^{-x}\right) \frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int (x^2 - y) \, \mathrm{e}^{-x} \, \mathrm{d}x$$

$$\phi = -\left(x^2 + 2x - y + 2\right) \mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\left(x^2 + 2x - y + 2\right) \mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\left(x^2 + 2x - y + 2\right) \mathrm{e}^{-x}$$

The solution becomes

$$y = \left(x^2 \mathrm{e}^{-x} + 2x \, \mathrm{e}^{-x} + 2 \, \mathrm{e}^{-x} + c_1\right) \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = (x^2 e^{-x} + 2x\, e^{-x} + 2\, e^{-x} + c_1)\, e^{x} \tag{1}$$

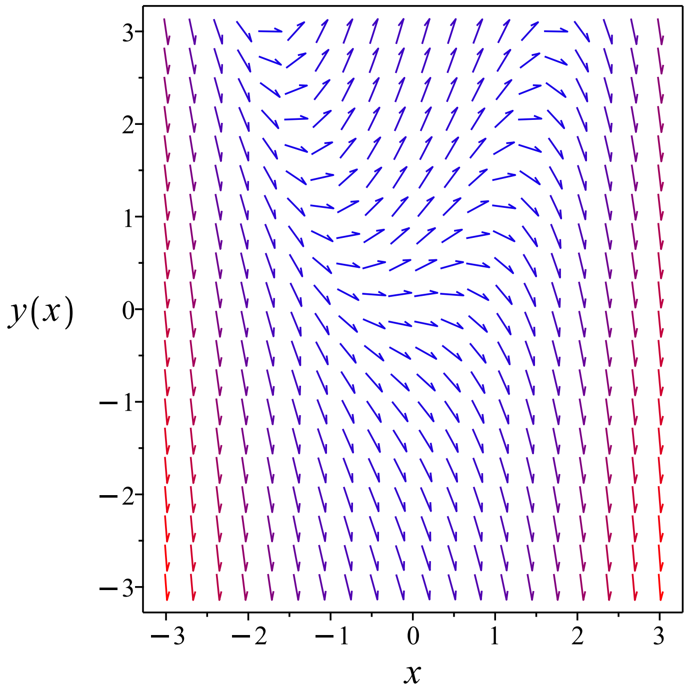

Figure 45: Slope field plot

Verification of solutions

$$y = (x^2 e^{-x} + 2x\, e^{-x} + 2\, e^{-x} + c_1)\, e^{x}$$

Verified OK.

2.9.4 Maple step by step solution

Let's solve

$y' - y = -x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -x^2 + y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = -x^2$
- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - y) = -\mu(x)\,x^2$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' - y) = \mu'(x)\,y + \mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{-x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int -\mu(x)\,x^2 dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y = \int -\mu(x)\,x^2 dx + c_1$
- Solve for y

  $y = \frac{\int -\mu(x)x^2 dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{-x}$

  $y = \frac{\int -x^2 \mathrm{e}^{-x} dx + c_1}{\mathrm{e}^{-x}}$
- Evaluate the integrals on the rhs

  $y = \frac{(x^2+2x+2)\mathrm{e}^{-x} + c_1}{\mathrm{e}^{-x}}$
- Simplify

  $y = x^2 + 2x + 2 + \mathrm{e}^{x} c_1$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' + y = x^2 + 2x}$$

2.10.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = x^2 + 2x$$

Hence the ode is

$$y' + y = x^2 + 2x$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 1dx} \\
&= e^{x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(x^2+2x\right) \\
\frac{d}{dx}(e^{x} y) &= (e^{x})\left(x^2+2x\right) \\
d(e^{x} y) &= (x\,e^{x}(x+2))\,dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{x} y &= \int x\,e^{x}(x+2)\,dx \\
e^{x} y &= x^2 e^{x} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$
y = e^{-x} x^2 e^{x} + c_1 e^{-x}
$$

which simplifies to

$$
y = x^2 + c_1 e^{-x}
$$

Summary

The solution(s) found are the following

$$
y = x^2 + c_1 e^{-x} \tag{1}
$$

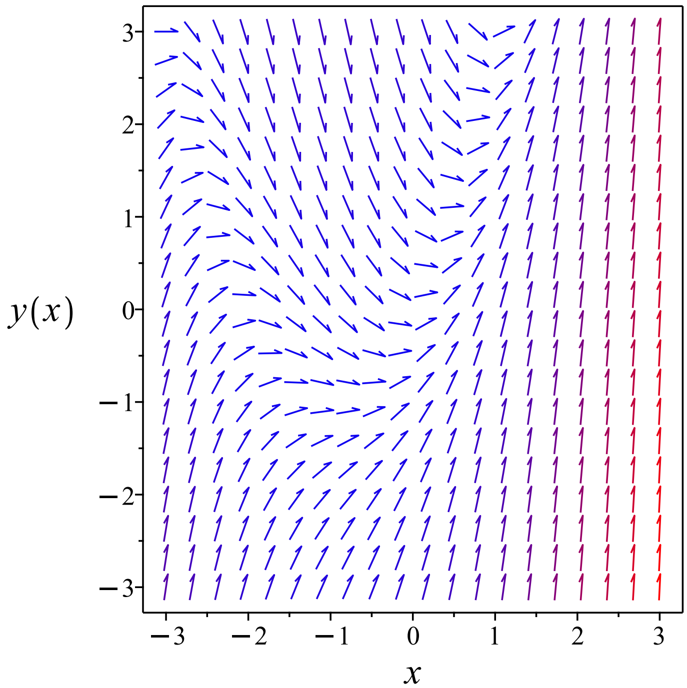

Figure 46: Slope field plot

Verification of solutions

$$y = x^2 + c_1 e^{-x}$$

Verified OK.

2.10.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = x^2 + 2x - y$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 32: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-x}} dy\end{aligned}$$

Which results in

$$S = e^{x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = x^2 + 2x - y$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1 \\ R_y &= 0 \\ S_x &= e^{x} y \\ S_y &= e^{x}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x\, e^{x} (x + 2) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R\, e^{R} (R + 2)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 e^R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\, e^x = x^2 e^x + c_1$$

Which simplifies to

$$y\, e^x = x^2 e^x + c_1$$

Which gives

$$y = \left(x^2 e^x + c_1\right) e^{-x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = x^2 + 2x - y$ 	$R = x$ $S = e^x y$	$\frac{dS}{dR} = R e^R (R + 2)$ 
Summary
The solution(s) found are the following

$$y = \left(x^2 e^x + c_1\right) e^{-x} \tag{1}$$

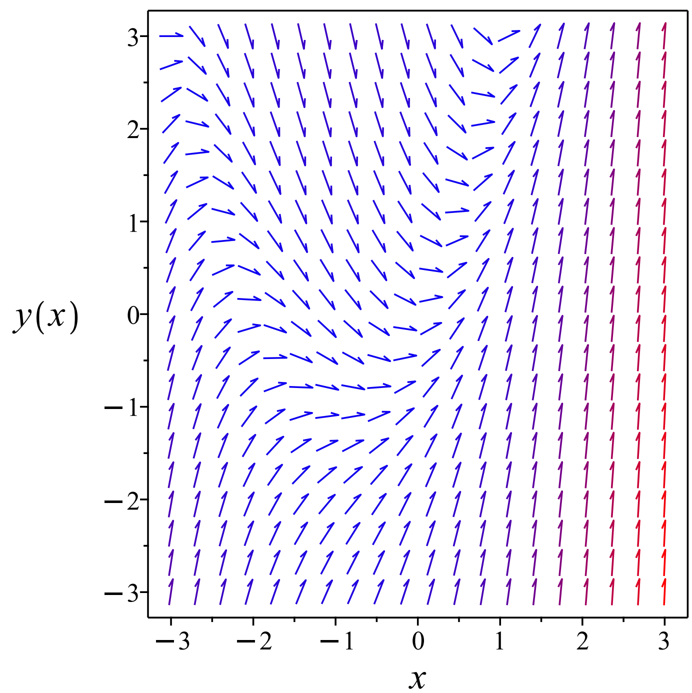

Figure 47: Slope field plot

Verification of solutions

$$y = (x^2 e^x + c_1) e^{-x}$$

Verified OK.

2.10.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= \left(x^2 + 2x - y\right)\mathrm{d}x \\ \left(-x^2 - 2x + y\right)\mathrm{d}x + \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x^2 - 2x + y \\ N(x, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2 - 2x + y\right) \\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((1) - (0)) \\
&= 1
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int 1 \, \mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{x} \\
&= \mathrm{e}^{x}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{x}(-x^2 - 2x + y) \\
&= -\mathrm{e}^{x}(x^2 + 2x - y)
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{x}(1) \\
&= \mathrm{e}^{x}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{x}(x^2 + 2x - y)\right) + (\mathrm{e}^{x})\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\mathrm{e}^{x}\left(x^{2}+2x-y\right) \mathrm{d}x$$
$$\phi = -\left(x^{2}-y\right)\mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{x}$. Therefore equation (4) becomes

$$\mathrm{e}^{x} = \mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\left(x^{2}-y\right)\mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\left(x^{2}-y\right)\mathrm{e}^{x}$$

The solution becomes

$$y = \left(x^{2}\mathrm{e}^{x} + c_1\right)\mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = \left(x^{2}\mathrm{e}^{x} + c_1\right)\mathrm{e}^{-x} \tag{1}$$

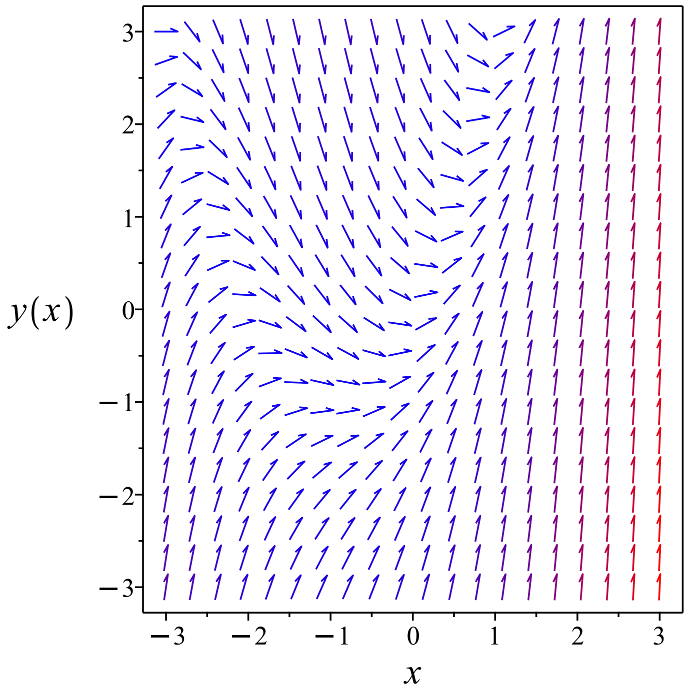

Figure 48: Slope field plot

Verification of solutions

$$y = \left(x^2 e^x + c_1\right) e^{-x}$$

Verified OK.

2.10.4 Maple step by step solution

Let's solve

$y' + y = x^2 + 2x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = x^2 + 2x - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + y = x^2 + 2x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + y\right) = \mu(x)\left(x^2 + 2x\right)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y'+y) = \mu'(x)\,y + \mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,(x^2+2x)\,dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,(x^2+2x)\,dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x)(x^2+2x)dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{x}$

  $y = \frac{\int (x^2+2x)\mathrm{e}^{x}dx + c_1}{\mathrm{e}^{x}}$
- Evaluate the integrals on the rhs

  $y = \frac{x^2\mathrm{e}^{x}+c_1}{\mathrm{e}^{x}}$
- Simplify

  $y = x^2 + c_1\mathrm{e}^{-x}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 2. The method of isoclines. Exercises page 27
Problem number: 31.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{y+1}{x-1} = 0}$$

2.11.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y+1}{x-1} \end{aligned}$$

Where $f(x) = \frac{1}{x-1}$ and $g(y) = y+1$. Integrating both sides gives

$$\frac{1}{y+1}\,dy = \frac{1}{x-1}\,dx$$
$$\int \frac{1}{y+1}\,dy = \int \frac{1}{x-1}\,dx$$
$$\ln(y+1) = \ln(x-1) + c_1$$

Raising both side to exponential gives

$$y + 1 = e^{\ln(x-1)+c_1}$$

Which simplifies to

$$y + 1 = c_2(x-1)$$

Summary

The solution(s) found are the following

$$y = c_2 e^{\ln(x-1)+c_1} - 1 \tag{1}$$

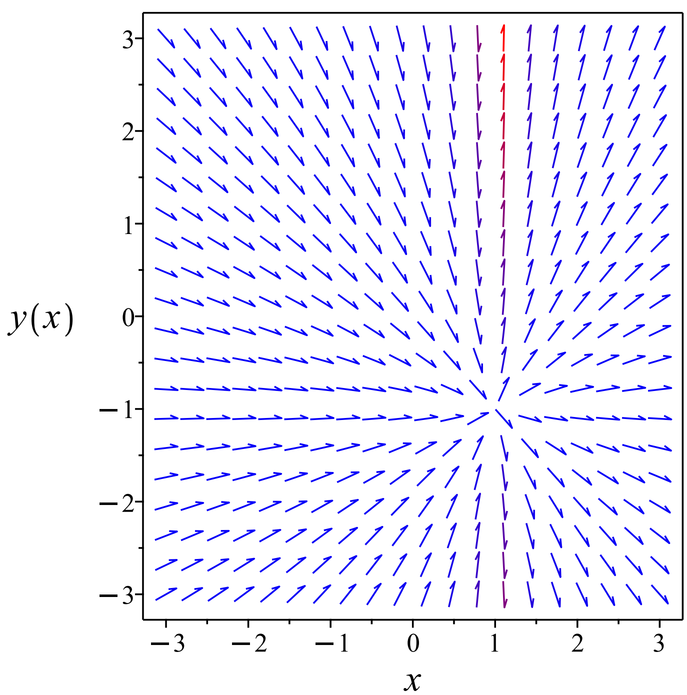

Figure 49: Slope field plot

Verification of solutions

$$y = c_2 e^{\ln(x-1)+c_1} - 1$$

Verified OK.

2.11.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x-1} \\ q(x) &= \frac{1}{x-1} \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x-1} = \frac{1}{x-1}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{x-1}dx} \\ &= \frac{1}{x-1} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{1}{x-1}\right) \\ \frac{d}{dx}\left(\frac{y}{x-1}\right) &= \left(\frac{1}{x-1}\right)\left(\frac{1}{x-1}\right) \\ d\left(\frac{y}{x-1}\right) &= \frac{1}{(x-1)^2}\, dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x-1} &= \int \frac{1}{(x-1)^2}\, dx \\ \frac{y}{x-1} &= -\frac{1}{x-1} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x-1}$ results in

$$y = c_1(x-1) - 1$$

Summary

The solution(s) found are the following

$$y = c_1(x-1) - 1 \tag{1}$$

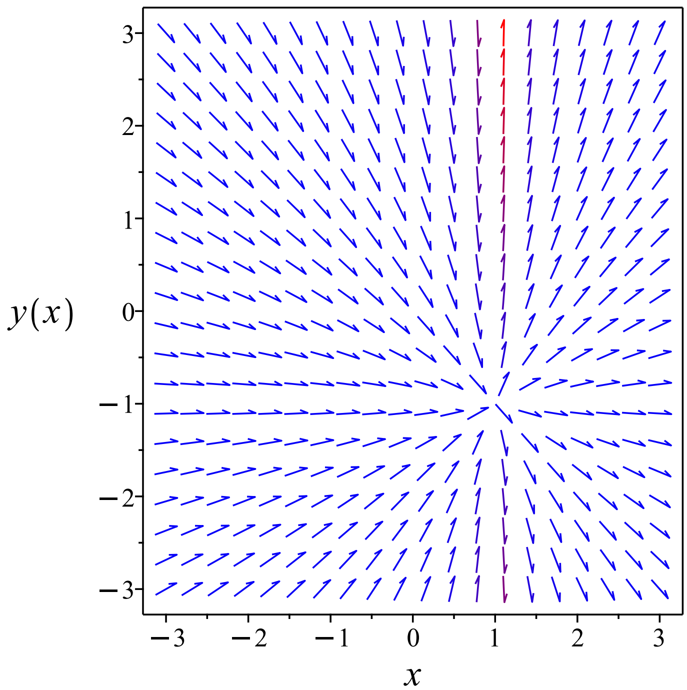

Figure 50: Slope field plot

Verification of solutions

$$y = c_1(x-1) - 1$$

Verified OK.

2.11.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{u(x)\,x + 1}{x - 1} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u+1}{x\,(x-1)} \end{aligned}$$

Where $f(x) = \frac{1}{x(x-1)}$ and $g(u) = u + 1$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u+1}\,du &= \frac{1}{x\,(x-1)}\,dx \\ \int \frac{1}{u+1}\,du &= \int \frac{1}{x\,(x-1)}\,dx \\ \ln(u+1) &= \ln(x-1) - \ln(x) + c_2 \end{aligned}$$

Raising both side to exponential gives

$$u + 1 = \mathrm{e}^{\ln(x-1) - \ln(x) + c_2}$$

Which simplifies to

$$u + 1 = c_3 \mathrm{e}^{\ln(x-1) - \ln(x)}$$

Which simplifies to

$$u(x) = c_3\left(\mathrm{e}^{c_2} - \frac{\mathrm{e}^{c_2}}{x}\right) - 1$$

Therefore the solution y is

$$\begin{aligned} y &= ux \\ &= x\left(c_3\left(\mathrm{e}^{c_2} - \frac{\mathrm{e}^{c_2}}{x}\right) - 1\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = x\left(c_3\left(\mathrm{e}^{c_2} - \frac{\mathrm{e}^{c_2}}{x}\right) - 1\right) \tag{1}$$

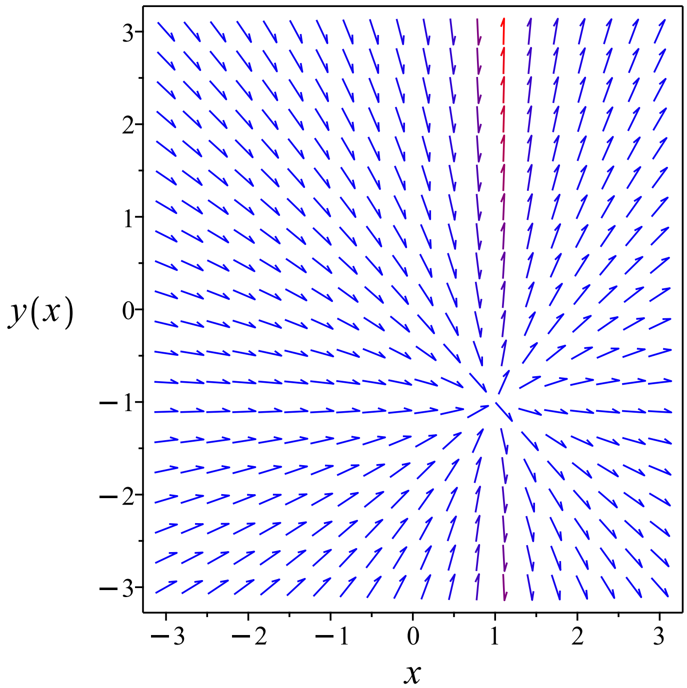

Figure 51: Slope field plot

Verification of solutions

$$y = x\left(c_3\left(e^{c_2} - \frac{e^{c_2}}{x}\right) - 1\right)$$

Verified OK.

2.11.4 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{Y(X) + y_0 + 1}{X + x_0 - 1}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = 1$$
$$y_0 = -1$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{Y(X)}{X}$$

In canonical form, the ODE is

$$
\begin{aligned}
Y' &= F(X, Y) \\
&= \frac{Y}{X}
\end{aligned} \tag{1}
$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$
f(t^n X, t^n Y) = t^n f(X, Y)
$$

In this case, it can be seen that both $M = Y$ and $N = X$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$
\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X} X + u
$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$
\begin{aligned}
\frac{\mathrm{d}u}{\mathrm{d}X} X + u &= u \\
\frac{\mathrm{d}u}{\mathrm{d}X} &= 0
\end{aligned}
$$

Or

$$
\frac{d}{dX} u(X) = 0
$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. Integrating both sides gives

$$
\begin{aligned}
u(X) &= \int 0 \, \mathrm{d}X \\
&= c_2
\end{aligned}
$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$
Y(X) = X c_2
$$

Using the solution for $Y(X)$

$$
Y(X) = X c_2
$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y - 1$$
$$X = x + 1$$

Then the solution in y becomes

$$y + 1 = c_2(x - 1)$$

Summary
The solution(s) found are the following

$$y + 1 = c_2(x - 1) \tag{1}$$

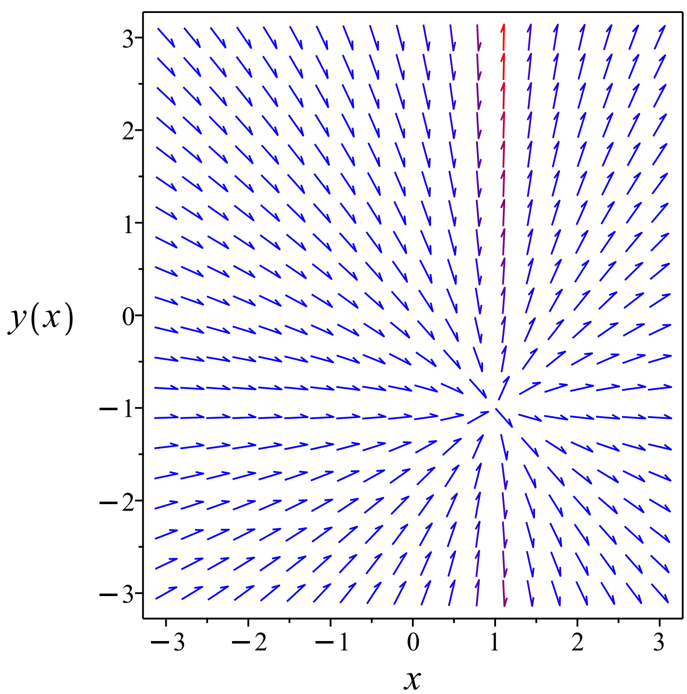

Figure 52: Slope field plot

Verification of solutions

$$y + 1 = c_2(x - 1)$$

Verified OK.

2.11.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{y+1}{x-1} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 35: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= x-1\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{x-1} dy\end{aligned}$$

Which results in

$$S = \frac{y}{x-1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y+1}{x-1}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{y}{(x-1)^2} \\
S_y &= \frac{1}{x-1}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{(x-1)^2} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{(R-1)^2}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\frac{1}{R-1} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{y}{x-1} = -\frac{1}{x-1} + c_1
$$

Which simplifies to

$$
\frac{-c_1 x + c_1 + y + 1}{x-1} = 0
$$

Which gives

$$
y = c_1 x - c_1 - 1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y+1}{x-1}$ 	$R = x$ $S = \frac{y}{x-1}$	$\frac{dS}{dR} = \frac{1}{(R-1)^2}$ 
Summary
The solution(s) found are the following

$$y = c_1 x - c_1 - 1 \tag{1}$$

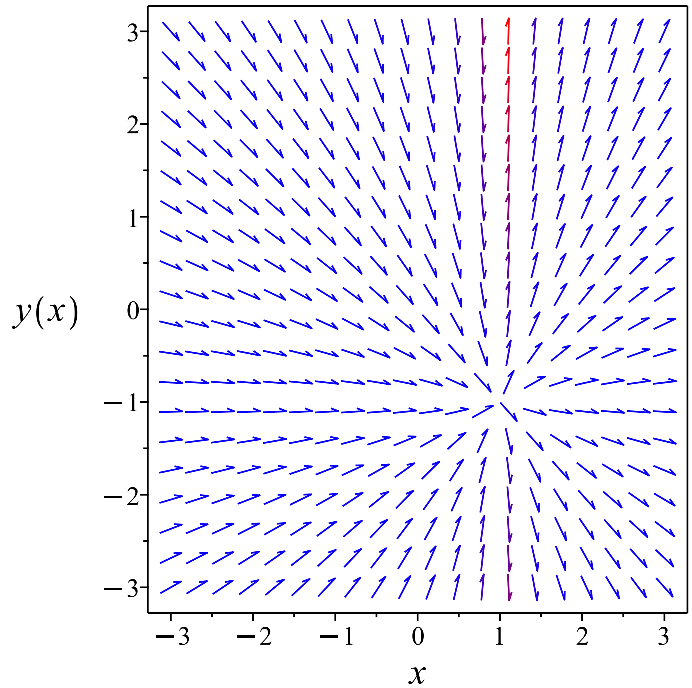

Figure 53: Slope field plot

Verification of solutions

$$y = c_1x - c_1 - 1$$

Verified OK.

2.11.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y+1}\right)\mathrm{d}y = \left(\frac{1}{x-1}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x-1}\right)\mathrm{d}x + \left(\frac{1}{y+1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{1}{x-1}$$
$$N(x,y) = \frac{1}{y+1}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x-1}\right)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y+1}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{1}{x-1}\,\mathrm{d}x \\
\phi &= -\ln(x-1) + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y+1}$. Therefore equation (4) becomes

$$
\frac{1}{y+1} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y+1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\,\mathrm{d}y &= \int \left(\frac{1}{y+1}\right)\mathrm{d}y \\
f(y) &= \ln(y+1) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln (x-1) + \ln (y+1) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln (x-1) + \ln (y+1)$$

The solution becomes

$$y = e^{c_1} x - e^{c_1} - 1$$

Summary

The solution(s) found are the following

$$y = e^{c_1} x - e^{c_1} - 1 \tag{1}$$

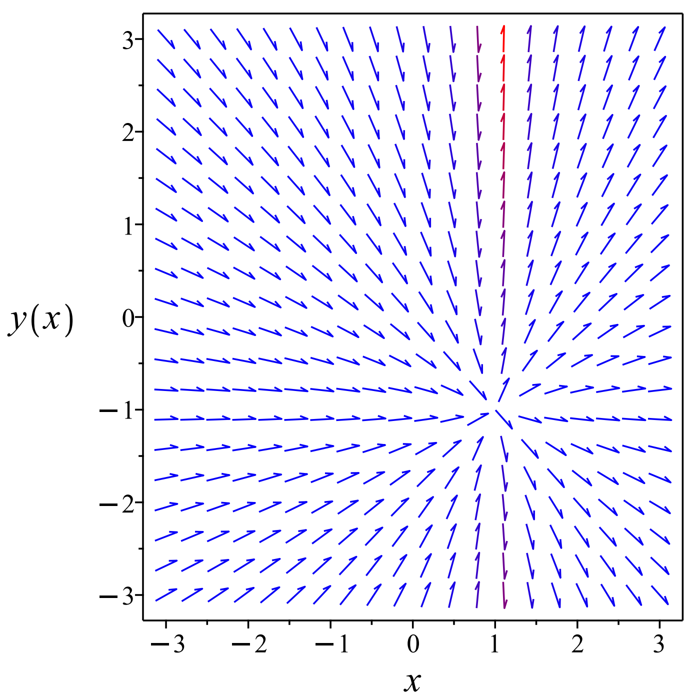

Figure 54: Slope field plot

Verification of solutions

$$y = e^{c_1} x - e^{c_1} - 1$$

Verified OK.

2.11.7 Maple step by step solution

Let's solve

$y' - \frac{y+1}{x-1} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y+1} = \frac{1}{x-1}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y+1} dx = \int \frac{1}{x-1} dx + c_1$

- Evaluate integral

  $\ln (y+1) = \ln (x-1) + c_1$

- Solve for y

  $y = e^{c_1} x - e^{c_1} - 1$

Section: Section 2. The method of isoclines. Exercises page 27
Problem number: 32.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exactByInspection", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{y' - \frac{y + x}{-y + x} = 0}$$

2.12.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) - \frac{u(x)\,x + x}{-u\,(x)\,x + x} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u^2+1}{x\,(u-1)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2+1}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+1}{u-1}}\,du = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{u^2+1}{u-1}}\,du = \int -\frac{1}{x}\,dx$$

$$\frac{\ln(u^2+1)}{2} - \arctan(u) = -\ln(x) + c_2$$

The solution is

$$\frac{\ln\left(u(x)^2+1\right)}{2} - \arctan(u(x)) + \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{\ln\left(\frac{y^2}{x^2}+1\right)}{2} - \arctan\left(\frac{y}{x}\right) + \ln(x) - c_2 = 0$$

$$\frac{\ln\left(\frac{y^2}{x^2}+1\right)}{2} - \arctan\left(\frac{y}{x}\right) + \ln(x) - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{\ln\left(\frac{y^2}{x^2}+1\right)}{2} - \arctan\left(\frac{y}{x}\right) + \ln(x) - c_2 = 0 \tag{1}$$

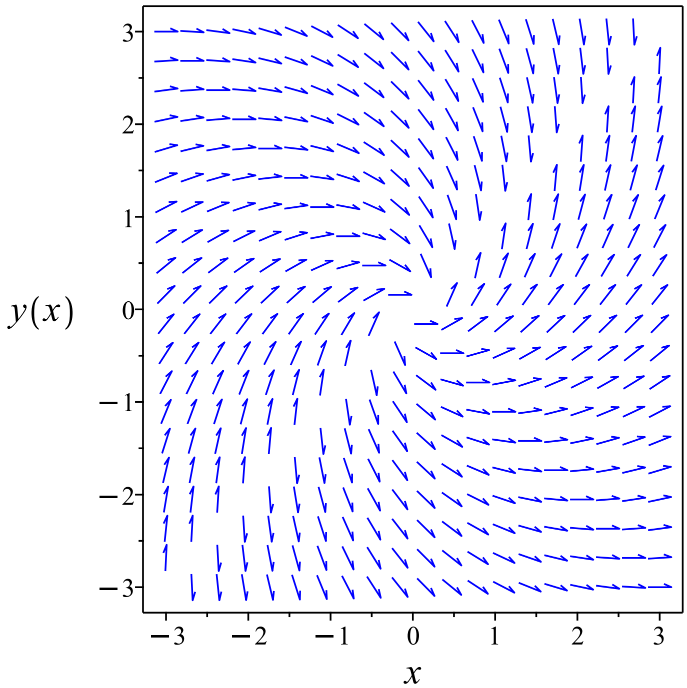

Figure 55: Slope field plot

Verification of solutions

$$\frac{\ln\left(\frac{y^2}{x^2}+1\right)}{2}-\arctan\left(\frac{y}{x}\right)+\ln(x)-c_2=0$$

Verified OK.

2.12.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{y+x}{y-x}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(y+x)(b_3-a_2)}{y-x} - \frac{(y+x)^2 a_3}{(y-x)^2} - \left(-\frac{1}{y-x} - \frac{y+x}{(y-x)^2}\right)(xa_2+ya_3+a_1) - \left(-\frac{1}{y-x} + \frac{y+x}{(y-x)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^2a_2 + x^2a_3 + x^2b_2 - x^2b_3 - 2xya_2 + 2xya_3 + 2xyb_2 + 2xyb_3 - y^2a_2 - y^2a_3 - y^2b_2 + y^2b_3 + 2xb_1 - 2ya}{(-y+x)^2} = 0$$

Setting the numerator to zero gives

$$-x^2a_2 - x^2a_3 - x^2b_2 + x^2b_3 + 2xya_2 - 2xya_3 - 2xyb_2 - 2xyb_3 + y^2a_2 + y^2a_3 + y^2b_2 - y^2b_3 - 2xb_1 + 2ya_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_2v_1^2 + 2a_2v_1v_2 + a_2v_2^2 - a_3v_1^2 - 2a_3v_1v_2 + a_3v_2^2 - b_2v_1^2 - 2b_2v_1v_2 + b_2v_2^2 + b_3v_1^2 - 2b_3v_1v_2 - b_3v_2^2 + 2a_1v_2 - 2b_1v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&(-a_2 - a_3 - b_2 + b_3)\, v_1^2 + (2a_2 - 2a_3 - 2b_2 - 2b_3)\, v_1 v_2 \\
&- 2b_1 v_1 + (a_2 + a_3 + b_2 - b_3)\, v_2^2 + 2a_1 v_2 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
2a_1 &= 0 \\
-2b_1 &= 0 \\
-a_2 - a_3 - b_2 + b_3 &= 0 \\
a_2 + a_3 + b_2 - b_3 &= 0 \\
2a_2 - 2a_3 - 2b_2 - 2b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= -b_2 \\
b_1 &= 0 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y - \left(-\frac{y + x}{y - x}\right)(x) \\
&= \frac{-x^2 - y^2}{-y + x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-x^2-y^2}{-y+x}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln(x^2 + y^2)}{2} - \arctan\left(\frac{y}{x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y + x}{y - x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y + x}{x^2 + y^2} \\ S_y &= \frac{y - x}{x^2 + y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(x^2+y^2)}{2} - \arctan\left(\frac{y}{x}\right) = c_1$$

Which simplifies to

$$\frac{\ln(x^2+y^2)}{2} - \arctan\left(\frac{y}{x}\right) = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y+x}{y-x}$ 	$R = x$ $S = \frac{\ln(x^2+y^2)}{2} - \text{arctar}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$\frac{\ln (x^2+y^2)}{2}-\arctan\left(\frac{y}{x}\right)=c_1 \tag{1}$$

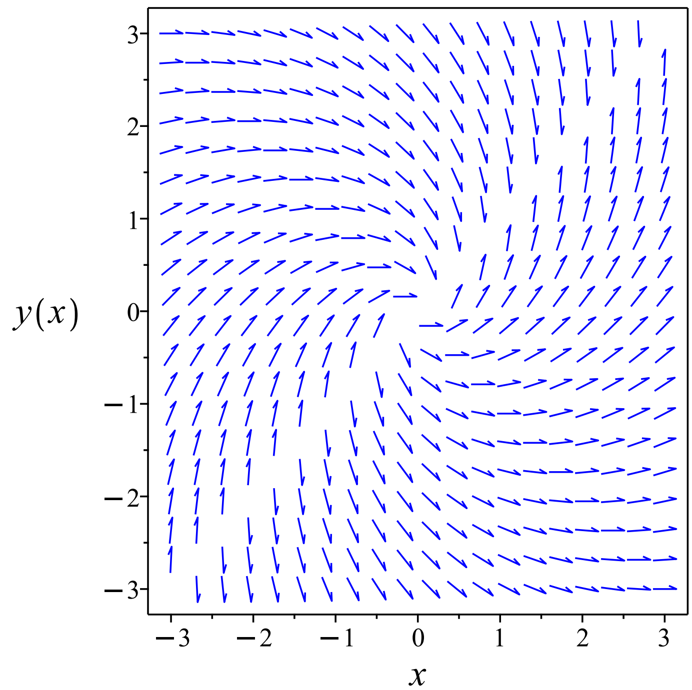

Figure 56: Slope field plot

Verification of solutions

$$\frac{\ln (x^2+y^2)}{2}-\arctan\left(\frac{y}{x}\right)=c_1$$

Verified OK.

2.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(y-x)\,\mathrm{d}y&=(-y-x)\,\mathrm{d}x\\ (y+x)\,\mathrm{d}x+(y-x)\,\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=y+x\\ N(x,y)&=y-x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(y+x)\\ &=1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y-x)\\ &= -1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. By inspection $\frac{1}{x^2+y^2}$ is an integrating factor. Therefore by multiplying $M = y + x$ and $N = y - x$ by this integrating factor the ode becomes exact. The new M, N are

$$\begin{aligned}M &= \frac{y+x}{x^2+y^2}\\ N &= \frac{y-x}{x^2+y^2}\end{aligned}$$

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{y-x}{x^2+y^2}\right)\mathrm{d}y = \left(-\frac{y+x}{x^2+y^2}\right)\mathrm{d}x$$
$$\left(\frac{y+x}{x^2+y^2}\right)\mathrm{d}x + \left(\frac{y-x}{x^2+y^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{y+x}{x^2+y^2}$$
$$N(x,y) = \frac{y-x}{x^2+y^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(\frac{y+x}{x^2+y^2}\right)$$
$$= \frac{x^2-2xy-y^2}{(x^2+y^2)^2}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\frac{y-x}{x^2+y^2}\right)$$
$$= \frac{x^2-2xy-y^2}{(x^2+y^2)^2}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{y+x}{x^2+y^2}\,\mathrm{d}x$$

$$\phi = \frac{\ln\left(x^2+y^2\right)}{2} + \arctan\left(\frac{x}{y}\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{y}{x^2+y^2} - \frac{x}{y^2\left(\frac{x^2}{y^2}+1\right)} + f'(y) \tag{4}$$

$$= \frac{y-x}{x^2+y^2} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{y-x}{x^2+y^2}$. Therefore equation (4) becomes

$$\frac{y-x}{x^2+y^2} = \frac{y-x}{x^2+y^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\ln\left(x^2+y^2\right)}{2} + \arctan\left(\frac{x}{y}\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\ln\left(x^2+y^2\right)}{2} + \arctan\left(\frac{x}{y}\right)$$

Summary

The solution(s) found are the following

$$\frac{\ln\left(x^2+y^2\right)}{2}+\arctan\left(\frac{x}{y}\right)=c_1 \tag{1}$$

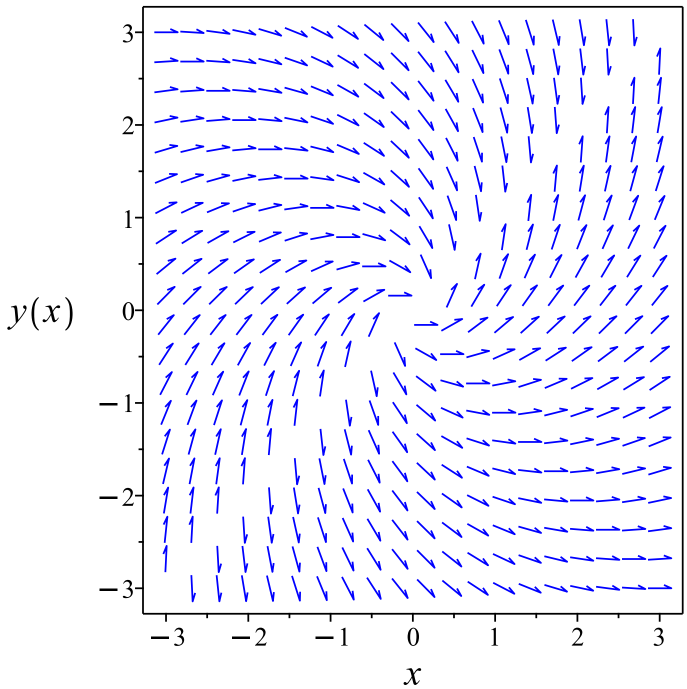

Figure 57: Slope field plot

Verification of solutions

$$\frac{\ln\left(x^2+y^2\right)}{2}+\arctan\left(\frac{x}{y}\right)=c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' + y = 2x}$$

2.14.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = 2x$$

Hence the ode is

$$y' + y = 2x$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int 1dx} \\
&= e^{x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)(2x) \\
\frac{d}{dx}(e^{x} y) &= (e^{x})(2x) \\
d(e^{x} y) &= (2x\, e^{x})\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{x} y &= \int 2x\, e^{x}\, dx \\
e^{x} y &= 2\, e^{x}(x-1) + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$
y = 2\, e^{-x} e^{x}(x-1) + c_1 e^{-x}
$$

which simplifies to

$$
y = 2x - 2 + c_1 e^{-x}
$$

Summary

The solution(s) found are the following

$$
y = 2x - 2 + c_1 e^{-x} \tag{1}
$$

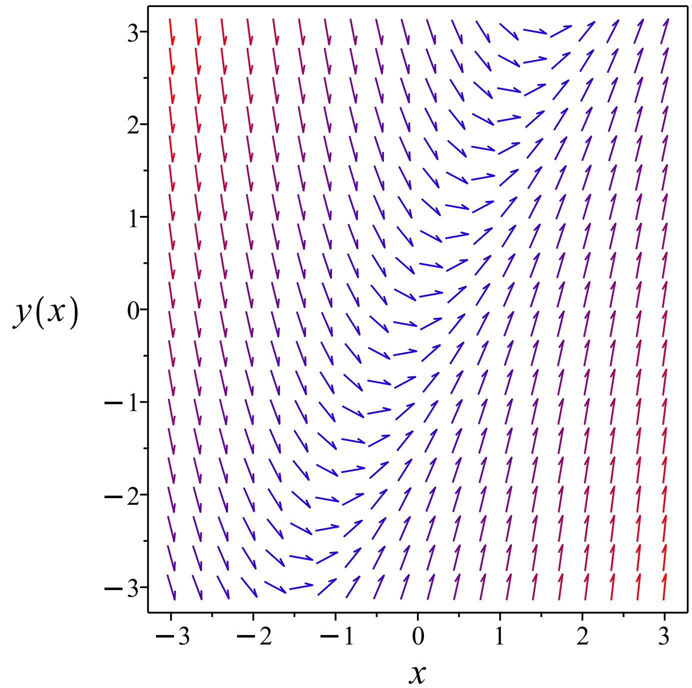

Figure 59: Slope field plot

Verification of solutions

$$y = 2x - 2 + c_1 e^{-x}$$

Verified OK.

2.14.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = 2x - y$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 39: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \mathrm{e}^{-x} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-x}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = 2x - y$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \mathrm{e}^{x} y \\ S_y &= \mathrm{e}^{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2x\,\mathrm{e}^{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R\,\mathrm{e}^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = 2(R-1)\,e^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,e^{x} = 2\,e^{x}(x-1) + c_1$$

Which simplifies to

$$y\,e^{x} = 2\,e^{x}(x-1) + c_1$$

Which gives

$$y = (2x\,e^{x} - 2\,e^{x} + c_1)\,e^{-x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2x - y$ 	$R = x$ $S = e^{x} y$	$\frac{dS}{dR} = 2R\,e^{R}$ 
Summary

The solution(s) found are the following

$$y = (2x\,e^{x} - 2\,e^{x} + c_1)\,e^{-x} \tag{1}$$

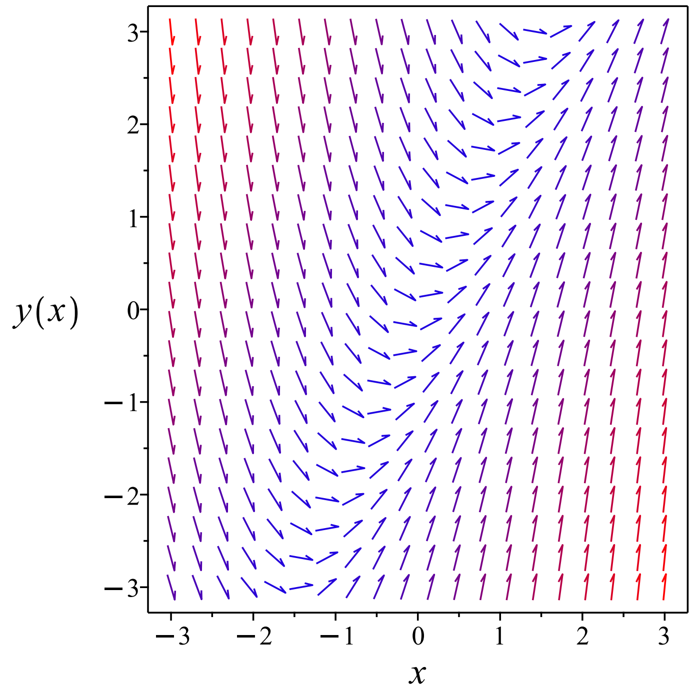

Figure 60: Slope field plot

Verification of solutions

$$y = (2x\,\mathrm{e}^{x} - 2\,\mathrm{e}^{x} + c_1)\,\mathrm{e}^{-x}$$

Verified OK.

2.14.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= (2x - y) \, \mathrm{d}x \\ (-2x + y) \, \mathrm{d}x + \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -2x + y \\ N(x, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-2x + y) \\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((1) - (0)) \\ &= 1 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int 1 \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{x} \\ &= \mathrm{e}^{x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{x}(-2x + y) \\ &= (-2x + y)\,\mathrm{e}^{x} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{x}(1) \\ &= \mathrm{e}^{x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ ((-2x + y)\,\mathrm{e}^{x}) + (\mathrm{e}^{x})\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int (-2x + y) \mathrm{e}^{x} \mathrm{d}x$$
$$\phi = (-2x + y + 2) \mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{x}$. Therefore equation (4) becomes

$$\mathrm{e}^{x} = \mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (-2x + y + 2) \mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (-2x + y + 2) \mathrm{e}^{x}$$

The solution becomes

$$y = (2x \mathrm{e}^{x} - 2 \mathrm{e}^{x} + c_1) \mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = (2x \mathrm{e}^{x} - 2 \mathrm{e}^{x} + c_1) \mathrm{e}^{-x} \tag{1}$$

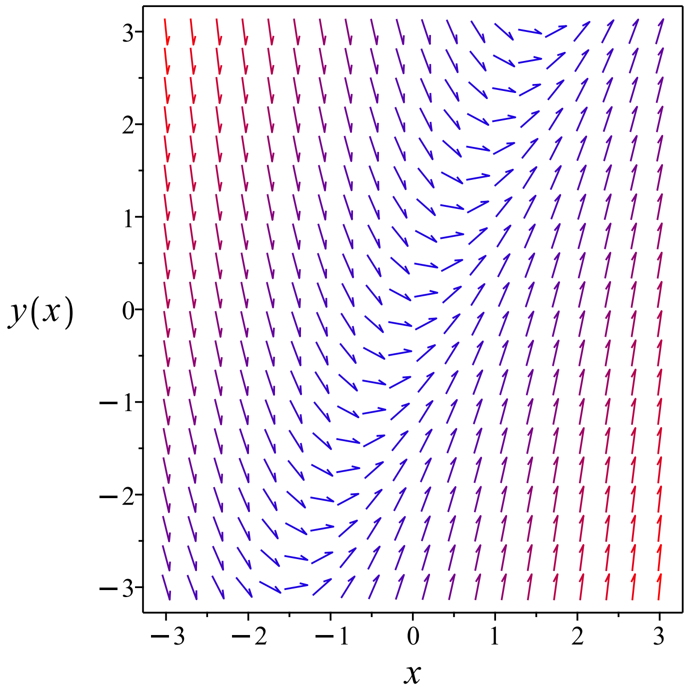

Figure 61: Slope field plot

Verification of solutions

$$y = (2x\,\mathrm{e}^{x} - 2\,\mathrm{e}^{x} + c_1)\,\mathrm{e}^{-x}$$

Verified OK.

2.14.4 Maple step by step solution

Let's solve

$y' + y = 2x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2x - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + y = 2x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' + y) = 2\mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\,(y'+y) = \mu'(x)\, y + \mu(x)\, y'$
- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int 2\mu(x)\, x dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\, y = \int 2\mu(x)\, x dx + c_1$
- Solve for y

  $y = \frac{\int 2\mu(x)x dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{x}$

  $y = \frac{\int 2x\, \mathrm{e}^{x} dx + c_1}{\mathrm{e}^{x}}$
- Evaluate the integrals on the rhs

  $y = \frac{2\, \mathrm{e}^{x}(x-1) + c_1}{\mathrm{e}^{x}}$
- Simplify

  $y = 2x - 2 + c_1 \mathrm{e}^{-x}$

Problem number: 35.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = x^2}$$

2.15.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= x^2 \end{aligned}$$

Hence the ode is

$$y' - y = x^2$$

The integrating factor μ is

$$\mu = e^{\int (-1)dx}$$
$$= e^{-x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(x^2\right)$$
$$\frac{d}{dx}\left(e^{-x}y\right) = \left(e^{-x}\right)\left(x^2\right)$$
$$d\left(e^{-x}y\right) = \left(x^2 e^{-x}\right) dx$$

Integrating gives

$$e^{-x}y = \int x^2 e^{-x} dx$$
$$e^{-x}y = -\left(x^2 + 2x + 2\right) e^{-x} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = -e^x\left(x^2 + 2x + 2\right) e^{-x} + e^x c_1$$

which simplifies to

$$y = -x^2 - 2x - 2 + e^x c_1$$

Summary

The solution(s) found are the following

$$y = -x^2 - 2x - 2 + e^x c_1 \tag{1}$$

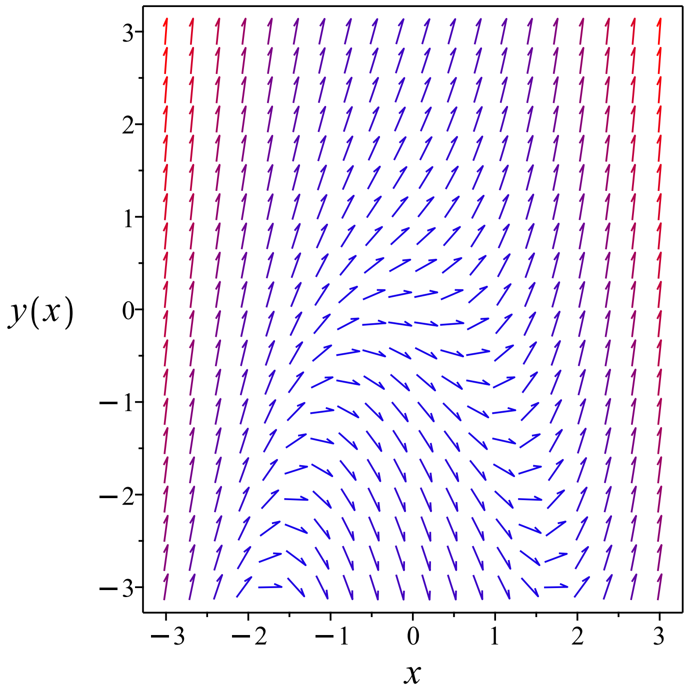

Figure 62: Slope field plot

Verification of solutions

$$y = -x^2 - 2x - 2 + e^x c_1$$

Verified OK.

2.15.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = x^2 + y$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 42: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{x}} dy \end{aligned}$$

Which results in

$$S = e^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = x^2 + y$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -e^{-x} y \\ S_y &= e^{-x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x^2 e^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2 e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -(R^2 + 2R + 2)\,e^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-x}y = -(x^2 + 2x + 2)\,e^{-x} + c_1$$

Which simplifies to

$$(x^2 + 2x + y + 2)\,e^{-x} - c_1 = 0$$

Which gives

$$y = -(x^2e^{-x} + 2x\,e^{-x} + 2\,e^{-x} - c_1)\,e^x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = x^2 + y$ 	$R = x$ $S = e^{-x}y$	$\frac{dS}{dR} = R^2e^{-R}$ 
Summary

The solution(s) found are the following

$$y = -(x^2e^{-x} + 2x\,e^{-x} + 2\,e^{-x} - c_1)\,e^x \tag{1}$$

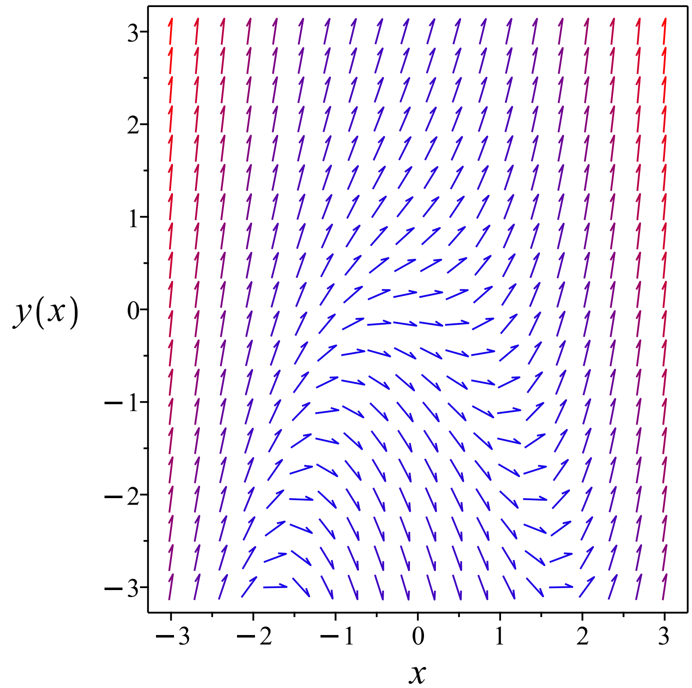

Figure 63: Slope field plot

Verification of solutions

$$y = -\left(x^2 e^{-x} + 2x\, e^{-x} + 2\, e^{-x} - c_1\right) e^{x}$$

Verified OK.

2.15.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\mathrm{d}y &= \left(x^2 + y\right) \mathrm{d}x \\
\left(-x^2 - y\right) \mathrm{d}x + \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -x^2 - y \\
N(x, y) &= 1
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2 - y\right) \\
&= -1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((-1) - (0)) \\
&= -1
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -1 \, \mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{-x} \\
&= \mathrm{e}^{-x}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-x}(-x^2 - y) \\
&= -\mathrm{e}^{-x}(x^2 + y)
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-x}(1) \\
&= \mathrm{e}^{-x}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{-x}(x^2 + y)\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\mathrm{e}^{-x} \left(x^2 + y\right) \mathrm{d}x$$

$$\phi = \left(x^2 + 2x + y + 2\right) \mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \left(x^2 + 2x + y + 2\right) \mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \left(x^2 + 2x + y + 2\right) \mathrm{e}^{-x}$$

The solution becomes

$$y = -\left(x^2 \mathrm{e}^{-x} + 2x \, \mathrm{e}^{-x} + 2 \, \mathrm{e}^{-x} - c_1\right) \mathrm{e}^{x}$$

Summary
The solution(s) found are the following

$$y = -\left(x^2 e^{-x} + 2x e^{-x} + 2 e^{-x} - c_1\right) e^x \tag{1}$$

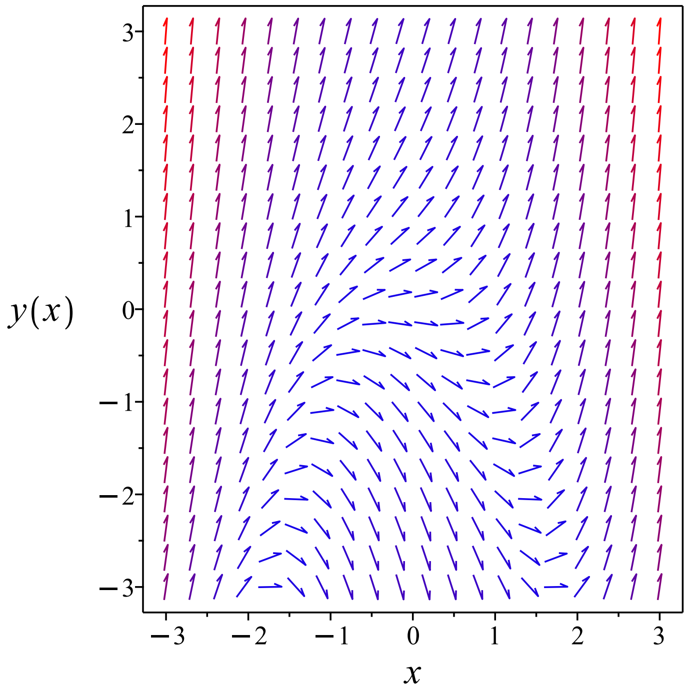

Figure 64: Slope field plot

Verification of solutions

$$y = -\left(x^2 e^{-x} + 2x e^{-x} + 2 e^{-x} - c_1\right) e^x$$

Verified OK.

2.15.4 Maple step by step solution

Let's solve

$y' - y = x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = x^2 + y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = x^2$
- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - y) = \mu(x)\,x^2$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' - y) = \mu'(x)\,y + \mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{-x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,x^2 dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,x^2 dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x)x^2 dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{-x}$

  $y = \frac{\int x^2 \mathrm{e}^{-x} dx + c_1}{\mathrm{e}^{-x}}$
- Evaluate the integrals on the rhs

  $y = \frac{-(x^2+2x+2)\,\mathrm{e}^{-x} + c_1}{\mathrm{e}^{-x}}$
- Simplify

  $y = -x^2 - 2x - 2 + \mathrm{e}^{x} c_1$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' + \frac{y}{x} = 0}$$

2.16.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y}\,dy &= -\frac{1}{x}\,dx \\
\int \frac{1}{y}\,dy &= \int -\frac{1}{x}\,dx \\
\ln (y) &= -\ln (x) + c_1 \\
y &= \mathrm{e}^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x} \tag{1}
$$

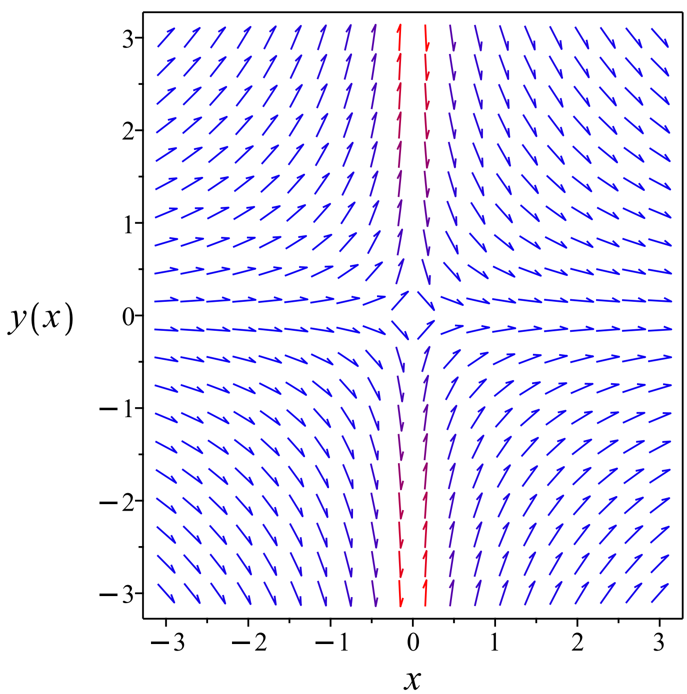

Figure 65: Slope field plot

Verification of solutions

$$
y = \frac{c_1}{x}
$$

Verified OK.

2.16.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= \frac{1}{x}\\ q(x) &= 0\end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = 0$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int \frac{1}{x}dx}\\ &= x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}\mu y &= 0\\ \frac{\mathrm{d}}{\mathrm{d}x}(xy) &= 0\end{aligned}$$

Integrating gives

$$xy = c_1$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{c_1}{x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

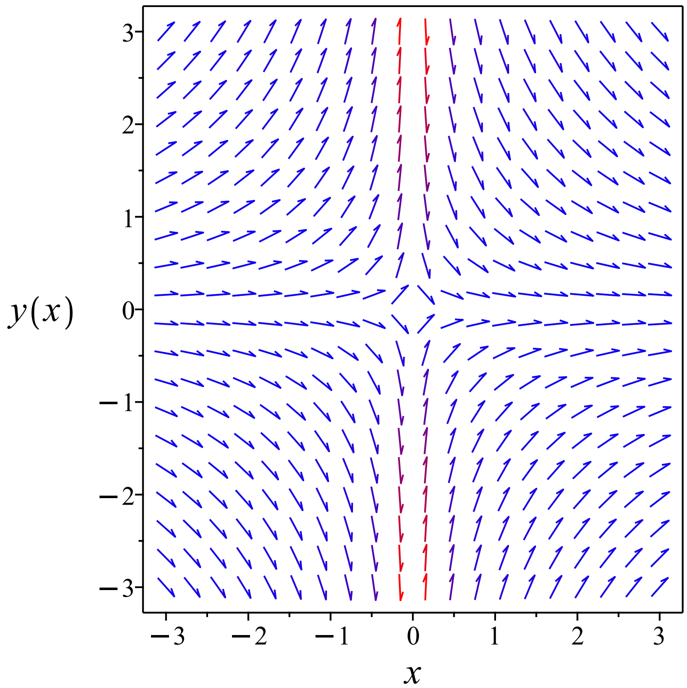

Figure 66: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

2.16.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + 2u(x) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{2}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{2}{x}\, dx \\
\ln(u) &= -2\ln(x) + c_2 \\
u &= e^{-2\ln(x)+c_2} \\
&= \frac{c_2}{x^2}
\end{aligned}$$

Therefore the solution y is

$$\begin{aligned}
y &= xu \\
&= \frac{c_2}{x}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_2}{x} \tag{1}$$

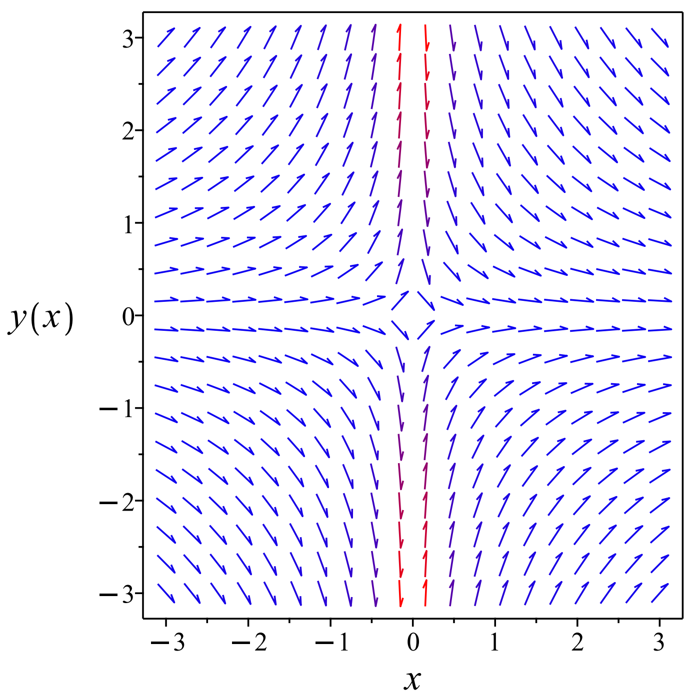

Figure 67: Slope field plot

Verification of solutions

$$y = \frac{c_2}{x}$$

Verified OK.

2.16.4 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{y}{x} \tag{1}$$

Which becomes

$$0 = (-x)\,dy + (-y)\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + (-y)\,dx = d(-xy)$$

Hence (2) becomes

$$0 = d(-xy)$$

Integrating both sides gives gives these solutions

$$y = \frac{c_1}{x} + c_1$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + c_1 \tag{1}$$

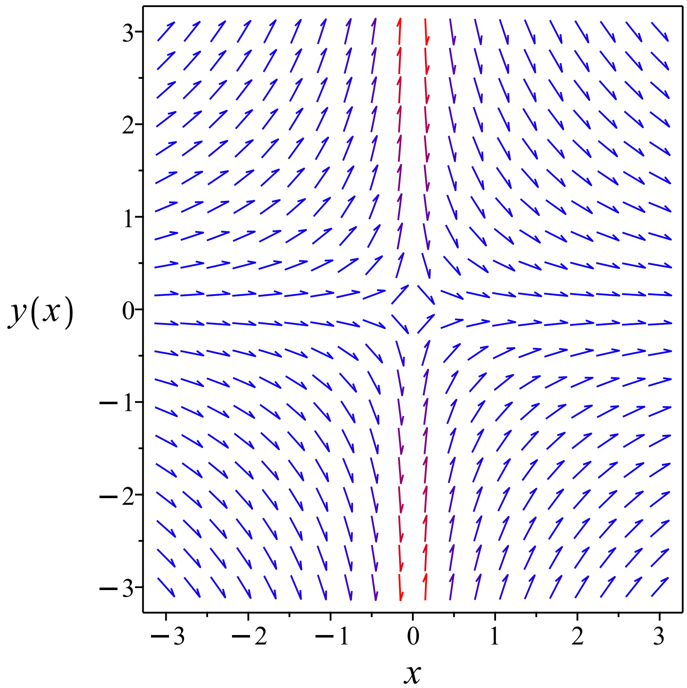

Figure 68: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x} + c_1$$

Verified OK.

2.16.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 45: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = c_1$$

Which simplifies to

$$yx = c_1$$

Which gives

$$y = \frac{c_1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y}{x}$ 	$R = x$ $S = xy$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

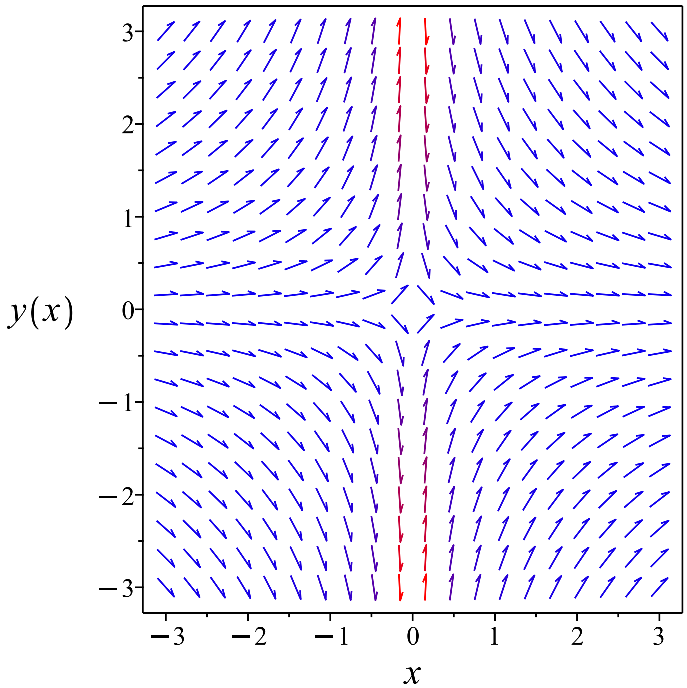

Figure 69: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

2.16.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{1}{y}\right) \mathrm{d}y &= \left(\frac{1}{x}\right) \mathrm{d}x \\ \left(-\frac{1}{x}\right) \mathrm{d}x + \left(-\frac{1}{y}\right) \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -\frac{1}{x} \\ N(x, y) &= -\frac{1}{y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right) \\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{1}{y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\, dx &= \int M\, dx\\ \int \frac{\partial \phi}{\partial x}\, dx &= \int -\frac{1}{x}\, dx\\ \phi &= -\ln(x) + f(y) \qquad (3)\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y}$. Therefore equation (4) becomes

$$-\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y}$$

Integrating the above w.r.t y gives

$$\begin{aligned}\int f'(y)\, dy &= \int \left(-\frac{1}{y}\right) dy\\ f(y) &= -\ln(y) + c_1\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \ln(y)$$

The solution becomes

$$y = \frac{e^{-c_1}}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-c_1}}{x} \tag{1}$$

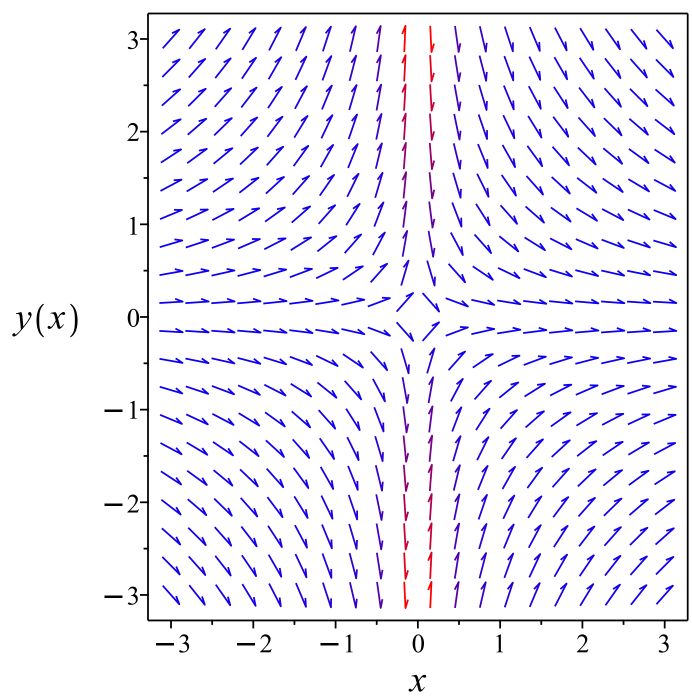

Figure 70: Slope field plot

Verification of solutions

$$y = \frac{e^{-c_1}}{x}$$

Problem number: 41.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' + y^2 = x^2}$$

With initial conditions

$$[y(-1) = 0]$$

3.1.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= x^2 - y^2 \end{aligned}$$

The x domain of $f(x, y)$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = -1$ is inside this domain. The y domain of $f(x, y)$ when $x = -1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}(x^2 - y^2)\\ &= -2y\end{aligned}$$

The y domain of $\frac{\partial f}{\partial y}$ when $x = -1$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

3.1.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y)\\ &= x^2 - y^2\end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x^2 - y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = x^2$, $f_1(x) = 0$ and $f_2(x) = -1$. Let

$$\begin{aligned}y &= \frac{-u'}{f_2 u}\\ &= \frac{-u'}{-u} \qquad (1)\end{aligned}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \qquad (2)$$

But

$$\begin{aligned}f_2' &= 0\\ f_1 f_2 &= 0\\ f_2^2 f_0 &= x^2\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x) + x^2 u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \sqrt{x}\left(c_1 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + c_2 \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)\right)$$

The above shows that

$$u'(x) = \left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) c_2 + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_1\right) x^{\frac{3}{2}}$$

Using the above in (1) gives the solution

$$y = \frac{\left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) c_2 + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_1\right) x}{c_1 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + c_2 \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\left(-\operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) + \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right) c_3\right) x}{c_3 \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right)}$$

Initial conditions are used to solve for c_3. Substituting $x = -1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{\operatorname{BesselK}\left(\frac{3}{4}, \frac{1}{2}\right) - \operatorname{BesselI}\left(-\frac{3}{4}, \frac{1}{2}\right) c_3}{c_3 \operatorname{BesselI}\left(\frac{1}{4}, \frac{1}{2}\right) + \operatorname{BesselK}\left(\frac{1}{4}, \frac{1}{2}\right)}$$

$$c_3 = \frac{\operatorname{BesselK}\left(\frac{3}{4}, \frac{1}{2}\right)}{\operatorname{BesselI}\left(-\frac{3}{4}, \frac{1}{2}\right)}$$

Substituting c_3 found above in the general solution gives

$$y = \frac{-x \operatorname{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) \operatorname{BesselI}\left(-\frac{3}{4}, \frac{1}{2}\right) + x \operatorname{BesselK}\left(\frac{3}{4}, \frac{1}{2}\right) \operatorname{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right)}{\operatorname{BesselK}\left(\frac{3}{4}, \frac{1}{2}\right) \operatorname{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + \operatorname{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right) \operatorname{BesselI}\left(-\frac{3}{4}, \frac{1}{2}\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{-x\,\mathrm{BesselK}\left(\frac{3}{4}, \frac{x^2}{2}\right) \mathrm{BesselI}\left(-\frac{3}{4}, \frac{1}{2}\right) + x\,\mathrm{BesselK}\left(\frac{3}{4}, \frac{1}{2}\right) \mathrm{BesselI}\left(-\frac{3}{4}, \frac{x^2}{2}\right)}{\mathrm{BesselK}\left(\frac{3}{4}, \frac{1}{2}\right) \mathrm{BesselI}\left(\frac{1}{4}, \frac{x^2}{2}\right) + \mathrm{BesselK}\left(\frac{1}{4}, \frac{x^2}{2}\right) \mathrm{BesselI}\left(-\frac{3}{4}, \frac{1}{2}\right)} \tag{1}$$

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[[_Riccati, _special]]
```

$$\boxed{y' - y^2 = x}$$

With initial conditions

$$[y(0) = 0]$$

3.2.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= y^2 + x \end{aligned}$$

The x domain of $f(x, y)$ when $y = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}
\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}(y^2 + x) \\
&= 2y
\end{aligned}$$

The y domain of $\frac{\partial f}{\partial y}$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 0$ is inside this domain. Therefore solution exists and is unique.

3.2.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x, y) \\
&= y^2 + x
\end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + x$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = x$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{u} \qquad (1)
\end{aligned}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \qquad (2)$$

But

$$\begin{aligned}
f_2' &= 0 \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= x
\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + xu(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 \operatorname{AiryAi}(-x) + c_2 \operatorname{AiryBi}(-x)$$

The above shows that

$$u'(x) = -c_1 \operatorname{AiryAi}(1, -x) - c_2 \operatorname{AiryBi}(1, -x)$$

Using the above in (1) gives the solution

$$y = -\frac{-c_1 \operatorname{AiryAi}(1, -x) - c_2 \operatorname{AiryBi}(1, -x)}{c_1 \operatorname{AiryAi}(-x) + c_2 \operatorname{AiryBi}(-x)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{c_3 \operatorname{AiryAi}(1, -x) + \operatorname{AiryBi}(1, -x)}{c_3 \operatorname{AiryAi}(-x) + \operatorname{AiryBi}(-x)}$$

Initial conditions are used to solve for c_3. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{3\Gamma\left(\frac{2}{3}\right)^2 3^{\frac{2}{3}} - 3\Gamma\left(\frac{2}{3}\right)^2 c_3 3^{\frac{1}{6}}}{2\, 3^{\frac{5}{6}}\pi + 2\pi c_3 3^{\frac{1}{3}}}$$

$$c_3 = \sqrt{3}$$

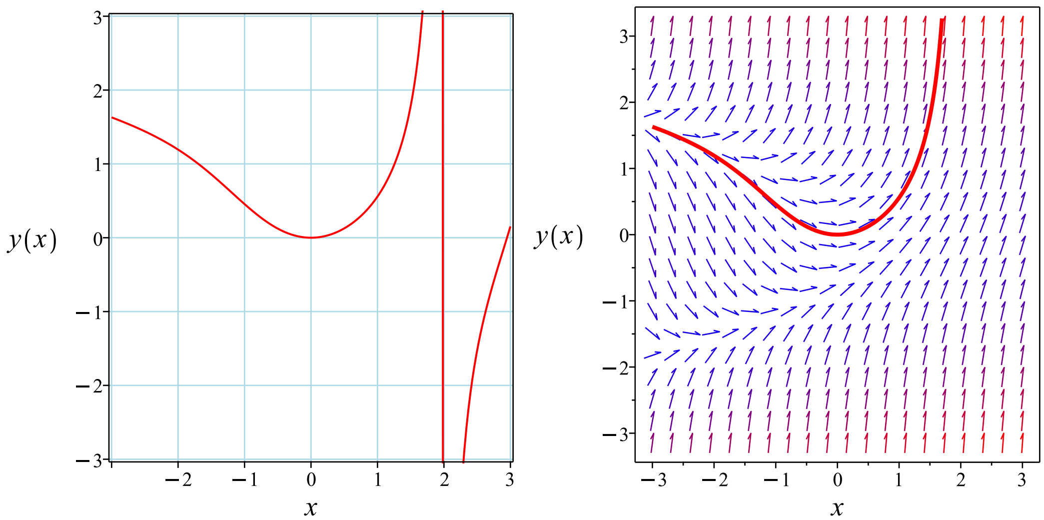
Substituting c_3 found above in the general solution gives

$$y = \frac{\operatorname{AiryAi}(1, -x)\sqrt{3} + \operatorname{AiryBi}(1, -x)}{\operatorname{AiryAi}(-x)\sqrt{3} + \operatorname{AiryBi}(-x)}$$

Summary

The solution(s) found are the following

$$y = \frac{\operatorname{AiryAi}(1, -x)\sqrt{3} + \operatorname{AiryBi}(1, -x)}{\operatorname{AiryAi}(-x)\sqrt{3} + \operatorname{AiryBi}(-x)} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{\operatorname{AiryAi}(1, -x)\sqrt{3} + \operatorname{AiryBi}(1, -x)}{\operatorname{AiryAi}(-x)\sqrt{3} + \operatorname{AiryBi}(-x)}$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = x}$$

With initial conditions

$$[y(0) = 1]$$

3.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = x$$

Hence the ode is

$$y' - y = x$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

3.3.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-1)dx} \\ &= e^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(x) \\ \frac{d}{dx}\left(e^{-x}y\right) &= \left(e^{-x}\right)(x) \\ d\left(e^{-x}y\right) &= \left(x\,e^{-x}\right)\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-x}y &= \int x\,e^{-x}\,dx \\ e^{-x}y &= -(x+1)\,e^{-x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = -e^{x}(x+1)\,e^{-x} + e^{x}c_1$$

which simplifies to

$$y = e^{x}c_1 - x - 1$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -1 + c_1$$

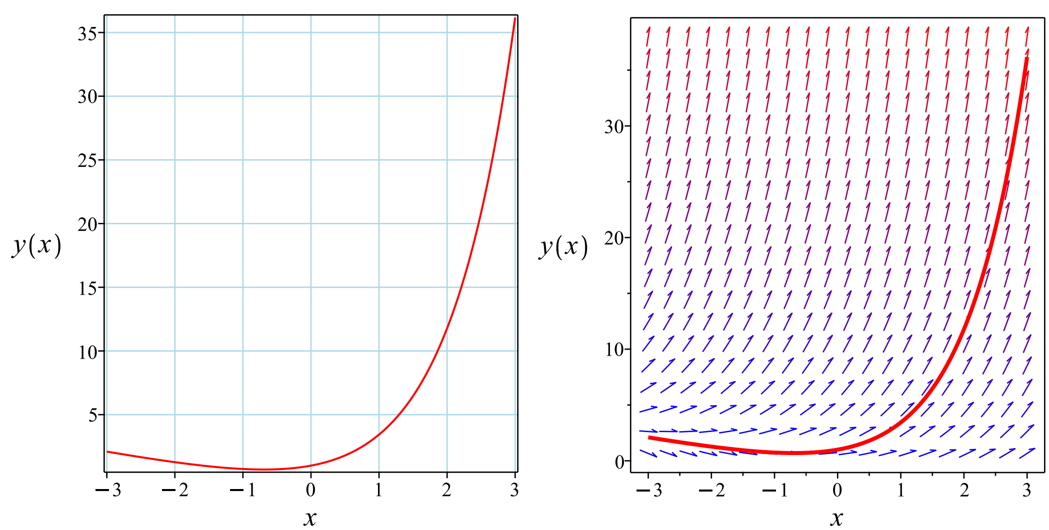
$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$y = -1 + 2\,\mathrm{e}^{x} - x$$

Summary
The solution(s) found are the following

$$y = -1 + 2\,\mathrm{e}^{x} - x \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = -1 + 2\,\mathrm{e}^{x} - x$$

Verified OK.

3.3.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= y + x \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 52: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0 \\ \eta(x,y) &= e^{x}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{x}} dy\end{aligned}$$

Which results in

$$S = e^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = y + x$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1 \\ R_y &= 0 \\ S_x &= -e^{-x} y \\ S_y &= e^{-x}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x\,\mathrm{e}^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R\,\mathrm{e}^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -(R+1)\,\mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-x} y = -(x+1)\,\mathrm{e}^{-x} + c_1$$

Which simplifies to

$$(x+y+1)\,\mathrm{e}^{-x} - c_1 = 0$$

Which gives

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = y + x$ 	$R = x$ $S = \mathrm{e}^{-x} y$	$\frac{dS}{dR} = R\,\mathrm{e}^{-R}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -1 + c_1$$

$$c_1 = 2$$

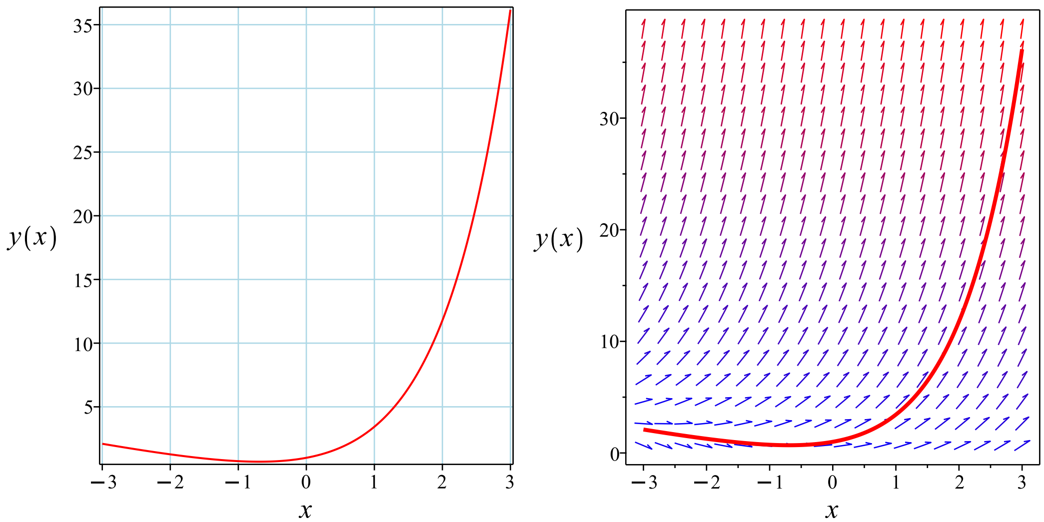
Substituting c_1 found above in the general solution gives

$$y = -1 + 2\,\mathrm{e}^{x} - x$$

Summary

The solution(s) found are the following

$$y = -1 + 2\,\mathrm{e}^{x} - x \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -1 + 2\,e^{x} - x$$

Verified OK.

3.3.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y&=(y+x)\,\mathrm{d}x\\(-y-x)\,\mathrm{d}x+\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-y-x\\N(x,y)&=1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(-y-x)\\&=-1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}(1)\\&=0\end{aligned}$$

Since $\frac{\partial M}{\partial y}\neq\frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A&=\frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\&=1((-1)-(0))\\&=-1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, dx} \\
&= e^{\int -1 \, dx}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{-x} \\
&= \mathrm{e}^{-x}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-x}(-y - x) \\
&= -\mathrm{e}^{-x}(y + x)
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-x}(1) \\
&= \mathrm{e}^{-x}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{-x}(y + x)\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int \overline{M} \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\mathrm{e}^{-x}(y + x) \, \mathrm{d}x
\end{aligned}$$

$$\phi = (x + y + 1)\,\mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (x + y + 1)\,\mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (x + y + 1)\,\mathrm{e}^{-x}$$

The solution becomes

$$y = -\left(x\,\mathrm{e}^{-x} + \mathrm{e}^{-x} - c_1\right)\mathrm{e}^{x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -1 + c_1$$

$$c_1 = 2$$

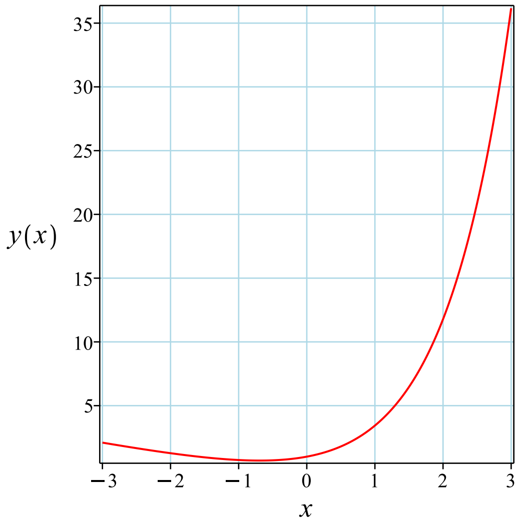
Substituting c_1 found above in the general solution gives

$$y = -1 + 2\,\mathrm{e}^{x} - x$$

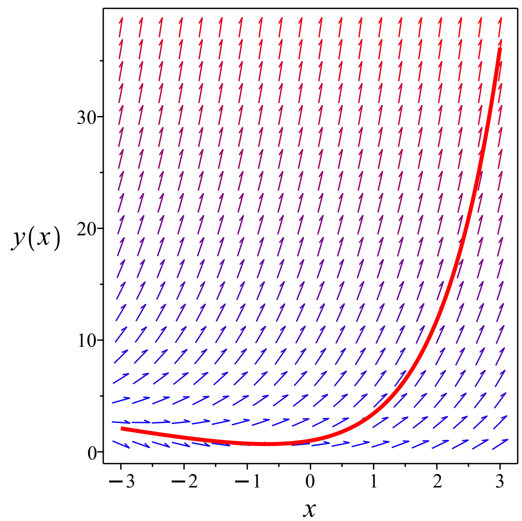
Summary

The solution(s) found are the following

$$y = -1 + 2\,e^{x} - x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -1 + 2\,e^{x} - x$$

Verified OK.

3.3.5 Maple step by step solution

Let's solve

$[y' - y = x, y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = y + x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$\mu(x)\left(y'-y\right)=\mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'-y\right)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x)=-\mu(x)$

- Solve to find the integrating factor

  $\mu(x)=\mathrm{e}^{-x}$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\mu(x)\,xdx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\mu(x)\,xdx+c_1$

- Solve for y

  $y=\frac{\int\mu(x)xdx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\mathrm{e}^{-x}$

  $y=\frac{\int x\,\mathrm{e}^{-x}dx+c_1}{\mathrm{e}^{-x}}$

- Evaluate the integrals on the rhs

  $y=\frac{-(x+1)\mathrm{e}^{-x}+c_1}{\mathrm{e}^{-x}}$

- Simplify

  $y=\mathrm{e}^{x}c_1-x-1$

- Use initial condition $y(0)=1$

  $1=-1+c_1$

- Solve for c_1

  $c_1=2$

- Substitute $c_1=2$ into general solution and simplify

  $y=-1+2\,\mathrm{e}^{x}-x$

- Solution to the IVP

  $y=-1+2\,\mathrm{e}^{x}-x$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - 2y = -2x^2 - 3}$$

With initial conditions

$$[y(0) = 2]$$

3.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= -2x^2 - 3 \end{aligned}$$

Hence the ode is

$$y' - 2y = -2x^2 - 3$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -2x^2 - 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

3.4.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-2)dx} \\ &= e^{-2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(-2x^2 - 3\right) \\ \frac{d}{dx}\left(e^{-2x}y\right) &= \left(e^{-2x}\right)\left(-2x^2 - 3\right) \\ d\left(e^{-2x}y\right) &= \left(\left(-2x^2 - 3\right)e^{-2x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-2x}y &= \int \left(-2x^2 - 3\right)e^{-2x} dx \\ e^{-2x}y &= e^{-2x}\left(x^2 + x + 2\right) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-2x}$ results in

$$y = e^{2x}e^{-2x}\left(x^2 + x + 2\right) + c_1e^{2x}$$

which simplifies to

$$y = x^2 + x + 2 + c_1e^{2x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1 + 2$$

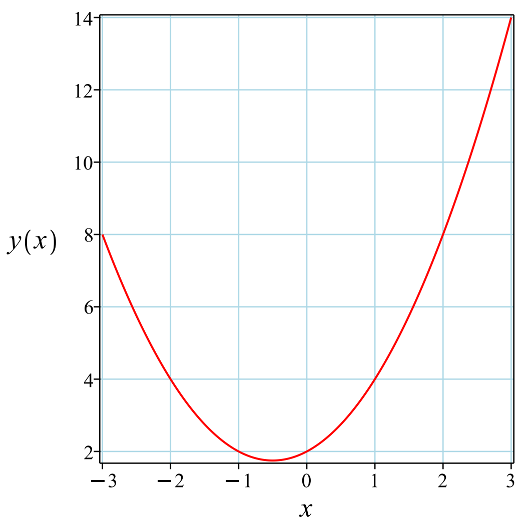
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

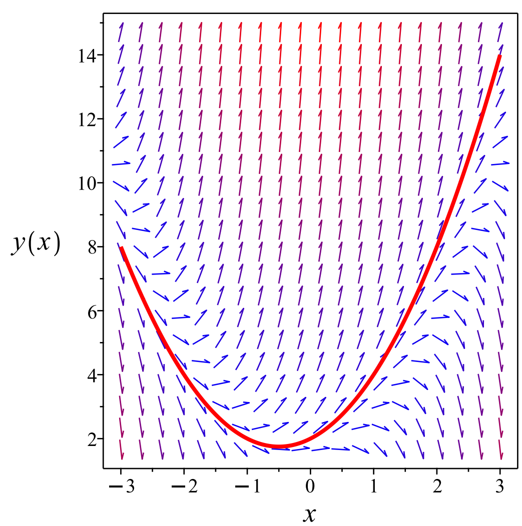
$$y = x^2 + x + 2$$

Summary
The solution(s) found are the following

$$y = x^2 + x + 2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x^2 + x + 2$$

Verified OK.

3.4.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -2x^2 + 2y - 3 \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 55: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \mathrm{e}^{2x}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\mathrm{e}^{2x}} dy\end{aligned}$$

Which results in

$$S = \mathrm{e}^{-2x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -2x^2 + 2y - 3$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1\\ R_y &= 0\\ S_x &= -2\,\mathrm{e}^{-2x} y\\ S_y &= \mathrm{e}^{-2x}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \left(-2x^2 - 3\right) e^{-2x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \left(-2R^2 - 3\right) e^{-2R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \left(R^2 + R + 2\right) e^{-2R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-2x} y = e^{-2x}\left(x^2 + x + 2\right) + c_1$$

Which simplifies to

$$e^{-2x} y = e^{-2x}\left(x^2 + x + 2\right) + c_1$$

Which gives

$$y = \left(x^2 e^{-2x} + x\, e^{-2x} + 2\, e^{-2x} + c_1\right) e^{2x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -2x^2 + 2y - 3$ 	$R = x$ $S = \mathrm{e}^{-2x} y$	$\frac{dS}{dR} = (-2R^2 - 3)\,\mathrm{e}^{-2R}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1 + 2$$

$$c_1 = 0$$

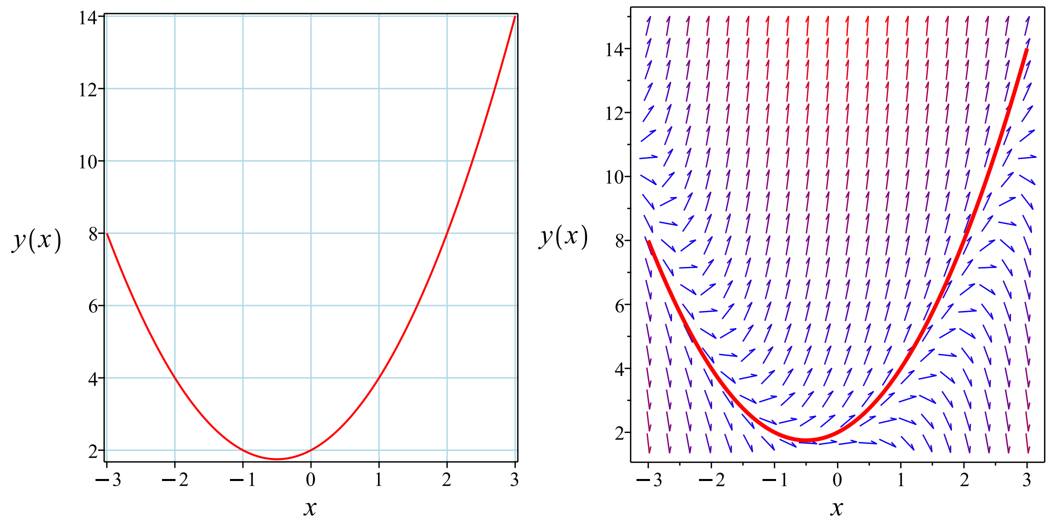
Substituting c_1 found above in the general solution gives

$$y = x^2 + x + 2$$

Summary

The solution(s) found are the following

$$y = x^2 + x + 2 \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = x^2 + x + 2$$

Verified OK.

3.4.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned} \frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N \end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} \mathrm{d}y &= \left(-2x^2+2y-3\right)\mathrm{d}x \\ \left(2x^2-2y+3\right)\mathrm{d}x + \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= 2x^2-2y+3 \\ N(x,y) &= 1 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2x^2-2y+3\right) \\ &= -2 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-2)-(0)) \\ &= -2 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -2 \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-2x} \\
&= \mathrm{e}^{-2x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-2x}\left(2x^2 - 2y + 3\right) \\
&= \left(2x^2 - 2y + 3\right) \mathrm{e}^{-2x}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-2x}(1) \\
&= \mathrm{e}^{-2x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\left(2x^2 - 2y + 3\right) \mathrm{e}^{-2x}\right) + \left(\mathrm{e}^{-2x}\right) \frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \left(2x^2 - 2y + 3\right) \mathrm{e}^{-2x} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -\left(x^2 + x - y + 2\right) \mathrm{e}^{-2x} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-2x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-2x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-2x} = \mathrm{e}^{-2x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\left(x^2 + x - y + 2\right)\mathrm{e}^{-2x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\left(x^2 + x - y + 2\right)\mathrm{e}^{-2x}$$

The solution becomes

$$y = \left(x^2\mathrm{e}^{-2x} + x\,\mathrm{e}^{-2x} + 2\,\mathrm{e}^{-2x} + c_1\right)\mathrm{e}^{2x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1 + 2$$

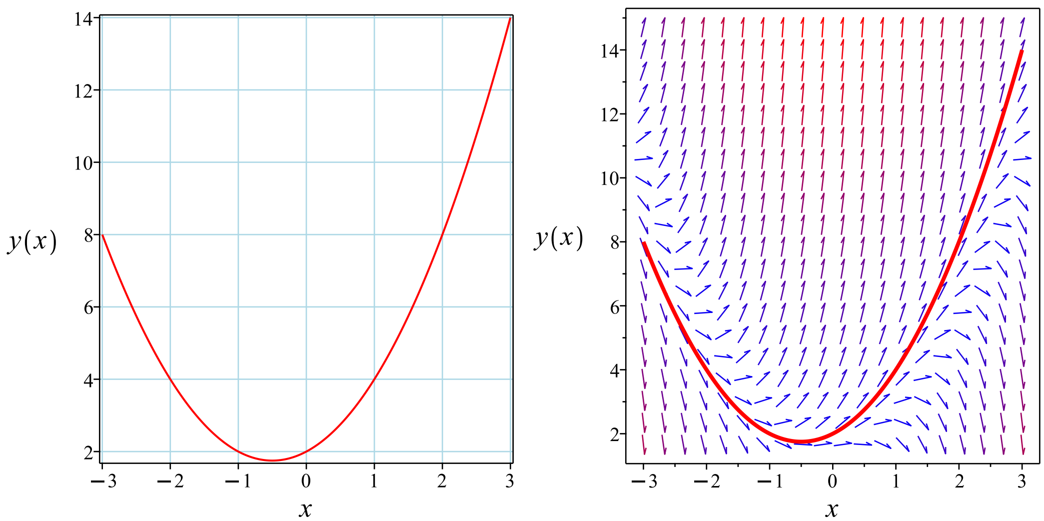
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = x^2 + x + 2$$

Summary
The solution(s) found are the following

$$y = x^2 + x + 2 \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = x^2 + x + 2$$

Verified OK.

3.4.5 Maple step by step solution

Let's solve

$[y' - 2y = -2x^2 - 3, y(0) = 2]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2y - 2x^2 - 3$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - 2y = -2x^2 - 3$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$\mu(x)\,(y'-2y)=\mu(x)\,(-2x^2-3)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

$\mu(x)\,(y'-2y)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

$\mu'(x)=-2\mu(x)$

- Solve to find the integrating factor

$\mu(x)=\mathrm{e}^{-2x}$

- Integrate both sides with respect to x

$\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\mu(x)\,(-2x^2-3)\,dx+c_1$

- Evaluate the integral on the lhs

$\mu(x)\,y=\int\mu(x)\,(-2x^2-3)\,dx+c_1$

- Solve for y

$y=\frac{\int\mu(x)(-2x^2-3)dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\mathrm{e}^{-2x}$

$y=\frac{\int(-2x^2-3)\mathrm{e}^{-2x}dx+c_1}{\mathrm{e}^{-2x}}$

- Evaluate the integrals on the rhs

$y=\frac{\mathrm{e}^{-2x}(x^2+x+2)+c_1}{\mathrm{e}^{-2x}}$

- Simplify

$y=x^2+x+2+c_1\mathrm{e}^{2x}$

- Use initial condition $y(0)=2$

$2=c_1+2$

- Solve for c_1

$c_1=0$

- Substitute $c_1=0$ into general solution and simplify

$y=x^2+x+2$

- Solution to the IVP

$y=x^2+x+2$

The type(s) of ODE detected by this program : **"exact", "linear", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{y'x + y = 2x}$$

With initial conditions

$$[y(1) = 2]$$

3.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= 2 \end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = 2$$

The domain of $p(x) = \frac{1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

3.5.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int \frac{1}{x}dx} \\ &= x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(2) \\ \frac{\mathrm{d}}{\mathrm{d}x}(xy) &= (x)(2) \\ \mathrm{d}(xy) &= (2x)\,\mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} xy &= \int 2x\,\mathrm{d}x \\ xy &= x^2 + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = x + \frac{c_1}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = 1 + c_1$$

$$c_1 = 1$$

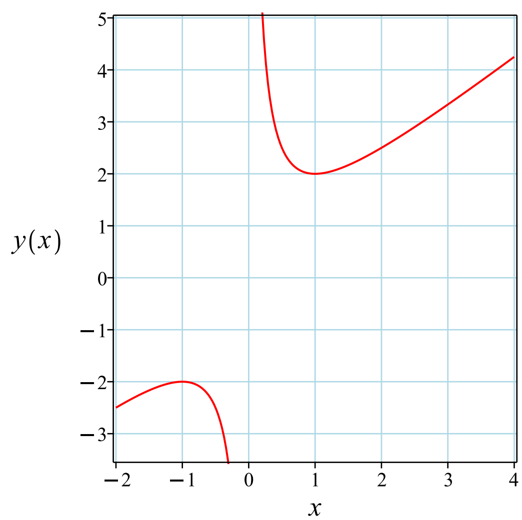
Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 + 1}{x}$$

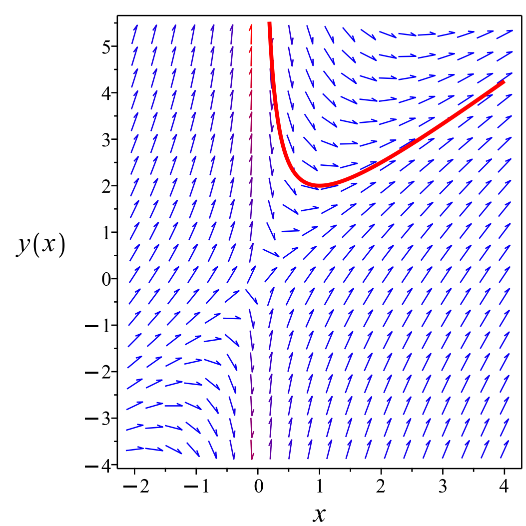
Summary

The solution(s) found are the following

$$y = \frac{x^2 + 1}{x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{x^2 + 1}{x}$$

Verified OK.

3.5.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x + u(x))\,x + u(x)\,x = 2x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{-2u+2}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = -2u + 2$. Integrating both sides gives

$$\begin{aligned} \frac{1}{-2u+2}\,du &= \frac{1}{x}\,dx \\ \int \frac{1}{-2u+2}\,du &= \int \frac{1}{x}\,dx \\ -\frac{\ln(u-1)}{2} &= \ln(x) + c_2 \end{aligned}$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{u-1}} = \mathrm{e}^{\ln(x)+c_2}$$

Which simplifies to

$$\frac{1}{\sqrt{u-1}} = c_3 x$$

Therefore the solution y is

$$\begin{aligned} y &= ux \\ &= \frac{(c_3^2\mathrm{e}^{2c_2}x^2+1)\,\mathrm{e}^{-2c_2}}{x\,c_3^2} \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = \frac{\mathrm{e}^{2c_2}\mathrm{e}^{-2c_2}c_3^2 + \mathrm{e}^{-2c_2}}{c_3^2}$$

$$
c_2 = -\ln(c_3)
$$

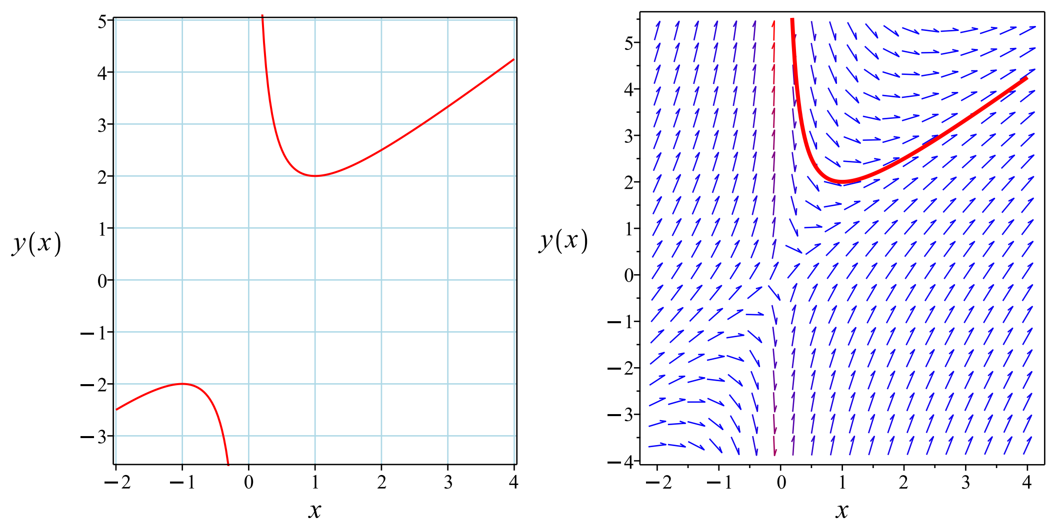
Substituting c_2 found above in the general solution gives

$$
y = \frac{x^2+1}{x}
$$

Summary

The solution(s) found are the following

$$
y = \frac{x^2+1}{x} \tag{1}
$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$
y = \frac{x^2+1}{x}
$$

Verified OK.

3.5.4 Solving as differentialType ode

Writing the ode as

$$y' = \frac{2x - y}{x} \tag{1}$$

Which becomes

$$0 = (-x)\, dy + (2x - y)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + (2x - y)\, dx = d\left(x^2 - xy\right)$$

Hence (2) becomes

$$0 = d\left(x^2 - xy\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{x^2 + c_1}{x} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = 2c_1 + 1$$

$$c_1 = \frac{1}{2}$$

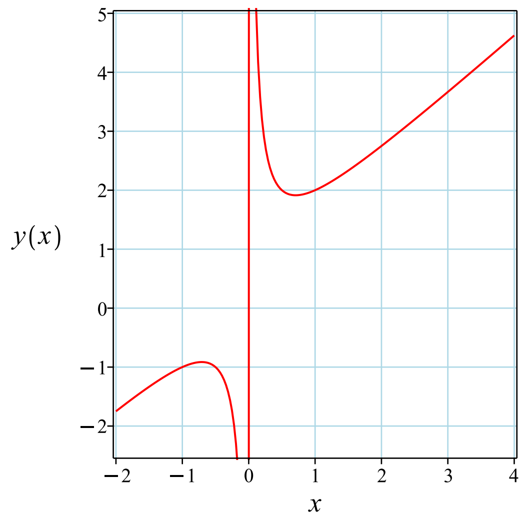
Substituting c_1 found above in the general solution gives

$$y = \frac{2x^2 + x + 1}{2x}$$

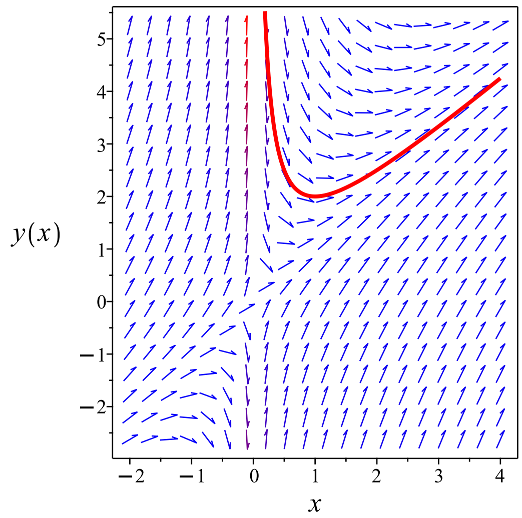
Summary

The solution(s) found are the following

$$y = \frac{2x^2 + x + 1}{2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{2x^2 + x + 1}{2x}$$

Warning, solution could not be verified

3.5.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-2x + y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 58: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-2x + y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = x^2 + c_1$$

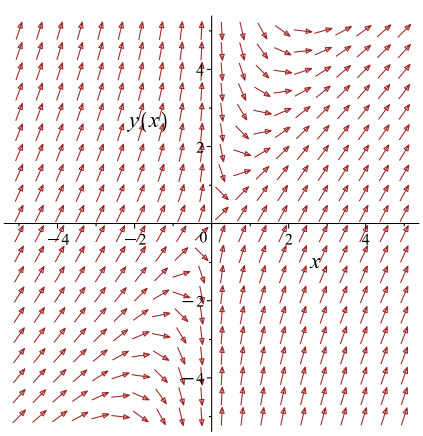
Which simplifies to

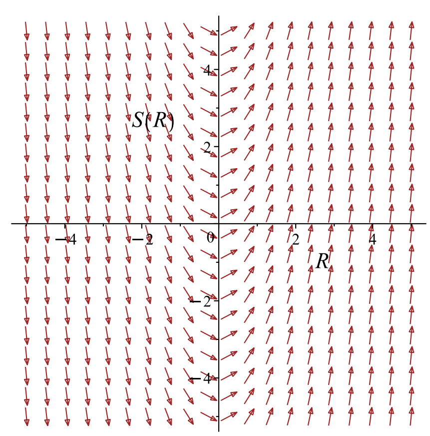
$$yx = x^2 + c_1$$

Which gives

$$y = \frac{x^2 + c_1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = -\frac{-2x+y}{x}$


</td><td>$R = x$
$S = xy$</td><td>$\frac{dS}{dR} = 2R$


</td></tr>
</table>

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = 1 + c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 + 1}{x}$$

3.5.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y&=(2x-y)\,\mathrm{d}x\\ (-2x+y)\,\mathrm{d}x+(x)\,\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-2x+y\\ N(x,y)&=x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(-2x+y)\\&=1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}(x)\\&=1\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$

$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x&=\int M\,\mathrm{d}x\\\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x&=\int -2x+y\,\mathrm{d}x\end{aligned}$$

$$\phi=-x(-y+x)+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=x+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=x$. Therefore equation (4) becomes

$$x=x+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x(-y + x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x(-y + x)$$

The solution becomes

$$y = \frac{x^2 + c_1}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 2$ in the above solution gives an equation to solve for the constant of integration.

$$2 = 1 + c_1$$

$$c_1 = 1$$

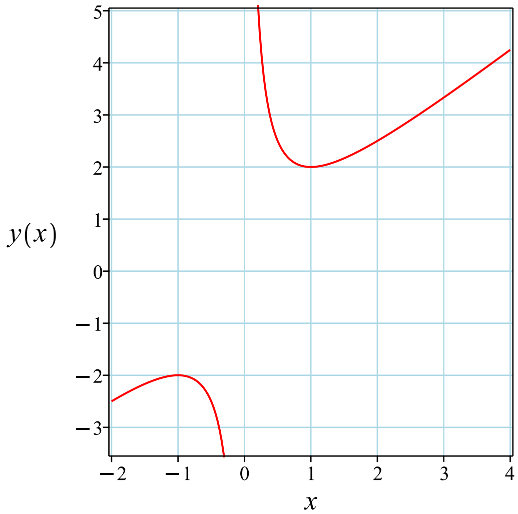
Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 + 1}{x}$$

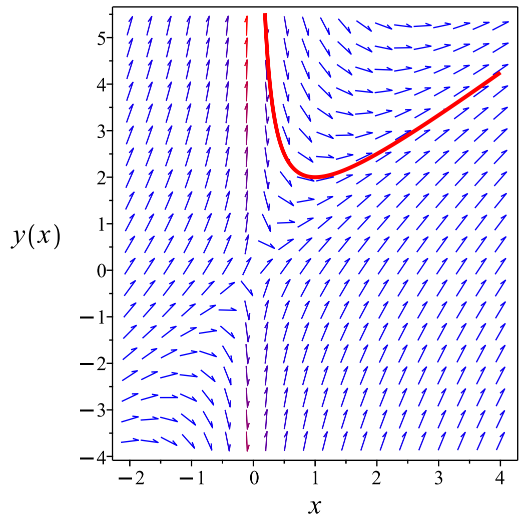
Summary

The solution(s) found are the following

$$y = \frac{x^2 + 1}{x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

3.5.7 Maple step by step solution

Let's solve

$[y'x + y = 2x, y(1) = 2]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2 - \frac{y}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{x} = 2$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = 2\mu(x)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{x}$
- Solve to find the integrating factor

  $\mu(x) = x$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int 2\mu(x)\, dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\, y = \int 2\mu(x)\, dx + c_1$
- Solve for y

  $y = \frac{\int 2\mu(x)dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = x$

  $y = \frac{\int 2x dx + c_1}{x}$
- Evaluate the integrals on the rhs

  $y = \frac{x^2 + c_1}{x}$
- Use initial condition $y(1) = 2$

  $2 = 1 + c_1$
- Solve for c_1

  $c_1 = 1$
- Substitute $c_1 = 1$ into general solution and simplify

  $y = \frac{x^2 + 1}{x}$
- Solution to the IVP

  $y = \frac{x^2 + 1}{x}$

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y^2 + \left(x^2+1\right) y' = -1}$$

4.1.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{-y^2-1}{x^2+1} \end{aligned}$$

Where $f(x) = \frac{1}{x^2+1}$ and $g(y) = -y^2-1$. Integrating both sides gives

$$\frac{1}{-y^2-1}\,dy = \frac{1}{x^2+1}\,dx$$

$$\int \frac{1}{-y^2-1}\,dy = \int \frac{1}{x^2+1}\,dx$$
$$-\arctan(y) = \arctan(x) + c_1$$

Which results in

$$y = -\tan(\arctan(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = -\tan(\arctan(x) + c_1) \tag{1}$$

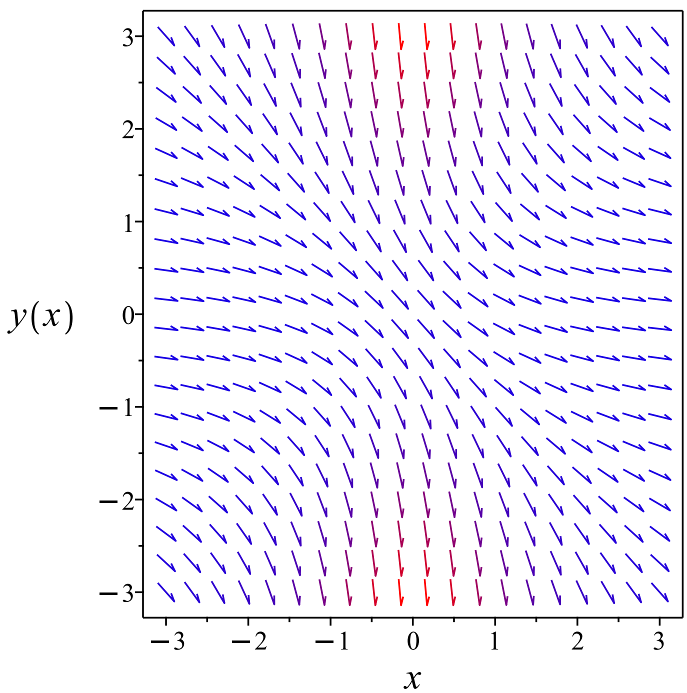

Figure 88: Slope field plot

Verification of solutions

$$y = -\tan(\arctan(x) + c_1)$$

Verified OK.

4.1.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y^2+1}{x^2+1}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 61: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x, y) &= x^2 + 1 \\ \eta(x, y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x^2 + 1} dx\end{aligned}$$

Which results in

$$S = \arctan(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y^2 + 1}{x^2 + 1}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{1}{x^2+1} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{y^2+1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R^2+1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\arctan(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\arctan(x) = -\arctan(y) + c_1$$

Which simplifies to

$$\arctan(x) = -\arctan(y) + c_1$$

Which gives

$$y = \tan(-\arctan(x) + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y^2+1}{x^2+1}$ 	$R = y$ $S = \arctan(x)$	$\frac{dS}{dR} = -\frac{1}{R^2+1}$ 
<u>Summary</u>

The solution(s) found are the following

$$y = \tan(-\arctan(x) + c_1) \tag{1}$$

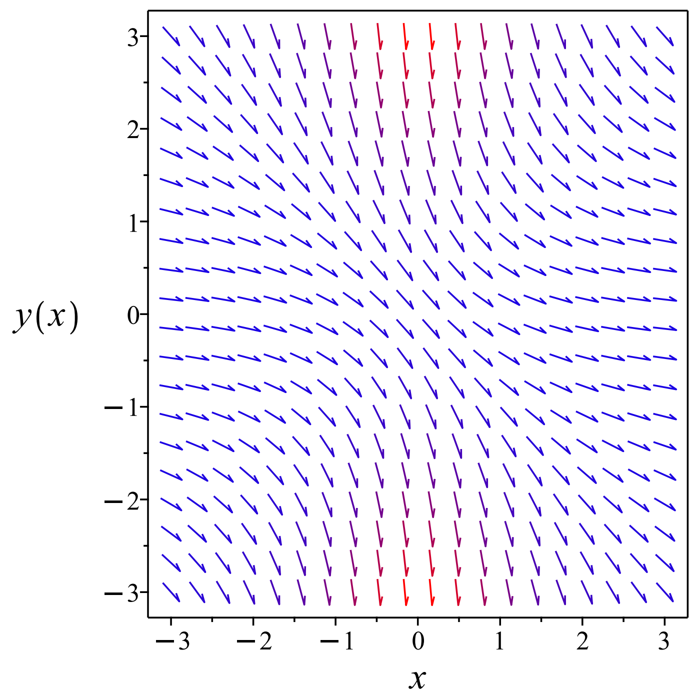

Figure 89: Slope field plot

Verification of solutions

$$y = \tan(-\arctan(x) + c_1)$$

Verified OK.

4.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\left(\frac{1}{-y^2 - 1}\right) \mathrm{d}y = \left(\frac{1}{x^2 + 1}\right) \mathrm{d}x
$$

$$
\left(-\frac{1}{x^2 + 1}\right) \mathrm{d}x + \left(\frac{1}{-y^2 - 1}\right) \mathrm{d}y = 0 \tag{2A}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{1}{x^2 + 1} \\
N(x, y) &= \frac{1}{-y^2 - 1}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2 + 1}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{-y^2-1}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -\frac{1}{x^2+1} \,\mathrm{d}x \\
\phi &= -\arctan(x) + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{-y^2-1}$. Therefore equation (4) becomes

$$
\frac{1}{-y^2-1} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{1}{y^2+1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(-\frac{1}{y^2+1}\right) \mathrm{d}y \\
f(y) &= -\arctan(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\arctan(x) - \arctan(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\arctan(x) - \arctan(y)$$

Summary

The solution(s) found are the following

$$-\arctan(x) - \arctan(y) = c_1 \tag{1}$$

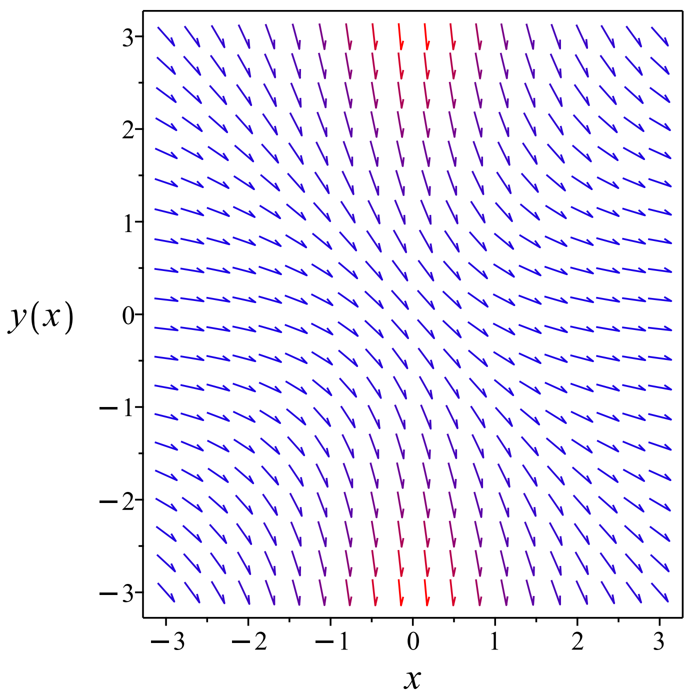

Figure 90: Slope field plot

Verification of solutions

$$-\arctan(x) - \arctan(y) = c_1$$

Verified OK.

4.1.4 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{y^2+1}{x^2+1} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{y^2}{x^2+1} - \frac{1}{x^2+1}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -\frac{1}{x^2+1}$, $f_1(x) = 0$ and $f_2(x) = -\frac{1}{x^2+1}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-\frac{u}{x^2+1}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= \frac{2x}{(x^2+1)^2} \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= -\frac{1}{(x^2+1)^3} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-\frac{u''(x)}{x^2+1} - \frac{2xu'(x)}{(x^2+1)^2} - \frac{u(x)}{(x^2+1)^3} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \frac{c_1 x + c_2}{\sqrt{x^2+1}}$$

The above shows that

$$u'(x) = \frac{-c_2 x + c_1}{(x^2+1)^{\frac{3}{2}}}$$

Using the above in (1) gives the solution

$$y = \frac{-c_2 x + c_1}{c_1 x + c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{c_3 - x}{c_3 x + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{c_3 - x}{c_3 x + 1} \tag{1}$$

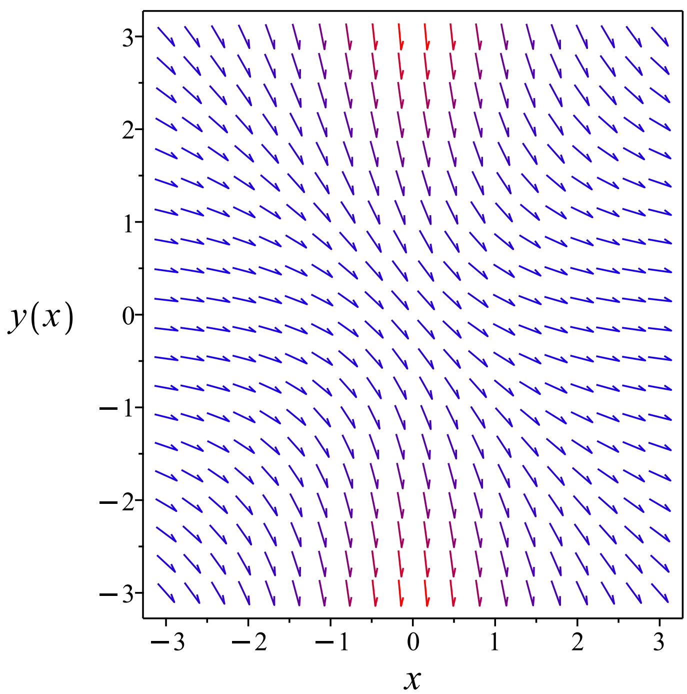

Figure 91: Slope field plot

Verification of solutions

$$y = \frac{c_3 - x}{c_3 x + 1}$$

Verified OK.

4.1.5 Maple step by step solution

Let's solve

$y^2 + (x^2+1)\, y' = -1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{-y^2-1} = \frac{1}{x^2+1}$

- Integrate both sides with respect to x

  $\int \frac{y'}{-y^2-1} dx = \int \frac{1}{x^2+1} dx + c_1$

- Evaluate integral

  $-\arctan(y) = \arctan(x) + c_1$

- Solve for y

  $y = -\tan(\arctan(x) + c_1)$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 4. Equations with variables separable and equations reducible to them. Exercises page 38
Problem number: 47.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y^2 + xyy' = -1}$$

4.2.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y^2+1}{xy} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(y) = \frac{y^2+1}{y}$. Integrating both sides gives

$$\frac{1}{\frac{y^2+1}{y}}\,dy = -\frac{1}{x}\,dx$$

$$\int \frac{1}{\frac{y^2+1}{y}} dy = \int -\frac{1}{x} dx$$

$$\frac{\ln(y^2+1)}{2} = -\ln(x) + c_1$$

Raising both side to exponential gives

$$\sqrt{y^2+1} = e^{-\ln(x)+c_1}$$

Which simplifies to

$$\sqrt{y^2+1} = \frac{c_2}{x}$$

Which simplifies to

$$\sqrt{1+y^2} = \frac{c_2 e^{c_1}}{x}$$

The solution is

$$\sqrt{1+y^2} = \frac{c_2 e^{c_1}}{x}$$

<u>Summary</u>

The solution(s) found are the following

$$\sqrt{1+y^2} = \frac{c_2 e^{c_1}}{x} \tag{1}$$

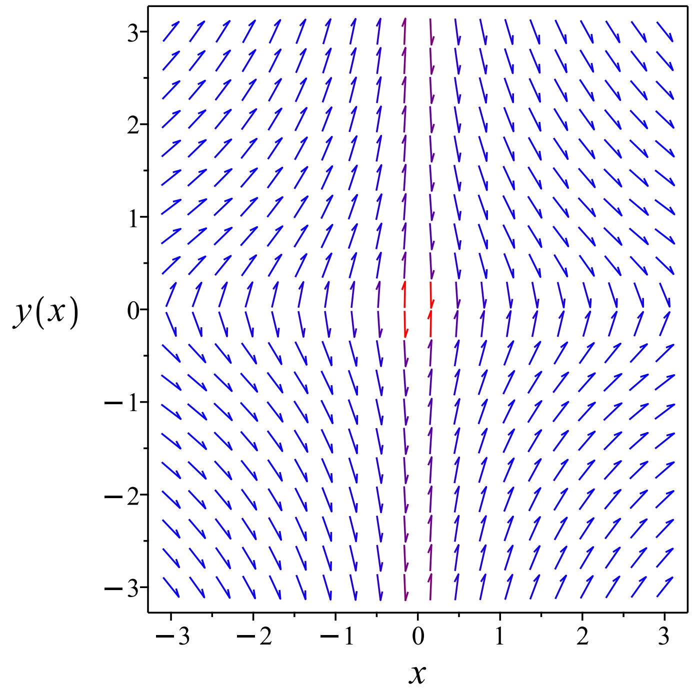

Figure 92: Slope field plot

Verification of solutions

$$\sqrt{1+y^2} = \frac{c_2 e^{c_1}}{x}$$

Verified OK.

4.2.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y^2+1}{xy}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 64: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= -x \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-x} dx \end{aligned}$$

Which results in

$$S = -\ln(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y^2 + 1}{xy}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -\frac{1}{x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{y}{y^2 + 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R}{R^2 + 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\ln(R^2+1)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln(x) = \frac{\ln(1+y^2)}{2} + c_1$$

Which simplifies to

$$-\ln(x) = \frac{\ln(1+y^2)}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y^2+1}{xy}$ 	$R = y$ $S = -\ln(x)$	$\frac{dS}{dR} = \frac{R}{R^2+1}$ 
Summary
The solution(s) found are the following

$$-\ln(x) = \frac{\ln(1+y^2)}{2} + c_1 \tag{1}$$

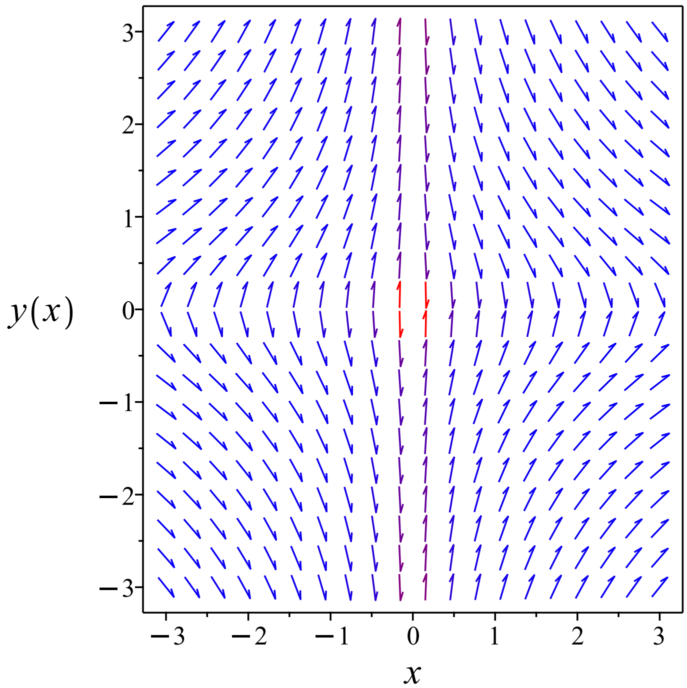

Figure 93: Slope field plot

<u>Verification of solutions</u>

$$-\ln(x) = \frac{\ln(1+y^2)}{2} + c_1$$

Verified OK.

4.2.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{y^2+1}{xy} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{x}y - \frac{1}{x}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{1}{x} \\ f_1(x) &= -\frac{1}{x} \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = -\frac{y^2}{x} - \frac{1}{x} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= -\frac{w(x)}{x} - \frac{1}{x} \\ w' &= -\frac{2w}{x} - \frac{2}{x} \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{2}{x} \\ q(x) &= -\frac{2}{x} \end{aligned}$$

Hence the ode is

$$w'(x) + \frac{2w(x)}{x} = -\frac{2}{x}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{x}dx} \\ &= x^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)\left(-\frac{2}{x}\right) \\ \frac{d}{dx}(x^2 w) &= (x^2)\left(-\frac{2}{x}\right) \\ d(x^2 w) &= (-2x)\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}x^2 w &= \int -2x\, dx \\ x^2 w &= -x^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2$ results in

$$w(x) = -1 + \frac{c_1}{x^2}$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = -1 + \frac{c_1}{x^2}$$

Solving for y gives

$$\begin{aligned}y(x) &= \frac{\sqrt{-x^2 + c_1}}{x} \\ y(x) &= -\frac{\sqrt{-x^2 + c_1}}{x}\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{-x^2 + c_1}}{x} \tag{1}$$

$$y = -\frac{\sqrt{-x^2 + c_1}}{x} \tag{2}$$

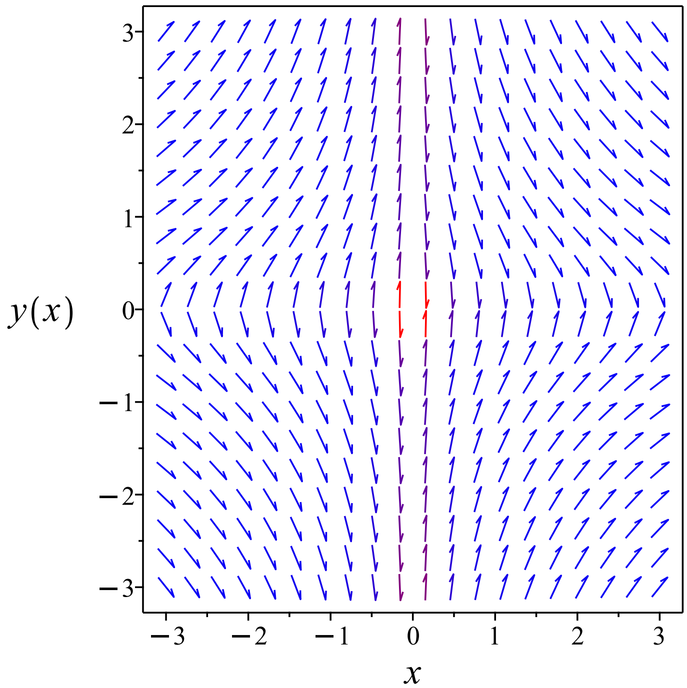

Figure 94: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{-x^2 + c_1}}{x}$$

Verified OK.

$$y = -\frac{\sqrt{-x^2 + c_1}}{x}$$

Verified OK.

4.2.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}
\frac{\partial \phi}{\partial x}&=M\\
\frac{\partial \phi}{\partial y}&=N
\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(-\frac{y}{y^2+1}\right)\mathrm{d}y&=\left(\frac{1}{x}\right)\mathrm{d}x\\
\left(-\frac{1}{x}\right)\mathrm{d}x+\left(-\frac{y}{y^2+1}\right)\mathrm{d}y&=0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y)&=-\frac{1}{x}\\
N(x,y)&=-\frac{y}{y^2+1}
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-\frac{1}{x}\right)\\
&=0
\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{y}{y^2+1}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{1}{x} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -\ln(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y}{y^2+1}$. Therefore equation (4) becomes

$$
-\frac{y}{y^2+1} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{y}{y^2+1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int \left(-\frac{y}{y^2+1}\right) \mathrm{d}y \\
f(y) &= -\frac{\ln(y^2+1)}{2} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \frac{\ln(y^2+1)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \frac{\ln(y^2+1)}{2}$$

Summary

The solution(s) found are the following

$$-\ln(x) - \frac{\ln(1+y^2)}{2} = c_1 \tag{1}$$

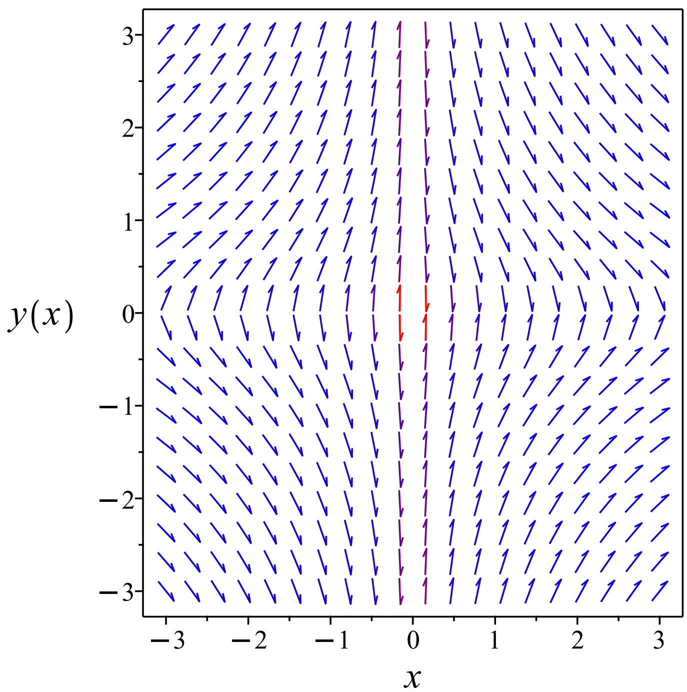

Figure 95: Slope field plot

Verification of solutions

$$-\ln(x) - \frac{\ln(1+y^2)}{2} = c_1$$

Verified OK.

Problem number: 48.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' \sin (x) - y \cos (x) = 0}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 1\right]$$

4.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\cot(x) \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - y\cot(x) = 0$$

The domain of $p(x) = -\cot(x)$ is

$$\{x < \pi\_Z796 \lor \pi\_Z796 < x\}$$

And the point $x_0 = \frac{\pi}{2}$ is inside this domain. Hence solution exists and is unique.

4.3.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y\cos(x)}{\sin(x)} \end{aligned}$$

Where $f(x) = \frac{\cos(x)}{\sin(x)}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned} \frac{1}{y}\,dy &= \frac{\cos(x)}{\sin(x)}\,dx \\ \int \frac{1}{y}\,dy &= \int \frac{\cos(x)}{\sin(x)}\,dx \\ \ln(y) &= \ln(\sin(x)) + c_1 \\ y &= e^{\ln(\sin(x))+c_1} \\ &= \sin(x)\,c_1 \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

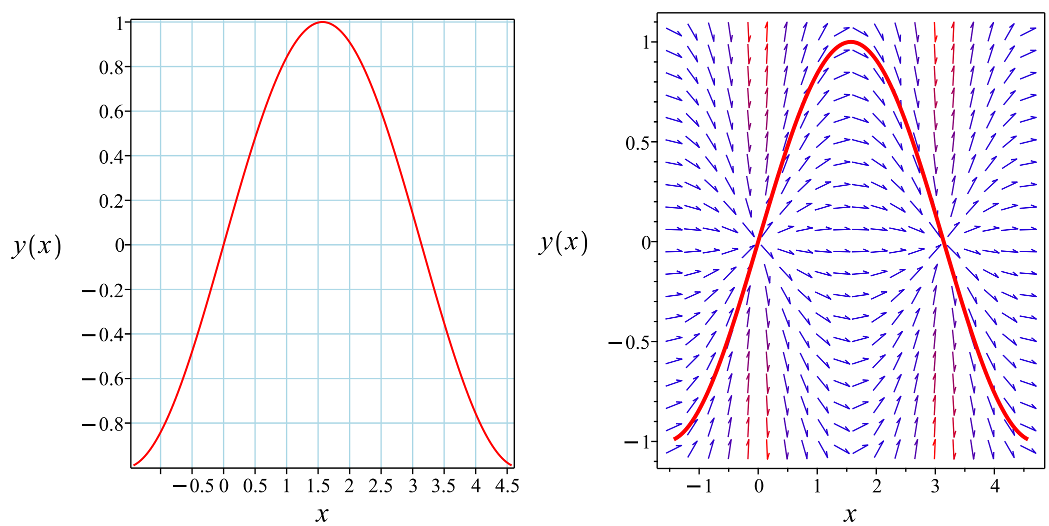
Substituting c_1 found above in the general solution gives

$$y = \sin(x)$$

Summary

The solution(s) found are the following

$$y = \sin(x) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \sin(x)$$

Verified OK.

4.3.3 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\cot(x)dx} \\ &= \frac{1}{\sin(x)}\end{aligned}$$

Which simplifies to

$$\mu = \csc(x)$$

The ode becomes

$$\frac{d}{dx}\mu y = 0$$

$$\frac{d}{dx}(\csc(x)\, y) = 0$$

Integrating gives

$$\csc(x)\, y = c_1$$

Dividing both sides by the integrating factor $\mu = \csc(x)$ results in

$$y = \sin(x)\, c_1$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

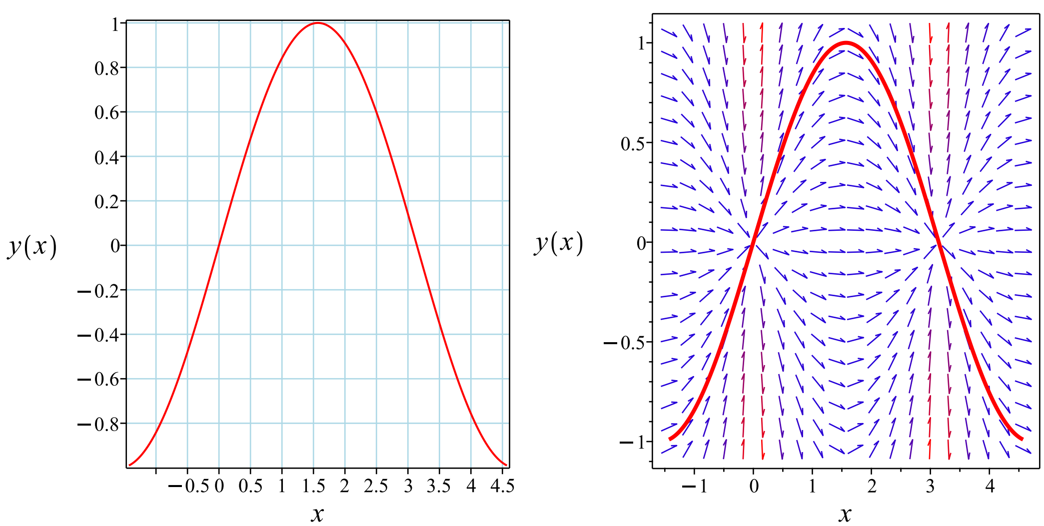
$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$y = \sin(x)$$

Summary
The solution(s) found are the following

$$y = \sin(x) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \sin(x)$$

Verified OK.

4.3.4 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x + u(x))\sin(x) - u(x)\,x\cos(x) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u(\cos(x)\,x - \sin(x))}{x\sin(x)}
\end{aligned}$$

Where $f(x) = \frac{\cos(x)x-\sin(x)}{x\sin(x)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{\cos(x)\,x - \sin(x)}{x\sin(x)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{\cos(x)\,x - \sin(x)}{x\sin(x)}\,dx \\
\ln(u) &= \ln(\sin(x)) - \ln(x) + c_2 \\
u &= e^{\ln(\sin(x))-\ln(x)+c_2} \\
&= c_2 e^{\ln(\sin(x))-\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_2\sin(x)}{x}$$

Therefore the solution y is

$$\begin{aligned}
y &= xu \\
&= c_2\sin(x)
\end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_2$$

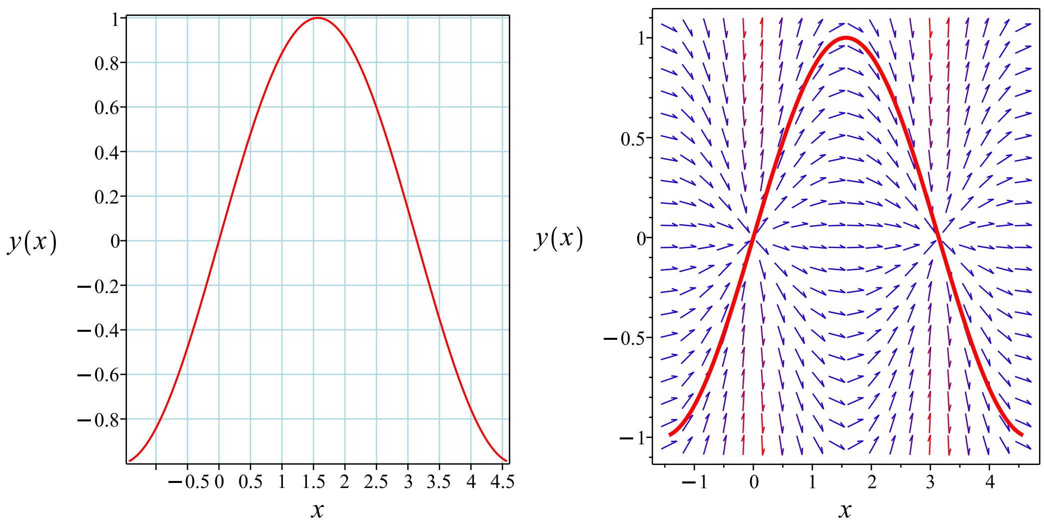
$$c_2 = 1$$

Substituting c_2 found above in the general solution gives

$$y = \sin(x)$$

Summary
The solution(s) found are the following

$$y = \sin(x) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \sin(x)$$

Verified OK.

4.3.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y\cos(x)}{\sin(x)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 67: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int b f(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \sin(x) \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\sin(x)} dy \end{aligned}$$

Which results in

$$S = \frac{y}{\sin(x)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y\cos(x)}{\sin(x)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\csc(x)\cot(x)\, y \\ S_y &= \csc(x) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\csc(x)\, y = c_1$$

Which simplifies to

$$\csc(x)\, y = c_1$$

Which gives

$$y = \frac{c_1}{\csc(x)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y\cos(x)}{\sin(x)}$ 	$R = x$ $S = \csc(x)\, y$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$y = \sin(x)$$

Summary
The solution(s) found are the following

$$y = \sin(x) \tag{1}$$

4.3.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y} \frac{d y}{d x}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}$$

But since $\frac{\partial^{2} \phi}{\partial x \partial y}=\frac{\partial^{2} \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^{2} \phi}{\partial x \partial y}=\frac{\partial^{2} \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \mathrm{d} x+N(x, y) \mathrm{d} y=0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(\frac{1}{y}\right) \mathrm{d} y &= \left(\frac{\cos (x)}{\sin (x)}\right) \mathrm{d} x \\
\left(-\frac{\cos (x)}{\sin (x)}\right) \mathrm{d} x+\left(\frac{1}{y}\right) \mathrm{d} y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= -\frac{\cos (x)}{\sin (x)} \\
N(x, y) &= \frac{1}{y}
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\cos (x)}{\sin (x)}\right) \\
&= 0
\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{\cos(x)}{\sin(x)}\,\mathrm{d}x\end{aligned}$$

$$\phi = -\ln(\sin(x)) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\begin{aligned}\int f'(y)\,\mathrm{d}y &= \int \left(\frac{1}{y}\right)\mathrm{d}y\\ f(y) &= \ln(y) + c_1\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(\sin(x)) + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(\sin(x)) + \ln(y)$$

The solution becomes

$$y = e^{c_1} \sin(x)$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = e^{c_1}$$

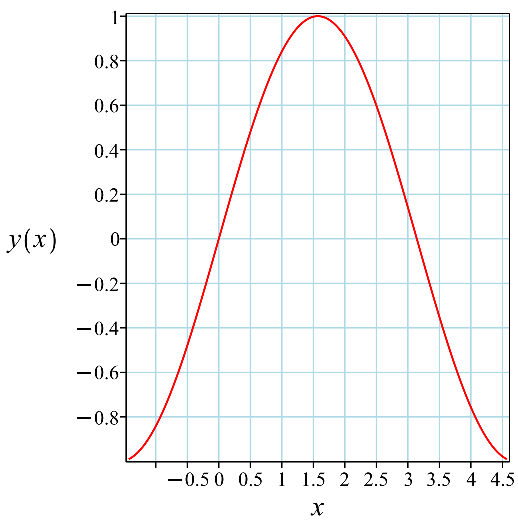
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

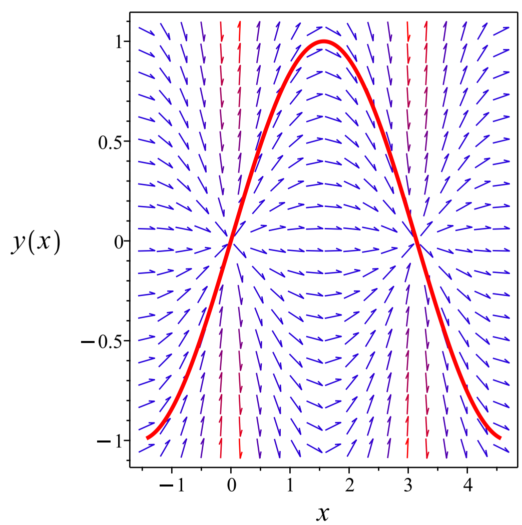
$$y = \sin(x)$$

Summary
The solution(s) found are the following

$$y = \sin(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sin(x)$$

Verified OK.

4.3.7 Maple step by step solution

Let's solve

$\left[y' \sin(x) - y \cos(x) = 0, y\left(\frac{\pi}{2}\right) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{\cos(x)}{\sin(x)}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int \frac{\cos(x)}{\sin(x)} dx + c_1$

- Evaluate integral

  $\ln(y) = \ln(\sin(x)) + c_1$

- Solve for y

  $y = e^{c_1} \sin(x)$

- Use initial condition $y\left(\frac{\pi}{2}\right) = 1$

  $1 = e^{c_1}$

- Solve for c_1

  $c_1 = 0$

- Substitute $c_1 = 0$ into general solution and simplify

  $y = \sin(x)$

- Solution to the IVP

  $y = \sin(x)$

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y^2 - y'x = -1}$$

4.4.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y^2+1}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = y^2 + 1$. Integrating both sides gives

$$\frac{1}{y^2+1}\,dy = \frac{1}{x}\,dx$$

$$\int \frac{1}{y^2+1}\,dy = \int \frac{1}{x}\,dx$$
$$\arctan(y) = \ln(x) + c_1$$

Which results in

$$y = \tan(\ln(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = \tan(\ln(x) + c_1) \tag{1}$$

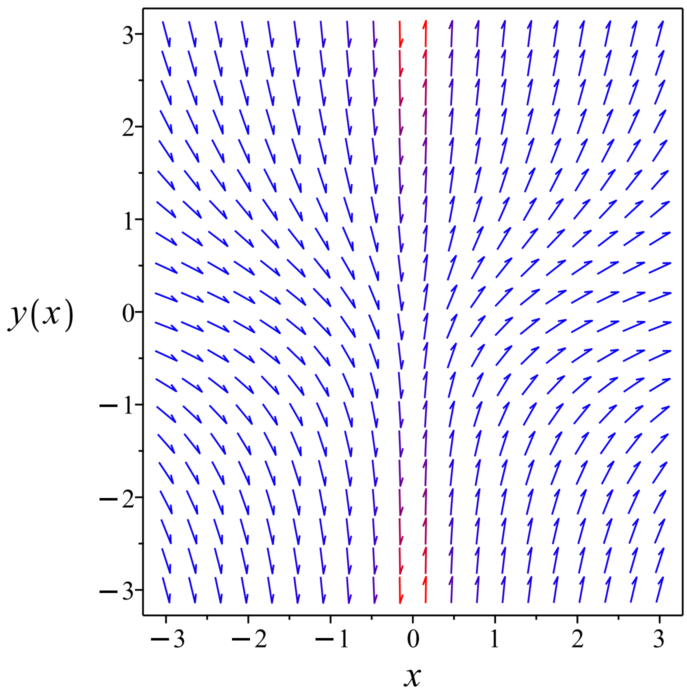

Figure 101: Slope field plot

Verification of solutions

$$y = \tan(\ln(x) + c_1)$$

Verified OK.

4.4.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{y^2+1}{x} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 70: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= x \\
\eta(x, y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{x} dx
\end{aligned}
$$

Which results in

$$
S = \ln(x)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x, y) = \frac{y^2 + 1}{x}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{1}{x} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2 + 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2 + 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \arctan(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(x) = \arctan(y) + c_1$$

Which simplifies to

$$\ln(x) = \arctan(y) + c_1$$

Which gives

$$y = -\tan(-\ln(x) + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y^2+1}{x}$ 	$R = y$ $S = \ln(x)$	$\frac{dS}{dR} = \frac{1}{R^2+1}$ 
Summary

The solution(s) found are the following

$$y = -\tan(-\ln(x) + c_1) \tag{1}$$

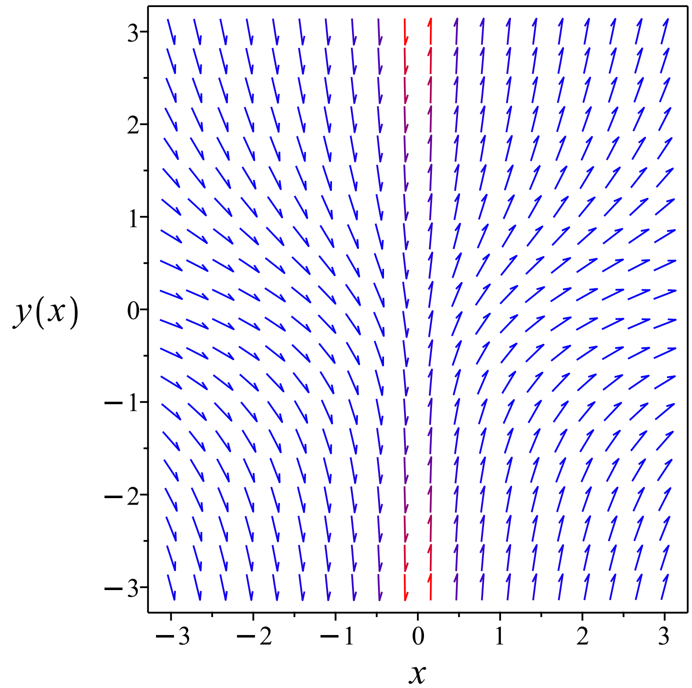

Figure 102: Slope field plot

Verification of solutions

$$y = -\tan(-\ln(x) + c_1)$$

Verified OK.

4.4.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y^2+1}\right)\mathrm{d}y = \left(\frac{1}{x}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x}\right)\mathrm{d}x + \left(\frac{1}{y^2+1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{1}{x}$$
$$N(x, y) = \frac{1}{y^2+1}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y^2+1}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{1}{x} \, \mathrm{d}x \\
\phi &= -\ln(x) + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y^2+1}$. Therefore equation (4) becomes

$$
\frac{1}{y^2+1} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y^2+1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int \left(\frac{1}{y^2+1}\right) \mathrm{d}y \\
f(y) &= \arctan(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) + \arctan(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) + \arctan(y)$$

The solution becomes

$$y = \tan(\ln(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = \tan(\ln(x) + c_1) \tag{1}$$

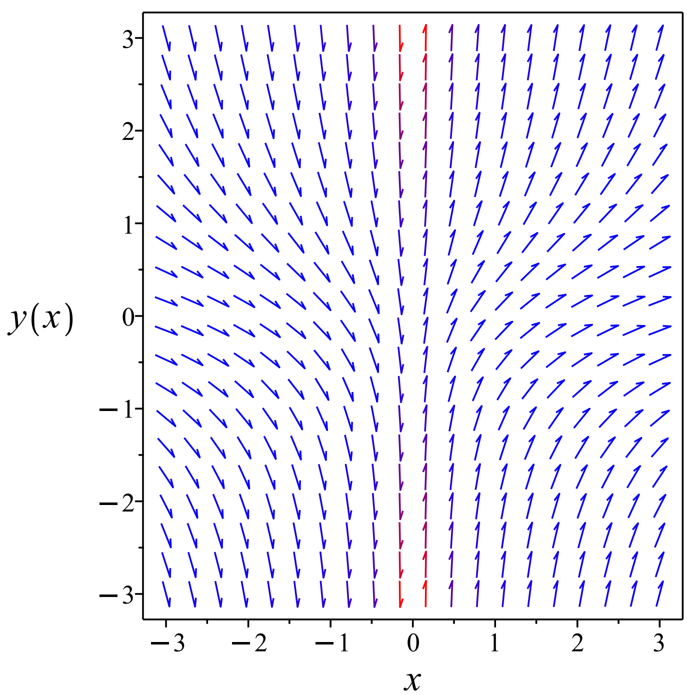

Figure 103: Slope field plot

Verification of solutions

$$y = \tan(\ln(x) + c_1)$$

Verified OK.

4.4.4 Solving as riccati ode

In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x, y) \\
&= \frac{y^2+1}{x}
\end{aligned}
$$

This is a Riccati ODE. Comparing the ODE to solve

$$
y' = \frac{y^2}{x} + \frac{1}{x}
$$

With Riccati ODE standard form

$$
y' = f_0(x) + f_1(x)y + f_2(x)y^2
$$

Shows that $f_0(x) = \frac{1}{x}$, $f_1(x) = 0$ and $f_2(x) = \frac{1}{x}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{u}{x}}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= -\frac{1}{x^2} \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= \frac{1}{x^3}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{u''(x)}{x} + \frac{u'(x)}{x^2} + \frac{u(x)}{x^3} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = \sin(\ln(x))\, c_1 + c_2 \cos(\ln(x))
$$

The above shows that

$$u'(x) = \frac{\cos(\ln(x))\,c_1 - c_2 \sin(\ln(x))}{x}$$

Using the above in (1) gives the solution

$$y = -\frac{\cos(\ln(x))\,c_1 - c_2 \sin(\ln(x))}{\sin(\ln(x))\,c_1 + c_2 \cos(\ln(x))}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-\cos(\ln(x))\,c_3 + \sin(\ln(x))}{c_3 \sin(\ln(x)) + \cos(\ln(x))}$$

Summary

The solution(s) found are the following

$$y = \frac{-\cos(\ln(x))\,c_3 + \sin(\ln(x))}{c_3 \sin(\ln(x)) + \cos(\ln(x))} \tag{1}$$

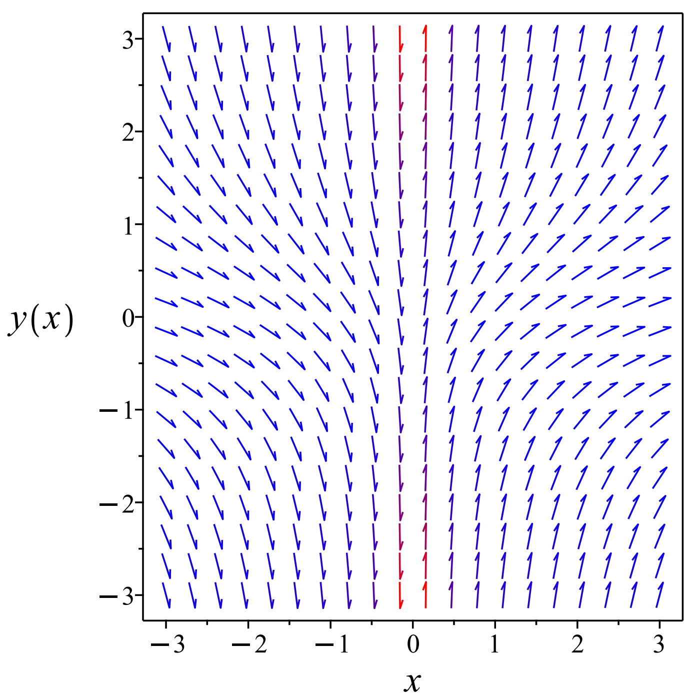

Figure 104: Slope field plot

Verification of solutions

$$y = \frac{-\cos(\ln(x)) c_3 + \sin(\ln(x))}{c_3 \sin(\ln(x)) + \cos(\ln(x))}$$

Verified OK.

4.4.5 Maple step by step solution

Let's solve

$y^2 - y'x = -1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{-y^2-1} = -\frac{1}{x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{-y^2-1} dx = \int -\frac{1}{x} dx + c_1$

- Evaluate integral

  $-\arctan(y) = -\ln(x) + c_1$

- Solve for y

  $y = -\tan(-\ln(x) + c_1)$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{x\sqrt{1+y^2}+yy'\sqrt{x^2+1}=0}$$

4.5.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{x\sqrt{y^2+1}}{y\sqrt{x^2+1}} \end{aligned}$$

Where $f(x)=-\frac{x}{\sqrt{x^2+1}}$ and $g(y)=\frac{\sqrt{y^2+1}}{y}$. Integrating both sides gives

$$\frac{1}{\frac{\sqrt{y^2+1}}{y}}\,dy = -\frac{x}{\sqrt{x^2+1}}\,dx$$

$$\int \frac{1}{\frac{\sqrt{y^2+1}}{y}}\, dy = \int -\frac{x}{\sqrt{x^2+1}}\, dx$$

$$\sqrt{y^2+1} = -\sqrt{x^2+1} + c_1$$

The solution is

$$\sqrt{1+y^2} + \sqrt{x^2+1} - c_1 = 0$$

Summary

The solution(s) found are the following

$$\sqrt{1+y^2} + \sqrt{x^2+1} - c_1 = 0 \tag{1}$$

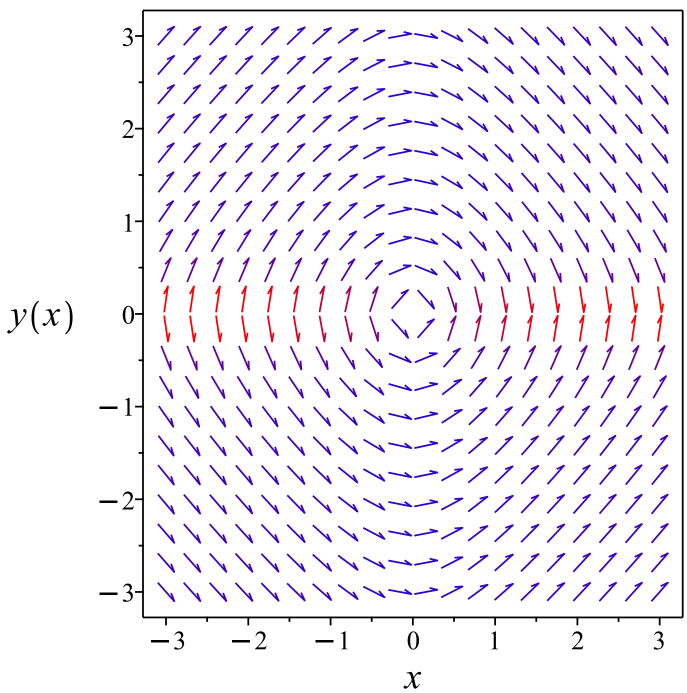

Figure 105: Slope field plot

Verification of solutions

$$\sqrt{1+y^2} + \sqrt{x^2+1} - c_1 = 0$$

Verified OK.

4.5.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{x\sqrt{y^2+1}}{y\sqrt{x^2+1}}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 73: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x, y) &= -\frac{\sqrt{x^2+1}}{x} \\ \eta(x, y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{\sqrt{x^2+1}}{x}} dx\end{aligned}$$

Which results in

$$S = -\sqrt{x^2+1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x\sqrt{y^2+1}}{y\sqrt{x^2+1}}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\frac{x}{\sqrt{x^2+1}} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{y}{\sqrt{y^2+1}} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R}{\sqrt{R^2+1}}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \sqrt{R^2+1} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\sqrt{x^2+1} = \sqrt{1+y^2} + c_1
$$

Which simplifies to

$$
-\sqrt{x^2+1} = \sqrt{1+y^2} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x\sqrt{y^2+1}}{y\sqrt{x^2+1}}$ 	$R = y$ $S = -\sqrt{x^2+1}$	$\frac{dS}{dR} = \frac{R}{\sqrt{R^2+1}}$ 
Summary

The solution(s) found are the following

$$-\sqrt{x^2+1} = \sqrt{1+y^2} + c_1 \tag{1}$$

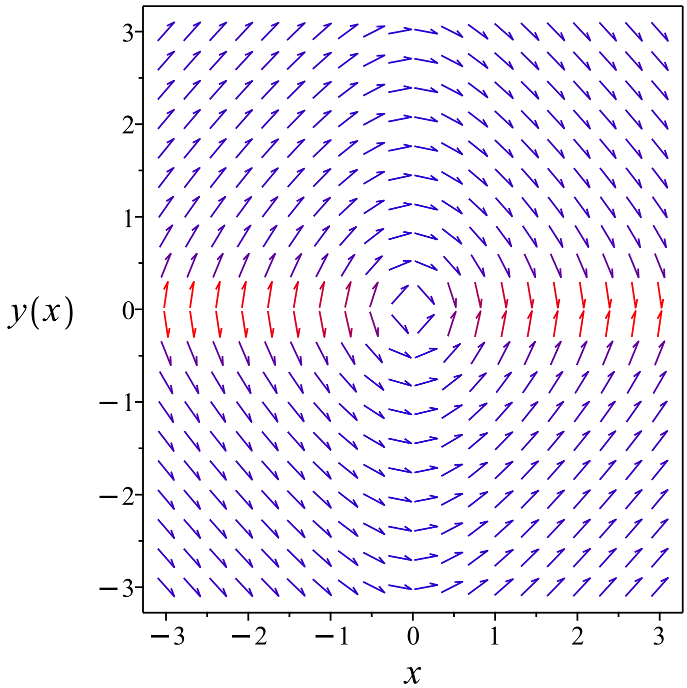

Figure 106: Slope field plot

Verification of solutions

$$-\sqrt{x^2+1} = \sqrt{1+y^2} + c_1$$

Verified OK.

4.5.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{y}{\sqrt{y^2+1}}\right) \mathrm{d}y &= \left(\frac{x}{\sqrt{x^2+1}}\right) \mathrm{d}x \\
\left(-\frac{x}{\sqrt{x^2+1}}\right) \mathrm{d}x + \left(-\frac{y}{\sqrt{y^2+1}}\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{x}{\sqrt{x^2+1}} \\
N(x, y) &= -\frac{y}{\sqrt{y^2+1}}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{\sqrt{x^2+1}}\right) \\
&= 0
\end{aligned}
$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{y}{\sqrt{y^2+1}}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x\\ \int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{x}{\sqrt{x^2+1}} \, \mathrm{d}x\end{aligned}$$

$$\phi = -\sqrt{x^2+1} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y}{\sqrt{y^2+1}}$. Therefore equation (4) becomes

$$-\frac{y}{\sqrt{y^2+1}} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{y}{\sqrt{y^2+1}}$$

Integrating the above w.r.t y gives

$$\begin{aligned}\int f'(y) \, \mathrm{d}y &= \int \left(-\frac{y}{\sqrt{y^2+1}}\right) \mathrm{d}y\\ f(y) &= -\sqrt{y^2+1} + c_1\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sqrt{x^2+1} - \sqrt{y^2+1} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sqrt{x^2+1} - \sqrt{y^2+1}$$

Summary

The solution(s) found are the following

$$-\sqrt{1+y^2} - \sqrt{x^2+1} = c_1 \tag{1}$$

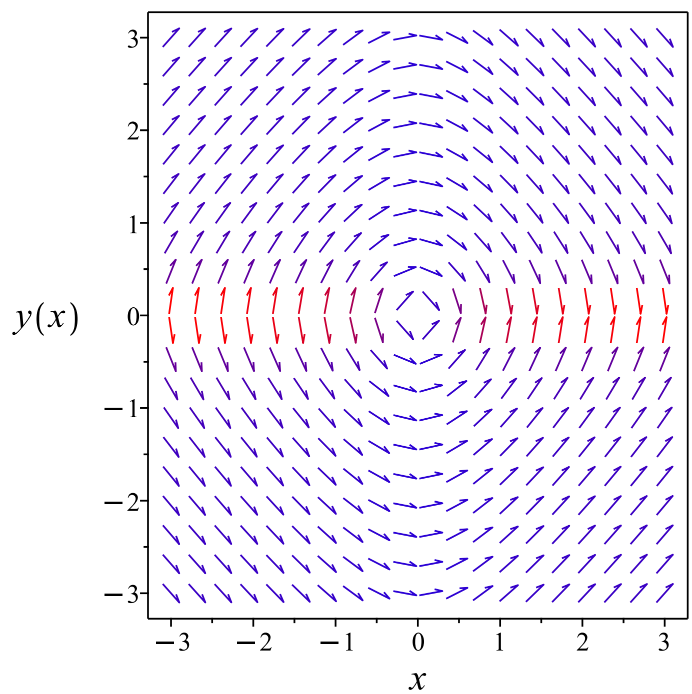

Figure 107: Slope field plot

Verification of solutions

$$-\sqrt{1+y^2} - \sqrt{x^2+1} = c_1$$

Verified OK.

4.5.4 Maple step by step solution

Let's solve

$x\sqrt{1+y^2}+yy'\sqrt{x^2+1}=0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{yy'}{\sqrt{1+y^2}}=-\frac{x}{\sqrt{x^2+1}}$

- Integrate both sides with respect to x

  $\int \frac{yy'}{\sqrt{1+y^2}}dx=\int -\frac{x}{\sqrt{x^2+1}}dx+c_1$

- Evaluate integral

  $\sqrt{1+y^2}=-\sqrt{x^2+1}+c_1$

- Solve for y

  $\left\{y=\sqrt{x^2-2c_1\sqrt{x^2+1}+c_1^2}, y=-\sqrt{x^2-2c_1\sqrt{x^2+1}+c_1^2}\right\}$

Problem number: 51.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{x\sqrt{1-y^2}+y\sqrt{-x^2+1}\,y'=0}$$

With initial conditions

$$[y(0)=1]$$

4.6.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= -\frac{x\sqrt{-y^2+1}}{y\sqrt{-x^2+1}} \end{aligned}$$

The x domain of $f(x,y)$ when $y=1$ is

$$\{-\infty<x<\infty\}$$

And the point $x_0 = 0$ is inside this domain. The y domain of $f(x, y)$ when $x = 0$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x\sqrt{-y^2+1}}{y\sqrt{-x^2+1}}\right)\\ &= \frac{x}{\sqrt{-y^2+1}\,\sqrt{-x^2+1}} + \frac{x\sqrt{-y^2+1}}{y^2\sqrt{-x^2+1}}\end{aligned}$$

$\frac{\partial f}{\partial y}$ is not defined at $y = 1$ therefore existence and uniqueness theorem do not apply. Solution exist but not guaranteed to be unique.

4.6.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x, y)\\ &= f(x)g(y)\\ &= -\frac{x\sqrt{-y^2+1}}{y\sqrt{-x^2+1}}\end{aligned}$$

Where $f(x) = -\frac{x}{\sqrt{-x^2+1}}$ and $g(y) = \frac{\sqrt{-y^2+1}}{y}$. Integrating both sides gives

$$\begin{aligned}\frac{1}{\frac{\sqrt{-y^2+1}}{y}}\,dy &= -\frac{x}{\sqrt{-x^2+1}}\,dx\\ \int\frac{1}{\frac{\sqrt{-y^2+1}}{y}}\,dy &= \int -\frac{x}{\sqrt{-x^2+1}}\,dx\\ -\sqrt{-y^2+1} &= \sqrt{-x^2+1} + c_1\end{aligned}$$

The solution is

$$-\sqrt{1-y^2} - \sqrt{-x^2+1} - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 - c_1 = 0$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$-\sqrt{-y^2+1} - \sqrt{-x^2+1} + 1 = 0$$

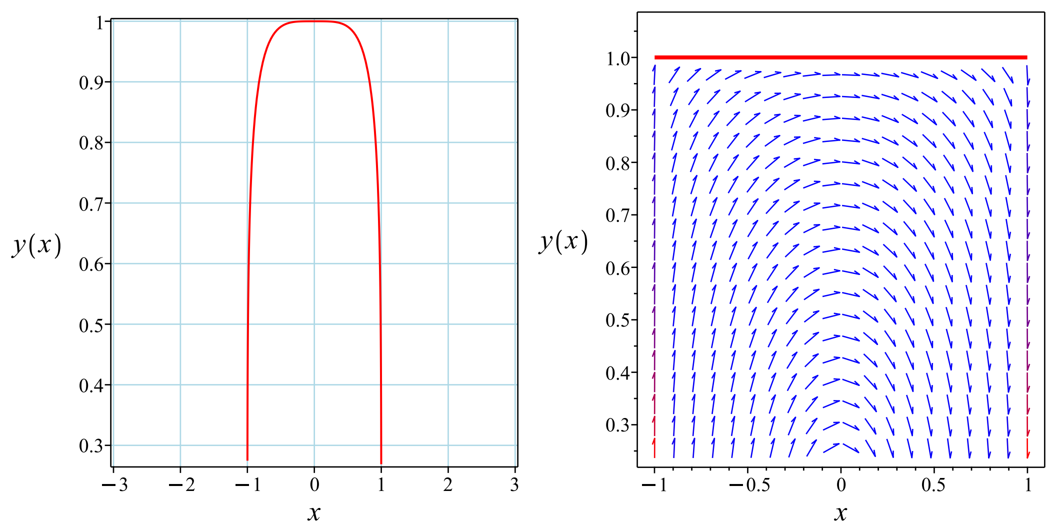
Solving for y from the above gives

$$y = \sqrt{x^2 - 1 + 2\sqrt{-x^2+1}}$$

Summary

The solution(s) found are the following

$$y = \sqrt{x^2 - 1 + 2\sqrt{-x^2+1}} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \sqrt{x^2 - 1 + 2\sqrt{-x^2+1}}$$

Verified OK.

4.6.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{x\sqrt{-y^2+1}}{y\sqrt{-x^2+1}} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 76: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= -\frac{\sqrt{-x^2+1}}{x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{-\frac{\sqrt{-x^2+1}}{x}} dx
\end{aligned}
$$

Which results in

$$
S = -\frac{(x-1)(x+1)}{\sqrt{-x^2+1}}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{x\sqrt{-y^2+1}}{y\sqrt{-x^2+1}}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\frac{x}{\sqrt{-x^2+1}} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{y}{\sqrt{-y^2+1}} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R}{\sqrt{-R^2+1}}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{(R-1)(R+1)}{\sqrt{-R^2+1}} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\sqrt{-x^2+1} = \frac{(y-1)(y+1)}{\sqrt{1-y^2}} + c_1
$$

Which simplifies to

$$
\sqrt{-x^2+1} = \frac{(y-1)(y+1)}{\sqrt{1-y^2}} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x\sqrt{-y^2+1}}{y\sqrt{-x^2+1}}$ 	$R = y$ $S = \sqrt{-x^2+1}$	$\frac{dS}{dR} = \frac{R}{\sqrt{-R^2+1}}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$\sqrt{-x^2+1} = \frac{y^2 + \sqrt{-y^2+1} - 1}{\sqrt{-y^2+1}}$$

The above simplifies to

$$\sqrt{-y^2+1}\,\sqrt{-x^2+1} - y^2 - \sqrt{-y^2+1} + 1 = 0$$

Summary

The solution(s) found are the following

$$\left(\sqrt{-x^2+1} - 1\right)\sqrt{1-y^2} - y^2 + 1 = 0 \tag{1}$$

Verification of solutions

$$\left(\sqrt{-x^2+1} - 1\right)\sqrt{1-y^2} - y^2 + 1 = 0$$

Verified OK.

4.6.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{y}{\sqrt{-y^2+1}}\right)\mathrm{d}y = \left(\frac{x}{\sqrt{-x^2+1}}\right)\mathrm{d}x$$
$$\left(-\frac{x}{\sqrt{-x^2+1}}\right)\mathrm{d}x + \left(-\frac{y}{\sqrt{-y^2+1}}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{x}{\sqrt{-x^2+1}} \\
N(x, y) &= -\frac{y}{\sqrt{-y^2+1}}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{\sqrt{-x^2+1}}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{y}{\sqrt{-y^2+1}}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -\frac{x}{\sqrt{-x^2+1}} \,\mathrm{d}x \\
\phi &= \sqrt{-x^2+1} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y}{\sqrt{-y^2+1}}$. Therefore equation (4) becomes

$$-\frac{y}{\sqrt{-y^2+1}} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{y}{\sqrt{-y^2+1}}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{y}{\sqrt{-y^2+1}}\right) \mathrm{d}y$$

$$f(y) = -\frac{(y-1)(y+1)}{\sqrt{-y^2+1}} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \sqrt{-x^2+1} - \frac{(y-1)(y+1)}{\sqrt{-y^2+1}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \sqrt{-x^2+1} - \frac{(y-1)(y+1)}{\sqrt{-y^2+1}}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$\sqrt{-x^2+1} - \frac{(y-1)(y+1)}{\sqrt{-y^2+1}} = 1$$

The above simplifies to

$$\sqrt{-y^2+1}\,\sqrt{-x^2+1}-y^2-\sqrt{-y^2+1}+1=0$$

Summary

The solution(s) found are the following

$$\left(\sqrt{-x^2+1}-1\right)\sqrt{1-y^2}-y^2+1=0 \tag{1}$$

Verification of solutions

$$\left(\sqrt{-x^2+1}-1\right)\sqrt{1-y^2}-y^2+1=0$$

Verified OK.

4.6.5 Maple step by step solution

Let's solve

$\left[x\sqrt{1-y^2}+y\sqrt{-x^2+1}\,y'=0, y(0)=1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'y}{\sqrt{1-y^2}}=-\frac{x}{\sqrt{-x^2+1}}$

- Integrate both sides with respect to x

  $\int \frac{y'y}{\sqrt{1-y^2}}dx=\int -\frac{x}{\sqrt{-x^2+1}}dx+c_1$

- Evaluate integral

  $-\sqrt{1-y^2}=-\frac{(x-1)(x+1)}{\sqrt{-x^2+1}}+c_1$

- Solve for y

  $\left\{y=\sqrt{-2c_1\sqrt{-x^2+1}-c_1^2+x^2}, y=-\sqrt{-2c_1\sqrt{-x^2+1}-c_1^2+x^2}\right\}$

- Use initial condition $y(0)=1$

  $1=\sqrt{-c_1^2-2c_1}$

- Solve for c_1

  $c_1=-1$

- Substitute $c_1=-1$ into general solution and simplify

$$y = \sqrt{x^2 - 1 + 2\sqrt{-x^2 + 1}}$$

- Use initial condition $y(0) = 1$

$$1 = -\sqrt{-c_1^2 - 2c_1}$$

- Solution does not satisfy initial condition
- Solution to the IVP

$$y = \sqrt{x^2 - 1 + 2\sqrt{-x^2 + 1}}$$

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\ln(y)\, y + y'x = 1}$$

With initial conditions

$$[y(1) = 1]$$

4.8.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{\ln(y)\, y - 1}{x} \end{aligned}$$

The x domain of $f(x, y)$ when $y = 1$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x,y)$ when $x = 1$ is

$$\{0 < y\}$$

And the point $y_0 = 1$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\ln(y)\,y - 1}{x}\right)\\ &= -\frac{1 + \ln(y)}{x}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 1$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\{0 < y\}$$

And the point $y_0 = 1$ is inside this domain. Therefore solution exists and is unique.

4.8.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\ &= f(x)g(y)\\ &= \frac{-\ln(y)\,y + 1}{x}\end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = -\ln(y)\,y + 1$. Integrating both sides gives

$$\begin{aligned}\frac{1}{-\ln(y)\,y + 1}\,dy &= \frac{1}{x}\,dx\\ \int \frac{1}{-\ln(y)\,y + 1}\,dy &= \int \frac{1}{x}\,dx\\ \int^{y} \frac{1}{-\ln(\_a)\,\_a + 1}d\_a &= \ln(x) + c_1\end{aligned}$$

Which results in

$$\int^{y} \frac{1}{-\ln (\_a) \_a+1} d\_a = \ln (x) + c_1$$

The solution is

$$\int^{y} \frac{1}{-\ln (\_a) \_a+1} d\_a - \ln (x) - c_1 = 0$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\int^{1} -\frac{1}{\ln (\_a) \_a-1} d\_a - c_1 = 0$$

$$c_1 = -\left(\int^{1} \frac{1}{\ln (\_a) \_a-1} d\_a\right)$$

Substituting c_1 found above in the general solution gives

$$\int^{y} -\frac{1}{\ln (\_a) \_a-1} d\_a - \ln (x) + \int^{1} \frac{1}{\ln (\_a) \_a-1} d\_a = 0$$

Solving for y from the above gives

$$y = \operatorname{RootOf}\left(\int^{\_Z} \frac{1}{\ln (\_a) \_a-1} d\_a + \ln (x) - \left(\int^{1} \frac{1}{\ln (\_a) \_a-1} d\_a\right)\right)$$

Summary

The solution(s) found are the following

$$y = \operatorname{RootOf}\left(\int^{\_Z} \frac{1}{\ln (\_a) \_a-1} d\_a + \ln (x) - \left(\int^{1} \frac{1}{\ln (\_a) \_a-1} d\_a\right)\right) \tag{1}$$

Verification of solutions

$$y = \operatorname{RootOf}\left(\int^{\_Z} \frac{1}{\ln (\_a) \_a-1} d\_a + \ln (x) - \left(\int^{1} \frac{1}{\ln (\_a) \_a-1} d\_a\right)\right)$$

Verified OK.

4.8.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{\ln(y)\, y - 1}{x} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 80: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int b f(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= x \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x} dx \end{aligned}$$

Which results in

$$S = \ln(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{\ln(y)\, y - 1}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{\ln(y)\, y - 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{\ln(R)\, R - 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int -\frac{1}{\ln(R)\, R - 1} dR + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(x) = \int^{y} -\frac{1}{\ln(\_a)\_a - 1} d\_a + c_1$$

Which simplifies to

$$\ln(x) = \int^{y} -\frac{1}{\ln(\_a)\_a - 1} d\_a + c_1$$

This results in

$$\ln(x) = \int^{y} -\frac{1}{\ln(\_a)\_a - 1} d\_a + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \int^{1} -\frac{1}{\ln(\_a)\_a - 1} d\_a + c_1$$

$$c_1 = \int^{1} \frac{1}{\ln(\_a)\_a - 1} d\_a$$

Substituting c_1 found above in the general solution gives

$$\ln(x) = \int^{y} -\frac{1}{\ln(\_a)\_a - 1} d\_a + \int^{1} \frac{1}{\ln(\_a)\_a - 1} d\_a$$

Solving for y from the above gives

$$y = \text{RootOf}\left(\ln(x) + \int^{\_Z} \frac{1}{\ln(\_a)\_a - 1} d\_a - \left(\int^{1} \frac{1}{\ln(\_a)\_a - 1} d\_a\right)\right)$$

Summary

The solution(s) found are the following

$$y = \text{RootOf}\left(\ln(x) + \int^{\_Z} \frac{1}{\ln(\_a)\_a - 1} d\_a - \left(\int^{1} \frac{1}{\ln(\_a)\_a - 1} d\_a\right)\right) \tag{1}$$

Verification of solutions

$$y = \text{RootOf}\left(\ln(x) + \int^{\_Z} \frac{1}{\ln(\_a)\_a - 1} d\_a - \left(\int^{1} \frac{1}{\ln(\_a)\_a - 1} d\_a\right)\right)$$

Verified OK.

4.8.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{-\ln(y)\,y+1}\right)\mathrm{d}y = \left(\frac{1}{x}\right)\mathrm{d}x$$

$$\left(-\frac{1}{x}\right)\mathrm{d}x + \left(\frac{1}{-\ln(y)\,y+1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= -\frac{1}{x} \\ N(x,y) &= \frac{1}{-\ln(y)\,y+1} \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right) \\ &= 0 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{-\ln(y)\,y+1}\right) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\frac{1}{x} \mathrm{d}x$$
$$\phi = -\ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{-\ln(y)y+1}$. Therefore equation (4) becomes

$$\frac{1}{-\ln(y)\, y + 1} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{\ln(y)\, y - 1}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(-\frac{1}{\ln(y)\, y - 1}\right) \mathrm{d}y$$
$$f(y) = \int_0^y -\frac{1}{\ln(\_a)\_a - 1} d\_a + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) + \int_0^y -\frac{1}{\ln(\_a)\_a - 1} d\_a + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) + \int_0^y -\frac{1}{\ln(\_a)\_a - 1} d\_a$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\int_0^1 -\frac{1}{\ln(\_a)\_a - 1} d\_a = c_1$$

$$c_1 = -\left(\int_0^1 \frac{1}{\ln(\_a)\_a - 1} d\_a\right)$$

Substituting c_1 found above in the general solution gives

$$-\ln(x) + \int_0^y -\frac{1}{\ln(\_a)\_a - 1} d\_a = -\left(\int_0^1 \frac{1}{\ln(\_a)\_a - 1} d\_a\right)$$

Summary

The solution(s) found are the following

$$-\ln(x) - \left(\int_0^y \frac{1}{\ln(\_a)\_a - 1} d\_a\right) = -\left(\int_0^1 \frac{1}{\ln(\_a)\_a - 1} d\_a\right) \tag{1}$$

Verification of solutions

$$-\ln(x) - \left(\int_0^y \frac{1}{\ln(\_a)\_a - 1} d\_a\right) = -\left(\int_0^1 \frac{1}{\ln(\_a)\_a - 1} d\_a\right)$$

Verified OK.

Section: Section 4. Equations with variables separable and equations reducible to them. Exercises page 38
Problem number: 54.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y' - a^{y+x} = 0}$$

4.9.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= a^y a^x \end{aligned}$$

Where $f(x) = a^x$ and $g(y) = a^y$. Integrating both sides gives

$$\begin{aligned} \frac{1}{a^y}\,dy &= a^x\,dx \\ \int \frac{1}{a^y}\,dy &= \int a^x\,dx \\ -\frac{a^{-y}}{\ln(a)} &= \frac{a^x}{\ln(a)} + c_1 \end{aligned}$$

The solution is

$$-\frac{a^{-y}}{\ln(a)}-\frac{a^{x}}{\ln(a)}-c_1=0$$

Summary

The solution(s) found are the following

$$-\frac{a^{-y}}{\ln(a)}-\frac{a^{x}}{\ln(a)}-c_1=0 \tag{1}$$

Verification of solutions

$$-\frac{a^{-y}}{\ln(a)}-\frac{a^{x}}{\ln(a)}-c_1=0$$

Verified OK.

4.9.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y'=a^{y+x}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 82: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= a^{-x} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{a^{-x}} dx \end{aligned}$$

Which results in

$$S = \frac{a^x}{\ln(a)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = a^{y+x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= a^x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = a^{-y} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = a^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{a^{-R}}{\ln(a)} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{a^x}{\ln(a)} = -\frac{a^{-y}}{\ln(a)} + c_1$$

Which simplifies to

$$\frac{a^x + a^{-y} - c_1 \ln(a)}{\ln(a)} = 0$$

Which gives

$$y = -\frac{\ln\left(-e^{\ln(a)x} + c_1 \ln(a)\right)}{\ln(a)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln\left(-e^{\ln(a)x} + c_1 \ln(a)\right)}{\ln(a)} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln\left(-e^{\ln(a)x} + c_1 \ln(a)\right)}{\ln(a)}$$

Verified OK.

4.9.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(a^{-y})\,\mathrm{d}y&=(a^{x})\,\mathrm{d}x\\ (-a^{x})\,\mathrm{d}x+(a^{-y})\,\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-a^{x}\\ N(x,y)&=a^{-y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(-a^{x})\\ &=0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(a^{-y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -a^{x} \mathrm{d}x$$

$$\phi = -\frac{a^{x}}{\ln(a)} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = a^{-y}$. Therefore equation (4) becomes

$$a^{-y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = a^{-y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(a^{-y}\right) \mathrm{d}y$$

$$f(y) = -\frac{a^{-y}}{\ln(a)} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{a^x}{\ln(a)} - \frac{a^{-y}}{\ln(a)} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{a^x}{\ln(a)} - \frac{a^{-y}}{\ln(a)}$$

The solution becomes

$$y = -\frac{\ln\left(-c_1 \ln(a) - e^{\ln(a)x}\right)}{\ln(a)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\ln\left(-c_1 \ln(a) - e^{\ln(a)x}\right)}{\ln(a)} \tag{1}$$

Verification of solutions

$$y = -\frac{\ln\left(-c_1 \ln(a) - e^{\ln(a)x}\right)}{\ln(a)}$$

Verified OK.

Problem number: 55.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{e^{y}\left(x^{2}+1\right) y'-2x(e^{y}+1)=0}$$

4.10.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y)\\ &= f(x)g(y)\\ &= \frac{2x(e^{-y}+1)}{x^{2}+1} \end{aligned}$$

Where $f(x)=\frac{2x}{x^{2}+1}$ and $g(y)=e^{-y}+1$. Integrating both sides gives

$$\frac{1}{e^{-y}+1}\,dy = \frac{2x}{x^{2}+1}\,dx$$

$$\int \frac{1}{e^{-y}+1}\,dy = \int \frac{2x}{x^{2}+1}\,dx$$

$$\ln\left(\mathrm{e}^{-y}+1\right)-\ln\left(\mathrm{e}^{-y}\right)=\ln\left(x^2+1\right)+c_1$$

Raising both side to exponential gives

$$\mathrm{e}^{\ln\left(\mathrm{e}^{-y}+1\right)-\ln\left(\mathrm{e}^{-y}\right)}=\mathrm{e}^{\ln\left(x^2+1\right)+c_1}$$

Which simplifies to

$$1+\mathrm{e}^{y}=c_2\left(x^2+1\right)$$

Summary

The solution(s) found are the following

$$y=\ln\left(c_2x^2+c_2-1\right) \tag{1}$$

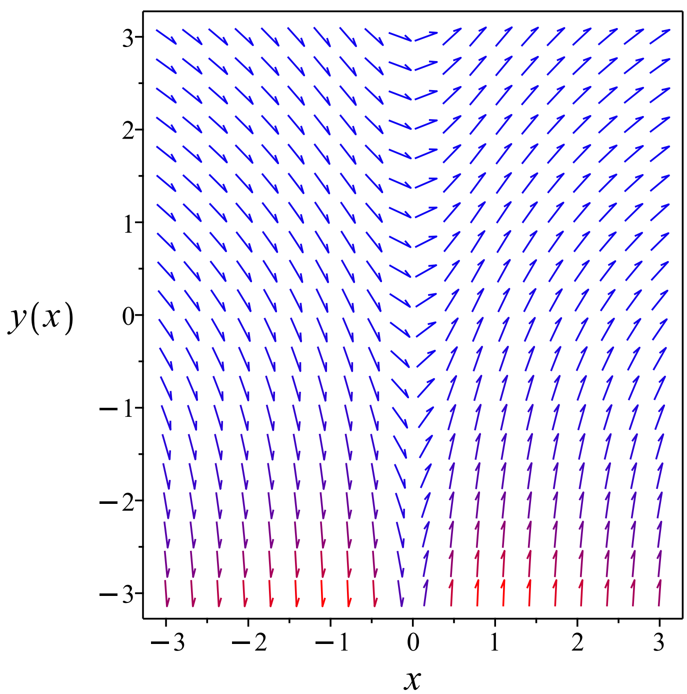

Figure 110: Slope field plot

Verification of solutions

$$y=\ln\left(c_2x^2+c_2-1\right)$$

Verified OK.

4.10.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{2x(1+e^{y})\,e^{-y}}{x^2+1} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 84: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{x^2+1}{2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{x^2+1}{2x}} dx
\end{aligned}
$$

Which results in

$$
S = \ln\left(x^2+1\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{2x(1+e^{y})\,e^{-y}}{x^2+1}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{2x}{x^2+1} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{e^y}{1+e^y} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{e^R}{1+e^R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \ln\left(1+e^R\right) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\ln\left(x^2+1\right) = \ln\left(e^y+1\right) + c_1
$$

Which simplifies to

$$
\ln\left(x^2+1\right) = \ln\left(e^y+1\right) + c_1
$$

Which gives

$$
y = \ln\left(1+x^2-e^{c_1}\right) - c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>

Summary

The solution(s) found are the following

$$y = \ln(1 + x^2 - e^{c_1}) - c_1 \quad (1)$$

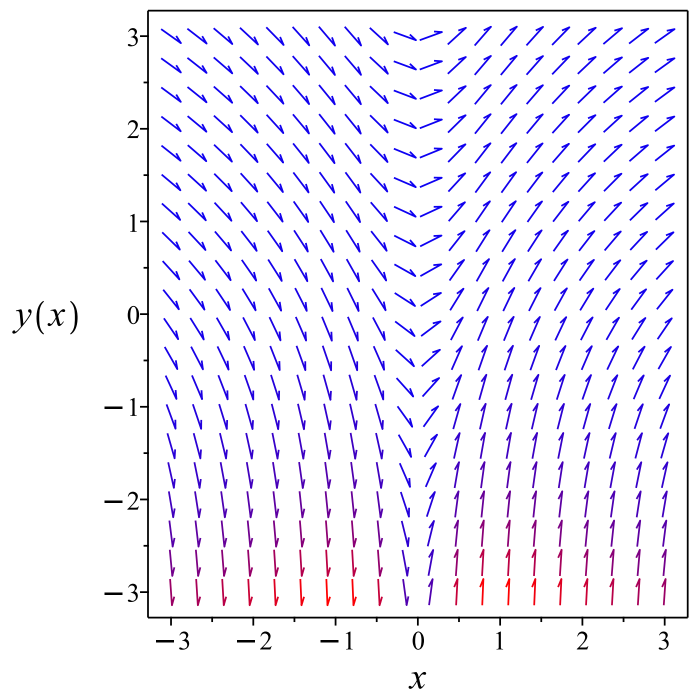

Figure 111: Slope field plot

Verification of solutions

$$y = \ln\left(1 + x^2 - e^{c_1}\right) - c_1$$

Verified OK.

4.10.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}\right) \mathrm{d}y &= \left(\frac{x}{x^{2}+1}\right) \mathrm{d}x \\
\left(-\frac{x}{x^{2}+1}\right) \mathrm{d}x + \left(\frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{x}{x^{2}+1} \\
N(x, y) &= \frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{x^{2}+1}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{x}{x^{2}+1}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{\ln\left(x^{2}+1\right)}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=\frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}$. Therefore equation (4) becomes

$$
\frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\,\mathrm{d}y &= \int \left(\frac{\mathrm{e}^{y}}{2+2\,\mathrm{e}^{y}}\right)\mathrm{d}y\\
f(y) &= \frac{\ln\left(1+\mathrm{e}^{y}\right)}{2} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x^2+1)}{2} + \frac{\ln(1+e^y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x^2+1)}{2} + \frac{\ln(1+e^y)}{2}$$

The solution becomes

$$y = \ln\left(x^2 e^{2c_1} + e^{2c_1} - 1\right)$$

Summary

The solution(s) found are the following

$$y = \ln\left(x^2 e^{2c_1} + e^{2c_1} - 1\right) \tag{1}$$

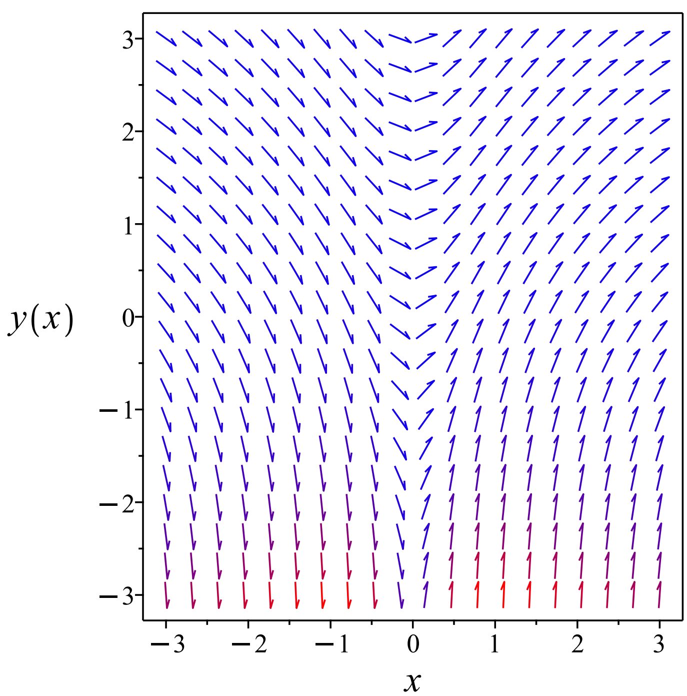

Figure 112: Slope field plot

Verification of solutions

$$y = \ln\left(x^2 e^{2c_1} + e^{2c_1} - 1\right)$$

4.10.4 Maple step by step solution

Let's solve

$e^y (x^2+1)\, y' - 2x(e^y+1) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y' e^y}{e^y+1} = \frac{2x}{x^2+1}$

- Integrate both sides with respect to x

  $\int \frac{y' e^y}{e^y+1} dx = \int \frac{2x}{x^2+1} dx + c_1$

- Evaluate integral

  $\ln(e^y+1) = \ln(x^2+1) + c_1$

- Solve for y

  $y = \ln(x^2 e^{c_1} + e^{c_1} - 1)$

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{2x\sqrt{1-y^2}-\left(x^2+1\right)y'=0}$$

4.11.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y)\\ &= f(x)g(y)\\ &= \frac{2x\sqrt{-y^2+1}}{x^2+1} \end{aligned}$$

Where $f(x)=\frac{2x}{x^2+1}$ and $g(y)=\sqrt{-y^2+1}$. Integrating both sides gives

$$\frac{1}{\sqrt{-y^2+1}}\,dy=\frac{2x}{x^2+1}\,dx$$

$$\int \frac{1}{\sqrt{-y^2+1}}\, dy = \int \frac{2x}{x^2+1}\, dx$$

$$\arcsin(y) = \ln(x^2+1) + c_1$$

Which results in

$$y = \sin(\ln(x^2+1) + c_1)$$

Summary

The solution(s) found are the following

$$y = \sin(\ln(x^2+1) + c_1) \tag{1}$$

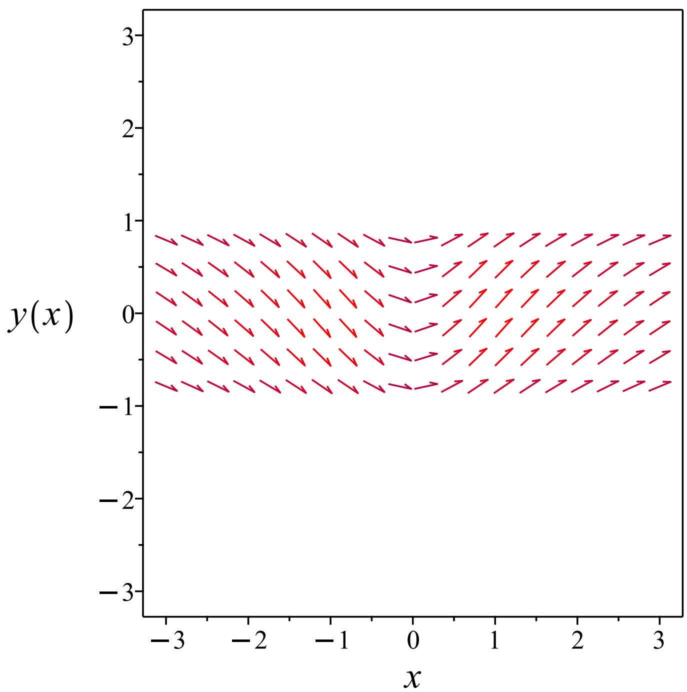

Figure 113: Slope field plot

Verification of solutions

$$y = \sin(\ln(x^2+1) + c_1)$$

Verified OK.

4.11.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{2x\sqrt{-y^2+1}}{x^2+1} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 87: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{x^2+1}{2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{x^2+1}{2x}} dx
\end{aligned}
$$

Which results in

$$
S = \ln\left(x^2+1\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{2x\sqrt{-y^2+1}}{x^2+1}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{2x}{x^2+1} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{\sqrt{-y^2+1}} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{\sqrt{-R^2+1}}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \arcsin(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\ln\left(x^2+1\right) = \arcsin(y) + c_1
$$

Which simplifies to

$$
\ln\left(x^2+1\right) = \arcsin(y) + c_1
$$

Which gives

$$
y = -\sin\left(-\ln\left(x^2+1\right) + c_1\right)
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>

4.11.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{2\sqrt{-y^2+1}}\right) \mathrm{d}y = \left(\frac{x}{x^2+1}\right) \mathrm{d}x$$
$$\left(-\frac{x}{x^2+1}\right) \mathrm{d}x + \left(\frac{1}{2\sqrt{-y^2+1}}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{x}{x^2+1}$$
$$N(x, y) = \frac{1}{2\sqrt{-y^2+1}}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x}{x^2+1}\right) \\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2\sqrt{-y^2+1}}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{x}{x^2+1}\, \mathrm{d}x\\ \phi &= -\frac{\ln(x^2+1)}{2} + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2\sqrt{-y^2+1}}$. Therefore equation (4) becomes

$$\frac{1}{2\sqrt{-y^2+1}} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{2\sqrt{-y^2+1}}$$

Integrating the above w.r.t y gives

$$
\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{2\sqrt{-y^2+1}}\right)\mathrm{d}y
$$

$$
f(y) = \frac{\arcsin(y)}{2} + c_1
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$
\phi = -\frac{\ln(x^2+1)}{2} + \frac{\arcsin(y)}{2} + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = -\frac{\ln(x^2+1)}{2} + \frac{\arcsin(y)}{2}
$$

The solution becomes

$$
y = \sin\left(2c_1 + \ln\left(x^2+1\right)\right)
$$

Summary

The solution(s) found are the following

$$
y = \sin\left(2c_1 + \ln\left(x^2+1\right)\right) \tag{1}
$$

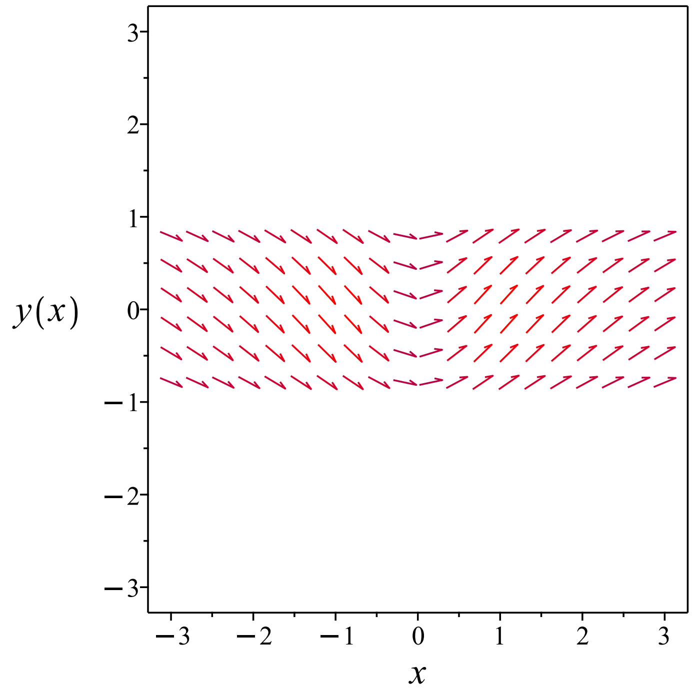

Figure 115: Slope field plot

Verification of solutions

$$y = \sin\left(2c_1 + \ln\left(x^2 + 1\right)\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{e^{x} \sin(y)^{3}+\left(e^{2 x}+1\right) \cos(y) y'=0}$$

4.12.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y)\\ &= f(x)g(y)\\ &= -\frac{e^{x} \sin(y)^{2} \tan(y)}{e^{2 x}+1} \end{aligned}$$

Where $f(x)=-\frac{e^{x}}{e^{2x}+1}$ and $g(y)=\sin(y)^{2}\tan(y)$. Integrating both sides gives

$$\frac{1}{\sin(y)^{2} \tan(y)}\, dy = -\frac{e^{x}}{e^{2 x}+1}\, dx$$

$$\int \frac{1}{\sin(y)^2 \tan(y)}\, dy = \int -\frac{e^x}{e^{2x}+1}\, dx$$
$$-\frac{1}{2\tan(y)^2} = -\arctan(e^x) + c_1$$

Which results in

$$y = \arctan\left(\frac{\sqrt{2}\,\sqrt{\frac{1}{-c_1+\arctan(e^x)}}}{2}\right)$$
$$y = -\arctan\left(\frac{\sqrt{2}\,\sqrt{\frac{1}{-c_1+\arctan(e^x)}}}{2}\right)$$

Summary

The solution(s) found are the following

$$y = \arctan\left(\frac{\sqrt{2}\,\sqrt{\frac{1}{-c_1+\arctan(e^x)}}}{2}\right) \tag{1}$$
$$y = -\arctan\left(\frac{\sqrt{2}\,\sqrt{\frac{1}{-c_1+\arctan(e^x)}}}{2}\right) \tag{2}$$

4.12.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{e^x \sin(y)^3}{(e^{2x}+1)\cos(y)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 90: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= -\left(e^{2x} + 1\right) e^{-x} \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\left(e^{2x}+1\right) e^{-x}} dx \end{aligned}$$

Which results in

$$S = -\arctan\left(e^{x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{e^{x} \sin(y)^{3}}{\left(e^{2x}+1\right) \cos(y)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -\frac{e^{x}}{e^{2x}+1} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cot(y) \csc(y)^{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cot(R)\csc(R)^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\cot(R)^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\arctan(e^x) = -\frac{\cot(y)^2}{2} + c_1$$

Which simplifies to

$$-\arctan(e^x) = -\frac{\cot(y)^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{e^x \sin(y)^3}{(e^{2x}+1)\cos(y)}$ 	$R = y$ $S = -\arctan(e^x)$	$\frac{dS}{dR} = \cot(R)\csc(R)^2$ 
Summary

The solution(s) found are the following

$$-\arctan\left(\mathrm{e}^{x}\right) = -\frac{\cot\left(y\right)^{2}}{2}+c_{1} \tag{1}$$

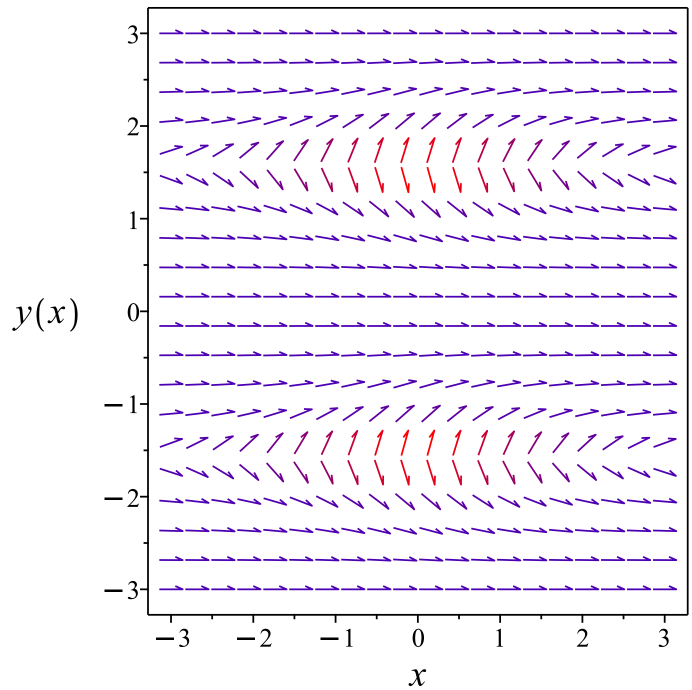

Figure 117: Slope field plot

Verification of solutions

$$-\arctan\left(\mathrm{e}^{x}\right) = -\frac{\cot\left(y\right)^{2}}{2}+c_{1}$$

Verified OK.

4.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{\cos(y)}{\sin(y)^3}\right)\mathrm{d}y&=\left(\frac{\mathrm{e}^x}{\mathrm{e}^{2x}+1}\right)\mathrm{d}x\\ \left(-\frac{\mathrm{e}^x}{\mathrm{e}^{2x}+1}\right)\mathrm{d}x+\left(-\frac{\cos(y)}{\sin(y)^3}\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-\frac{\mathrm{e}^x}{\mathrm{e}^{2x}+1}\\ N(x,y)&=-\frac{\cos(y)}{\sin(y)^3}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-\frac{\mathrm{e}^x}{\mathrm{e}^{2x}+1}\right)\\ &=0\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{\cos(y)}{\sin(y)^3}\right)\\
&= 0
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{\mathrm{e}^x}{\mathrm{e}^{2x}+1}\, \mathrm{d}x
\end{aligned}$$

$$\phi = -\arctan(\mathrm{e}^x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{\cos(y)}{\sin(y)^3}$. Therefore equation (4) becomes

$$-\frac{\cos(y)}{\sin(y)^3} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{\cos(y)}{\sin(y)^3}$$

Integrating the above w.r.t y gives

$$\begin{aligned}
\int f'(y)\, \mathrm{d}y &= \int \left(-\cot(y)\csc(y)^2\right) \mathrm{d}y\\
f(y) &= \frac{\cot(y)^2}{2} + c_1
\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\arctan\left(e^{x}\right)+\frac{\cot\left(y\right)^{2}}{2}+c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\arctan\left(e^{x}\right)+\frac{\cot\left(y\right)^{2}}{2}$$

Summary

The solution(s) found are the following

$$-\arctan\left(e^{x}\right)+\frac{\cot\left(y\right)^{2}}{2} = c_1 \tag{1}$$

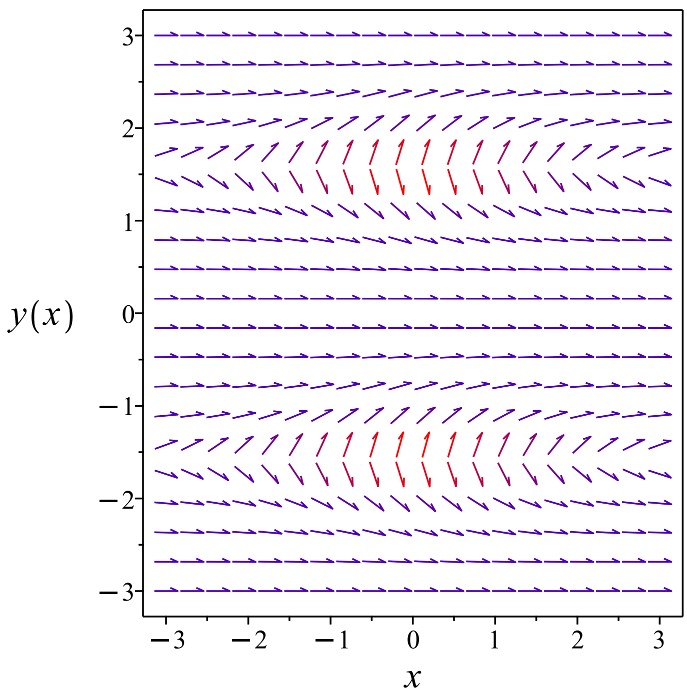

Figure 118: Slope field plot

Verification of solutions

$$-\arctan\left(e^{x}\right)+\frac{\cot\left(y\right)^{2}}{2} = c_1$$

Verified OK.

4.12.4 Maple step by step solution

Let's solve

$e^{x} \sin \left(y\right)^{3}+\left(e^{2 x}+1\right) \cos \left(y\right) y^{\prime}=0$

- Highest derivative means the order of the ODE is 1

  $y^{\prime}$

- Separate variables

  $\frac{y^{\prime} \cos\left(y\right)}{\sin\left(y\right)^{3}}=-\frac{e^{x}}{e^{2 x}+1}$

- Integrate both sides with respect to x

  $\int \frac{y^{\prime} \cos\left(y\right)}{\sin\left(y\right)^{3}}d x =\int -\frac{e^{x}}{e^{2 x}+1}d x +c_{1}$

- Evaluate integral

  $-\frac{1}{2 \sin\left(y\right)^{2}}=-\arctan \left(e^{x}\right)+c_{1}$

- Solve for y

  $\left\{y=-\arcsin \left(\frac{\sqrt{2}\, \sqrt{\frac{1}{-c_{1}+\arctan\left(e^{x}\right)}}}{2}\right), y=\arcsin \left(\frac{\sqrt{2}\, \sqrt{\frac{1}{-c_{1}+\arctan\left(e^{x}\right)}}}{2}\right)\right\}$

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\sin(x)\, y^2 + \cos(x)^2 \ln(y)\, y' = 0}$$

4.13.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{\sin(x)\, y^2}{\cos(x)^2 \ln(y)} \end{aligned}$$

Where $f(x) = -\frac{\sin(x)}{\cos(x)^2}$ and $g(y) = \frac{y^2}{\ln(y)}$. Integrating both sides gives

$$\frac{1}{\frac{y^2}{\ln(y)}}\, dy = -\frac{\sin(x)}{\cos(x)^2}\, dx$$

$$\int \frac{1}{\frac{y^2}{\ln(y)}}dy = \int -\frac{\sin(x)}{\cos(x)^2}dx$$

$$-\frac{\ln(y)}{y} - \frac{1}{y} = -\frac{1}{\cos(x)} + c_1$$

Which results in

$$y = e^{-\operatorname{LambertW}\left(\frac{(c_1\cos(x)-1)e^{-1}}{\cos(x)}\right)-1}$$

Summary

The solution(s) found are the following

$$y = e^{-\operatorname{LambertW}\left(\frac{(c_1\cos(x)-1)e^{-1}}{\cos(x)}\right)-1} \tag{1}$$

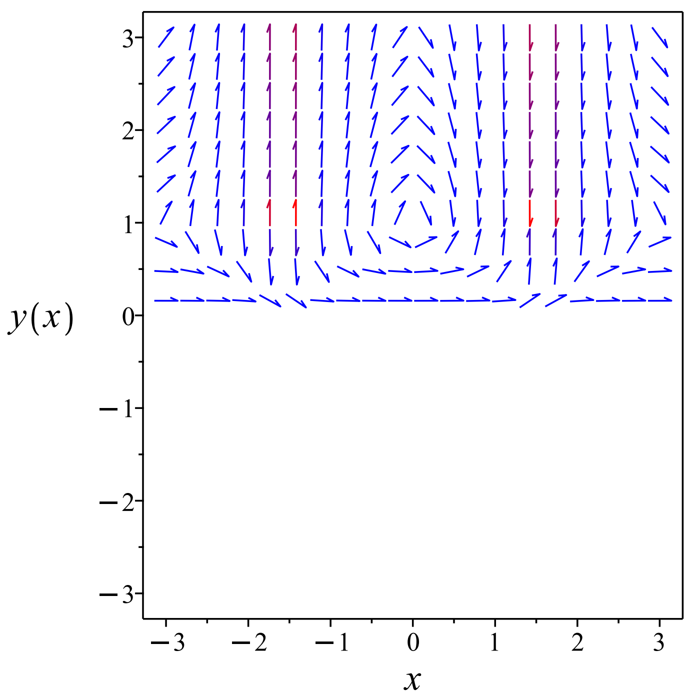

Figure 119: Slope field plot

Verification of solutions

$$y = e^{-\operatorname{LambertW}\left(\frac{(c_1\cos(x)-1)e^{-1}}{\cos(x)}\right)-1}$$

Verified OK.

4.13.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{\sin(x)\, y^2}{\cos(x)^2 \ln(y)} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 93: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= -\frac{\cos(x)^2}{\sin(x)} \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{-\frac{\cos(x)^2}{\sin(x)}} dx
\end{aligned}
$$

Which results in

$$
S = -\frac{1}{\cos(x)}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x, y) = -\frac{\sin(x)\, y^2}{\cos(x)^2 \ln(y)}
$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 0\\R_y &= 1\\S_x &= -\sec(x)\tan(x)\\S_y &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\ln(y)}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{\ln(R)}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{R} - \frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\sec(x) = -\frac{\ln(y)}{y} - \frac{1}{y} + c_1$$

Which simplifies to

$$-\sec(x) = -\frac{\ln(y)}{y} - \frac{1}{y} + c_1$$

Which gives

$$y = e^{-\operatorname{LambertW}\left(-\frac{(c_1\cos(x)+1)e^{-1}}{\cos(x)}\right)-1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{\sin(x) y^2}{\cos(x)^2 \ln(y)}$ 	$R = y$ $S = -\sec(x)$	$\frac{dS}{dR} = \frac{\ln(R)}{R^2}$ 
Summary

The solution(s) found are the following

$$y = e^{-\operatorname{LambertW}\left(-\frac{(c_1 \cos(x)+1)e^{-1}}{\cos(x)}\right)-1} \tag{1}$$

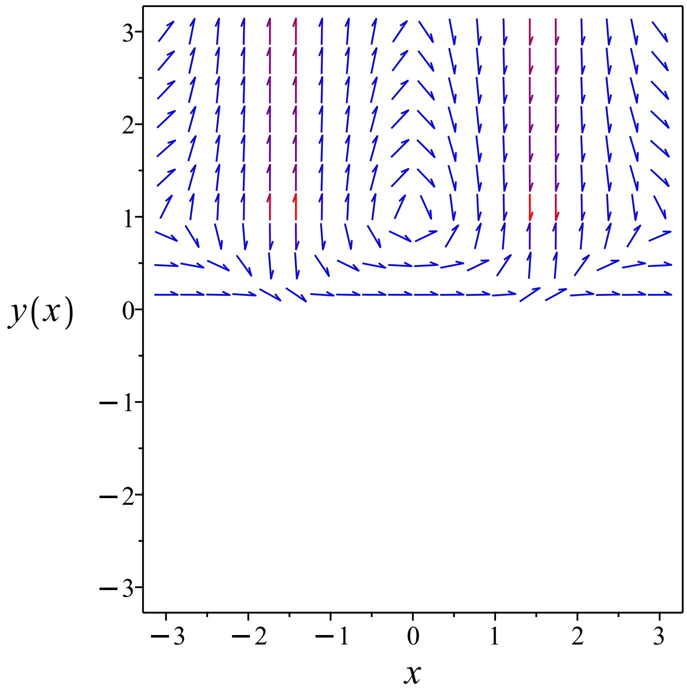

Figure 120: Slope field plot

<u>Verification of solutions</u>

$$y = e^{-\operatorname{LambertW}\left(-\frac{(c_1 \cos(x)+1)e^{-1}}{\cos(x)}\right)-1}$$

Verified OK.

4.13.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{\ln(y)}{y^2}\right) \mathrm{d}y &= \left(\frac{\sin(x)}{\cos(x)^2}\right) \mathrm{d}x \\
\left(-\frac{\sin(x)}{\cos(x)^2}\right) \mathrm{d}x + \left(-\frac{\ln(y)}{y^2}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{\sin(x)}{\cos(x)^2} \\
N(x, y) &= -\frac{\ln(y)}{y^2}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\sin(x)}{\cos(x)^2}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{\ln(y)}{y^2}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{\sin(x)}{\cos(x)^2} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = -\sec(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{\ln(y)}{y^2}$. Therefore equation (4) becomes

$$
-\frac{\ln(y)}{y^2} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{\ln(y)}{y^2}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int \left(-\frac{\ln(y)}{y^2}\right) \mathrm{d}y \\
f(y) &= \frac{\ln(y)}{y} + \frac{1}{y} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sec(x) + \frac{\ln(y)}{y} + \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sec(x) + \frac{\ln(y)}{y} + \frac{1}{y}$$

The solution becomes

$$y = e^{-\operatorname{LambertW}\left(-\frac{(c_1\cos(x)+1)e^{-1}}{\cos(x)}\right)-1}$$

Summary

The solution(s) found are the following

$$y = e^{-\operatorname{LambertW}\left(-\frac{(c_1\cos(x)+1)e^{-1}}{\cos(x)}\right)-1} \tag{1}$$

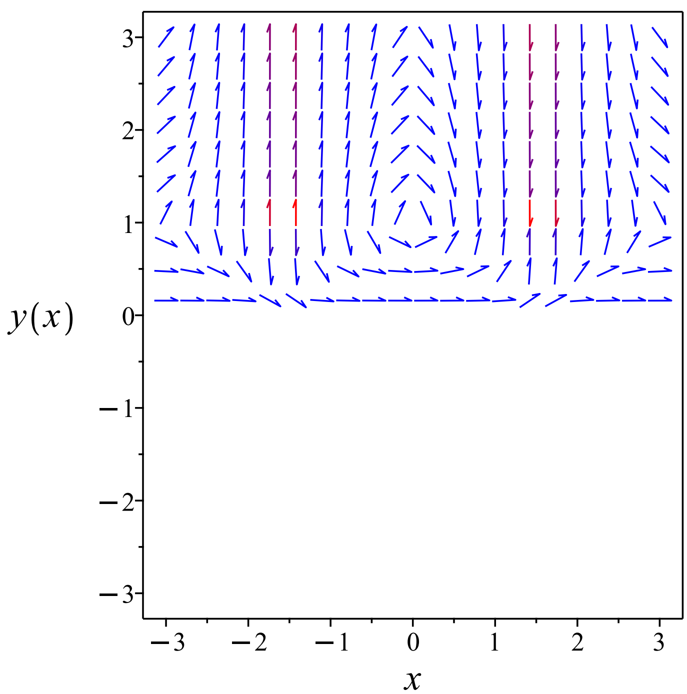

Figure 121: Slope field plot

Verification of solutions

$$y = e^{-\operatorname{LambertW}\left(-\frac{(c_1 \cos(x)+1)e^{-1}}{\cos(x)}\right)-1}$$

Verified OK.

4.13.4 Maple step by step solution

Let's solve

$\sin(x)\, y^2 + \cos(x)^2 \ln(y)\, y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y' \ln(y)}{y^2} = -\frac{\sin(x)}{\cos(x)^2}$

- Integrate both sides with respect to x

  $\int \frac{y' \ln(y)}{y^2} dx = \int -\frac{\sin(x)}{\cos(x)^2} dx + c_1$

- Evaluate integral

  $-\frac{\ln(y)}{y} - \frac{1}{y} = -\frac{1}{\cos(x)} + c_1$

- Solve for y

  $y = e^{-LambertW\left(\frac{c_1 \cos(x)-1}{e \cos(x)}\right)-1}$

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _dAlembert]
```

$$\boxed{y' - \sin(-y + x) = 0}$$

4.14.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \sin(-y + x) \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}&b_2 + \sin(-y+x)(b_3 - a_2) - \sin(-y+x)^2 a_3 \\ &- \cos(-y+x)(xa_2 + ya_3 + a_1) + \cos(-y+x)(xb_2 + yb_3 + b_1) = 0\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\begin{aligned}&-\cos(-y+x)xa_2 + \cos(-y+x)xb_2 - \cos(-y+x)ya_3 \\ &+ \cos(-y+x)yb_3 - \sin(-y+x)^2 a_3 - \cos(-y+x)a_1 \\ &+ \cos(-y+x)b_1 - \sin(-y+x)a_2 + \sin(-y+x)b_3 + b_2 = 0\end{aligned}$$

Setting the numerator to zero gives

$$\begin{aligned}&-\cos(-y+x)xa_2 + \cos(-y+x)xb_2 - \cos(-y+x)ya_3 \\ &+ \cos(-y+x)yb_3 - \sin(-y+x)^2 a_3 - \cos(-y+x)a_1 \\ &+ \cos(-y+x)b_1 - \sin(-y+x)a_2 + \sin(-y+x)b_3 + b_2 = 0\end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned}&b_2 - \frac{a_3}{2} - \cos(-y+x)xa_2 + \cos(-y+x)xb_2 - \cos(-y+x)ya_3 \\ &+ \cos(-y+x)yb_3 + \frac{a_3\cos(-2y+2x)}{2} - \cos(-y+x)a_1 \\ &+ \cos(-y+x)b_1 - \sin(-y+x)a_2 + \sin(-y+x)b_3 = 0\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, \cos(-2y+2x), \cos(-y+x), \sin(-y+x)\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, \cos(-2y+2x) = v_3, \cos(-y+x) = v_4, \sin(-y+x) = v_5\}$$

The above PDE (6E) now becomes

$$b_2 - \frac{1}{2}a_3 - v_4v_1a_2 + v_4v_1b_2 - v_4v_2a_3 + v_4v_2b_3 + \frac{1}{2}a_3v_3 - v_4a_1 + v_4b_1 - v_5a_2 + v_5b_3 = 0 \quad (7E)$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5\}$$

Equation (7E) now becomes

$$b_2 - \frac{a_3}{2} + (-a_2 + b_2)\,v_1v_4 + (-a_3 + b_3)\,v_2v_4 + \frac{a_3v_3}{2} + (-a_1 + b_1)\,v_4 + (b_3 - a_2)\,v_5 = 0 \quad (8E)$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
\frac{a_3}{2} &= 0 \\
-a_1 + b_1 &= 0 \\
-a_2 + b_2 &= 0 \\
-a_3 + b_3 &= 0 \\
b_2 - \frac{a_3}{2} &= 0 \\
b_3 - a_2 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= b_1 \\
a_2 &= 0 \\
a_3 &= 0 \\
b_1 &= b_1 \\
b_2 &= 0 \\
b_3 &= 0
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= 1 \\
\eta &= 1
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 1 - (\sin(-y+x))\,(1) \\
&= 1 + \sin(y)\cos(x) - \cos(y)\sin(x) \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{1 + \sin(y)\cos(x) - \cos(y)\sin(x)} dy
\end{aligned}$$

Which results in

$$S = -\frac{2}{-\tan\left(-\frac{y}{2} + \frac{x}{2}\right) + 1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \sin(-y+x)$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{\sin\left(-y+x\right)-1} \\
S_y &= -\frac{1}{\sin\left(-y+x\right)-1}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -1 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -1
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -R + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{2}{\tan\left(-\frac{y}{2}+\frac{x}{2}\right)-1} = -x + c_1
$$

Which simplifies to

$$
\frac{2}{\tan\left(-\frac{y}{2}+\frac{x}{2}\right)-1} = -x + c_1
$$

Which gives

$$
y = x - 2\arctan\left(\frac{c_1 - x + 2}{-x + c_1}\right)
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \sin(-y + x)$ 	$R = x$ $S = \frac{2}{\tan\left(-\frac{y}{2} + \frac{x}{2}\right) - 1}$	$\frac{dS}{dR} = -1$ 
Summary
The solution(s) found are the following

$$y = x - 2\arctan\left(\frac{c_1 - x + 2}{-x + c_1}\right) \tag{1}$$

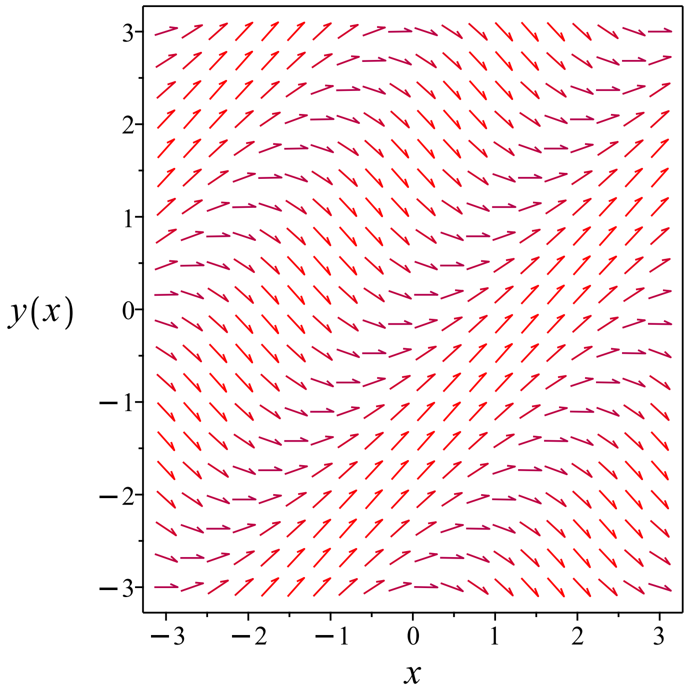

Figure 122: Slope field plot

Verification of solutions

$$y = x - 2\arctan\left(\frac{c_1 - x + 2}{-x + c_1}\right)$$

Verified OK.

Problem number: 60.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - yb = ax + c}$$

4.15.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -b$$
$$q(x) = ax + c$$

Hence the ode is

$$y' - yb = ax + c$$

The integrating factor μ is

$$\mu = e^{\int -b dx}$$
$$= e^{-bx}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(ax + c)$$
$$\frac{d}{dx}(e^{-bx} y) = (e^{-bx})(ax + c)$$
$$d(e^{-bx} y) = ((ax + c) e^{-bx}) dx$$

Integrating gives

$$e^{-bx} y = \int (ax + c) e^{-bx} dx$$
$$e^{-bx} y = -\frac{(abx + bc + a) e^{-bx}}{b^2} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-bx}$ results in

$$y = -\frac{e^{bx}(abx + bc + a) e^{-bx}}{b^2} + c_1 e^{bx}$$

which simplifies to

$$y = \frac{c_1 e^{bx} b^2 + (-ax - c) b - a}{b^2}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 e^{bx} b^2 + (-ax - c) b - a}{b^2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 e^{bx} b^2 + (-ax - c) b - a}{b^2}$$

Verified OK.

4.15.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= ax + by + c \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 96: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \mathrm{e}^{bx}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\mathrm{e}^{bx}} dy\end{aligned}$$

Which results in

$$S = \mathrm{e}^{-bx} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = ax + by + c$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1\\ R_y &= 0\\ S_x &= -b\,\mathrm{e}^{-bx} y\\ S_y &= \mathrm{e}^{-bx}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = (ax + c)\,\mathrm{e}^{-bx} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = (Ra + c)\,\mathrm{e}^{-bR}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{(Rab + bc + a)\,\mathrm{e}^{-bR}}{b^2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-bx}y = -\frac{(abx + bc + a)\,\mathrm{e}^{-bx}}{b^2} + c_1$$

Which simplifies to

$$\mathrm{e}^{-bx}y = -\frac{(abx + bc + a)\,\mathrm{e}^{-bx}}{b^2} + c_1$$

Which gives

$$y = -\frac{\left(\mathrm{e}^{-bx}abx + \mathrm{e}^{-bx}bc - c_1 b^2 + a\,\mathrm{e}^{-bx}\right)\mathrm{e}^{bx}}{b^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(\mathrm{e}^{-bx}abx + \mathrm{e}^{-bx}bc - c_1 b^2 + a\,\mathrm{e}^{-bx}\right)\mathrm{e}^{bx}}{b^2} \tag{1}$$

Verification of solutions

$$y = -\frac{\left(\mathrm{e}^{-bx}abx + \mathrm{e}^{-bx}bc - c_1 b^2 + a\,\mathrm{e}^{-bx}\right)\mathrm{e}^{bx}}{b^2}$$

Verified OK.

4.15.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y&=(ax+by+c)\,\mathrm{d}x\\ (-ax-by-c)\,\mathrm{d}x+\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-ax-by-c\\ N(x,y)&=1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-ax - by - c) \\ &= -b\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-b) - (0)) \\ &= -b\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -b \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-bx} \\ &= \mathrm{e}^{-bx}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{-bx}(-ax - by - c) \\ &= -\mathrm{e}^{-bx}(ax + by + c)\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-bx}(1) \\
&= \mathrm{e}^{-bx}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{-bx}(ax+by+c)\right) + \left(\mathrm{e}^{-bx}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\mathrm{e}^{-bx}(ax+by+c)\,\mathrm{d}x \\
\phi &= \frac{(b^2y+(ax+c)\,b+a)\,\mathrm{e}^{-bx}}{b^2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{-bx} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-bx}$. Therefore equation (4) becomes

$$
\mathrm{e}^{-bx} = \mathrm{e}^{-bx} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(b^2 y + (ax + c) b + a) e^{-bx}}{b^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(b^2 y + (ax + c) b + a) e^{-bx}}{b^2}$$

The solution becomes

$$y = -\frac{(e^{-bx} abx + e^{-bx} bc - c_1 b^2 + a e^{-bx}) e^{bx}}{b^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{(e^{-bx} abx + e^{-bx} bc - c_1 b^2 + a e^{-bx}) e^{bx}}{b^2} \tag{1}$$

Verification of solutions

$$y = -\frac{(e^{-bx} abx + e^{-bx} bc - c_1 b^2 + a e^{-bx}) e^{bx}}{b^2}$$

Verified OK.

4.15.4 Maple step by step solution

Let's solve

$y' - yb = ax + c$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = ax + yb + c$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

$$y' - yb = ax + c$$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$$\mu(x)\,(y' - yb) = \mu(x)\,(ax + c)$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

$$\mu(x)\,(y' - yb) = \mu'(x)\,y + \mu(x)\,y'$$

- Isolate $\mu'(x)$

$$\mu'(x) = -\mu(x)\,b$$

- Solve to find the integrating factor

$$\mu(x) = \mathrm{e}^{-bx}$$

- Integrate both sides with respect to x

$$\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,(ax + c)\,dx + c_1$$

- Evaluate the integral on the lhs

$$\mu(x)\,y = \int \mu(x)\,(ax + c)\,dx + c_1$$

- Solve for y

$$y = \frac{\int \mu(x)(ax+c)dx + c_1}{\mu(x)}$$

- Substitute $\mu(x) = \mathrm{e}^{-bx}$

$$y = \frac{\int (ax+c)\mathrm{e}^{-bx}dx + c_1}{\mathrm{e}^{-bx}}$$

- Evaluate the integrals on the rhs

$$y = \frac{-\frac{(abx+bc+a)\mathrm{e}^{-bx}}{b^2} + c_1}{\mathrm{e}^{-bx}}$$

- Simplify

$$y = \frac{c_1\mathrm{e}^{bx}b^2 + (-ax-c)b - a}{b^2}$$

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _dAlembert]
```

$$\boxed{(y+x)^2 y' = a^2}$$

4.16.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{a^2}{x^2 + 2xy + y^2} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{a^2(b_3 - a_2)}{x^2 + 2xy + y^2} - \frac{a^4 a_3}{(x^2 + 2xy + y^2)^2} + \frac{a^2(2y + 2x)(x a_2 + y a_3 + a_1)}{(x^2 + 2xy + y^2)^2} + \frac{a^2(2y + 2x)(x b_2 + y b_3 + b_1)}{(x^2 + 2xy + y^2)^2} = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{a^4 a_3 - a^2 x^2 a_2 - 2a^2 x^2 b_2 - a^2 x^2 b_3 - 2a^2 xy a_3 - 2a^2 xy b_2 - 4a^2 xy b_3 + a^2 y^2 a_2 - 2a^2 y^2 a_3 - 3a^2 y^2 b_3 - x^4 b}{(x^2 + 2xy + y^2)^2} = 0$$

Setting the numerator to zero gives

$$-a^4 a_3 + a^2 x^2 a_2 + 2a^2 x^2 b_2 + a^2 x^2 b_3 + 2a^2 xy a_3 + 2a^2 xy b_2 + 4a^2 xy b_3 - a^2 y^2 a_2 + 2a^2 y^2 a_3 + 3a^2 y^2 b_3 + x^4 b_2 + 4x^3 y b_2 + 6x^2 y^2 b_2 + 4x y^3 b_2 + y^4 b_2 + 2a^2 x a_1 + 2a^2 x b_1 + 2a^2 y a_1 + 2a^2 y b_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a^4 a_3 + a^2 a_2 v_1^2 - a^2 a_2 v_2^2 + 2a^2 a_3 v_1 v_2 + 2a^2 a_3 v_2^2 + 2a^2 b_2 v_1^2 + 2a^2 b_2 v_1 v_2 + a^2 b_3 v_1^2 + 4a^2 b_3 v_1 v_2 + 3a^2 b_3 v_2^2 + b_2 v_1^4 + 4b_2 v_1^3 v_2 + 6b_2 v_1^2 v_2^2 + 4b_2 v_1 v_2^3 + b_2 v_2^4 + 2a^2 a_1 v_1 + 2a^2 a_1 v_2 + 2a^2 b_1 v_1 + 2a^2 b_1 v_2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} & b_2v_1^4 + 4b_2v_1^3v_2 + 6b_2v_1^2v_2^2 + \left(a^2a_2 + 2a^2b_2 + a^2b_3\right)v_1^2 + 4b_2v_1v_2^3 \\ & + \left(2a^2a_3 + 2a^2b_2 + 4a^2b_3\right)v_1v_2 + \left(2a^2a_1 + 2a^2b_1\right)v_1 + b_2v_2^4 \\ & + \left(-a^2a_2 + 2a^2a_3 + 3a^2b_3\right)v_2^2 + \left(2a^2a_1 + 2a^2b_1\right)v_2 - a^4a_3 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} b_2 &= 0 \\ 4b_2 &= 0 \\ 6b_2 &= 0 \\ -a^4a_3 &= 0 \\ 2a^2a_1 + 2a^2b_1 &= 0 \\ -a^2a_2 + 2a^2a_3 + 3a^2b_3 &= 0 \\ a^2a_2 + 2a^2b_2 + a^2b_3 &= 0 \\ 2a^2a_3 + 2a^2b_2 + 4a^2b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= -b_1 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= b_1 \\ b_2 &= 0 \\ b_3 &= 0 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= -1 \\ \eta &= 1 \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 1 - \left(\frac{a^2}{x^2+2xy+y^2}\right)(-1) \\
&= \frac{a^2+x^2+2xy+y^2}{x^2+2xy+y^2} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{a^2+x^2+2xy+y^2}{x^2+2xy+y^2}} dy
\end{aligned}$$

Which results in

$$S = y - a\arctan\left(\frac{2y+2x}{2a}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{a^2}{x^2+2xy+y^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{a^2}{(y+x)^2 + a^2} \\
S_y &= 1 - \frac{a^2}{(y+x)^2 + a^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
y - a \arctan\left(\frac{y+x}{a}\right) = c_1
$$

Which simplifies to

$$
y - a \arctan\left(\frac{y+x}{a}\right) = c_1
$$

Summary

The solution(s) found are the following

$$
y - a \arctan\left(\frac{y+x}{a}\right) = c_1 \tag{1}
$$

Verification of solutions

$$
y - a \arctan\left(\frac{y+x}{a}\right) = c_1
$$

Verified OK.

Problem number: 62.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y'x + y - a(yx + 1) = 0}$$

With initial conditions

$$\left[y\left(\frac{1}{a}\right) = -a\right]$$

4.17.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{ax - 1}{x}$$
$$q(x) = \frac{a}{x}$$

Hence the ode is

$$y' - \frac{(ax-1)\,y}{x} = \frac{a}{x}$$

The domain of $p(x) = -\frac{ax-1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

But the point $x_0 = \frac{1}{a}$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

4.17.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{ax-1}{x}dx} \\ &= e^{-ax+\ln(x)}\end{aligned}$$

Which simplifies to

$$\mu = x\,e^{-ax}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{a}{x}\right) \\ \frac{d}{dx}\left(x\,e^{-ax}y\right) &= \left(x\,e^{-ax}\right)\left(\frac{a}{x}\right) \\ d\left(x\,e^{-ax}y\right) &= \left(a\,e^{-ax}\right)\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}x\,e^{-ax}y &= \int a\,e^{-ax}\,dx \\ x\,e^{-ax}y &= -e^{-ax} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x\,e^{-ax}$ results in

$$y = -\frac{e^{ax}e^{-ax}}{x} + \frac{c_1 e^{ax}}{x}$$

which simplifies to

$$y = \frac{c_1 e^{ax} - 1}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{1}{a}$ and $y = -a$ in the above solution gives an equation to solve for the constant of integration.

$$-a = a\,e c_1 - a$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{1}{x}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{x} \tag{1}$$

Verification of solutions

$$y = -\frac{1}{x}$$

Verified OK.

4.17.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{axy + a - y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 99: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \mathrm{e}^{ax-\ln(x)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{ax - \ln(x)}} dy \end{aligned}$$

Which results in

$$S = x\,e^{-ax} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{axy + a - y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= e^{-ax} y(-ax + 1) \\ S_y &= x\,e^{-ax} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = a\,e^{-ax} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = a\,e^{-aR}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -e^{-aR} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x\,e^{-ax}y = -e^{-ax} + c_1$$

Which simplifies to

$$x\,e^{-ax}y = -e^{-ax} + c_1$$

Which gives

$$y = -\frac{(e^{-ax} - c_1)\,e^{ax}}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{1}{a}$ and $y = -a$ in the above solution gives an equation to solve for the constant of integration.

$$-a = a\,e c_1 - a$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{1}{x}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{x} \tag{1}$$

Verification of solutions

$$y = -\frac{1}{x}$$

Verified OK.

4.17.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y&=(-y+a(xy+1))\,\mathrm{d}x\\ (y-a(xy+1))\,\mathrm{d}x+(x)\,\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=y-a(xy+1)\\ N(x,y)&=x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y - a(xy+1)) \\ &= -ax + 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x) \\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{x}((-ax+1) - (1)) \\ &= -a\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -a \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-ax} \\ &= \mathrm{e}^{-ax}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{-ax}(y - a(xy+1)) \\ &= -\mathrm{e}^{-ax}(axy + a - y)\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-ax}(x) \\
&= x\,\mathrm{e}^{-ax}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{-ax}(axy + a - y)\right) + \left(x\,\mathrm{e}^{-ax}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\mathrm{e}^{-ax}(axy + a - y)\,\mathrm{d}x \\
\phi &= (xy + 1)\,\mathrm{e}^{-ax} + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = x\,\mathrm{e}^{-ax} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x\,\mathrm{e}^{-ax}$. Therefore equation (4) becomes

$$
x\,\mathrm{e}^{-ax} = x\,\mathrm{e}^{-ax} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (xy + 1)\,\mathrm{e}^{-ax} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (xy + 1)\,\mathrm{e}^{-ax}$$

The solution becomes

$$y = -\frac{(\mathrm{e}^{-ax} - c_1)\,\mathrm{e}^{ax}}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{1}{a}$ and $y = -a$ in the above solution gives an equation to solve for the constant of integration.

$$-a = a\,\mathrm{e}c_1 - a$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = -\frac{1}{x}$$

Summary
The solution(s) found are the following

$$y = -\frac{1}{x} \tag{1}$$

Verification of solutions

$$y = -\frac{1}{x}$$

Verified OK.

4.17.5 Maple step by step solution

Let's solve

$\left[y'x+y-a(yx+1)=0, y\left(\frac{1}{a}\right)=-a\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=\frac{(ax-1)y}{x}+\frac{a}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y'-\frac{(ax-1)y}{x}=\frac{a}{x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y'-\frac{(ax-1)y}{x}\right)=\frac{\mu(x)a}{x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'-\frac{(ax-1)y}{x}\right)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x)=-\frac{\mu(x)(ax-1)}{x}$

- Solve to find the integrating factor

  $\mu(x)=x\,\mathrm{e}^{-ax}$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\frac{\mu(x)a}{x}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\frac{\mu(x)a}{x}dx+c_1$

- Solve for y

  $y=\frac{\int\frac{\mu(x)a}{x}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=x\mathrm{e}^{-ax}$

  $y=\frac{\int a\,\mathrm{e}^{-ax}dx+c_1}{x\,\mathrm{e}^{-ax}}$

- Evaluate the integrals on the rhs

  $y=\frac{-\mathrm{e}^{-ax}+c_1}{x\,\mathrm{e}^{-ax}}$

- Simplify

$y = \frac{c_1 e^{ax} - 1}{x}$

- Use initial condition $y\left(\frac{1}{a}\right) = -a$

$-a = (e c_1 - 1)\, a$

- Solve for c_1

$c_1 = 0$

- Substitute $c_1 = 0$ into general solution and simplify

$y = -\frac{1}{x}$

- Solution to the IVP

$y = -\frac{1}{x}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y^2 + 2x\sqrt{ax - x^2}\, y' = -a^2}$$

With initial conditions

$$[y(a) = 0]$$

4.18.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{a^2 + y^2}{2x\sqrt{ax - x^2}} \end{aligned}$$

$f(x, y)$ is not defined at $x = a$ therefore existence and uniqueness theorem do not apply.

4.18.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{-\frac{a^2}{2}-\frac{y^2}{2}}{x\sqrt{ax-x^2}}
\end{aligned}$$

Where $f(x)=\frac{1}{x\sqrt{ax-x^2}}$ and $g(y)=-\frac{a^2}{2}-\frac{y^2}{2}$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{-\frac{a^2}{2}-\frac{y^2}{2}}\,dy &= \frac{1}{x\sqrt{ax-x^2}}\,dx \\
\int \frac{1}{-\frac{a^2}{2}-\frac{y^2}{2}}\,dy &= \int \frac{1}{x\sqrt{ax-x^2}}\,dx \\
-\frac{2\arctan\left(\frac{y}{a}\right)}{a} &= -\frac{2\sqrt{x\,(a-x)}}{xa}+c_1
\end{aligned}$$

Which results in

$$y=\tan\left(\frac{-c_1ax+2\sqrt{x\,(a-x)}}{2x}\right)a$$

Initial conditions are used to solve for c_1. Substituting $x=a$ and $y=0$ in the above solution gives an equation to solve for the constant of integration.

$$0=-\tan\left(\frac{c_1a}{2}\right)a$$

$$c_1=0$$

Substituting c_1 found above in the general solution gives

$$y=\tan\left(\frac{\sqrt{x\,(a-x)}}{x}\right)a$$

Summary

The solution(s) found are the following

$$y=\tan\left(\frac{\sqrt{x\,(a-x)}}{x}\right)a \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{\sqrt{x\,(a-x)}}{x}\right) a$$

Verified OK.

4.18.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{a^2+y^2}{2x\sqrt{a x-x^2}} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 102: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= x\sqrt{ax - x^2} \\ \eta(x, y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x\sqrt{ax - x^2}} dx \end{aligned}$$

Which results in

$$S = -\frac{2(a - x)}{a\sqrt{ax - x^2}}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{a^2 + y^2}{2x\sqrt{ax - x^2}}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{\sqrt{a - x}\, x^{\frac{3}{2}}} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{2\sqrt{x\,(a - x)}}{\sqrt{a - x}\,\sqrt{x}\,(a^2 + y^2)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{2}{R^2 + a^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{2\arctan\left(\frac{R}{a}\right)}{a} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{2\sqrt{a-x}}{a\sqrt{x}} = -\frac{2\arctan\left(\frac{y}{a}\right)}{a} + c_1$$

Which simplifies to

$$-\frac{2\sqrt{a-x}}{a\sqrt{x}} = -\frac{2\arctan\left(\frac{y}{a}\right)}{a} + c_1$$

Which gives

$$y = \tan\left(\frac{c_1 a\sqrt{x} + 2\sqrt{a-x}}{2\sqrt{x}}\right) a$$

Initial conditions are used to solve for c_1. Substituting $x = a$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \tan\left(\frac{c_1 a}{2}\right) a$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \tan\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) a$$

Summary

The solution(s) found are the following

$$y = \tan\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) a \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) a$$

Verified OK.

4.18.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(\frac{1}{-\frac{a^2}{2}-\frac{y^2}{2}}\right)\mathrm{d}y=\left(\frac{1}{x\sqrt{ax-x^2}}\right)\mathrm{d}x$$

$$\left(-\frac{1}{x\sqrt{ax-x^2}}\right)\mathrm{d}x+\left(\frac{1}{-\frac{a^2}{2}-\frac{y^2}{2}}\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= -\frac{1}{x\sqrt{a x-x^{2}}}\\
N(x,y) &= \frac{1}{-\frac{a^{2}}{2}-\frac{y^{2}}{2}}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x\sqrt{a x-x^{2}}}\right)\\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{-\frac{a^{2}}{2}-\frac{y^{2}}{2}}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1)\\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{1}{x\sqrt{a x-x^{2}}}\, \mathrm{d}x\\
\phi &= \frac{2a-2x}{a\sqrt{x\left(a-x\right)}}+f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{-\frac{a^2}{2} - \frac{y^2}{2}}$. Therefore equation (4) becomes

$$\frac{1}{-\frac{a^2}{2} - \frac{y^2}{2}} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{2}{a^2 + y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{2}{a^2 + y^2}\right) \mathrm{d}y$$

$$f(y) = -\frac{2\arctan\left(\frac{y}{a}\right)}{a} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{2a - 2x}{a\sqrt{x\,(a - x)}} - \frac{2\arctan\left(\frac{y}{a}\right)}{a} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{2a - 2x}{a\sqrt{x\,(a - x)}} - \frac{2\arctan\left(\frac{y}{a}\right)}{a}$$

The solution becomes

$$y = -\tan\left(\frac{c_1 a\sqrt{x\,(a - x)} - 2a + 2x}{2\sqrt{x\,(a - x)}}\right) a$$

Initial conditions are used to solve for c_1. Substituting $x = a$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -\tan\left(\frac{c_1 a}{2}\right) a$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \tan\left(\frac{a-x}{\sqrt{x(a-x)}}\right) a$$

Summary

The solution(s) found are the following

$$y = \tan\left(\frac{a-x}{\sqrt{x(a-x)}}\right) a \tag{1}$$

Verification of solutions

$$y = \tan\left(\frac{a-x}{\sqrt{x(a-x)}}\right) a$$

Verified OK.

4.18.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{a^2+y^2}{2x\sqrt{ax-x^2}} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{a^2}{2x\sqrt{ax-x^2}} - \frac{y^2}{2x\sqrt{ax-x^2}}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -\frac{a^2}{2x\sqrt{ax-x^2}}$, $f_1(x) = 0$ and $f_2(x) = -\frac{1}{2x\sqrt{ax-x^2}}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{-\frac{u}{2x\sqrt{ax-x^2}}}
\end{aligned}
\tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= \frac{1}{2x^2\sqrt{ax-x^2}} + \frac{a-2x}{4x\,(ax-x^2)^{\frac{3}{2}}} \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= -\frac{a^2}{8x^3\,(ax-x^2)^{\frac{3}{2}}}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
-\frac{u''(x)}{2x\sqrt{ax-x^2}} - \left(\frac{1}{2x^2\sqrt{ax-x^2}} + \frac{a-2x}{4x\,(ax-x^2)^{\frac{3}{2}}}\right) u'(x) - \frac{a^2 u(x)}{8x^3\,(ax-x^2)^{\frac{3}{2}}} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = c_1 \sin\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) + c_2 \cos\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right)
$$

The above shows that

$$
u'(x) = \frac{a\left(c_2 \sin\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) - c_1 \cos\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right)\right)}{2\sqrt{a-x}\, x^{\frac{3}{2}}}
$$

Using the above in (1) gives the solution

$$
y = \frac{a\left(c_2 \sin\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) - c_1 \cos\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right)\right)\sqrt{ax-x^2}}{\sqrt{a-x}\,\sqrt{x}\,\left(c_1 \sin\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) + c_2 \cos\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right)\right)}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\left(\sin\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) - c_3 \cos\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right)\right) a\sqrt{x\,(a-x)}}{\left(c_3 \sin\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right) + \cos\left(\frac{\sqrt{a-x}}{\sqrt{x}}\right)\right) \sqrt{a-x}\,\sqrt{x}}$$

Initial conditions are used to solve for c_3. Substituting $x = a$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

Warning: Failed to find c_3 using initial conditions. Solution could be wrong or there is no solution that satisfies the given initial conditions.

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - \frac{y}{x} = 0}$$

With initial conditions

$$[y(0) = 0]$$

4.19.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = 0$$

The domain of $p(x) = -\frac{1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

But the point $x_0 = 0$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

4.19.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{y}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned} \frac{1}{y}\, dy &= \frac{1}{x}\, dx \\ \int \frac{1}{y}\, dy &= \int \frac{1}{x}\, dx \\ \ln(y) &= \ln(x) + c_1 \\ y &= e^{\ln(x)+c_1} \\ &= c_1 x \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 0$$

This solution is valid for any c_1. Hence there are infinite number of solutions.

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 x \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 x$$

Verified OK.

4.19.3 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\frac{d}{dx}\mu y = 0$$
$$\frac{d}{dx}\left(\frac{y}{x}\right) = 0$$

Integrating gives

$$\frac{y}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = c_1 x$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 0$$

This solution is valid for any c_1. Hence there are infinite number of solutions.
Summary
The solution(s) found are the following

$$y = c_1 x \tag{1}$$

Verification of solutions

$$y = c_1 x$$

Verified OK.

4.19.4 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x = 0$$

Integrating both sides gives

$$\begin{aligned} u(x) &= \int 0\,\mathrm{d}x \\ &= c_2 \end{aligned}$$

Therefore the solution y is

$$\begin{aligned} y &= xu \\ &= c_2 x \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 0$$

This solution is valid for any c_2. Hence there are infinite number of solutions.
Summary
The solution(s) found are the following

$$y = c_2 x \tag{1}$$

Verification of solutions

$$y = c_2 x$$

Verified OK.

4.19.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 104: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= x \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{x^2} \\ S_y &= \frac{1}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x} = c_1$$

Which simplifies to

$$\frac{y}{x} = c_1$$

Which gives

$$y = c_1 x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y}{x}$ 	$R = x$ $S = \frac{y}{x}$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 0$$

This solution is valid for any c_1. Hence there are infinite number of solutions.

Summary

The solution(s) found are the following

$$y = c_1 x \tag{1}$$

Verification of solutions

$$y = c_1 x$$

Verified OK.

4.19.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{y}\right)\mathrm{d}y&=\left(\frac{1}{x}\right)\mathrm{d}x\\ \left(-\frac{1}{x}\right)\mathrm{d}x+\left(\frac{1}{y}\right)\mathrm{d}y&=0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\frac{1}{x}\\N(x,y) &= \frac{1}{y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right)\\&= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right)\\&= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{1}{x}\,\mathrm{d}x\\\phi &= -\ln(x) + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{y}\right) \mathrm{d}y$$
$$f(y) = \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) + \ln(y)$$

The solution becomes

$$y = \mathrm{e}^{c_1} x$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 0$$

This solution is valid for any c_1. Hence there are infinite number of solutions.

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{c_1} x \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{c_1} x$$

Verified OK.

4.19.7 Maple step by step solution

Let's solve

$\left[y' - \frac{y}{x} = 0, y(0) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{1}{x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int \frac{1}{x}dx + c_1$

- Evaluate integral

  $\ln(y) = \ln(x) + c_1$

- Solve for y

  $y = \mathrm{e}^{c_1}x$

- Use initial condition $y(0) = 0$

  $0 = 0$

- Solve for c_1

  $c_1 = c_1$

- Substitute $c_1 = c_1$ into general solution and simplify

  $y = \mathrm{e}^{c_1}x$

- Solution to the IVP

  $y = \mathrm{e}^{c_1}x$

4.27 problem 92

Internal problem ID [14999]
Internal file name [`OUTPUT/14999_Friday_April_19_2024_04_43_38_AM_84918379/index.tex`]

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 4. Equations with variables separable and equations reducible to them. Exercises page 38
Problem number: 92.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

Unable to solve or complete the solution.

$$\boxed{x^2 y' \cos(y) = -1}$$

With initial conditions

$$\left[y(\infty) = \frac{16\pi}{3}\right]$$

4.27.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= -\frac{1}{x^2 \cos (y)} \end{aligned}$$

The x domain of $f(x, y)$ when $y = \frac{16\pi}{3}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is inside this domain. The y domain of $f(x, y)$ when $x = \infty$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = \frac{16\pi}{3}$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2 \cos (y)}\right) \\ &= -\frac{\sin (y)}{x^2 \cos (y)^2} \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = \frac{16\pi}{3}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = \infty$ is

$$\{-\infty < y < \infty\}$$

And the point $y_0 = \frac{16\pi}{3}$ is inside this domain. Therefore solution exists and is unique.

4.27.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= -\frac{\sec (y)}{x^2} \end{aligned}$$

Where $f(x) = -\frac{1}{x^2}$ and $g(y) = \sec(y)$. Integrating both sides gives

$$\frac{1}{\sec(y)}\,dy = -\frac{1}{x^2}\,dx$$
$$\int \frac{1}{\sec(y)}\,dy = \int -\frac{1}{x^2}\,dx$$
$$\sin(y) = \frac{1}{x} + c_1$$

Which results in

$$y = \arcsin\left(\frac{c_1 x + 1}{x}\right)$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{16\pi}{3}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{16\pi}{3} = \arcsin(c_1)$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

4.27.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{1}{x^2\cos(y)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 114: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= -x^2 \\ \eta(x,y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-x^2} dx \end{aligned}$$

Which results in

$$S = \frac{1}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{1}{x^2 \cos(y)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -\frac{1}{x^2} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cos(y) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cos(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \sin(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{1}{x} = \sin(y) + c_1$$

Which simplifies to

$$\frac{1}{x} = \sin(y) + c_1$$

Which gives

$$y = -\arcsin\left(\frac{c_1 x - 1}{x}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{1}{x^2 \cos(y)}$ 	$R = y$ $S = \frac{1}{x}$	$\frac{dS}{dR} = \cos(R)$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{16\pi}{3}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{16\pi}{3} = -\arcsin(c_1)$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

4.27.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$
\begin{aligned}
(-\cos(y))\,\mathrm{d}y &= \left(\frac{1}{x^2}\right)\mathrm{d}x \\
\left(-\frac{1}{x^2}\right)\mathrm{d}x + (-\cos(y))\,\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= -\frac{1}{x^2} \\
N(x,y) &= -\cos(y)
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-\cos(y)) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{1}{x^2}\,\mathrm{d}x \\
\phi &= \frac{1}{x} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\cos(y)$. Therefore equation (4) becomes

$$-\cos(y) = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\cos(y)$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (-\cos(y))\,\mathrm{d}y$$
$$f(y) = -\sin(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{x} - \sin(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{x} - \sin(y)$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{16\pi}{3}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\sqrt{3}}{2} = c_1$$

$$c_1 = \frac{\sqrt{3}}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{x} - \sin(y) = \frac{\sqrt{3}}{2}$$

The above simplifies to

$$-2\sin(y)\,x - \sqrt{3}\,x + 2 = 0$$

But this does not satisfy the initial conditions. Hence no solution can be found.

Verification of solutions N/A

4.27.5 Maple step by step solution

Let's solve

$\left[x^2 y' \cos(y) = -1, y(\infty) = \frac{16\pi}{3}\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\cos(y)\,y' = -\frac{1}{x^2}$

- Integrate both sides with respect to x

  $\int \cos(y)\,y' dx = \int -\frac{1}{x^2} dx + c_1$

- Evaluate integral

  $\sin(y) = \frac{1}{x} + c_1$

- Solve for y

  $y = \arcsin\left(\frac{c_1 x + 1}{x}\right)$

- Use initial condition $y(\infty) = \frac{16\pi}{3}$

  $\frac{16\pi}{3} = 0$

- Solution does not satisfy initial condition

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

Unable to solve or complete the solution.

$$\boxed{x^2y' + \cos(2y) = 1}$$

With initial conditions

$$\left[y(\infty) = \frac{10\pi}{3}\right]$$

4.28.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned}y' &= f(x,y)\\ &= -\frac{-1+\cos(2y)}{x^2}\end{aligned}$$

The x domain of $f(x,y)$ when $y=\frac{10\pi}{3}$ is

$$\{x<0\lor 0<x\}$$

And the point $x_0=\infty$ is inside this domain. The y domain of $f(x,y)$ when $x=\infty$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=\frac{10\pi}{3}$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{-1+\cos(2y)}{x^2}\right)\\ &= \frac{2\sin(2y)}{x^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=\frac{10\pi}{3}$ is

$$\{x<0\lor 0<x\}$$

And the point $x_0=\infty$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=\infty$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=\frac{10\pi}{3}$ is inside this domain. Therefore solution exists and is unique.

4.28.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\ &= f(x)g(y)\\ &= \frac{1-\cos(2y)}{x^2}\end{aligned}$$

Where $f(x) = \frac{1}{x^2}$ and $g(y) = 1 - \cos(2y)$. Integrating both sides gives

$$\frac{1}{1-\cos(2y)}\,dy = \frac{1}{x^2}\,dx$$
$$\int \frac{1}{1-\cos(2y)}\,dy = \int \frac{1}{x^2}\,dx$$
$$-\frac{1}{2\tan(y)} = -\frac{1}{x} + c_1$$

Which results in

$$y = -\arctan\left(\frac{x}{2c_1x-2}\right)$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{10\pi}{3}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{10\pi}{3} = -\arctan\left(\frac{1}{2c_1}\right)$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.28.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-1+\cos(2y)}{x^2}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 117: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= x^2 \\
\eta(x, y) &= 0
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x^2} dx \end{aligned}$$

Which results in

$$S = -\frac{1}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-1 + \cos(2y)}{x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{x^2} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{-1 + \cos(2y)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{-1 + \cos(2R)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{1}{2\tan(R)} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{x} = -\frac{1}{2\tan(y)} + c_1$$

Which simplifies to

$$-\frac{1}{x} = -\frac{1}{2\tan(y)} + c_1$$

Which gives

$$y = \arctan\left(\frac{x}{2c_1x + 2}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-1+\cos(2y)}{x^2}$ 	$R = y$ $S = -\frac{1}{x}$	$\frac{dS}{dR} = -\frac{1}{-1+\cos(2R)}$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{10\pi}{3}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{10\pi}{3} = \arctan\left(\frac{1}{2c_1}\right)$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.28.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{1-\cos(2y)}\right)\mathrm{d}y &= \left(\frac{1}{x^2}\right)\mathrm{d}x\\ \left(-\frac{1}{x^2}\right)\mathrm{d}x + \left(\frac{1}{1-\cos(2y)}\right)\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\frac{1}{x^2}\\ N(x,y) &= \frac{1}{1-\cos(2y)}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{1-\cos(2y)}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{1}{x^2} \, \mathrm{d}x \\
\phi &= \frac{1}{x} + f(y) \qquad (3)
\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{1-\cos(2y)}$. Therefore equation (4) becomes

$$\frac{1}{1 - \cos(2y)} = 0 + f'(y) \qquad (5)$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{-1 + \cos(2y)}$$

Integrating the above w.r.t y gives

$$\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int \left(-\frac{1}{-1 + \cos(2y)} \right) \mathrm{d}y \\
f(y) &= -\frac{1}{2\tan(y)} + c_1
\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{x} - \frac{1}{2\tan(y)} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{x} - \frac{1}{2\tan(y)}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{10\pi}{3}$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\sqrt{3}}{6} = c_1$$

$$c_1 = -\frac{\sqrt{3}}{6}$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{x} - \frac{1}{2\tan(y)} = -\frac{\sqrt{3}}{6}$$

The above simplifies to

$$\sqrt{3}\, x\tan(y) + 6\tan(y) - 3x = 0$$

But this does not satisfy the initial conditions. Hence no solution can be found.

Verification of solutions N/A

4.28.5 Maple step by step solution

Let's solve

$\left[x^2 y' + \cos(2y) = 1, y(\infty) = \frac{10\pi}{3}\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{-\cos(2y)+1} = \frac{1}{x^2}$

- Integrate both sides with respect to x

  $\int \frac{y'}{-\cos(2y)+1} dx = \int \frac{1}{x^2} dx + c_1$

- Evaluate integral

  $$-\frac{1}{2\tan(y)} = -\frac{1}{x} + c_1$$

- Solve for y

  $$y = -\arctan\left(\frac{x}{2(c_1 x - 1)}\right)$$

- Use initial condition $y(\infty) = \frac{10\pi}{3}$

  $$\frac{10\pi}{3} = -\arctan\left(\frac{\infty}{c_1 \infty - 1}\right)$$

- Solution does not satisfy initial condition

Problem number: 94.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

Unable to solve or complete the solution.

$$\boxed{y'x^3 - \sin(y) = 1}$$

With initial conditions

$$[y(\infty) = 5\pi]$$

4.29.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= \frac{\sin(y)+1}{x^3} \end{aligned}$$

The x domain of $f(x,y)$ when $y=5\pi$ is

$$\{x<0 \lor 0<x\}$$

And the point $x_0=\infty$ is inside this domain. The y domain of $f(x,y)$ when $x=\infty$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=5\pi$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned} \frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{\sin(y)+1}{x^3}\right) \\ &= \frac{\cos(y)}{x^3} \end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=5\pi$ is

$$\{x<0 \lor 0<x\}$$

And the point $x_0=\infty$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x=\infty$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=5\pi$ is inside this domain. Therefore solution exists and is unique.

4.29.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{\sin(y)+1}{x^3} \end{aligned}$$

Where $f(x) = \frac{1}{x^3}$ and $g(y) = \sin(y) + 1$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\sin(y) + 1}\, dy &= \frac{1}{x^3}\, dx \\
\int \frac{1}{\sin(y) + 1}\, dy &= \int \frac{1}{x^3}\, dx \\
-\frac{2}{\tan\left(\frac{y}{2}\right) + 1} &= -\frac{1}{2x^2} + c_1
\end{aligned}
$$

Which results in

$$
y = -2\arctan\left(\frac{2c_1x^2 + 4x^2 - 1}{2c_1x^2 - 1}\right)
$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 5\pi$ in the above solution gives an equation to solve for the constant of integration.

$$
5\pi = -2\arctan\left(\frac{c_1 + 2}{c_1}\right)
$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.29.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{\sin(y) + 1}{x^3} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 120: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= x^3 \\ \eta(x, y) &= 0 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x^3} dx \end{aligned}$$

Which results in

$$S = -\frac{1}{2x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\sin(y) + 1}{x^3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{x^3} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{\sin(y) + 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{\sin(R) + 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{2}{\tan\left(\frac{R}{2}\right)+1} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{2x^2} = -\frac{2}{\tan\left(\frac{y}{2}\right)+1} + c_1$$

Which simplifies to

$$-\frac{1}{2x^2} = -\frac{2}{\tan\left(\frac{y}{2}\right)+1} + c_1$$

Which gives

$$y = -2\arctan\left(\frac{2c_1x^2 - 4x^2 + 1}{2c_1x^2 + 1}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\sin(y)+1}{x^3}$ 	$R = y$ $S = -\frac{1}{2x^2}$	$\frac{dS}{dR} = \frac{1}{\sin(R)+1}$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 5\pi$ in the above solution gives an equation to solve for the constant of integration.

$$5\pi = -2\arctan\left(\frac{-2 + c_1}{c_1}\right)$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.29.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{\sin(y)+1}\right)\mathrm{d}y = \left(\frac{1}{x^3}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x^3}\right)\mathrm{d}x + \left(\frac{1}{\sin(y)+1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{1}{x^3}$$
$$N(x,y) = \frac{1}{\sin(y)+1}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^3}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{\sin(y)+1}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathop{\mathrm{d}x} &= \int M \mathop{\mathrm{d}x} \\
\int \frac{\partial \phi}{\partial x} \mathop{\mathrm{d}x} &= \int -\frac{1}{x^3} \mathop{\mathrm{d}x} \\
\phi &= \frac{1}{2x^2} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{\sin(y)+1}$. Therefore equation (4) becomes

$$
\frac{1}{\sin(y) + 1} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{\sin(y) + 1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \mathop{\mathrm{d}y} &= \int \left(\frac{1}{\sin(y) + 1}\right) \mathop{\mathrm{d}y} \\
f(y) &= -\frac{2}{\tan\left(\frac{y}{2}\right) + 1} + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$
\phi = \frac{1}{2x^2} - \frac{2}{\tan\left(\frac{y}{2}\right) + 1} + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{2x^2} - \frac{2}{\tan\left(\frac{y}{2}\right) + 1}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 5\pi$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{2x^2} - \frac{2}{\tan\left(\frac{y}{2}\right) + 1} = 0$$

The above simplifies to

$$-4x^2 + \tan\left(\frac{y}{2}\right) + 1 = 0$$

But this does not satisfy the initial conditions. Hence no solution can be found.

Verification of solutions N/A

4.29.5 Maple step by step solution

Let's solve

$[y'x^3 - \sin(y) = 1, y(\infty) = 5\pi]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\sin(y)+1} = \frac{1}{x^3}$

- Integrate both sides with respect to x

  $\int \frac{y'}{\sin(y)+1}dx = \int \frac{1}{x^3}dx + c_1$

- Evaluate integral

$$-\frac{2}{\tan\left(\frac{y}{2}\right)+1} = -\frac{1}{2x^2} + c_1$$

- Solve for y

$$y = -2\arctan\left(\frac{2c_1x^2+4x^2-1}{2c_1x^2-1}\right)$$

- Use initial condition $y(\infty) = 5\pi$

$$5\pi = -2\arctan\left(\frac{c_1\infty+\infty}{c_1\infty-1}\right)$$

- Solution does not satisfy initial condition

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 4. Equations with variables separable and equations reducible to them. Exercises page 38
Problem number: 95.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\left(x^2+1\right) y'-\frac{\cos\left(2y\right)^2}{2}=0}$$

With initial conditions

$$\left[y(-\infty)=\frac{7\pi}{2}\right]$$

4.30.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x, y) \\ &= \frac{\cos(2y)^2}{2x^2+2} \end{aligned}$$

The x domain of $f(x, y)$ when $y = \frac{7\pi}{2}$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = -\infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

4.30.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \frac{\cos(2y)^2}{2x^2+2} \end{aligned}$$

Where $f(x) = \frac{1}{2x^2+2}$ and $g(y) = \cos(2y)^2$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\cos(2y)^2}\,dy &= \frac{1}{2x^2+2}\,dx \\ \int \frac{1}{\cos(2y)^2}\,dy &= \int \frac{1}{2x^2+2}\,dx \\ \frac{\tan(2y)}{2} &= \frac{\arctan(x)}{2} + c_1 \end{aligned}$$

Which results in

$$y = \frac{\arctan(\arctan(x) + 2c_1)}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = -\infty$ and $y = \frac{7\pi}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{7\pi}{2} = \frac{\arctan\left(-\frac{\pi}{2} + 2c_1\right)}{2}$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.30.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{\cos(2y)^2}{2x^2+2} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 123: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 2x^2 + 2 \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{2x^2 + 2} dx \end{aligned}$$

Which results in

$$S = \frac{\arctan(x)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\cos(2y)^2}{2x^2 + 2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{2x^2 + 2} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \sec(2y)^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \sec(2R)^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\tan(2R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\arctan(x)}{2} = \frac{\tan(2y)}{2} + c_1$$

Which simplifies to

$$\frac{\arctan(x)}{2} = \frac{\tan(2y)}{2} + c_1$$

Which gives

$$y = -\frac{\arctan(-\arctan(x) + 2c_1)}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\cos(2y)^2}{2x^2+2}$ 	$R = y$ $S = \frac{\arctan(x)}{2}$	$\frac{dS}{dR} = \sec(2R)^2$ 
Initial conditions are used to solve for c_1. Substituting $x = -\infty$ and $y = \frac{7\pi}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{7\pi}{2} = -\frac{\arctan\left(\frac{\pi}{2} + 2c_1\right)}{2}$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.30.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{2}{\cos(2y)^2}\right)\mathrm{d}y = \left(\frac{1}{x^2+1}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x^2+1}\right)\mathrm{d}x + \left(\frac{2}{\cos(2y)^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{1}{x^2+1}$$
$$N(x,y) = \frac{2}{\cos(2y)^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{1}{x^2+1}\right)$$
$$= 0$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\frac{2}{\cos(2y)^2}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\frac{1}{x^2+1} \mathrm{d}x$$
$$\phi = -\arctan(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2}{\cos(2y)^2}$. Therefore equation (4) becomes

$$\frac{2}{\cos(2y)^2} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{2}{\cos(2y)^2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(2\sec(2y)^2\right) \mathrm{d}y$$
$$f(y) = \tan(2y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\arctan(x) + \tan(2y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\arctan(x) + \tan(2y)$$

Initial conditions are used to solve for c_1. Substituting $x = -\infty$ and $y = \frac{7\pi}{2}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{\pi}{2} = c_1$$

$$c_1 = \frac{\pi}{2}$$

Substituting c_1 found above in the general solution gives

$$-\arctan(x) + \tan(2y) = \frac{\pi}{2}$$

Summary

The solution(s) found are the following

$$-\arctan(x) + \tan(2y) = \frac{\pi}{2} \tag{1}$$

Verification of solutions

$$-\arctan(x) + \tan(2y) = \frac{\pi}{2}$$

Verified OK.

4.30.5 Maple step by step solution

Let's solve

$\left[(x^2+1)\, y' - \frac{\cos(2y)^2}{2} = 0, y(-\infty) = \frac{7\pi}{2}\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\cos(2y)^2} = \frac{1}{2(x^2+1)}$

- Integrate both sides with respect to x

  $\int \frac{y'}{\cos(2y)^2} dx = \int \frac{1}{2(x^2+1)} dx + c_1$

- Evaluate integral

  $\frac{\tan(2y)}{2} = \frac{\arctan(x)}{2} + c_1$

- Solve for y

  $y = \frac{\arctan(\arctan(x)+2c_1)}{2}$

- Use initial condition $y(-\infty) = \frac{7\pi}{2}$

  $\frac{7\pi}{2} = \frac{\arctan\left(-\frac{\pi}{2}+2c_1\right)}{2}$

- Solution does not satisfy initial condition

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{(x+1)\,y'-y=-1}$$

4.32.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y-1}{x+1} \end{aligned}$$

Where $f(x) = \frac{1}{x+1}$ and $g(y) = y - 1$. Integrating both sides gives

$$\frac{1}{y-1}\,dy = \frac{1}{x+1}\,dx$$
$$\int \frac{1}{y-1}\,dy = \int \frac{1}{x+1}\,dx$$
$$\ln\left(y-1\right) = \ln\left(x+1\right) + c_1$$

Raising both side to exponential gives

$$y - 1 = \mathrm{e}^{\ln(x+1)+c_1}$$

Which simplifies to

$$y - 1 = (x+1)\,c_2$$

Summary

The solution(s) found are the following

$$y = c_2\mathrm{e}^{\ln(x+1)+c_1} + 1 \tag{1}$$

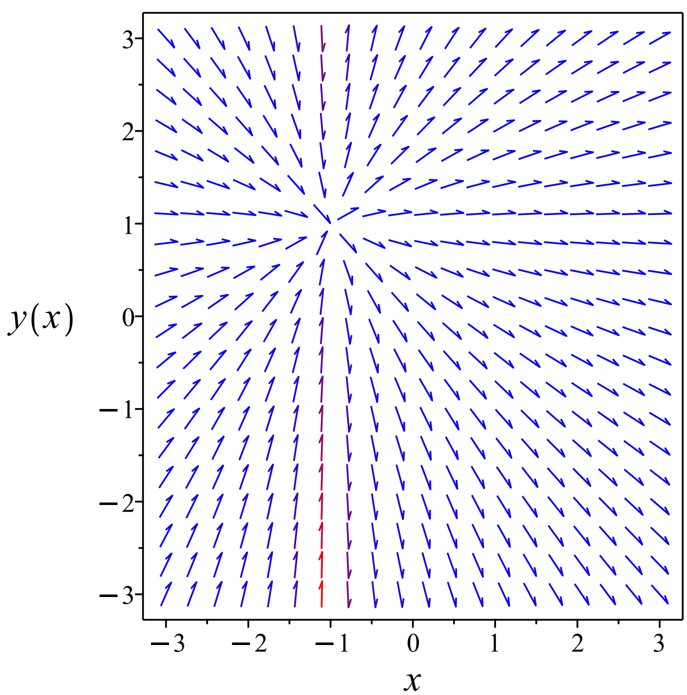

Figure 131: Slope field plot

Verification of solutions

$$y = c_2 e^{\ln(x+1)+c_1} + 1$$

Verified OK.

4.32.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x+1} \\ q(x) &= -\frac{1}{x+1} \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x+1} = -\frac{1}{x+1}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{x+1}dx} \\ &= \frac{1}{x+1} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(-\frac{1}{x+1}\right) \\ \frac{d}{dx}\left(\frac{y}{x+1}\right) &= \left(\frac{1}{x+1}\right)\left(-\frac{1}{x+1}\right) \\ d\left(\frac{y}{x+1}\right) &= \left(-\frac{1}{(x+1)^2}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x+1} &= \int -\frac{1}{(x+1)^2} dx \\ \frac{y}{x+1} &= \frac{1}{x+1} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x+1}$ results in

$$y = 1 + c_1(x + 1)$$

which simplifies to

$$y = c_1x + c_1 + 1$$

Summary

The solution(s) found are the following

$$y = c_1x + c_1 + 1 \tag{1}$$

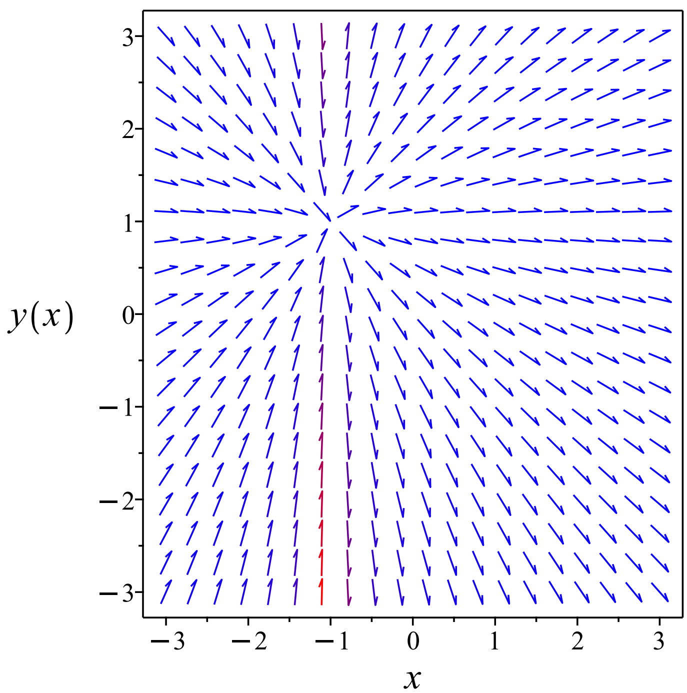

Figure 132: Slope field plot

Verification of solutions

$$y = c_1x + c_1 + 1$$

Verified OK.

4.32.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(x+1)\left(u'(x)\,x+u(x)\right)-u(x)\,x=-1$$

In canonical form the ODE is

$$\begin{aligned}u' &= F(x,u)\\ &= f(x)g(u)\\ &= \frac{-u-1}{x\,(x+1)}\end{aligned}$$

Where $f(x)=\frac{1}{x(x+1)}$ and $g(u)=-u-1$. Integrating both sides gives

$$\begin{aligned}\frac{1}{-u-1}\,du &= \frac{1}{x\,(x+1)}\,dx\\ \int \frac{1}{-u-1}\,du &= \int \frac{1}{x\,(x+1)}\,dx\\ -\ln\left(u+1\right) &= -\ln\left(x+1\right)+\ln\left(x\right)+c_2\end{aligned}$$

Raising both side to exponential gives

$$\frac{1}{u+1}=\mathrm{e}^{-\ln(x+1)+\ln(x)+c_2}$$

Which simplifies to

$$\frac{1}{u+1}=c_3\mathrm{e}^{-\ln(x+1)+\ln(x)}$$

Which simplifies to

$$u(x)=-\frac{\left(\frac{c_3\mathrm{e}^{c_2}x}{x+1}-1\right)(x+1)\,\mathrm{e}^{-c_2}}{c_3x}$$

Therefore the solution y is

$$\begin{aligned}y &= ux\\ &= -\frac{\left(\frac{c_3\mathrm{e}^{c_2}x}{x+1}-1\right)(x+1)\,\mathrm{e}^{-c_2}}{c_3}\end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{\left(\frac{c_3 e^{c_2 x}}{x+1} - 1\right)(x+1)\,e^{-c_2}}{c_3} \tag{1}$$

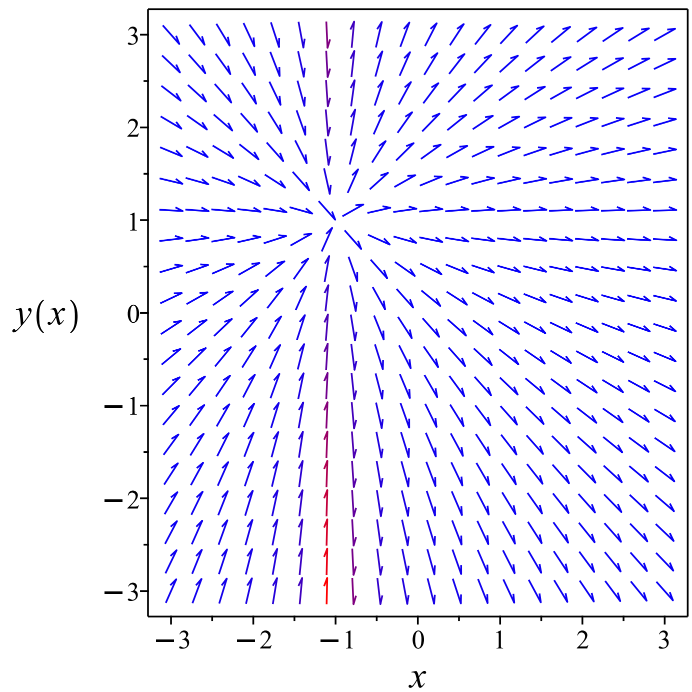

Figure 133: Slope field plot

Verification of solutions

$$y = -\frac{\left(\frac{c_3 e^{c_2 x}}{x+1} - 1\right)(x+1)\,e^{-c_2}}{c_3}$$

Verified OK.

4.32.4 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{Y(X) + y_0 - 1}{X + x_0 + 1}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$
\begin{aligned}
x_0 &= -1 \\
y_0 &= 1
\end{aligned}
$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$
\frac{d}{dX}Y(X) = \frac{Y(X)}{X}
$$

In canonical form, the ODE is

$$
\begin{aligned}
Y' &= F(X,Y) \\
&= \frac{Y}{X}
\end{aligned} \tag{1}
$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$
f(t^n X, t^n Y) = t^n f(X,Y)
$$

In this case, it can be seen that both $M = Y$ and $N = X$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$
\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u
$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$
\begin{aligned}
\frac{\mathrm{d}u}{\mathrm{d}X}X + u &= u \\
\frac{\mathrm{d}u}{\mathrm{d}X} &= 0
\end{aligned}
$$

Or

$$
\frac{d}{dX}u(X) = 0
$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. Integrating both sides gives

$$
\begin{aligned}
u(X) &= \int 0 \,\mathrm{d}X \\
&= c_2
\end{aligned}
$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$Y(X) = Xc_2$$

Using the solution for $Y(X)$

$$Y(X) = Xc_2$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y + 1$$
$$X = x - 1$$

Then the solution in y becomes

$$y - 1 = (x + 1) c_2$$

Summary
The solution(s) found are the following

$$y - 1 = (x + 1) c_2 \tag{1}$$

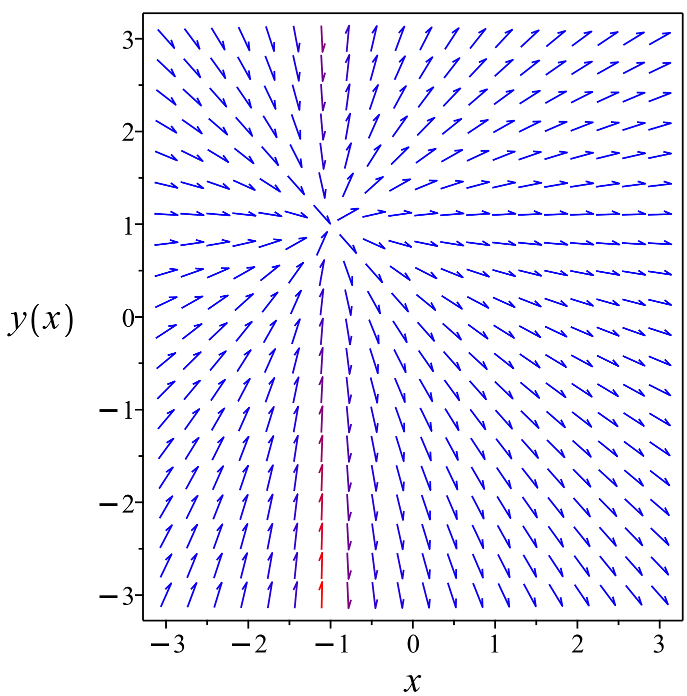

Figure 134: Slope field plot

Verification of solutions

$$
y - 1 = (x + 1) c_2
$$

Verified OK.

4.32.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
y' = \frac{y - 1}{x + 1}
$$
$$
y' = \omega(x, y)
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 127: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= 0 \\ \eta(x, y) &= x + 1 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x+1} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x+1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y-1}{x+1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{(x+1)^2} \\ S_y &= \frac{1}{x+1} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{(x+1)^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{(R+1)^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{1}{R+1} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x+1} = \frac{1}{x+1} + c_1$$

Which simplifies to

$$\frac{y}{x+1} = \frac{1}{x+1} + c_1$$

Which gives

$$y = c_1 x + c_1 + 1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y-1}{x+1}$ 	$R = x$ $S = \frac{y}{x+1}$	$\frac{dS}{dR} = -\frac{1}{(R+1)^2}$ 
Summary

The solution(s) found are the following

$$y = c_1 x + c_1 + 1 \tag{1}$$

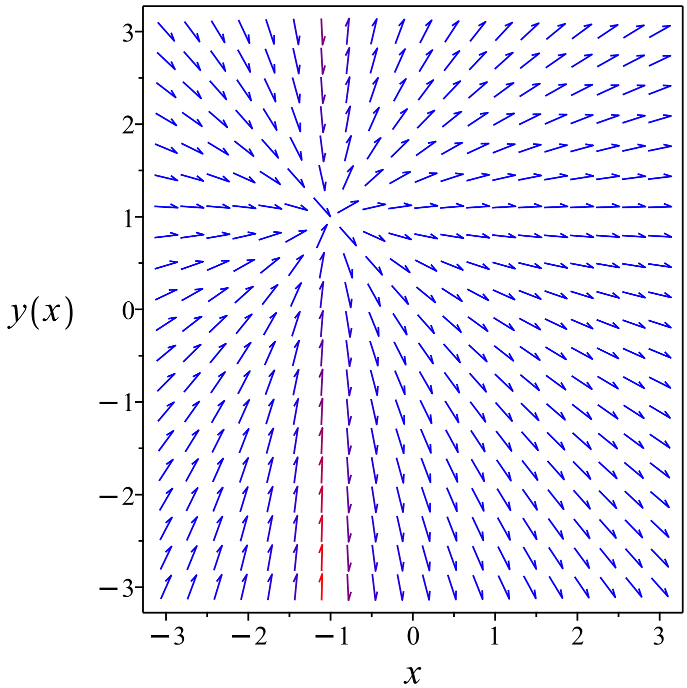

Figure 135: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 x + c_1 + 1$$

Verified OK.

4.32.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y-1}\right)\mathrm{d}y = \left(\frac{1}{x+1}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x+1}\right)\mathrm{d}x + \left(\frac{1}{y-1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{1}{x+1}$$
$$N(x,y) = \frac{1}{y-1}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x+1}\right)\\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y-1}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1)\\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{1}{x+1}\, \mathrm{d}x\\
\phi &= -\ln(x+1) + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y-1}$. Therefore equation (4) becomes

$$
\frac{1}{y-1} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y-1}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\, \mathrm{d}y &= \int \left(\frac{1}{y-1}\right) \mathrm{d}y\\
f(y) &= \ln(y-1) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x+1) + \ln(y-1) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x+1) + \ln(y-1)$$

The solution becomes

$$y = e^{c_1}x + e^{c_1} + 1$$

Summary

The solution(s) found are the following

$$y = e^{c_1}x + e^{c_1} + 1 \tag{1}$$

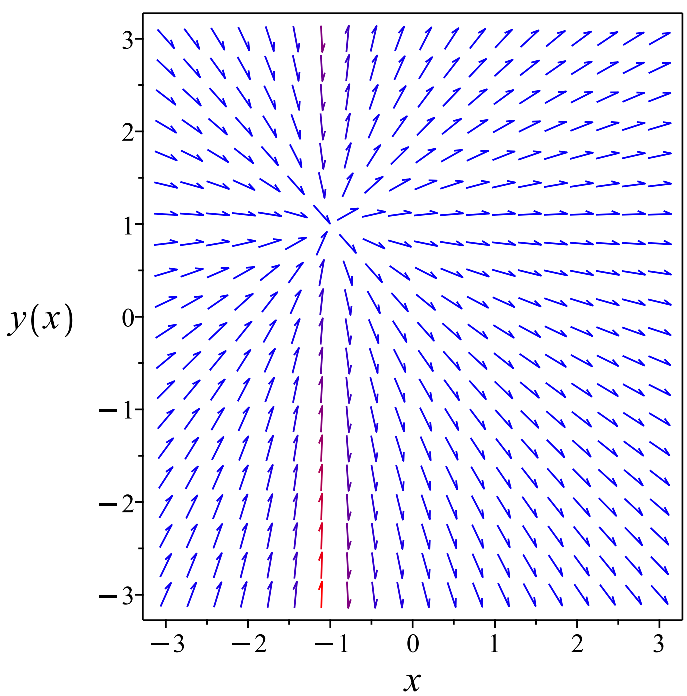

Figure 136: Slope field plot

Verification of solutions

$$y = e^{c_1}x + e^{c_1} + 1$$

Verified OK.

4.32.7 Maple step by step solution

Let's solve

$(x+1)\, y' - y = -1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y-1} = \frac{1}{x+1}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y-1}dx = \int \frac{1}{x+1}dx + c_1$

- Evaluate integral

  $\ln\left(y-1\right) = \ln\left(x+1\right) + c_1$

- Solve for y

  $y = \mathrm{e}^{c_1} x + \mathrm{e}^{c_1} + 1$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2x(\pi + y) = 0}$$

4.33.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= x(2\pi + 2y) \end{aligned}$$

Where $f(x) = x$ and $g(y) = 2\pi + 2y$. Integrating both sides gives

$$\frac{1}{2\pi + 2y}\, dy = x\, dx$$

$$\int \frac{1}{2\pi + 2y}\, dy = \int x\, dx$$

$$\frac{\ln(\pi + y)}{2} = \frac{x^2}{2} + c_1$$

Raising both side to exponential gives

$$\sqrt{\pi + y} = \mathrm{e}^{\frac{x^2}{2} + c_1}$$

Which simplifies to

$$\sqrt{\pi + y} = c_2 \mathrm{e}^{\frac{x^2}{2}}$$

Summary

The solution(s) found are the following

$$y = c_2^2 \mathrm{e}^{x^2 + 2c_1} - \pi \tag{1}$$

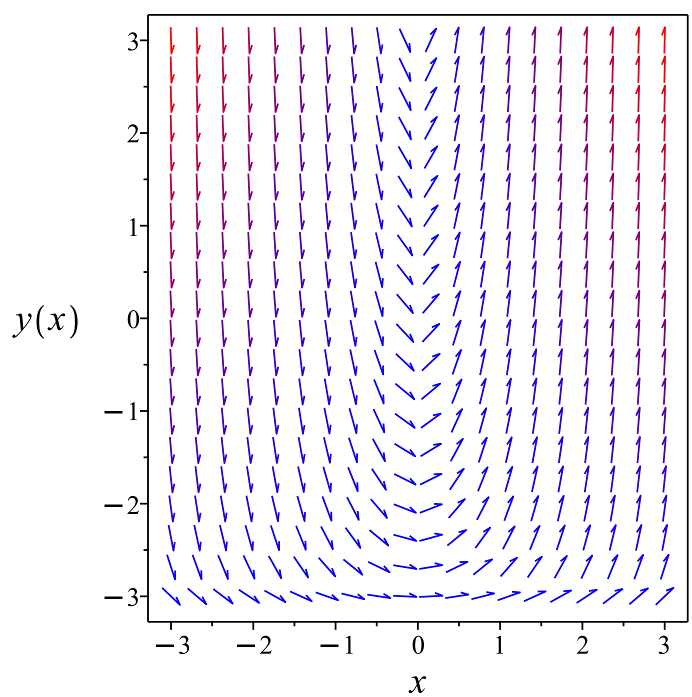

Figure 137: Slope field plot

Verification of solutions

$$y = c_2^2 \mathrm{e}^{x^2 + 2c_1} - \pi$$

Verified OK.

4.33.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -2x\\ q(x) &= 2\pi x\end{aligned}$$

Hence the ode is

$$y' - 2yx = 2\pi x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -2x dx}\\ &= e^{-x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(2\pi x)\\ \frac{d}{dx}\left(e^{-x^2}y\right) &= \left(e^{-x^2}\right)(2\pi x)\\ d\left(e^{-x^2}y\right) &= \left(2\pi x\, e^{-x^2}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-x^2}y &= \int 2\pi x\, e^{-x^2}\, dx\\ e^{-x^2}y &= -\pi\, e^{-x^2} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x^2}$ results in

$$y = -e^{x^2}\pi\, e^{-x^2} + c_1 e^{x^2}$$

which simplifies to

$$y = -\pi + c_1 e^{x^2}$$

Summary

The solution(s) found are the following

$$y = -\pi + c_1 e^{x^2} \tag{1}$$

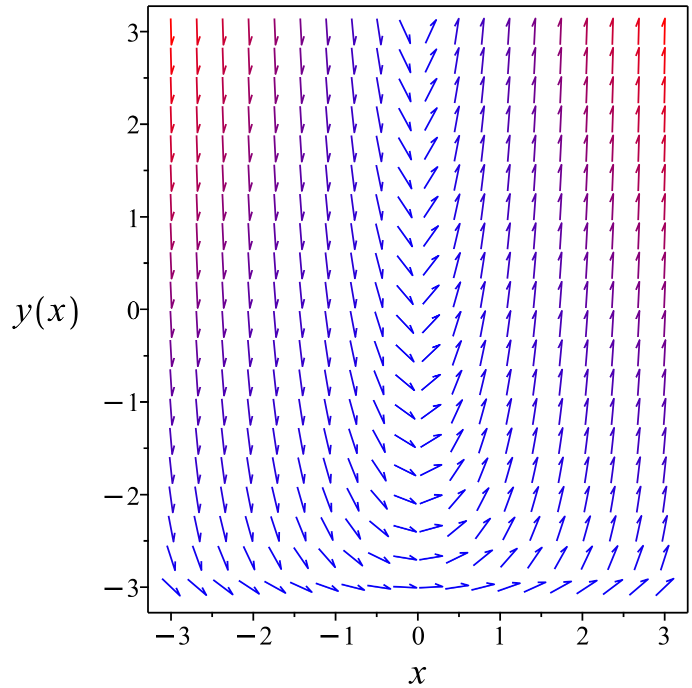

Figure 138: Slope field plot

Verification of solutions

$$y = -\pi + c_1 e^{x^2}$$

Verified OK.

4.33.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = 2x(\pi + y)$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \qquad \text{(A)}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 130: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^{x^2}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{x^2}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{-x^2} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = 2x(\pi + y)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -2x\,\mathrm{e}^{-x^2} y \\ S_y &= \mathrm{e}^{-x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2\pi x\,\mathrm{e}^{-x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2\pi R\,\mathrm{e}^{-R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\pi \,\mathrm{e}^{-R^2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-x^2} y = -\pi \,\mathrm{e}^{-x^2} + c_1$$

Which simplifies to

$$(\pi + y)\,\mathrm{e}^{-x^2} - c_1 = 0$$

Which gives

$$y = -\left(\pi \,\mathrm{e}^{-x^2} - c_1\right) \mathrm{e}^{x^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2x(\pi + y)$ 	$R = x$ $S = \mathrm{e}^{-x^2} y$	$\frac{dS}{dR} = 2\pi R \,\mathrm{e}^{-R^2}$ 
Summary

The solution(s) found are the following

$$y = -\left(\pi \,\mathrm{e}^{-x^2} - c_1\right) \mathrm{e}^{x^2} \tag{1}$$

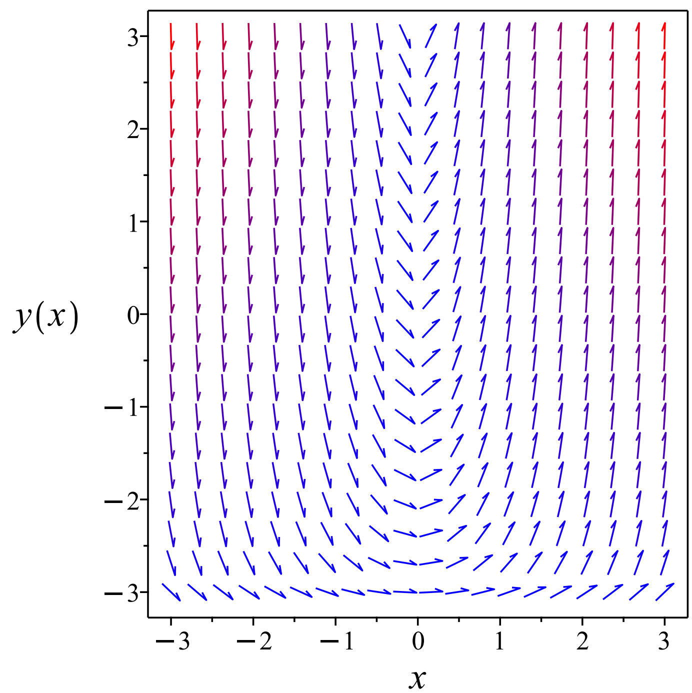

Figure 139: Slope field plot

Verification of solutions

$$y = -\left(\pi\, e^{-x^2} - c_1\right) e^{x^2}$$

Verified OK.

4.33.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{2\pi + 2y}\right) \mathrm{d}y &= (x)\, \mathrm{d}x \\
(-x)\, \mathrm{d}x + \left(\frac{1}{2\pi + 2y}\right) \mathrm{d}y &= 0
\end{aligned} \tag{2A}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -x \\
N(x, y) &= \frac{1}{2\pi + 2y}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x) \\
&= 0
\end{aligned}
$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2\pi + 2y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -x\,\mathrm{d}x\\ \phi &= -\frac{x^2}{2} + f(y) \end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2\pi + 2y}$. Therefore equation (4) becomes

$$\frac{1}{2\pi + 2y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{2\pi + 2y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{2\pi + 2y}\right) \mathrm{d}y$$
$$f(y) = \frac{\ln(\pi + y)}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} + \frac{\ln(\pi + y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} + \frac{\ln(\pi + y)}{2}$$

The solution becomes

$$y = \mathrm{e}^{x^2+2c_1} - \pi$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x^2+2c_1} - \pi \tag{1}$$

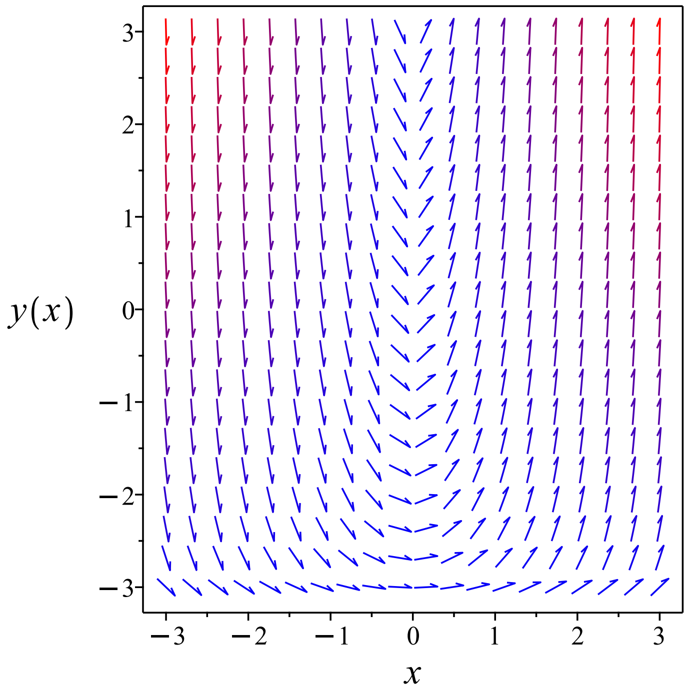

Figure 140: Slope field plot

<u>Verification of solutions</u>

$$y = e^{x^2+2c_1} - \pi$$

Verified OK.

4.33.5 Maple step by step solution

Let's solve

$y' - 2x(\pi + y) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\pi+y} = 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{\pi+y} dx = \int 2x dx + c_1$

- Evaluate integral

$$\ln(\pi + y) = x^2 + c_1$$

- Solve for y

$$y = e^{x^2+c_1} - \pi$$

4.34 problem 99

Internal problem ID [15006]
Internal file name [`OUTPUT/15006_Friday_April_19_2024_04_43_48_AM_20355238/index.tex`]

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 4. Equations with variables separable and equations reducible to them. Exercises page 38
Problem number: 99.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

Unable to solve or complete the solution.

$$\boxed{x^2y' + \sin(2y) = 1}$$

With initial conditions

$$\left[y(\infty) = \frac{11\pi}{4}\right]$$

4.34.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned}y' &= f(x,y)\\ &= -\frac{\sin(2y)-1}{x^2}\end{aligned}$$

The x domain of $f(x,y)$ when $y=\frac{11\pi}{4}$ is

$$\{x<0\lor 0<x\}$$

And the point $x_0=\infty$ is inside this domain. The y domain of $f(x,y)$ when $x=\infty$ is

$$\{-\infty<y<\infty\}$$

And the point $y_0=\frac{11\pi}{4}$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\sin(2y)-1}{x^2}\right)\\ &= -\frac{2\cos(2y)}{x^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y=\frac{11\pi}{4}$ is

$$\{-\infty<x<\infty\}$$

But the point $x_0=\infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. Solution exists but no guarantee that unique solution exists.

4.34.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}y' &= F(x,y)\\ &= f(x)g(y)\\ &= \frac{-\sin(2y)+1}{x^2}\end{aligned}$$

Where $f(x) = \frac{1}{x^2}$ and $g(y) = -\sin(2y) + 1$. Integrating both sides gives

$$\frac{1}{-\sin(2y) + 1} dy = \frac{1}{x^2} dx$$

$$\int \frac{1}{-\sin(2y) + 1} dy = \int \frac{1}{x^2} dx$$

$$-\frac{1}{\tan(y) - 1} = -\frac{1}{x} + c_1$$

Which results in

$$y = \arctan\left(\frac{c_1 x - x - 1}{c_1 x - 1}\right)$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{11\pi}{4}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{11\pi}{4} = \arctan\left(\frac{-1 + c_1}{c_1}\right)$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.34.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{\sin(2y) - 1}{x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 133: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= x^2 \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x^2} dx \end{aligned}$$

Which results in

$$S = -\frac{1}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{\sin(2y) - 1}{x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{x^2} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{\sin(2y) - 1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{\sin(2R) - 1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{\tan(R) - 1} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{x} = -\frac{1}{\tan(y) - 1} + c_1$$

Which simplifies to

$$-\frac{1}{x} = -\frac{1}{\tan(y) - 1} + c_1$$

Which gives

$$y = \arctan\left(\frac{c_1 x + x + 1}{c_1 x + 1}\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{\sin(2y)-1}{x^2}$ 	$R = y$ $S = -\frac{1}{x}$	$\frac{dS}{dR} = -\frac{1}{\sin(2R)-1}$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{11\pi}{4}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{11\pi}{4} = \arctan\left(\frac{1+c_1}{c_1}\right)$$

Warning: Unable to solve for c_1. No particular solution can be found using given initial conditions for this solution. removing this solution as not valid.

Verification of solutions N/A

4.34.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{-\sin(2y)+1}\right)\mathrm{d}y = \left(\frac{1}{x^2}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x^2}\right)\mathrm{d}x + \left(\frac{1}{-\sin(2y)+1}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -\frac{1}{x^2}$$
$$N(x,y) = \frac{1}{-\sin(2y)+1}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{-\sin(2y)+1}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\frac{1}{x^2} \, \mathrm{d}x$$
$$\phi = \frac{1}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{-\sin(2y)+1}$. Therefore equation (4) becomes

$$\frac{1}{-\sin(2y) + 1} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{\sin(2y) - 1}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(-\frac{1}{\sin(2y) - 1}\right) \mathrm{d}y$$
$$f(y) = -\frac{1}{\tan(y) - 1} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{x} - \frac{1}{\tan(y) - 1} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{x} - \frac{1}{\tan(y) - 1}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = \frac{11\pi}{4}$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} = c_1$$

$$c_1 = \frac{1}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{1}{x} - \frac{1}{\tan(y) - 1} = \frac{1}{2}$$

The above simplifies to

$$-\tan(y)\, x + 2\tan(y) - x - 2 = 0$$

But this does not satisfy the initial conditions. Hence no solution can be found.

Verification of solutions N/A

4.34.5 Maple step by step solution

Let's solve

$\left[x^2 y' + \sin(2y) = 1, y(\infty) = \frac{11\pi}{4}\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{-\sin(2y)+1} = \frac{1}{x^2}$

- Integrate both sides with respect to x

  $\int \frac{y'}{-\sin(2y)+1} dx = \int \frac{1}{x^2} dx + c_1$

- Evaluate integral

$-\frac{1}{\tan(y)-1} = -\frac{1}{x} + c_1$

- Solve for y

  $y = \arctan\left(\frac{c_1 x - x - 1}{c_1 x - 1}\right)$

- Use initial condition $y(\infty) = \frac{11\pi}{4}$

  $\frac{11\pi}{4} = \arctan\left(\frac{c_1\infty + -\infty}{c_1\infty - 1}\right)$

- Solution does not satisfy initial condition

The type(s) of ODE detected by this program : **"homogeneousTypeD", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _dAlembert]
```

$$\boxed{y'x - y - x\cos\left(\frac{y}{x}\right)^2 = 0}$$

5.1.1 Solving as homogeneousTypeD ode

Writing the ode as

$$y' = \cos\left(\frac{y}{x}\right)^2 + \frac{y}{x} \tag{A}$$

The given ode has the form

$$y' = \frac{y}{x} + g(x)\, f\left(b\frac{y}{x}\right)^{\frac{n}{m}} \tag{1}$$

Where b is scalar and $g(x)$ is function of x and n, m are integers. The solution is given in Kamke page 20. Using the substitution $y(x) = u(x)\, x$ then

$$\frac{dy}{dx} = \frac{du}{dx}x + u$$

Hence the given ode becomes

$$
\begin{aligned}
\frac{du}{dx}x + u &= u + g(x)\, f(bu)^{\frac{n}{m}} \\
u' &= \frac{1}{x} g(x)\, f(bu)^{\frac{n}{m}} \qquad (2)
\end{aligned}
$$

The above ode is always separable. This is easily solved for u assuming the integration can be resolved, and then the solution to the original ode becomes $y = ux$. Comapring the given ode (A) with the form (1) shows that

$$
\begin{aligned}
g(x) &= 1 \\
b &= 1 \\
f\left(\frac{bx}{y}\right) &= \cos\left(\frac{y}{x}\right)
\end{aligned}
$$

Substituting the above in (2) results in the $u(x)$ ode as

$$
u'(x) = \frac{\cos(u(x))^2}{x}
$$

Which is now solved as separable In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= \frac{\cos(u)^2}{x}
\end{aligned}
$$

Where $f(x) = \frac{1}{x}$ and $g(u) = \cos(u)^2$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\cos(u)^2}\, du &= \frac{1}{x}\, dx \\
\int \frac{1}{\cos(u)^2}\, du &= \int \frac{1}{x}\, dx \\
\tan(u) &= \ln(x) + c_1
\end{aligned}
$$

The solution is

$$
\tan(u(x)) - \ln(x) - c_1 = 0
$$

Therefore the solution is found using $y = ux$. Hence

$$
\tan\left(\frac{y}{x}\right) - \ln(x) - c_1 = 0
$$

Summary
The solution(s) found are the following

$$\tan\left(\frac{y}{x}\right)-\ln(x)-c_1=0 \tag{1}$$

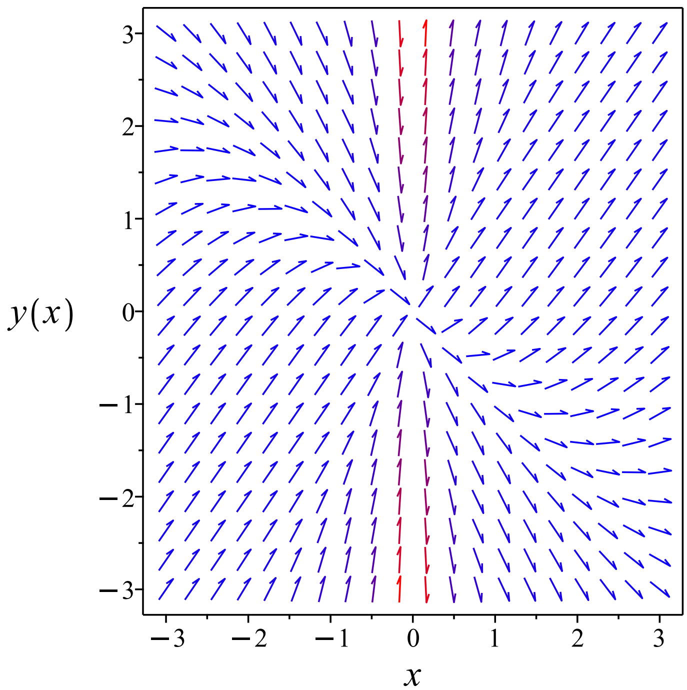

Figure 141: Slope field plot

Verification of solutions

$$\tan\left(\frac{y}{x}\right)-\ln(x)-c_1=0$$

Verified OK.

5.1.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x+u(x))\,x-u(x)\,x-x\cos(u(x))^2=0$$

In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\&=f(x)g(u)\\&=\frac{\cos(u)^2}{x}\end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = \cos(u)^2$. Integrating both sides gives

$$\frac{1}{\cos(u)^2}\,du = \frac{1}{x}\,dx$$

$$\int \frac{1}{\cos(u)^2}\,du = \int \frac{1}{x}\,dx$$

$$\tan(u) = \ln(x) + c_2$$

The solution is

$$\tan(u(x)) - \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\tan\left(\frac{y}{x}\right) - \ln(x) - c_2 = 0$$

$$\tan\left(\frac{y}{x}\right) - \ln(x) - c_2 = 0$$

Summary

The solution(s) found are the following

$$\tan\left(\frac{y}{x}\right) - \ln(x) - c_2 = 0 \tag{1}$$

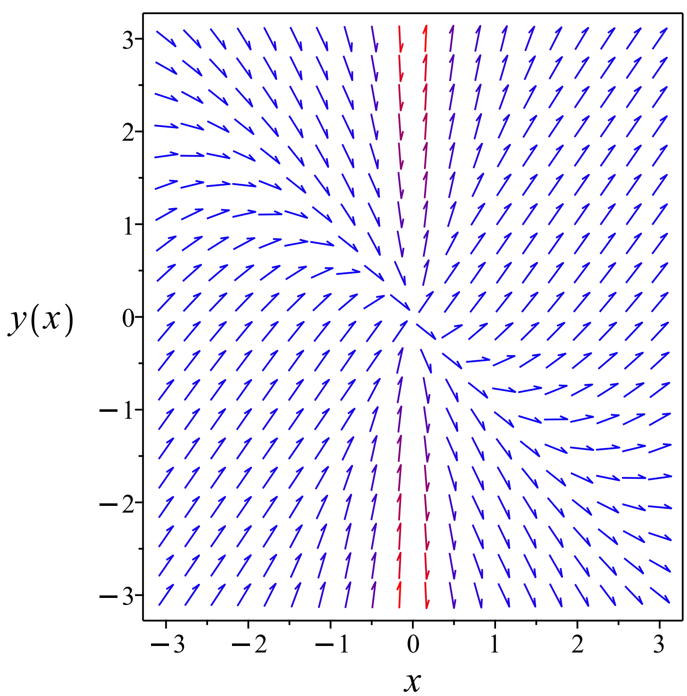

Figure 142: Slope field plot

Verification of solutions

$$\tan\left(\frac{y}{x}\right)-\ln\left(x\right)-c_2=0$$

Verified OK.

5.1.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y+x\cos\left(\frac{y}{x}\right)^2}{x}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is known. It is of type `homogeneous Type D`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 136: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= x^2 \\
\eta(x,y) &= xy
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Therefore

$$\begin{aligned}\frac{dy}{dx} &= \frac{\eta}{\xi} \\ &= \frac{xy}{x^2} \\ &= \frac{y}{x}\end{aligned}$$

This is easily solved to give

$$y = c_1 x$$

Where now the coordinate R is taken as the constant of integration. Hence

$$R = \frac{y}{x}$$

And S is found from

$$\begin{aligned}dS &= \frac{dx}{\xi} \\ &= \frac{dx}{x^2}\end{aligned}$$

Integrating gives

$$\begin{aligned}S &= \int \frac{dx}{T} \\ &= -\frac{1}{x}\end{aligned}$$

Where the constant of integration is set to zero as we just need one solution. Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y + x\cos\left(\frac{y}{x}\right)^2}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= -\frac{y}{x^2} \\ R_y &= \frac{1}{x} \\ S_x &= \frac{1}{x^2} \\ S_y &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\sec\left(\frac{y}{x}\right)^2}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\sec(R)^2 S(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 e^{-\tan(R)} \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{x} = c_1 e^{-\tan\left(\frac{y}{x}\right)}$$

Which simplifies to

$$-\frac{1}{x} = c_1 e^{-\tan\left(\frac{y}{x}\right)}$$

Which gives

$$y = -\arctan\left(\ln\left(-\frac{1}{c_1 x}\right)\right) x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y+x\cos\left(\frac{y}{x}\right)^2}{x}$ 	$R = \frac{y}{x}$ $S = -\frac{1}{x}$	$\frac{dS}{dR} = -\sec(R)^2 S(R)$ 
Summary

The solution(s) found are the following

$$y = -\arctan\left(\ln\left(-\frac{1}{c_1 x}\right)\right) x \tag{1}$$

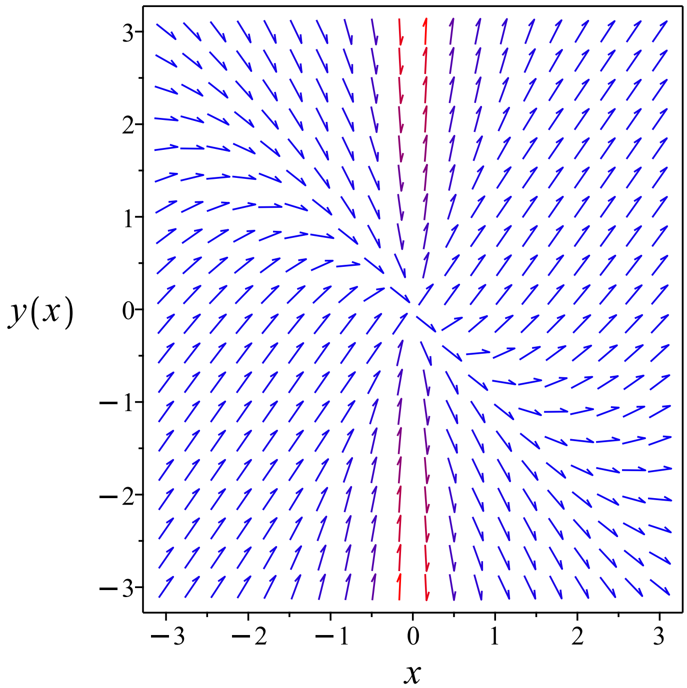

Figure 143: Slope field plot

Verification of solutions

$$y = -\arctan\left(\ln\left(-\frac{1}{c_1 x}\right)\right) x$$

Verified OK.

Section: Section 5. Homogeneous equations. Exercises page 44
Problem number: 101.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y'x - y = -x}$$

5.2.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = -1$$

Hence the ode is

$$y' - \frac{y}{x} = -1$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(-1)$$
$$\frac{d}{dx}\left(\frac{y}{x}\right) = \left(\frac{1}{x}\right)(-1)$$
$$d\left(\frac{y}{x}\right) = \left(-\frac{1}{x}\right) dx$$

Integrating gives

$$\frac{y}{x} = \int -\frac{1}{x} dx$$
$$\frac{y}{x} = -\ln(x) + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -x\ln(x) + c_1 x$$

which simplifies to

$$y = x(-\ln(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = x(-\ln(x) + c_1) \tag{1}$$

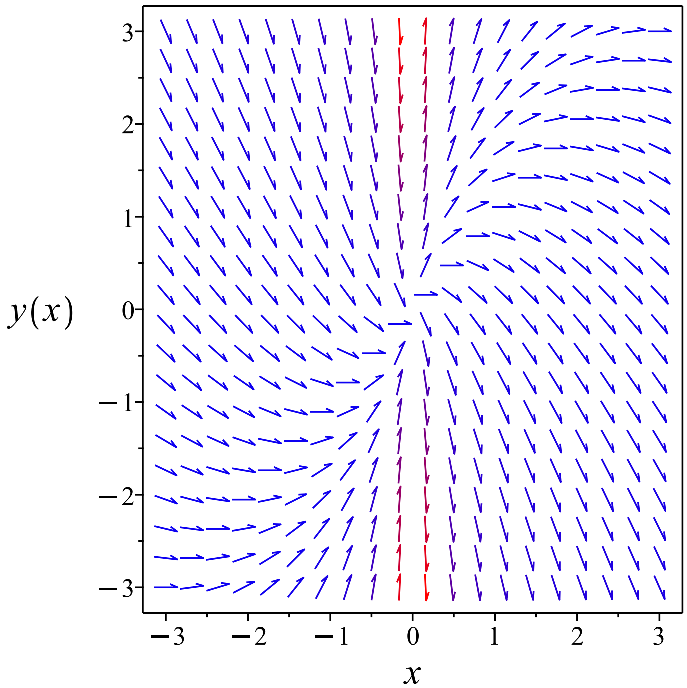

Figure 144: Slope field plot

Verification of solutions

$$y = x(-\ln(x) + c_1)$$

Verified OK.

5.2.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x + u(x))\,x - u(x)\,x = -x$$

Integrating both sides gives

$$\begin{aligned} u(x) &= \int -\frac{1}{x}\,\mathrm{d}x \\ &= -\ln(x) + c_2 \end{aligned}$$

Therefore the solution y is

$$\begin{aligned} y &= ux \\ &= x(-\ln(x) + c_2) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x(-\ln(x) + c_2) \tag{1}$$

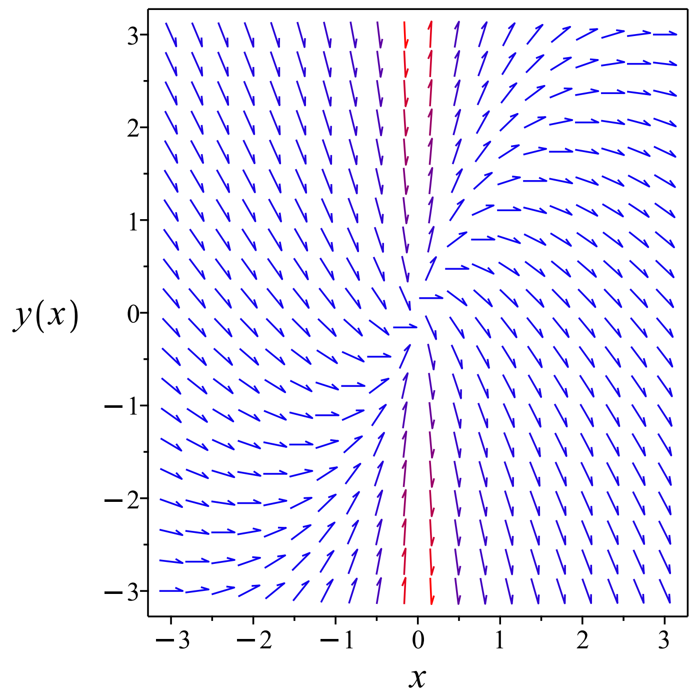

Figure 145: Slope field plot

Verification of solutions

$$y = x(-\ln(x) + c_2)$$

Verified OK.

5.2.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y - x}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 138: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= x
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y - x}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{x^2} \\ S_y &= \frac{1}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x} = -\ln(x) + c_1$$

Which simplifies to

$$\frac{y}{x} = -\ln(x) + c_1$$

Which gives

$$y = -x(\ln(x) - c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y-x}{x}$ 	$R = x$ $S = \frac{y}{x}$	$\frac{dS}{dR} = -\frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = -x(\ln(x) - c_1) \tag{1}$$

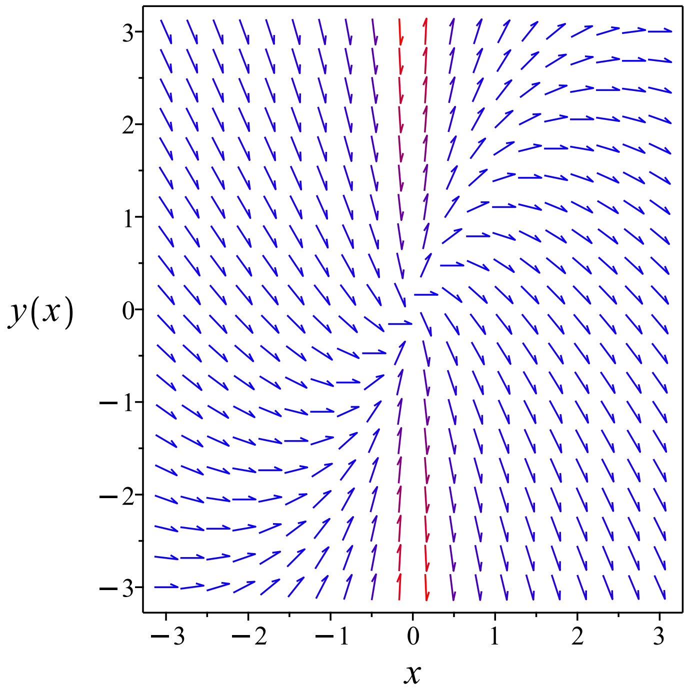

Figure 146: Slope field plot

Verification of solutions

$$y = -x(\ln(x) - c_1)$$

Verified OK.

5.2.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x)\,\mathrm{d}y = (y - x)\,\mathrm{d}x$$
$$(-y + x)\,\mathrm{d}x + (x)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -y + x$$
$$N(x,y) = x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y + x)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{x}((-1) - (1)) \\ &= -\frac{2}{x} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\frac{2}{x} \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(x)} \\ &= \frac{1}{x^2} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{x^2}(-y + x) \\ &= \frac{-y + x}{x^2} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{x^2}(x) \\ &= \frac{1}{x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{-y + x}{x^2}\right) + \left(\frac{1}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{-y+x}{x^2} \mathrm{d}x$$

$$\phi = \frac{y}{x} + \ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{1}{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{x}$. Therefore equation (4) becomes

$$\frac{1}{x} = \frac{1}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{y}{x} + \ln(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{y}{x} + \ln(x)$$

The solution becomes

$$y = -x(\ln(x) - c_1)$$

Summary

The solution(s) found are the following

$$y = -x(\ln(x) - c_1) \tag{1}$$

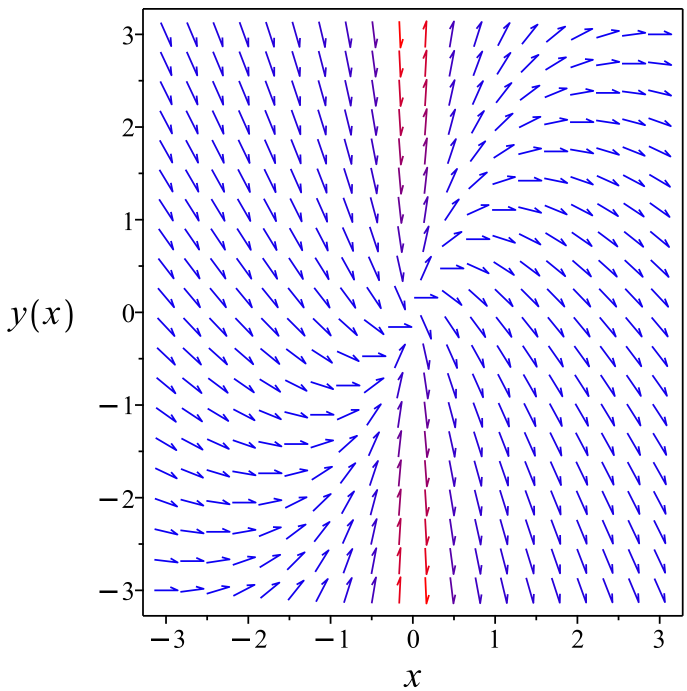

Figure 147: Slope field plot

Verification of solutions

$$y = -x(\ln(x) - c_1)$$

Verified OK.

5.2.5 Maple step by step solution

Let's solve

$y'x - y = -x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y}{x} - 1$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{x} = -1$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = -\mu(x)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int -\mu(x)\,dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int -\mu(x)\,dx + c_1$

- Solve for y

  $y = \frac{\int -\mu(x)dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{x}$

  $y = x\left(\int -\frac{1}{x}dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = x(-\ln(x) + c_1)$

The type(s) of ODE detected by this program : **"exactByInspection", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _dAlembert]
```

$$\boxed{y'x - y(\ln(y) - \ln(x)) = 0}$$

5.3.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{y(\ln(y) - \ln(x))}{x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 &+ \frac{y(\ln(y)-\ln(x))(b_3-a_2)}{x} - \frac{y^2(\ln(y)-\ln(x))^2 a_3}{x^2} \\ &- \left(-\frac{y}{x^2} - \frac{y(\ln(y)-\ln(x))}{x^2}\right)(xa_2+ya_3+a_1) \\ &- \left(\frac{\ln(y)-\ln(x)}{x} + \frac{1}{x}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{\ln(x)^2 y^2 a_3 - 2\ln(x)\ln(y)y^2a_3 + \ln(y)^2 y^2 a_3 - \ln(x)x^2b_2 + \ln(x)y^2a_3 + \ln(y)x^2b_2 - \ln(y)y^2a_3 - \ln}{x^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} &-\ln(x)^2 y^2 a_3 + 2\ln(x)\ln(y)y^2a_3 - \ln(y)^2y^2a_3 + \ln(x)x^2b_2 \\ &- \ln(x)y^2a_3 - \ln(y)x^2b_2 + \ln(y)y^2a_3 + \ln(x)xb_1 - \ln(x)ya_1 \\ &- \ln(y)xb_1 + \ln(y)ya_1 + xya_2 - xyb_3 + y^2a_3 - xb_1 + ya_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, \ln(x), \ln(y)\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, \ln(x) = v_3, \ln(y) = v_4\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &-v_3^2v_2^2a_3 + 2v_3v_4v_2^2a_3 - v_4^2v_2^2a_3 - v_3v_2^2a_3 + v_4v_2^2a_3 + v_3v_1^2b_2 - v_4v_1^2b_2 - v_3v_2a_1 \\ &+ v_4v_2a_1 + v_1v_2a_2 + v_2^2a_3 + v_3v_1b_1 - v_4v_1b_1 - v_1v_2b_3 + v_2a_1 - v_1b_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$v_3 v_1^2 b_2 - v_4 v_1^2 b_2 + (-b_3 + a_2) v_1 v_2 + v_3 v_1 b_1 - v_4 v_1 b_1 - v_1 b_1 - v_3^2 v_2^2 a_3 + 2 v_3 v_4 v_2^2 a_3 - v_3 v_2^2 a_3 - v_4^2 v_2^2 a_3 + v_4 v_2^2 a_3 + v_2^2 a_3 - v_3 v_2 a_1 + v_4 v_2 a_1 + v_2 a_1 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_1 &= 0 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ -a_1 &= 0 \\ -a_3 &= 0 \\ 2a_3 &= 0 \\ -b_1 &= 0 \\ -b_2 &= 0 \\ -b_3 + a_2 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{y(\ln(y) - \ln(x))}{x}\right)(x) \\
&= y - \ln(y)\,y + y\ln(x) \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{y - \ln(y)\,y + y\ln(x)} dy
\end{aligned}
$$

Which results in

$$
S = -\ln(1 - \ln(y) + \ln(x))
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{y(\ln(y) - \ln(x))}{x}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{1}{x\left(1-\ln\left(y\right)+\ln\left(x\right)\right)} \\
S_y &= \frac{1}{y\left(1-\ln\left(y\right)+\ln\left(x\right)\right)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{1}{x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{1}{R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\ln\left(R\right)+c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\ln\left(1-\ln\left(y\right)+\ln\left(x\right)\right) = -\ln\left(x\right)+c_1
$$

Which simplifies to

$$
-\ln\left(1-\ln\left(y\right)+\ln\left(x\right)\right) = -\ln\left(x\right)+c_1
$$

Which gives

$$
y = e^{\left(\ln(x)e^{c_1}+e^{c_1}-x\right)e^{-c_1}}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y(\ln(y)-\ln(x))}{x}$ 	$R = x$ $S = -\ln(1 - \ln(y) + \ln($	$\frac{dS}{dR} = -\frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{(\ln(x)\mathrm{e}^{c_1}+\mathrm{e}^{c_1}-x)\mathrm{e}^{-c_1}} \tag{1}$$

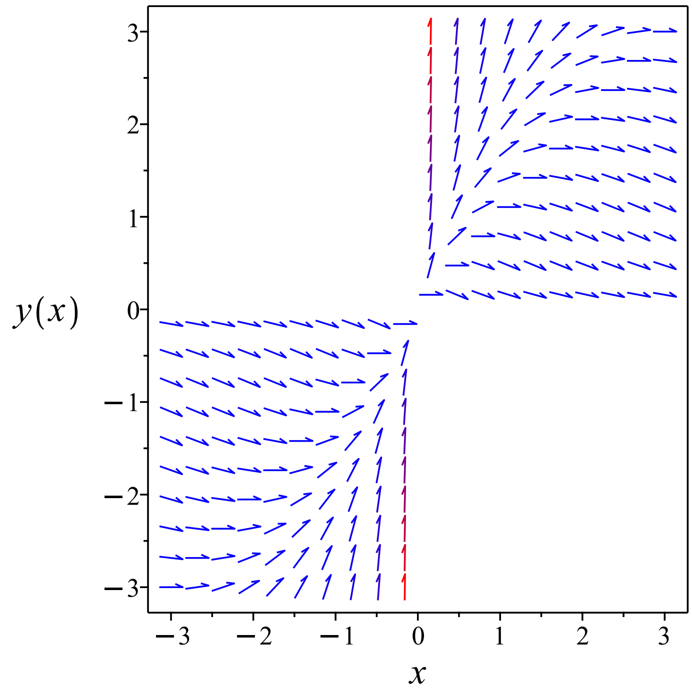

Figure 148: Slope field plot

Verification of solutions

$$y = e^{(\ln(x)e^{c_1}+e^{c_1}-x)e^{-c_1}}$$

Verified OK.

5.3.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(x)\, \mathrm{d}y &= (y(\ln(y) - \ln(x)))\, \mathrm{d}x \\
(-y(\ln(y) - \ln(x)))\, \mathrm{d}x + (x)\, \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -y(\ln(y) - \ln(x)) \\
N(x, y) &= x
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y(\ln(y) - \ln(x))) \\
&= -1 + \ln(x) - \ln(y)
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x) \\
&= 1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. By inspection $\frac{1}{x^2 y}$ is an integrating factor. Therefore by multiplying $M = -y(\ln(y) - \ln(x))$ and $N = x$ by this integrating factor the ode becomes exact. The new M, N are

$$
\begin{aligned}
M &= -\frac{\ln(y) - \ln(x)}{x^2} \\
N &= \frac{1}{yx}
\end{aligned}
$$

To solve an ode of the form

$$
M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}
$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x, y) = 0
$$

Hence

$$
\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}
$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$\left(\frac{1}{xy}\right) \mathrm{d}y = \left(\frac{\ln(y) - \ln(x)}{x^2}\right) \mathrm{d}x$$

$$\left(-\frac{\ln(y) - \ln(x)}{x^2}\right) \mathrm{d}x + \left(\frac{1}{xy}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{\ln(y) - \ln(x)}{x^2}$$
$$N(x, y) = \frac{1}{xy}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{\ln(y) - \ln(x)}{x^2}\right) = -\frac{1}{x^2 y}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\frac{1}{xy}\right) = -\frac{1}{x^2 y}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\frac{\ln(y) - \ln(x)}{x^2} \mathrm{d}x$$
$$\phi = \frac{-1 + \ln(y) - \ln(x)}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{1}{xy} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{xy}$. Therefore equation (4) becomes

$$\frac{1}{xy} = \frac{1}{xy} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{-1 + \ln(y) - \ln(x)}{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{-1 + \ln(y) - \ln(x)}{x}$$

The solution becomes

$$y = e^{c_1 x + 1} x$$

Summary

The solution(s) found are the following

$$y = e^{c_1 x + 1} x \tag{1}$$

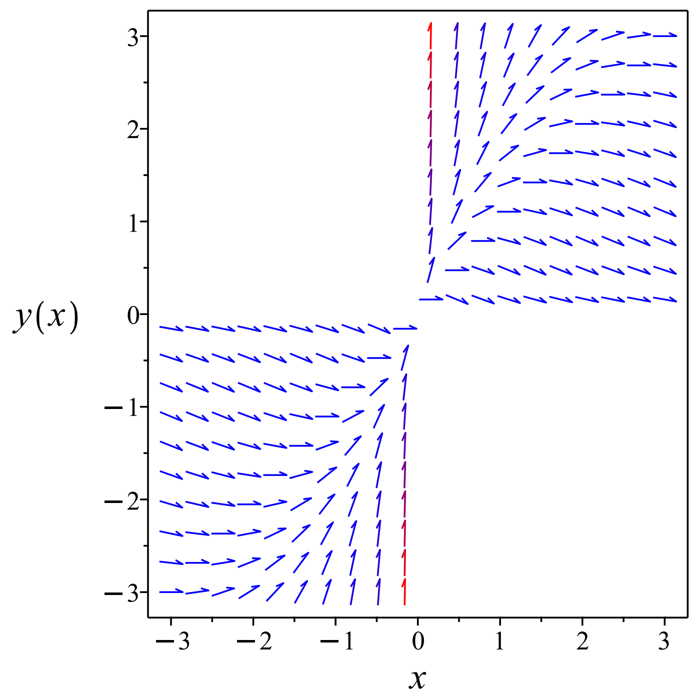

Figure 149: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{c_1 x+1} x$$

Verified OK.

Problem number: 103.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Riccati]
```

$$\boxed{x^2y' - y^2 + yx = x^2}$$

5.4.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$x^2(u'(x)\,x + u(x)) - u(x)^2\,x^2 + u(x)\,x^2 = x^2$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u^2 - 2u + 1}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u^2 - 2u + 1$. Integrating both sides gives

$$\frac{1}{u^2 - 2u + 1} \, du = \frac{1}{x} \, dx$$
$$\int \frac{1}{u^2 - 2u + 1} \, du = \int \frac{1}{x} \, dx$$
$$-\frac{1}{u - 1} = \ln(x) + c_2$$

The solution is

$$-\frac{1}{u(x) - 1} - \ln(x) - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$-\frac{1}{\frac{y}{x} - 1} - \ln(x) - c_2 = 0$$
$$\frac{(\ln(x) + c_2) y - x(c_2 + \ln(x) - 1)}{-y + x} = 0$$

Summary

The solution(s) found are the following

$$\frac{(\ln(x) + c_2) y - x(c_2 + \ln(x) - 1)}{-y + x} = 0 \tag{1}$$

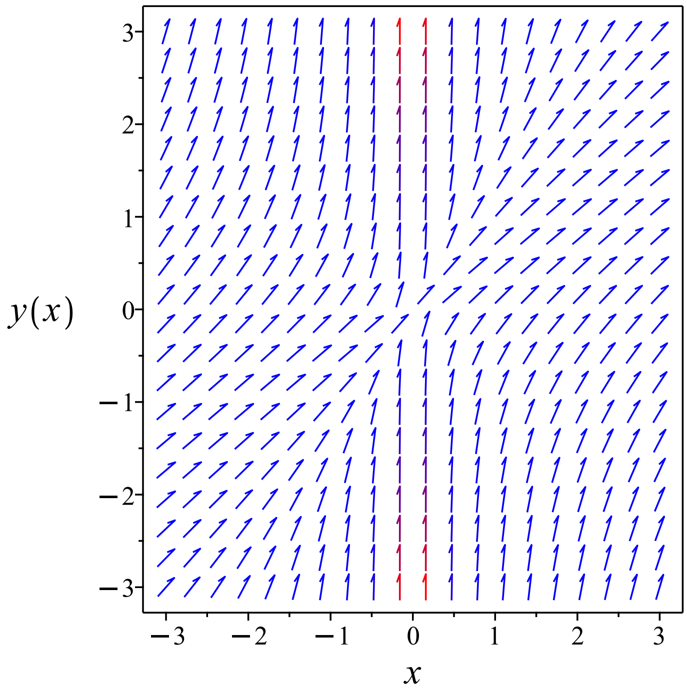

Figure 150: Slope field plot

Verification of solutions

$$\frac{(\ln(x)+c_2)\,y-x(c_2+\ln(x)-1)}{-y+x}=0$$

Verified OK.

5.4.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{x^2-xy+y^2}{x^2}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2+\frac{(x^2-xy+y^2)\,(b_3-a_2)}{x^2}-\frac{(x^2-xy+y^2)^2\,a_3}{x^4}-\left(\frac{2x-y}{x^2}-\frac{2(x^2-xy+y^2)}{x^3}\right)(xa_2+ya_3+a_1)-\frac{(-x+2y)\,(xb_2+yb_3+b_1)}{x^2}=0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^4a_2+x^4a_3-2b_2x^4-x^4b_3-2x^3ya_3+2x^3yb_2-x^2y^2a_2+4x^2y^2a_3+x^2y^2b_3-4x\,y^3a_3+y^4a_3-x^3b_1+}{x^4}$$
$$=0$$

Setting the numerator to zero gives

$$-x^4a_2-x^4a_3+2b_2x^4+x^4b_3+2x^3ya_3-2x^3yb_2+x^2y^2a_2-4x^2y^2a_3-x^2y^2b_3+4x\,y^3a_3-y^4a_3+x^3b_1-x^2ya_1-2x^2yb_1+2x\,y^2a_1=0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_2v_1^4+a_2v_1^2v_2^2-a_3v_1^4+2a_3v_1^3v_2-4a_3v_1^2v_2^2+4a_3v_1v_2^3-a_3v_2^4+2b_2v_1^4-2b_2v_1^3v_2+b_3v_1^4-b_3v_1^2v_2^2-a_1v_1^2v_2+2a_1v_1v_2^2+b_1v_1^3-2b_1v_1^2v_2=0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(-a_2 - a_3 + 2b_2 + b_3) v_1^4 + (2a_3 - 2b_2) v_1^3 v_2 + b_1 v_1^3 + (a_2 - 4a_3 - b_3) v_1^2 v_2^2 + (-a_1 - 2b_1) v_1^2 v_2 + 4a_3 v_1 v_2^3 + 2a_1 v_1 v_2^2 - a_3 v_2^4 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
b_1 &= 0 \\
2a_1 &= 0 \\
-a_3 &= 0 \\
4a_3 &= 0 \\
-a_1 - 2b_1 &= 0 \\
2a_3 - 2b_2 &= 0 \\
a_2 - 4a_3 - b_3 &= 0 \\
-a_2 - a_3 + 2b_2 + b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi \\ &= y - \left(\frac{x^2 - xy + y^2}{x^2}\right)(x) \\ &= \frac{-x^2 + 2xy - y^2}{x} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-x^2+2xy-y^2}{x}} dy\end{aligned}$$

Which results in

$$S = \frac{x}{y - x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2 - xy + y^2}{x^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{y}{(-y+x)^2} \\
S_y &= -\frac{x}{(-y+x)^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{1}{x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{1}{R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\ln(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{x}{y-x} = -\ln(x) + c_1
$$

Which simplifies to

$$
\frac{x}{y-x} = -\ln(x) + c_1
$$

Which gives

$$
y = \frac{x(\ln(x) - c_1 - 1)}{\ln(x) - c_1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2-xy+y^2}{x^2}$ 	$R = x$ $S = \frac{x}{y-x}$	$\frac{dS}{dR} = -\frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = \frac{x(\ln(x) - c_1 - 1)}{\ln(x) - c_1} \tag{1}$$

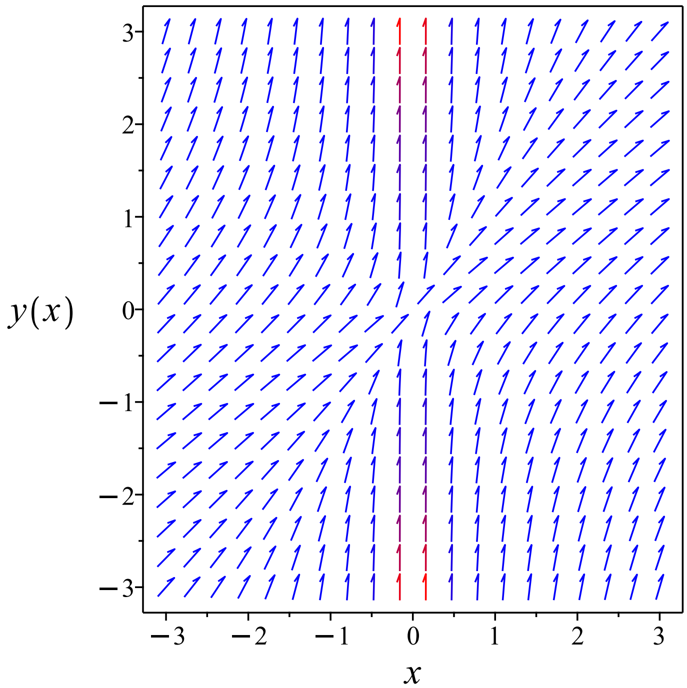

Figure 151: Slope field plot

Verification of solutions

$$y = \frac{x(\ln(x) - c_1 - 1)}{\ln(x) - c_1}$$

Verified OK.

5.4.3 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 - xy + y^2}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 1 - \frac{y}{x} + \frac{y^2}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 1$, $f_1(x) = -\frac{1}{x}$ and $f_2(x) = \frac{1}{x^2}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{u}{x^2}} \qquad (1)
\end{aligned}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \qquad (2)
$$

But

$$
\begin{aligned}
f_2' &= -\frac{2}{x^3} \\
f_1 f_2 &= -\frac{1}{x^3} \\
f_2^2 f_0 &= \frac{1}{x^4}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{u''(x)}{x^2} + \frac{3u'(x)}{x^3} + \frac{u(x)}{x^4} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = \frac{c_1 + \ln(x) c_2}{x}
$$

The above shows that

$$
u'(x) = \frac{c_2 - c_1 - \ln(x) c_2}{x^2}
$$

Using the above in (1) gives the solution

$$
y = -\frac{x(c_2 - c_1 - \ln(x) c_2)}{c_1 + \ln(x) c_2}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$
y = \frac{x(-1 + c_3 + \ln(x))}{c_3 + \ln(x)}
$$

Summary
The solution(s) found are the following

$$y = \frac{x(-1 + c_3 + \ln(x))}{c_3 + \ln(x)} \tag{1}$$

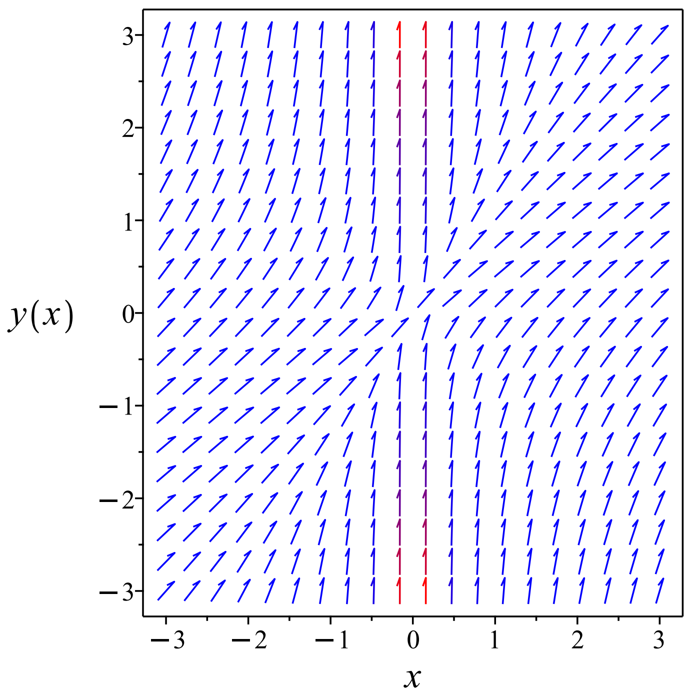

Figure 152: Slope field plot

Verification of solutions

$$y = \frac{x(-1 + c_3 + \ln(x))}{c_3 + \ln(x)}$$

Verified OK.

Problem number: 104.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _dAlembert]
```

$$\boxed{y'x - y - \sqrt{y^2 - x^2} = 0}$$

5.5.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{y + \sqrt{-x^2 + y^2}}{x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{\left(y+\sqrt{-x^2+y^2}\right)(b_3-a_2)}{x} - \frac{\left(y+\sqrt{-x^2+y^2}\right)^2 a_3}{x^2} \\ & - \left(-\frac{1}{\sqrt{-x^2+y^2}} - \frac{y+\sqrt{-x^2+y^2}}{x^2}\right)(x a_2 + y a_3 + a_1) \\ & - \frac{\left(1+\frac{y}{\sqrt{-x^2+y^2}}\right)(x b_2 + y b_3 + b_1)}{x} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{(-x^2+y^2)^{\frac{3}{2}} a_3 - x^3 a_2 + x^3 b_3 - 2x^2 y a_3 + x^2 y b_2 + y^3 a_3 + \sqrt{-x^2+y^2}\, x b_1 - \sqrt{-x^2+y^2}\, y a_1 + x y b_1 - y^2}{\sqrt{-x^2+y^2}\, x^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} & -\left(-x^2+y^2\right)^{\frac{3}{2}} a_3 + x^3 a_2 - x^3 b_3 + 2x^2 y a_3 - x^2 y b_2 - y^3 a_3 \\ & - \sqrt{-x^2+y^2}\, x b_1 + \sqrt{-x^2+y^2}\, y a_1 - x y b_1 + y^2 a_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} & -\left(-x^2+y^2\right)^{\frac{3}{2}} a_3 + \left(-x^2+y^2\right) x b_3 - \left(-x^2+y^2\right) y a_3 + x^3 a_2 + x^2 y a_3 - x^2 y b_2 \\ & - x\, y^2 b_3 + \left(-x^2+y^2\right) a_1 - \sqrt{-x^2+y^2}\, x b_1 + \sqrt{-x^2+y^2}\, y a_1 + x^2 a_1 - x y b_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned} & x^3 a_2 - x^3 b_3 + x^2 \sqrt{-x^2+y^2}\, a_3 + 2x^2 y a_3 - x^2 y b_2 - \sqrt{-x^2+y^2}\, y^2 a_3 \\ & - y^3 a_3 - \sqrt{-x^2+y^2}\, x b_1 - x y b_1 + \sqrt{-x^2+y^2}\, y a_1 + y^2 a_1 = 0 \end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{-x^2+y^2}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{-x^2 + y^2} = v_3\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned} v_1^3 a_2 + 2v_1^2 v_2 a_3 + v_1^2 v_3 a_3 - v_2^3 a_3 - v_3 v_2^2 a_3 - v_1^2 v_2 b_2 \\ - v_1^3 b_3 + v_2^2 a_1 + v_3 v_2 a_1 - v_1 v_2 b_1 - v_3 v_1 b_1 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$\begin{aligned} (-b_3 + a_2) v_1^3 + (2a_3 - b_2) v_1^2 v_2 + v_1^2 v_3 a_3 - v_1 v_2 b_1 \\ - v_3 v_1 b_1 - v_2^3 a_3 - v_3 v_2^2 a_3 + v_2^2 a_1 + v_3 v_2 a_1 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_1 &= 0 \\ a_3 &= 0 \\ -a_3 &= 0 \\ -b_1 &= 0 \\ 2a_3 - b_2 &= 0 \\ -b_3 + a_2 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{y + \sqrt{-x^2 + y^2}}{x}\right)(x) \\
&= -\sqrt{-x^2 + y^2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{-\sqrt{-x^2 + y^2}} dy
\end{aligned}
$$

Which results in

$$
S = -\ln\left(y + \sqrt{-x^2 + y^2}\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y+\sqrt{-x^2+y^2}}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{x}{\sqrt{-x^2+y^2}\,\left(y+\sqrt{-x^2+y^2}\right)} \\
S_y &= -\frac{1}{\sqrt{-x^2+y^2}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{2x^2-2y^2-2\sqrt{-x^2+y^2}\,y}{x\sqrt{-x^2+y^2}\,\left(y+\sqrt{-x^2+y^2}\right)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{2}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -2\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln\left(y+\sqrt{y^2-x^2}\right) = -2\ln(x) + c_1$$

Which simplifies to

$$-\ln\left(y+\sqrt{y^2-x^2}\right) = -2\ln(x) + c_1$$

Which gives

$$y = \frac{\left(e^{2c_1}+x^2\right)e^{-c_1}}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Riccati]
```

$$\boxed{2x^2y' - y^2 = x^2}$$

5.6.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$2x^2(u'(x)\,x + u(x)) - u(x)^2\,x^2 = x^2$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{\frac{1}{2}u^2 - u + \frac{1}{2}}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = \frac{1}{2}u^2 - u + \frac{1}{2}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{1}{2}u^2 - u + \frac{1}{2}}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{\frac{1}{2}u^2 - u + \frac{1}{2}}\,du &= \int \frac{1}{x}\,dx \\
-\frac{2}{u-1} &= \ln(x) + c_2
\end{aligned}
$$

The solution is

$$
-\frac{2}{u(x)-1} - \ln(x) - c_2 = 0
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
-\frac{2}{\frac{y}{x}-1} - \ln(x) - c_2 &= 0 \\
\frac{(\ln(x) + c_2)\,y - x(c_2 + \ln(x) - 2)}{-y + x} &= 0
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\frac{(\ln(x) + c_2)\,y - x(c_2 + \ln(x) - 2)}{-y + x} = 0 \tag{1}
$$

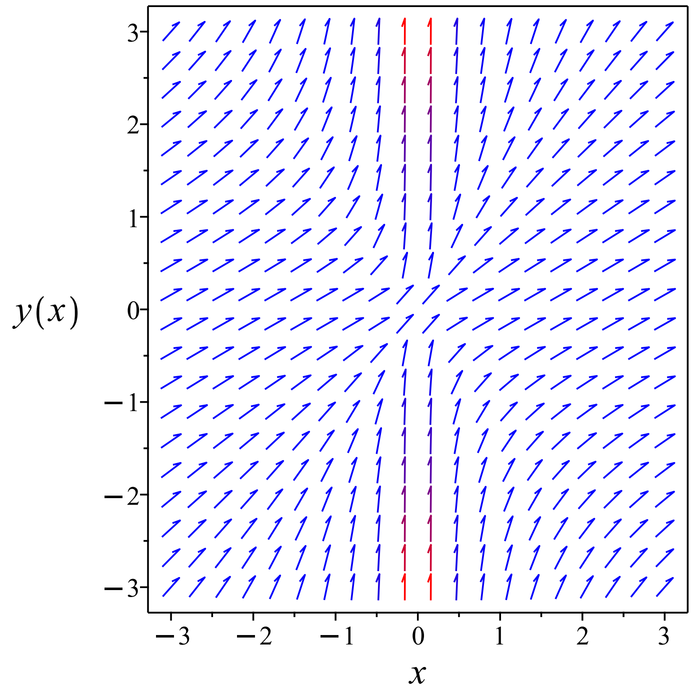

Figure 154: Slope field plot

Verification of solutions

$$
\frac{(\ln (x)+c_2)\, y-x(c_2+\ln (x)-2)}{-y+x}=0
$$

Verified OK.

5.6.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{x^2+y^2}{2x^2} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = xa_2+ya_3+a_1 \tag{1E}
$$

$$
\eta = xb_2+yb_3+b_1 \tag{2E}
$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{(x^2+y^2)(b_3-a_2)}{2x^2} - \frac{(x^2+y^2)^2 a_3}{4x^4} - \left(\frac{1}{x} - \frac{x^2+y^2}{x^3}\right)(xa_2 + ya_3 + a_1) - \frac{y(xb_2 + yb_3 + b_1)}{x^2} = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{2x^4a_2 + x^4a_3 - 4b_2x^4 - 2x^4b_3 + 4x^3yb_2 - 2x^2y^2a_2 + 2x^2y^2a_3 + 2x^2y^2b_3 - 4x\,y^3a_3 + y^4a_3 + 4x^2yb_1 - 4x}{4x^4} = 0$$

Setting the numerator to zero gives

$$-2x^4a_2 - x^4a_3 + 4b_2x^4 + 2x^4b_3 - 4x^3yb_2 + 2x^2y^2a_2 - 2x^2y^2a_3 - 2x^2y^2b_3 + 4x\,y^3a_3 - y^4a_3 - 4x^2yb_1 + 4x\,y^2a_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-2a_2v_1^4 + 2a_2v_1^2v_2^2 - a_3v_1^4 - 2a_3v_1^2v_2^2 + 4a_3v_1v_2^3 - a_3v_2^4 + 4b_2v_1^4 - 4b_2v_1^3v_2 + 2b_3v_1^4 - 2b_3v_1^2v_2^2 + 4a_1v_1v_2^2 - 4b_1v_1^2v_2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&(-2a_2 - a_3 + 4b_2 + 2b_3)\, v_1^4 - 4b_2 v_1^3 v_2 + (2a_2 - 2a_3 - 2b_3)\, v_1^2 v_2^2 \\
&- 4b_1 v_1^2 v_2 + 4a_3 v_1 v_2^3 + 4a_1 v_1 v_2^2 - a_3 v_2^4 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
4a_1 &= 0 \\
-a_3 &= 0 \\
4a_3 &= 0 \\
-4b_1 &= 0 \\
-4b_2 &= 0 \\
2a_2 - 2a_3 - 2b_3 &= 0 \\
-2a_2 - a_3 + 4b_2 + 2b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y - \left(\frac{x^2 + y^2}{2x^2}\right)(x) \\
&= \frac{-x^2 + 2xy - y^2}{2x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{-x^2+2xy-y^2}{2x}} dy \end{aligned}$$

Which results in

$$S = \frac{2x}{y-x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2+y^2}{2x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{2y}{(-y+x)^2} \\ S_y &= -\frac{2x}{(-y+x)^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{2x}{-y + x} = -\ln(x) + c_1$$

Which simplifies to

$$-\frac{2x}{-y + x} = -\ln(x) + c_1$$

Which gives

$$y = \frac{x(\ln(x) - c_1 - 2)}{\ln(x) - c_1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2+y^2}{2x^2}$ 	$R = x$ $S = -\frac{2x}{-y+x}$	$\frac{dS}{dR} = -\frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = \frac{x(\ln(x) - c_1 - 2)}{\ln(x) - c_1} \quad (1)$$

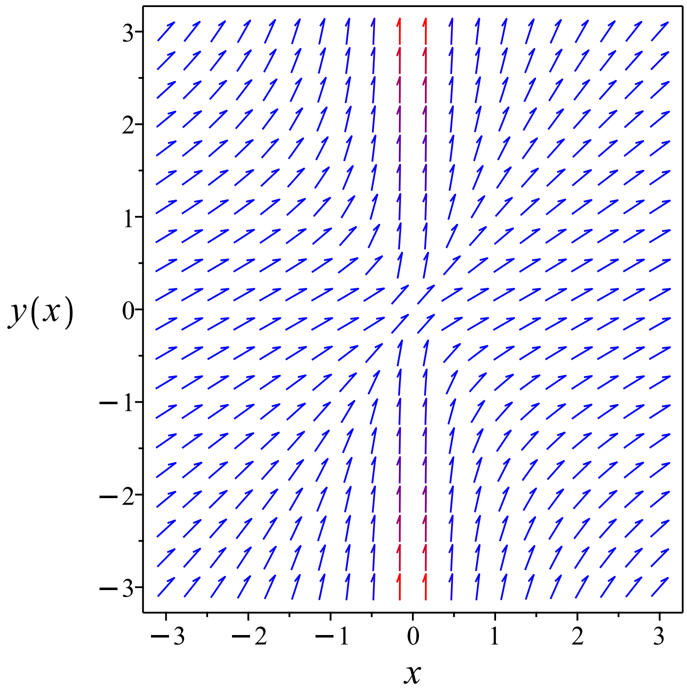

Figure 155: Slope field plot

Verification of solutions

$$y = \frac{x(\ln(x) - c_1 - 2)}{\ln(x) - c_1}$$

Verified OK.

5.6.3 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 + y^2}{2x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{1}{2} + \frac{y^2}{2x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{1}{2}$, $f_1(x) = 0$ and $f_2(x) = \frac{1}{2x^2}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{u}{2x^2}}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= -\frac{1}{x^3} \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= \frac{1}{8x^4}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{u''(x)}{2x^2} + \frac{u'(x)}{x^3} + \frac{u(x)}{8x^4} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = \frac{c_1 + \ln(x) c_2}{\sqrt{x}}
$$

The above shows that

$$
u'(x) = -\frac{\ln(x) c_2 + c_1 - 2c_2}{2x^{\frac{3}{2}}}
$$

Using the above in (1) gives the solution

$$
y = \frac{(\ln(x) c_2 + c_1 - 2c_2) x}{c_1 + \ln(x) c_2}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$
y = \frac{(\ln(x) + c_3 - 2) x}{c_3 + \ln(x)}
$$

Summary
The solution(s) found are the following

$$y = \frac{(\ln (x) + c_3 - 2) x}{c_3 + \ln (x)} \tag{1}$$

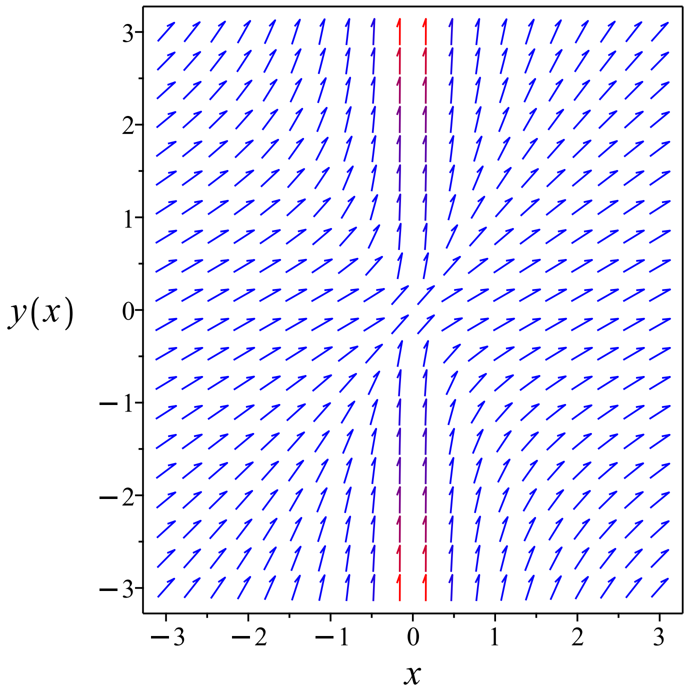

Figure 156: Slope field plot

Verification of solutions

$$y = \frac{(\ln (x) + c_3 - 2) x}{c_3 + \ln (x)}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 5. Homogeneous equations. Exercises page 44
Problem number: 106.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{-3y + (2y - 3x)\, y' = -4x}$$

5.7.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$-3u(x)\, x + (2u(x)\, x - 3x)\, (u'(x)\, x + u(x)) = -4x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2(u^2 - 3u + 2)}{x\,(2u - 3)} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = \frac{u^2-3u+2}{2u-3}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-3u+2}{2u-3}}\, du = -\frac{2}{x}\, dx$$
$$\int \frac{1}{\frac{u^2-3u+2}{2u-3}}\, du = \int -\frac{2}{x}\, dx$$
$$\ln\left(u^2-3u+2\right) = -2\ln(x) + c_2$$

Raising both side to exponential gives

$$u^2-3u+2 = \mathrm{e}^{-2\ln(x)+c_2}$$

Which simplifies to

$$u^2-3u+2 = \frac{c_3}{x^2}$$

Which simplifies to

$$u(x)^2-3u(x)+2 = \frac{c_3\mathrm{e}^{c_2}}{x^2}$$

The solution is

$$u(x)^2-3u(x)+2 = \frac{c_3\mathrm{e}^{c_2}}{x^2}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y^2}{x^2}-\frac{3y}{x}+2 = \frac{c_3\mathrm{e}^{c_2}}{x^2}$$
$$\frac{y^2}{x^2}-\frac{3y}{x}+2 = \frac{c_3\mathrm{e}^{c_2}}{x^2}$$

Which simplifies to

$$(2x-y)(-y+x) = c_3\mathrm{e}^{c_2}$$

Summary

The solution(s) found are the following

$$(2x-y)(-y+x) = c_3\mathrm{e}^{c_2} \tag{1}$$

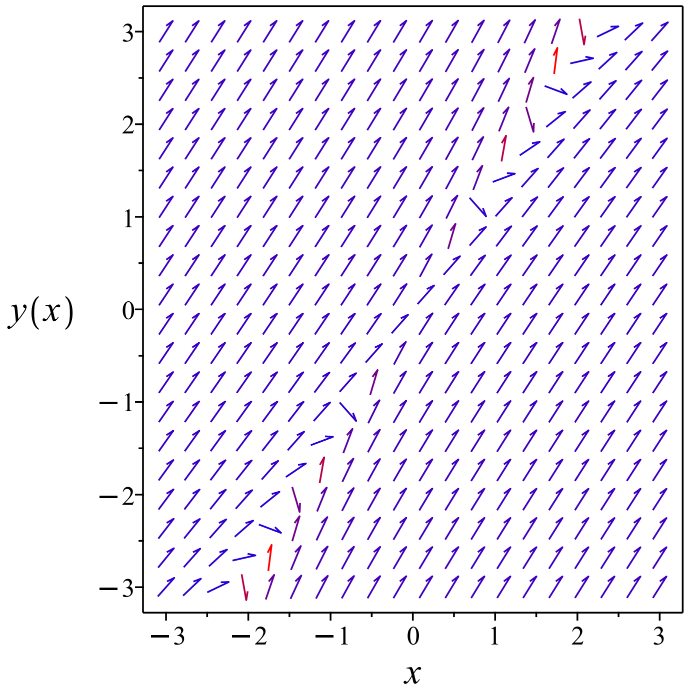

Figure 157: Slope field plot

<u>Verification of solutions</u>

$$(2x - y)(-y + x) = c_3 e^{c_2}$$

Verified OK.

5.7.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-4x + 3y}{2y - 3x} \tag{1}$$

Which becomes

$$(-2y)\, dy = (-3x)\, dy + (4x - 3y)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-3x)\, dy + (4x - 3y)\, dx = d\left(2x^2 - 3xy\right)$$

Hence (2) becomes

$$(-2y)\, dy = d\left(2x^2 - 3xy\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{3x}{2} + \frac{\sqrt{x^2 - 4c_1}}{2} + c_1$$
$$y = \frac{3x}{2} - \frac{\sqrt{x^2 - 4c_1}}{2} + c_1$$

Summary
The solution(s) found are the following

$$y = \frac{3x}{2} + \frac{\sqrt{x^2 - 4c_1}}{2} + c_1 \tag{1}$$
$$y = \frac{3x}{2} - \frac{\sqrt{x^2 - 4c_1}}{2} + c_1 \tag{2}$$

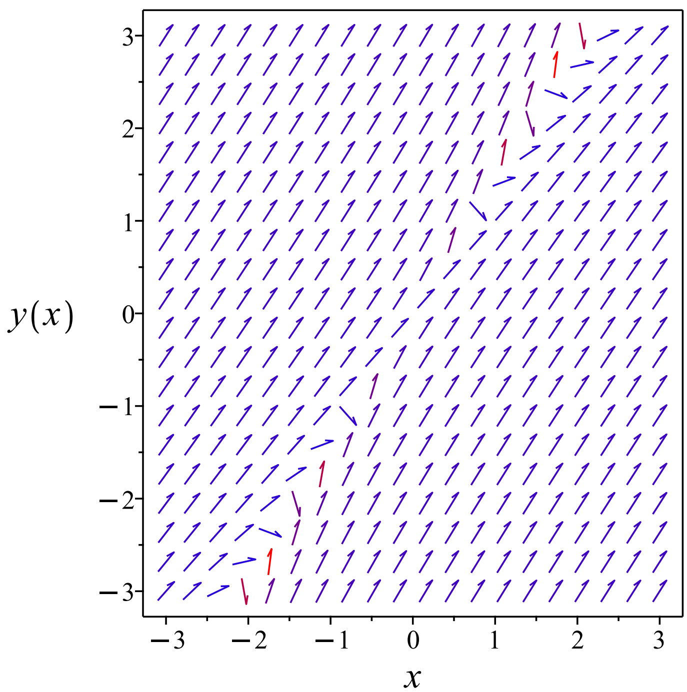

Figure 158: Slope field plot

Verification of solutions

$$y = \frac{3x}{2} + \frac{\sqrt{x^2 - 4c_1}}{2} + c_1$$

Verified OK.

$$y = \frac{3x}{2} - \frac{\sqrt{x^2 - 4c_1}}{2} + c_1$$

Verified OK.

5.7.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{-4x + 3y}{2y - 3x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{(-4x + 3y)(b_3 - a_2)}{2y - 3x} - \frac{(-4x + 3y)^2 a_3}{(2y - 3x)^2} - \left(-\frac{4}{2y - 3x} + \frac{-12x + 9y}{(2y - 3x)^2}\right)(x a_2 + y a_3 + a_1) - \left(\frac{3}{2y - 3x} - \frac{2(-4x + 3y)}{(2y - 3x)^2}\right)(x b_2 + y b_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{12x^2a_2+16x^2a_3-10x^2b_2-12x^2b_3-16xya_2-24xya_3+12xyb_2+16xyb_3+6y^2a_2+10y^2a_3-4y^2b_2-}{(3x-2y)^2}$$
$$=0$$

Setting the numerator to zero gives

$$\begin{aligned}&-12x^2a_2-16x^2a_3+10x^2b_2+12x^2b_3+16xya_2+24xya_3-12xyb_2\\&-16xyb_3-6y^2a_2-10y^2a_3+4y^2b_2+6y^2b_3+xb_1-ya_1=0\end{aligned}\tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$\{x,y\}$$

The following substitution is now made to be able to collect on all terms with $\{x,y\}$ in them

$$\{x=v_1,y=v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}&-12a_2v_1^2+16a_2v_1v_2-6a_2v_2^2-16a_3v_1^2+24a_3v_1v_2-10a_3v_2^2+10b_2v_1^2\\&-12b_2v_1v_2+4b_2v_2^2+12b_3v_1^2-16b_3v_1v_2+6b_3v_2^2-a_1v_2+b_1v_1=0\end{aligned}\tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1,v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}&(-12a_2-16a_3+10b_2+12b_3)\,v_1^2+(16a_2+24a_3-12b_2-16b_3)\,v_1v_2\\&+b_1v_1+(-6a_2-10a_3+4b_2+6b_3)\,v_2^2-a_1v_2=0\end{aligned}\tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}b_1&=0\\-a_1&=0\\-12a_2-16a_3+10b_2+12b_3&=0\\-6a_2-10a_3+4b_2+6b_3&=0\\16a_2+24a_3-12b_2-16b_3&=0\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -3a_3 + b_3 \\
a_3 &= a_3 \\
b_1 &= 0 \\
b_2 &= -2a_3 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{-4x + 3y}{2y - 3x}\right)(x) \\
&= \frac{-4x^2 + 6xy - 2y^2}{3x - 2y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-4x^2 + 6xy - 2y^2}{3x - 2y}} dy
\end{aligned}
$$

Which results in

$$S = \frac{\ln(2x^2 - 3xy + y^2)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{-4x + 3y}{2y - 3x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{2x - y} + \frac{1}{-2y + 2x} \\ S_y &= \frac{2y - 3x}{2(2x - y)(-y + x)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(2x - y)}{2} + \frac{\ln(-y + x)}{2} = c_1$$

Which simplifies to

$$\frac{\ln(2x-y)}{2}+\frac{\ln(-y+x)}{2}=c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx}=\frac{-4x+3y}{2y-3x}$ 	$R = x$ $S = \frac{\ln(2x-y)}{2} + \frac{\ln(-y}{2}$	$\frac{dS}{dR}=0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(2x-y)}{2}+\frac{\ln(-y+x)}{2}=c_1 \tag{1}$$

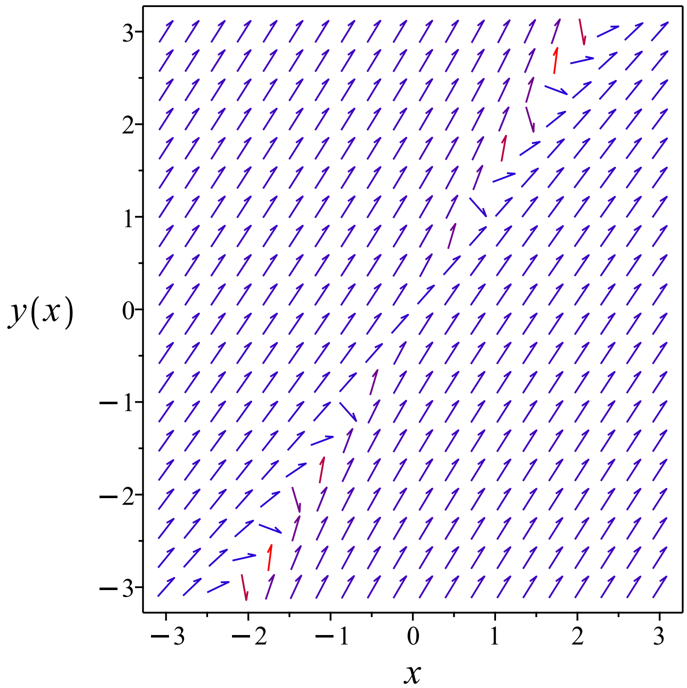

Figure 159: Slope field plot

Verification of solutions

$$\frac{\ln(2x-y)}{2}+\frac{\ln(-y+x)}{2}=c_1$$

Verified OK.

5.7.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(2y - 3x)\, \mathrm{d}y = (-4x + 3y)\, \mathrm{d}x$$
$$(4x - 3y)\, \mathrm{d}x + (2y - 3x)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 4x - 3y$$
$$N(x, y) = 2y - 3x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(4x - 3y)$$
$$= -3$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(2y - 3x)$$
$$= -3$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int 4x - 3y \,\mathrm{d}x$$
$$\phi = x(2x - 3y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -3x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2y - 3x$. Therefore equation (4) becomes

$$2y - 3x = -3x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (2y) \,\mathrm{d}y$$
$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(2x - 3y) + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(2x - 3y) + y^2$$

Summary
The solution(s) found are the following

$$x(2x - 3y) + y^2 = c_1 \tag{1}$$

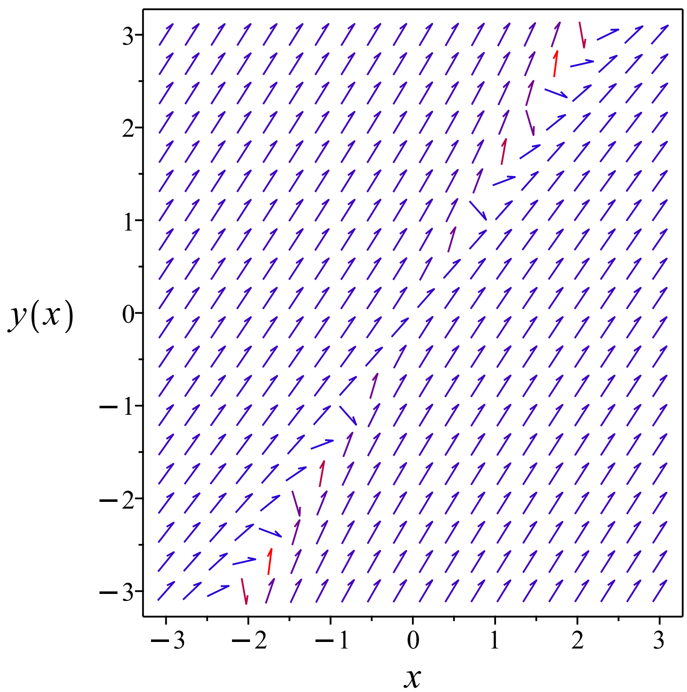

Figure 160: Slope field plot

Verification of solutions

$$x(2x - 3y) + y^2 = c_1$$

Verified OK.

5.7.5 Maple step by step solution

Let's solve

$-3y + (2y - 3x)\, y' = -4x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

  $F'(x, y) = 0$

  ◦ Compute derivative of lhs

  $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

  ◦ Evaluate derivatives

  $-3 = -3$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\,, N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (4x - 3y)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = 2x^2 - 3xy + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $2y - 3x = -3x + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = 2y$

- Solve for $f_1(y)$

  $f_1(y) = y^2$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$$F(x,y) = 2x^2 - 3xy + y^2$$

- Substitute $F(x,y)$ into the solution of the ODE

$$2x^2 - 3xy + y^2 = c_1$$

- Solve for y

$$\left\{y = \frac{3x}{2} - \frac{\sqrt{x^2+4c_1}}{2}, y = \frac{3x}{2} + \frac{\sqrt{x^2+4c_1}}{2}\right\}$$

Section: Section 5. Homogeneous equations. Exercises page 44
Problem number: 107.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{y + (y + x)\, y' = x}$$

5.8.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$u(x)\, x + (u(x)\, x + x)\, (u'(x)\, x + u(x)) = x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{u^2 + 2u - 1}{x\, (u + 1)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^2+2u-1}{u+1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+2u-1}{u+1}}\,du = -\frac{1}{x}\,dx$$
$$\int \frac{1}{\frac{u^2+2u-1}{u+1}}\,du = \int -\frac{1}{x}\,dx$$
$$\frac{\ln\left(u^2+2u-1\right)}{2} = -\ln\left(x\right) + c_2$$

Raising both side to exponential gives

$$\sqrt{u^2+2u-1} = \mathrm{e}^{-\ln(x)+c_2}$$

Which simplifies to

$$\sqrt{u^2+2u-1} = \frac{c_3}{x}$$

Which simplifies to

$$\sqrt{u\left(x\right)^2+2u\left(x\right)-1} = \frac{c_3\,\mathrm{e}^{c_2}}{x}$$

The solution is

$$\sqrt{u\left(x\right)^2+2u\left(x\right)-1} = \frac{c_3\,\mathrm{e}^{c_2}}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{y^2}{x^2}+\frac{2y}{x}-1} = \frac{c_3\,\mathrm{e}^{c_2}}{x}$$
$$\sqrt{\frac{y^2+2yx-x^2}{x^2}} = \frac{c_3\,\mathrm{e}^{c_2}}{x}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{y^2+2yx-x^2}{x^2}} = \frac{c_3\,\mathrm{e}^{c_2}}{x} \tag{1}$$

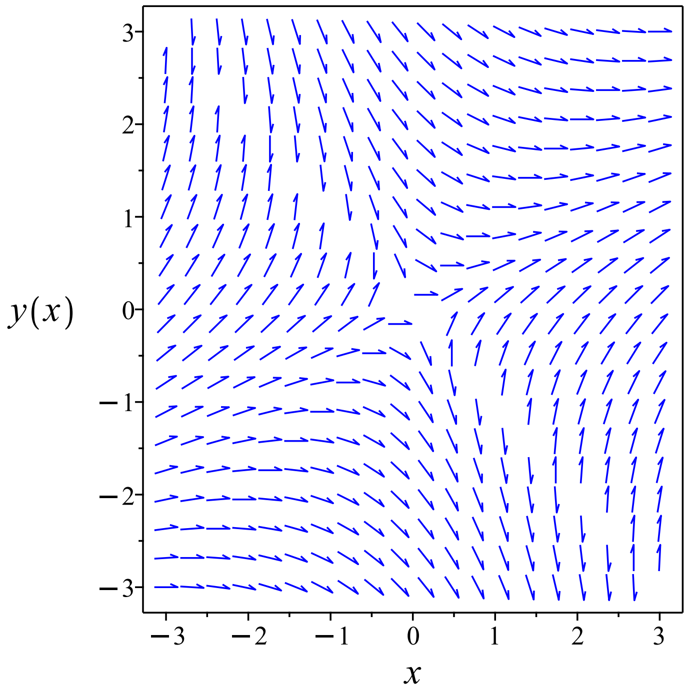

Figure 161: Slope field plot

<u>Verification of solutions</u>

$$\sqrt{\frac{y^2+2yx-x^2}{x^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x}$$

Verified OK.

5.8.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-y+x}{y+x} \tag{1}$$

Which becomes

$$(y)\,dy = (-x)\,dy + (-y+x)\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + (-y+x)\,dx = d\left(\frac{1}{2}x^2 - xy\right)$$

Hence (2) becomes

$$(y)\,dy = d\left(\frac{1}{2}x^2 - xy\right)$$

Integrating both sides gives gives these solutions

$$y = -x + \sqrt{2x^2 + 2c_1} + c_1$$
$$y = -x - \sqrt{2x^2 + 2c_1} + c_1$$

Summary

The solution(s) found are the following

$$y = -x + \sqrt{2x^2 + 2c_1} + c_1 \tag{1}$$
$$y = -x - \sqrt{2x^2 + 2c_1} + c_1 \tag{2}$$

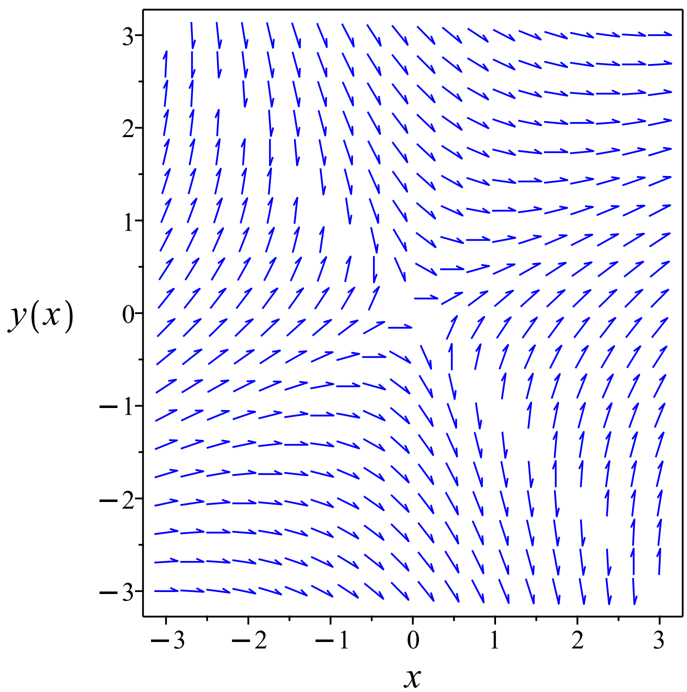

Figure 162: Slope field plot

Verification of solutions

$$y = -x + \sqrt{2x^2 + 2c_1} + c_1$$

Verified OK.

$$y = -x - \sqrt{2x^2 + 2c_1} + c_1$$

Verified OK.

5.8.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{y-x}{y+x} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 - \frac{(y-x)(b_3-a_2)}{y+x} - \frac{(y-x)^2 a_3}{(y+x)^2} - \left(\frac{1}{y+x} + \frac{y-x}{(y+x)^2}\right)(x a_2 + y a_3 + a_1) \\
&- \left(-\frac{1}{y+x} + \frac{y-x}{(y+x)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{x^2 a_2 + x^2 a_3 - 3x^2 b_2 - x^2 b_3 + 2xy a_2 - 2xy a_3 - 2xy b_2 - 2xy b_3 - y^2 a_2 + 3y^2 a_3 - y^2 b_2 + y^2 b_3 - 2x b_1 + 2}{(y+x)^2} = 0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-x^2 a_2 - x^2 a_3 + 3x^2 b_2 + x^2 b_3 - 2xy a_2 + 2xy a_3 + 2xy b_2 \\
&+ 2xy b_3 + y^2 a_2 - 3y^2 a_3 + y^2 b_2 - y^2 b_3 + 2x b_1 - 2y a_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_2 v_1^2 - 2a_2 v_1 v_2 + a_2 v_2^2 - a_3 v_1^2 + 2a_3 v_1 v_2 - 3a_3 v_2^2 + 3b_2 v_1^2 + 2b_2 v_1 v_2 + b_2 v_2^2 + b_3 v_1^2 + 2b_3 v_1 v_2 - b_3 v_2^2 - 2a_1 v_2 + 2b_1 v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(-a_2 - a_3 + 3b_2 + b_3) v_1^2 + (-2a_2 + 2a_3 + 2b_2 + 2b_3) v_1 v_2 + 2b_1 v_1 + (a_2 - 3a_3 + b_2 - b_3) v_2^2 - 2a_1 v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-2a_1 &= 0 \\
2b_1 &= 0 \\
-2a_2 + 2a_3 + 2b_2 + 2b_3 &= 0 \\
-a_2 - a_3 + 3b_2 + b_3 &= 0 \\
a_2 - 3a_3 + b_2 - b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= 2b_2 + b_3 \\
a_3 &= b_2 \\
b_1 &= 0 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{y-x}{y+x}\right)(x) \\
&= \frac{-x^2 + 2xy + y^2}{y+x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-x^2+2xy+y^2}{y+x}} dy
\end{aligned}
$$

Which results in

$$
S = \frac{\ln\left(-x^2 + 2xy + y^2\right)}{2}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{y - x}{y + x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{-y + x}{x^2 - 2xy - y^2} \\
S_y &= \frac{-y - x}{x^2 - 2xy - y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y^2 + 2yx - x^2)}{2} = c_1$$

Which simplifies to

$$\frac{\ln(y^2 + 2yx - x^2)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>

$$\frac{\ln\left(y^2+2yx-x^2\right)}{2}=c_1$$

Verified OK.

5.8.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\,\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y + x) \,\mathrm{d}y = (-y + x) \,\mathrm{d}x$$
$$(y - x) \,\mathrm{d}x + (y + x) \,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = y - x$$
$$N(x, y) = y + x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(y - x)$$
$$= 1$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(y + x)$$
$$= 1$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int y - x \, \mathrm{d}x$$
$$\phi = -\frac{x(x - 2y)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y + x$. Therefore equation (4) becomes

$$y + x = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (y) \, \mathrm{d}y$$
$$f(y) = \frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x(x-2y)}{2} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x(x-2y)}{2} + \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x(x-2y)}{2} + \frac{y^2}{2} = c_1 \tag{1}$$

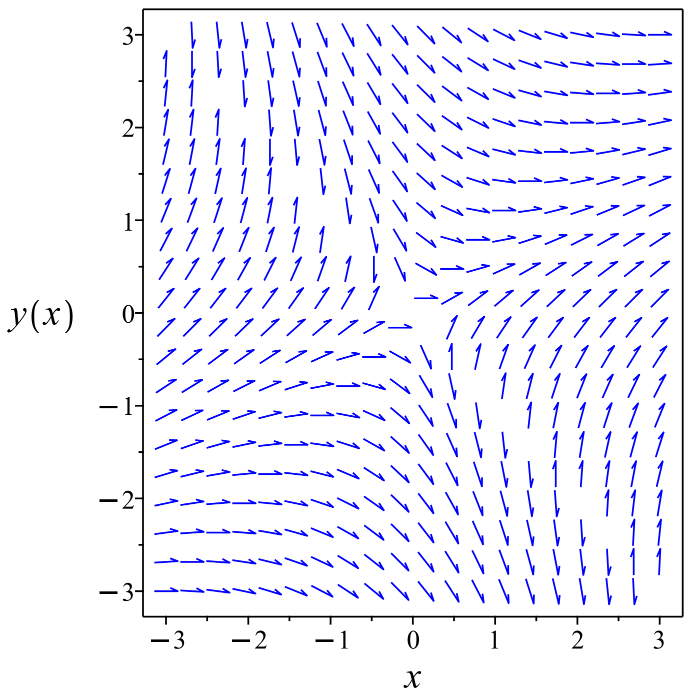

Figure 164: Slope field plot

Verification of solutions

$$-\frac{x(x-2y)}{2} + \frac{y^2}{2} = c_1$$

Verified OK.

5.8.5 Maple step by step solution

Let's solve

$y+(y+x)\,y'=x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

- ◦ ODE is exact if the lhs is the total derivative of a C^2 function

  $F'(x,y)=0$

- ◦ Compute derivative of lhs

  $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

- ◦ Evaluate derivatives

  $1=1$

- ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1,M(x,y)=F'(x,y)\,,N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int(y-x)\,dx+f_1(y)$

- Evaluate integral

  $F(x,y)=xy-\frac{x^2}{2}+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $y+x=x+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=y$

- Solve for $f_1(y)$

  $f_1(y)=\frac{y^2}{2}$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$F(x,y) = xy - \frac{1}{2}x^2 + \frac{1}{2}y^2$

- Substitute $F(x,y)$ into the solution of the ODE

  $xy - \frac{1}{2}x^2 + \frac{1}{2}y^2 = c_1$

- Solve for y

  $\left\{y = -x - \sqrt{2x^2 + 2c_1}, y = -x + \sqrt{2x^2 + 2c_1}\right\}$

Problem number: 108.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "homogeneousTypeMapleC", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y + (1 - x)\, y' = -x + 2}$$

5.9.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x-1}$$
$$q(x) = \frac{x-2}{x-1}$$

Hence the ode is

$$y' - \frac{y}{x-1} = \frac{x-2}{x-1}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x-1}dx}$$
$$= \frac{1}{x-1}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x-2}{x-1}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x-1}\right) = \left(\frac{1}{x-1}\right)\left(\frac{x-2}{x-1}\right)$$
$$d\left(\frac{y}{x-1}\right) = \left(\frac{x-2}{(x-1)^2}\right) dx$$

Integrating gives

$$\frac{y}{x-1} = \int \frac{x-2}{(x-1)^2} dx$$
$$\frac{y}{x-1} = \frac{1}{x-1} + \ln(x-1) + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x-1}$ results in

$$y = (x-1)\left(\frac{1}{x-1} + \ln(x-1)\right) + c_1(x-1)$$

which simplifies to

$$y = (x-1)\ln(x-1) + 1 + c_1(x-1)$$

Summary

The solution(s) found are the following

$$y = (x-1)\ln(x-1) + 1 + c_1(x-1) \tag{1}$$

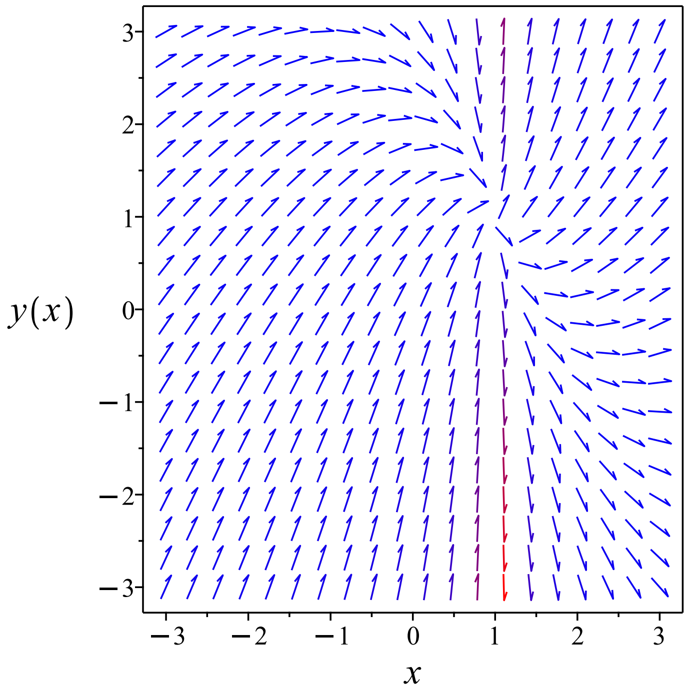

Figure 165: Slope field plot

Verification of solutions

$$y = (x-1)\ln(x-1) + 1 + c_1(x-1)$$

Verified OK.

5.9.2 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{X + x_0 + Y(X) + y_0 - 2}{X + x_0 - 1}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0 = 1$$
$$y_0 = 1$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{X + Y(X)}{X}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X, Y) \\ &= \frac{X + Y}{X} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X, Y)$$

In this case, it can be seen that both $M = X + Y$ and $N = X$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X}X + u &= 1 + u \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{1}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{1}{X} = 0$$

Or

$$\left(\frac{d}{dX}u(X)\right)X - 1 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. Integrating both sides gives

$$\begin{aligned} u(X) &= \int \frac{1}{X}\,\mathrm{d}X \\ &= \ln(X) + c_2 \end{aligned}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$Y(X) = X(\ln(X) + c_2)$$

Using the solution for $Y(X)$

$$Y(X) = X(\ln(X) + c_2)$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y + 1$$
$$X = x + 1$$

Then the solution in y becomes

$$y - 1 = (x - 1)(\ln(x - 1) + c_2)$$

Summary

The solution(s) found are the following

$$y - 1 = (x - 1)(\ln(x - 1) + c_2) \tag{1}$$

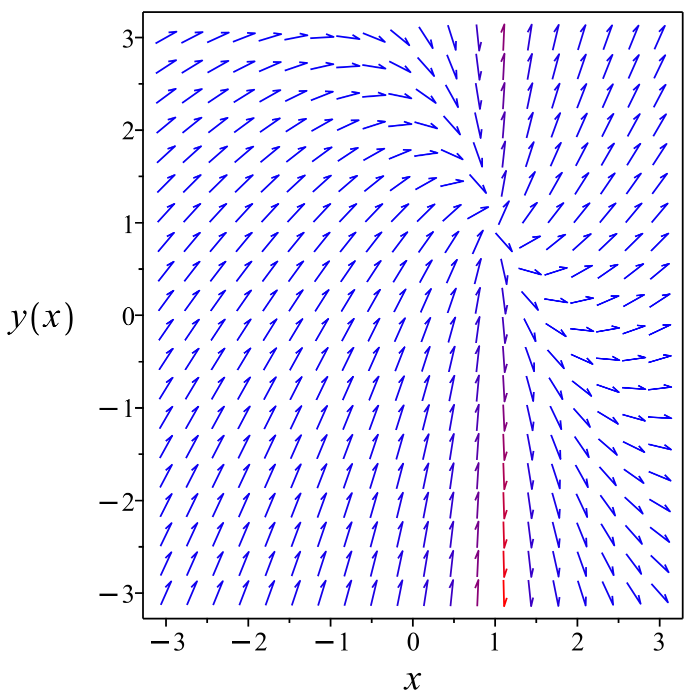

Figure 166: Slope field plot

Verification of solutions

$$y - 1 = (x - 1)(\ln(x - 1) + c_2)$$

Verified OK.

5.9.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{x+y-2}{x-1} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 143: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= x-1
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R,S. The canonical coordinates map $(x,y)\to(R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{x-1} dy
\end{aligned}
$$

Which results in

$$
S = \frac{y}{x-1}
$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x+\omega(x,y)S_y}{R_x+\omega(x,y)R_y} \tag{2}
$$

Where in the above R_x,R_y,S_x,S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{x+y-2}{x-1}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{y}{(x-1)^2} \\
S_y &= \frac{1}{x-1}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{x-2}{(x-1)^2} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R-2}{(R-1)^2}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{1}{R-1} + \ln(R-1) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{y}{x-1} = \frac{1}{x-1} + \ln(x-1) + c_1
$$

Which simplifies to

$$
\frac{y}{x-1} = \frac{1}{x-1} + \ln(x-1) + c_1
$$

Which gives

$$
y = \ln(x-1)\, x + c_1 x - \ln(x-1) - c_1 + 1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x+y-2}{x-1}$ 	$R = x$ $S = \frac{y}{x-1}$	$\frac{dS}{dR} = \frac{R-2}{(R-1)^2}$ 
Summary

The solution(s) found are the following

$$y = \ln(x-1)\,x + c_1 x - \ln(x-1) - c_1 + 1 \tag{1}$$

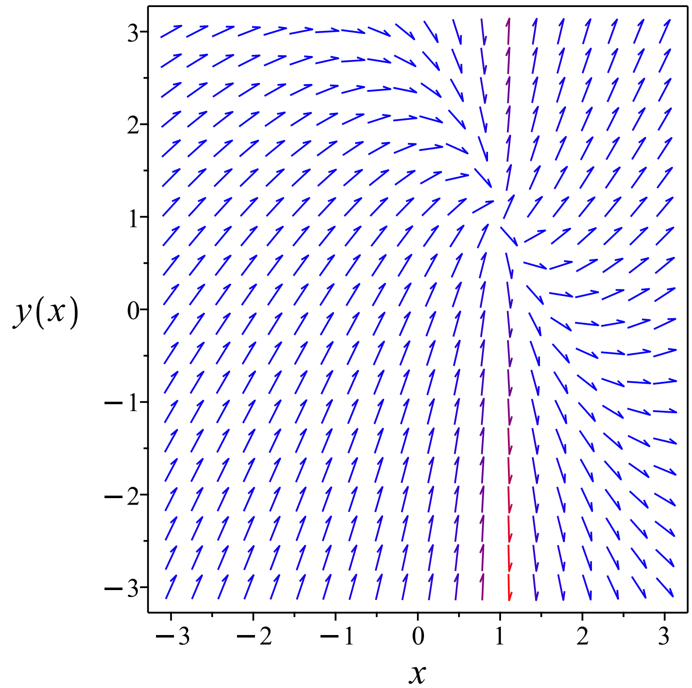

Figure 167: Slope field plot

Verification of solutions

$$y = \ln(x-1)\, x + c_1 x - \ln(x-1) - c_1 + 1$$

Verified OK.

5.9.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(1 - x)\,\mathrm{d}y &= (-x - y + 2)\,\mathrm{d}x \\
(x + y - 2)\,\mathrm{d}x + (1 - x)\,\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= x + y - 2 \\
N(x, y) &= 1 - x
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x + y - 2) \\
&= 1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1 - x) \\
&= -1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{1-x}((1) - (-1)) \\
&= -\frac{2}{x-1}
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\frac{2}{x-1} \, \mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{-2\ln(x-1)} \\
&= \frac{1}{(x-1)^2}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{(x-1)^2}(x+y-2) \\
&= \frac{x+y-2}{(x-1)^2}
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{(x-1)^2}(1-x) \\
&= -\frac{1}{x-1}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{x+y-2}{(x-1)^2}\right) + \left(-\frac{1}{x-1}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \frac{x+y-2}{(x-1)^2} \, \mathrm{d}x$$

$$\phi = \frac{1-y}{x-1} + \ln(x-1) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{1}{x-1} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{x-1}$. Therefore equation (4) becomes

$$-\frac{1}{x-1} = -\frac{1}{x-1} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1-y}{x-1} + \ln(x-1) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1-y}{x-1} + \ln(x-1)$$

The solution becomes

$$y = \ln(x-1)\,x - c_1 x - \ln(x-1) + c_1 + 1$$

Summary

The solution(s) found are the following

$$y = \ln(x-1)\,x - c_1 x - \ln(x-1) + c_1 + 1 \tag{1}$$

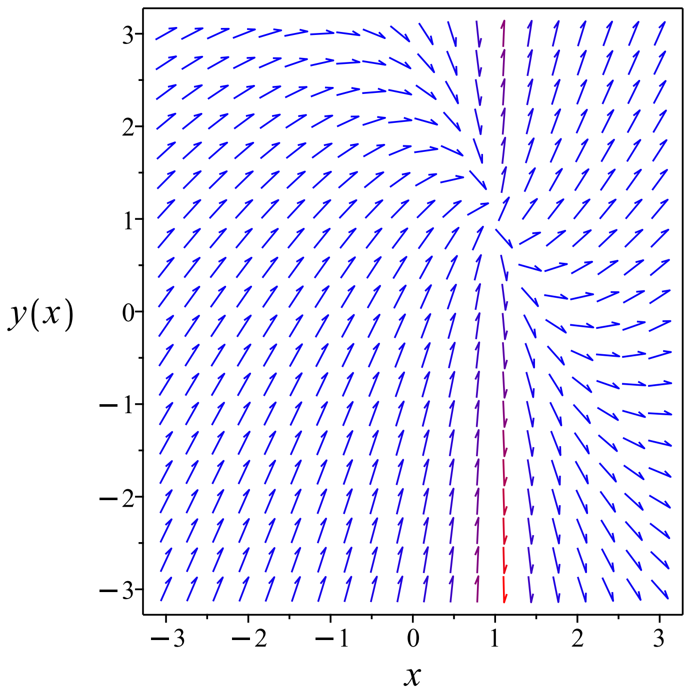

Figure 168: Slope field plot

Verification of solutions

$$y = \ln(x-1)\,x - c_1 x - \ln(x-1) + c_1 + 1$$

Verified OK.

5.9.5 Maple step by step solution

Let's solve

$y + (1 - x)\, y' = -x + 2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y}{x-1} + \frac{x-2}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{x-1} = \frac{x-2}{x-1}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{y}{x-1}\right) = \frac{\mu(x)(x-2)}{x-1}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' - \frac{y}{x-1}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)}{x-1}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{x-1}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)(x-2)}{x-1} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)(x-2)}{x-1} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)(x-2)}{x-1} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{x-1}$

  $y = (x-1)\left(\int \frac{x-2}{(x-1)^2} dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = (x-1)\left(\frac{1}{x-1} + \ln(x-1) + c_1\right)$

- Simplify

$$y = (x-1)\ln(x-1) + 1 + c_1(x-1)$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{3y-(3x-7y-3)\,y'=7x-7}$$

5.10.1 Solving as homogeneousTypeMapleC ode

Let $Y=y+y_0$ and $X=x+x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X)=-\frac{3Y(X)+3y_0-7X-7x_0+7}{-3X-3x_0+7Y(X)+7y_0+3}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$x_0=1$$
$$y_0=0$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X)=-\frac{3Y(X)-7X}{-3X+7Y(X)}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X,Y) \\ &= -\frac{3Y-7X}{-3X+7Y} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$f(t^nX, t^nY) = t^n f(X,Y)$$

In this case, it can be seen that both $M = 3Y - 7X$ and $N = 3X - 7Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X}X + u &= \frac{-3u+7}{7u-3} \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{\frac{-3u(X)+7}{7u(X)-3} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{\frac{-3u(X)+7}{7u(X)-3} - u(X)}{X} = 0$$

Or

$$7\left(\frac{d}{dX}u(X)\right)Xu(X) - 3\left(\frac{d}{dX}u(X)\right)X + 7u(X)^2 - 7 = 0$$

Or

$$-7 + X(7u(X)-3)\left(\frac{d}{dX}u(X)\right) + 7u(X)^2 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X,u) \\ &= f(X)g(u) \\ &= -\frac{7(u^2-1)}{X\,(7u-3)} \end{aligned}$$

Where $f(X) = -\frac{7}{X}$ and $g(u) = \frac{u^2-1}{7u-3}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-1}{7u-3}}\,du = -\frac{7}{X}\,dX$$
$$\int \frac{1}{\frac{u^2-1}{7u-3}}\,du = \int -\frac{7}{X}\,dX$$
$$2\ln(u-1) + 5\ln(u+1) = -7\ln(X) + c_2$$

Raising both side to exponential gives

$$e^{2\ln(u-1)+5\ln(u+1)} = e^{-7\ln(X)+c_2}$$

Which simplifies to

$$(u-1)^2 (u+1)^5 = \frac{c_3}{X^7}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$Y(X) = \mathrm{RootOf}\left(X^7 + 3X^6\_Z + X^5\_Z^2 - 5X^4\_Z^3 - 5X^3\_Z^4 + X^2\_Z^5 + 3X\_Z^6 + \_Z^7 - c_3\right)$$

Using the solution for $Y(X)$

$$Y(X) = \mathrm{RootOf}\left(X^7 + 3X^6\_Z + X^5\_Z^2 - 5X^4\_Z^3 - 5X^3\_Z^4 + X^2\_Z^5 + 3X\_Z^6 + \_Z^7 - c_3\right)$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y$$
$$X = x + 1$$

Then the solution in y becomes

$$y = \mathrm{RootOf}\left(\_Z^7 + (-3+3x)\_Z^6 + \left(x^2 - 2x + 1\right)\_Z^5 + \left(-5x^3 + 15x^2 - 15x + 5\right)\_Z^4 + \left(-5x^4 + 20x\right.$$

Summary
The solution(s) found are the following

$$y = \operatorname{RootOf}\left(\_Z^7 + (-3+3x)\_Z^6 + (x^2-2x+1)\_Z^5 + (-5x^3+15x^2-15x+5)\_Z^4 + (-5x^4+20x^3-30x^2+20x-5)\_Z^3 + (x^5-5x^4+10x^3-10x^2+5x-1)\_Z^2 + (3x^6-18x^5+45x^4-60x^3+45x^2-18x+3)\_Z + x^7-7x^6+21x^5-35x^4 + 35x^3-21x^2-c_3+7x-1\right) \tag{1}$$

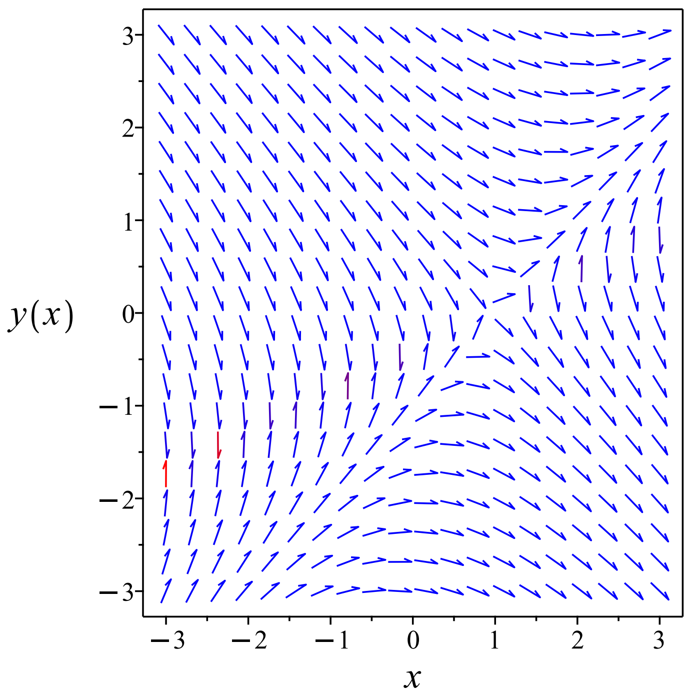

Figure 169: Slope field plot

Verification of solutions

$$y = \operatorname{RootOf}\left(\_Z^7 + (-3+3x)\_Z^6 + (x^2-2x+1)\_Z^5 + (-5x^3+15x^2-15x+5)\_Z^4 + (-5x^4+20x^3-30x^2+20x-5)\_Z^3 + (x^5-5x^4+10x^3-10x^2+5x-1)\_Z^2 + (3x^6-18x^5+45x^4-60x^3+45x^2-18x+3)\_Z + x^7-7x^6+21x^5-35x^4 + 35x^3-21x^2-c_3+7x-1\right)$$

Verified OK.

5.10.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{3y - 7x + 7}{-3x + 7y + 3}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 &- \frac{(3y - 7x + 7)(b_3 - a_2)}{-3x + 7y + 3} - \frac{(3y - 7x + 7)^2 a_3}{(-3x + 7y + 3)^2} \\ &- \left(\frac{7}{-3x + 7y + 3} - \frac{3(3y - 7x + 7)}{(-3x + 7y + 3)^2}\right)(xa_2 + ya_3 + a_1) \\ &- \left(-\frac{3}{-3x + 7y + 3} + \frac{21y - 49x + 49}{(-3x + 7y + 3)^2}\right)(xb_2 + yb_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{21x^2a_2 - 49x^2a_3 + 49x^2b_2 - 21x^2b_3 - 98xya_2 + 42xya_3 - 42xyb_2 + 98xyb_3 + 21y^2a_2 - 49y^2a_3 + 49y^2b_2 -}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &21x^2a_2 - 49x^2a_3 + 49x^2b_2 - 21x^2b_3 - 98xya_2 + 42xya_3 - 42xyb_2 + 98xyb_3 \\ &+ 21y^2a_2 - 49y^2a_3 + 49y^2b_2 - 21y^2b_3 - 42xa_2 + 98xa_3 + 40xb_1 - 58xb_2 + 42xb_3 \\ &- 40ya_1 + 58ya_2 - 42ya_3 + 42yb_2 - 98yb_3 + 21a_2 - 49a_3 - 40b_1 + 9b_2 - 21b_3 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&21a_2v_1^2 - 98a_2v_1v_2 + 21a_2v_2^2 - 49a_3v_1^2 + 42a_3v_1v_2 - 49a_3v_2^2 + 49b_2v_1^2 \\
&- 42b_2v_1v_2 + 49b_2v_2^2 - 21b_3v_1^2 + 98b_3v_1v_2 - 21b_3v_2^2 - 40a_1v_2 \\
&- 42a_2v_1 + 58a_2v_2 + 98a_3v_1 - 42a_3v_2 + 40b_1v_1 - 58b_2v_1 + 42b_2v_2 \\
&+ 42b_3v_1 - 98b_3v_2 + 21a_2 - 49a_3 - 40b_1 + 9b_2 - 21b_3 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(21a_2 - 49a_3 + 49b_2 - 21b_3)\, v_1^2 + (-98a_2 + 42a_3 - 42b_2 + 98b_3)\, v_1v_2 \\
&+ (-42a_2 + 98a_3 + 40b_1 - 58b_2 + 42b_3)\, v_1 + (21a_2 - 49a_3 + 49b_2 - 21b_3)\, v_2^2 \\
&+ (-40a_1 + 58a_2 - 42a_3 + 42b_2 - 98b_3)\, v_2 + 21a_2 - 49a_3 - 40b_1 + 9b_2 - 21b_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-98a_2 + 42a_3 - 42b_2 + 98b_3 &= 0 \\
21a_2 - 49a_3 + 49b_2 - 21b_3 &= 0 \\
-40a_1 + 58a_2 - 42a_3 + 42b_2 - 98b_3 &= 0 \\
-42a_2 + 98a_3 + 40b_1 - 58b_2 + 42b_3 &= 0 \\
21a_2 - 49a_3 - 40b_1 + 9b_2 - 21b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= -b_3 \\
a_2 &= b_3 \\
a_3 &= b_2 \\
b_1 &= -b_2 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = y$$
$$\eta = x - 1$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= x - 1 - \left(-\frac{3y - 7x + 7}{-3x + 7y + 3}\right)(y) \\
&= \frac{3x^2 - 3y^2 - 6x + 3}{3x - 7y - 3} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{3x^2 - 3y^2 - 6x + 3}{3x - 7y - 3}} dy
\end{aligned}$$

Which results in

$$S = \frac{2 \ln (1 - x + y)}{3} + \frac{5 \ln (x - 1 + y)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{3y - 7x + 7}{-3x + 7y + 3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{2}{3x - 3 - 3y} + \frac{5}{3x - 3 + 3y} \\ S_y &= -\frac{2}{3x - 3 - 3y} + \frac{5}{3x - 3 + 3y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{2\ln(1 - x + y)}{3} + \frac{5\ln(y - 1 + x)}{3} = c_1$$

Which simplifies to

$$\frac{2\ln(1 - x + y)}{3} + \frac{5\ln(y - 1 + x)}{3} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{3y-7x+7}{-3x+7y+3}$ 	$R = x$ $S = \frac{2\ln(1-x+y)}{3} + \frac{5\mathrm{l}}{}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{2\ln(1-x+y)}{3} + \frac{5\ln(y-1+x)}{3} = c_1 \tag{1}$$

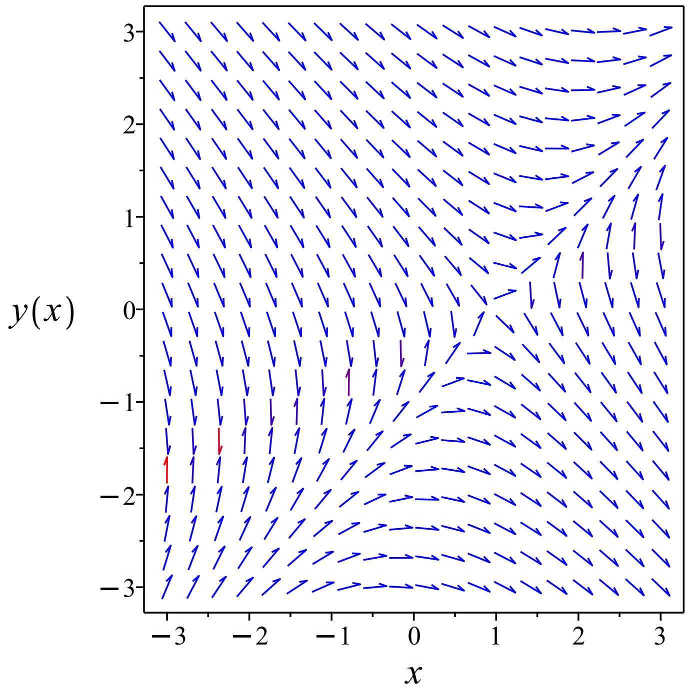

Figure 170: Slope field plot

Verification of solutions

$$\frac{2\ln(1-x+y)}{3}+\frac{5\ln(y-1+x)}{3}=c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{y + (x - y + 4)\, y' = -x + 2}$$

5.11.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-x - y + 2}{x - y + 4} \tag{1}$$

Which becomes

$$(-y + 4)\, dy = (-x)\, dy + (-x - y + 2)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + (-x - y + 2)\, dx = d\left(-\frac{1}{2}x^2 - xy + 2x\right)$$

Hence (2) becomes

$$(-y+4)\,dy = d\left(-\frac{1}{2}x^2 - xy + 2x\right)$$

Integrating both sides gives gives these solutions

$$y = x + 4 + \sqrt{2x^2 - 2c_1 + 4x + 16} + c_1$$
$$y = x + 4 - \sqrt{2x^2 - 2c_1 + 4x + 16} + c_1$$

Summary

The solution(s) found are the following

$$y = x + 4 + \sqrt{2x^2 - 2c_1 + 4x + 16} + c_1 \tag{1}$$
$$y = x + 4 - \sqrt{2x^2 - 2c_1 + 4x + 16} + c_1 \tag{2}$$

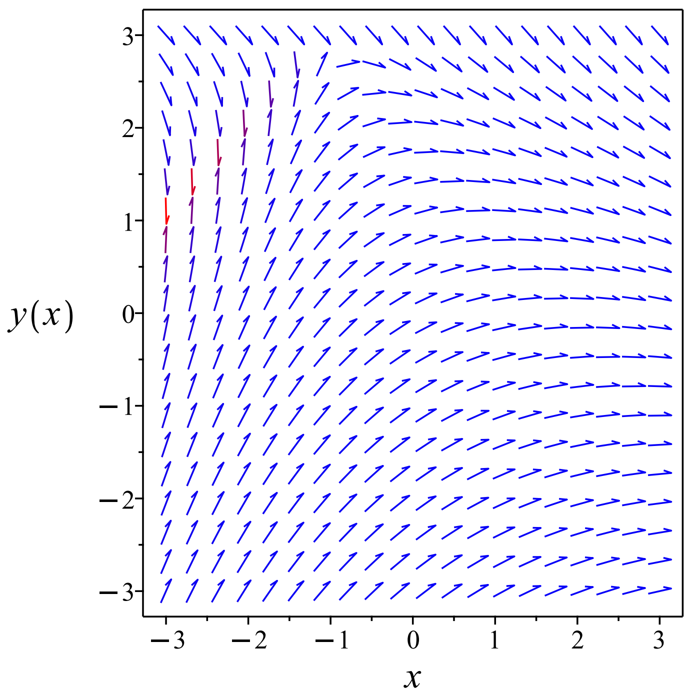

Figure 171: Slope field plot

Verification of solutions

$$y = x + 4 + \sqrt{2x^2 - 2c_1 + 4x + 16} + c_1$$

Verified OK.

$$y = x + 4 - \sqrt{2x^2 - 2c_1 + 4x + 16} + c_1$$

Verified OK.

5.11.2 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{X + x_0 + Y(X) + y_0 - 2}{-X - x_0 + Y(X) + y_0 - 4}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$\begin{aligned} x_0 &= -1 \\ y_0 &= 3 \end{aligned}$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{X + Y(X)}{-X + Y(X)}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X, Y) \\ &= \frac{X + Y}{-X + Y} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X, Y)$$

In this case, it can be seen that both $M = -X - Y$ and $N = X - Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{dY}{dX} = \frac{du}{dX}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{du}{dX}X + u &= \frac{u + 1}{u - 1} \\ \frac{du}{dX} &= \frac{\frac{u(X)+1}{u(X)-1} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{\frac{u(X)+1}{u(X)-1} - u(X)}{X} = 0$$

Or

$$\left(\frac{d}{dX}u(X)\right) X u(X) - \left(\frac{d}{dX}u(X)\right) X + u(X)^2 - 2u(X) - 1 = 0$$

Or

$$X(u(X) - 1)\left(\frac{d}{dX}u(X)\right) + u(X)^2 - 2u(X) - 1 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X, u) \\ &= f(X)g(u) \\ &= -\frac{u^2 - 2u - 1}{X\,(u - 1)} \end{aligned}$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u^2-2u-1}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-2u-1}{u-1}}\,du = -\frac{1}{X}\,dX$$

$$\int \frac{1}{\frac{u^2-2u-1}{u-1}}\,du = \int -\frac{1}{X}\,dX$$

$$\frac{\ln\left(u^2 - 2u - 1\right)}{2} = -\ln\left(X\right) + c_2$$

Raising both side to exponential gives

$$\sqrt{u^2 - 2u - 1} = \mathrm{e}^{-\ln(X)+c_2}$$

Which simplifies to

$$\sqrt{u^2 - 2u - 1} = \frac{c_3}{X}$$

Which simplifies to

$$\sqrt{u\left(X\right)^2 - 2u\left(X\right) - 1} = \frac{c_3 \mathrm{e}^{c_2}}{X}$$

The solution is

$$\sqrt{u\left(X\right)^2 - 2u\left(X\right) - 1} = \frac{c_3 \mathrm{e}^{c_2}}{X}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\sqrt{\frac{Y(X)^{2}}{X^{2}}-\frac{2Y(X)}{X}-1} = \frac{c_3 e^{c_2}}{X}$$

Using the solution for $Y(X)$

$$\sqrt{\frac{Y(X)^{2}-2Y(X)X-X^{2}}{X^{2}}} = \frac{c_3 e^{c_2}}{X}$$

And replacing back terms in the above solution using

$$\begin{aligned} Y &= y + y_0 \\ X &= x + x_0 \end{aligned}$$

Or

$$\begin{aligned} Y &= 3 + y \\ X &= x - 1 \end{aligned}$$

Then the solution in y becomes

$$\sqrt{\frac{(y-3)^{2}-2(y-3)(x+1)-(x+1)^{2}}{(x+1)^{2}}} = \frac{c_3 e^{c_2}}{x+1}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{(y-3)^{2}-2(y-3)(x+1)-(x+1)^{2}}{(x+1)^{2}}} = \frac{c_3 e^{c_2}}{x+1} \tag{1}$$

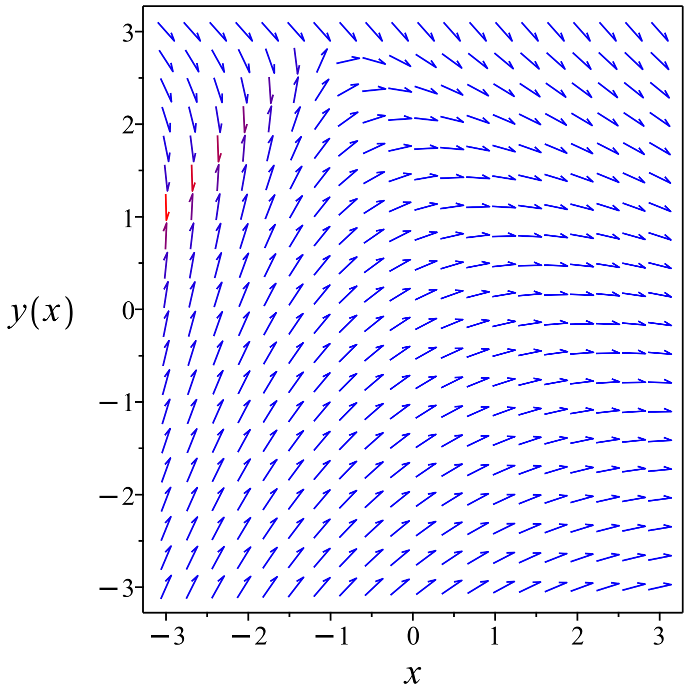

Figure 172: Slope field plot

Verification of solutions

$$\sqrt{\frac{(y-3)^2-2(y-3)(x+1)-(x+1)^2}{(x+1)^2}}=\frac{c_3 e^{c_2}}{x+1}$$

Verified OK.

5.11.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=\frac{x+y-2}{-x+y-4}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{(x+y-2)(b_3-a_2)}{-x+y-4} - \frac{(x+y-2)^2 a_3}{(-x+y-4)^2} \\ & - \left(\frac{1}{-x+y-4} + \frac{x+y-2}{(-x+y-4)^2}\right)(xa_2+ya_3+a_1) \\ & - \left(\frac{1}{-x+y-4} - \frac{x+y-2}{(-x+y-4)^2}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^2a_2 - x^2a_3 + 3x^2b_2 - x^2b_3 - 2xya_2 - 2xya_3 - 2xyb_2 + 2xyb_3 - y^2a_2 - 3y^2a_3 + y^2b_2 + y^2b_3 + 8xa_2 + 4x}{(x-y+} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} & x^2a_2 - x^2a_3 + 3x^2b_2 - x^2b_3 - 2xya_2 - 2xya_3 - 2xyb_2 + 2xyb_3 - y^2a_2 \\ & - 3y^2a_3 + y^2b_2 + y^2b_3 + 8xa_2 + 4xa_3 + 2xb_1 + 10xb_2 - 2xb_3 - 2ya_1 \\ & + 6ya_2 + 10ya_3 - 8yb_2 - 4yb_3 + 6a_1 - 8a_2 - 4a_3 + 2b_1 + 16b_2 + 8b_3 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & a_2v_1^2 - 2a_2v_1v_2 - a_2v_2^2 - a_3v_1^2 - 2a_3v_1v_2 - 3a_3v_2^2 + 3b_2v_1^2 - 2b_2v_1v_2 + b_2v_2^2 \\ & - b_3v_1^2 + 2b_3v_1v_2 + b_3v_2^2 - 2a_1v_2 + 8a_2v_1 + 6a_2v_2 + 4a_3v_1 + 10a_3v_2 + 2b_1v_1 \\ & + 10b_2v_1 - 8b_2v_2 - 2b_3v_1 - 4b_3v_2 + 6a_1 - 8a_2 - 4a_3 + 2b_1 + 16b_2 + 8b_3 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(a_2 - a_3 + 3b_2 - b_3) v_1^2 + (-2a_2 - 2a_3 - 2b_2 + 2b_3) v_1 v_2 \\
&+ (8a_2 + 4a_3 + 2b_1 + 10b_2 - 2b_3) v_1 + (-a_2 - 3a_3 + b_2 + b_3) v_2^2 \\
&+ (-2a_1 + 6a_2 + 10a_3 - 8b_2 - 4b_3) v_2 + 6a_1 - 8a_2 - 4a_3 + 2b_1 + 16b_2 + 8b_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-2a_2 - 2a_3 - 2b_2 + 2b_3 &= 0 \\
-a_2 - 3a_3 + b_2 + b_3 &= 0 \\
a_2 - a_3 + 3b_2 - b_3 &= 0 \\
-2a_1 + 6a_2 + 10a_3 - 8b_2 - 4b_3 &= 0 \\
8a_2 + 4a_3 + 2b_1 + 10b_2 - 2b_3 &= 0 \\
6a_1 - 8a_2 - 4a_3 + 2b_1 + 16b_2 + 8b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= -5b_2 + b_3 \\
a_2 &= -2b_2 + b_3 \\
a_3 &= b_2 \\
b_1 &= b_2 - 3b_3 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x + 1 \\
\eta &= y - 3
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - 3 - \left(\frac{x + y - 2}{-x + y - 4}\right)(x + 1) \\
&= \frac{x^2 + 2xy - y^2 - 4x + 8y - 14}{x - y + 4} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2+2xy-y^2-4x+8y-14}{x-y+4}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln\left(-x^2 - 2xy + y^2 + 4x - 8y + 14\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x + y - 2}{-x + y - 4}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{x + y - 2}{x^2 + (2y - 4)x - y^2 + 8y - 14} \\ S_y &= \frac{x - y + 4}{x^2 + (2y - 4)x - y^2 + 8y - 14} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln\left(-x^2 + (-2y+4)\,x + y^2 - 8y + 14\right)}{2} = c_1$$

Which simplifies to

$$\frac{\ln\left(-x^2 + (-2y+4)\,x + y^2 - 8y + 14\right)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x+y-2}{-x+y-4}$ 	$R = x$ $S = \frac{\ln\left(-x^2 + (-2y+4)\right)}{2}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln\left(-x^2+(-2y+4)\,x+y^2-8y+14\right)}{2}=c_1 \tag{1}$$

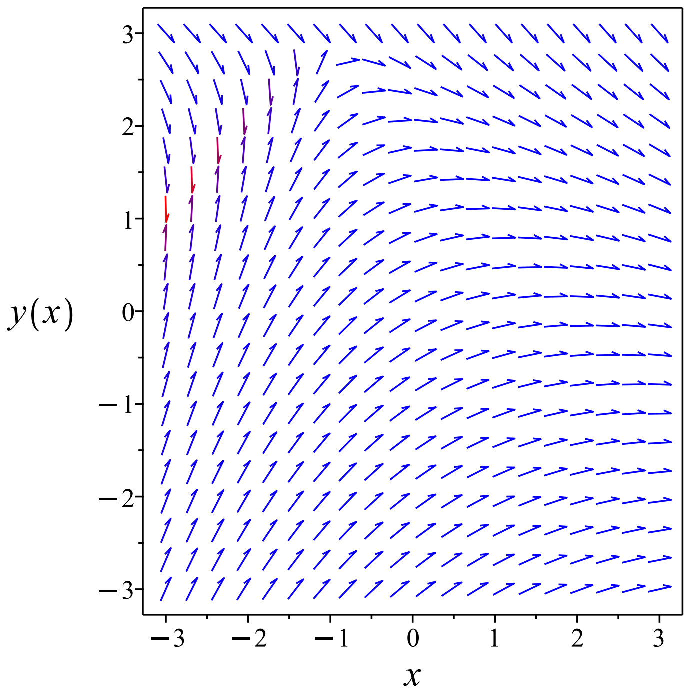

Figure 173: Slope field plot

Verification of solutions

$$\frac{\ln\left(-x^2+(-2y+4)\,x+y^2-8y+14\right)}{2}=c_1$$

Verified OK.

5.11.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\,\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y} \frac{d y}{d x}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \mathrm{d} x+N(x, y) \mathrm{d} y=0 \tag{1A}$$

Therefore

$$\begin{aligned}
(x-y+4) \mathrm{d} y &= (-x-y+2) \mathrm{d} x \\
(x+y-2) \mathrm{d} x+(x-y+4) \mathrm{d} y &= 0
\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= x+y-2 \\
N(x, y) &= x-y+4
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x+y-2) \\
&= 1
\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x-y+4)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int x+y-2\,\mathrm{d}x\end{aligned}$$

$$\phi = \frac{x(x+2y-4)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x - y + 4$. Therefore equation (4) becomes

$$x - y + 4 = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y + 4$$

Integrating the above w.r.t y gives

$$\begin{aligned}\int f'(y)\,\mathrm{d}y &= \int (-y+4)\,\mathrm{d}y\\ f(y) &= -\frac{1}{2}y^2 + 4y + c_1\end{aligned}$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x(x+2y-4)}{2} - \frac{y^2}{2} + 4y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x(x+2y-4)}{2} - \frac{y^2}{2} + 4y$$

Summary

The solution(s) found are the following

$$\frac{x(x+2y-4)}{2} - \frac{y^2}{2} + 4y = c_1 \tag{1}$$

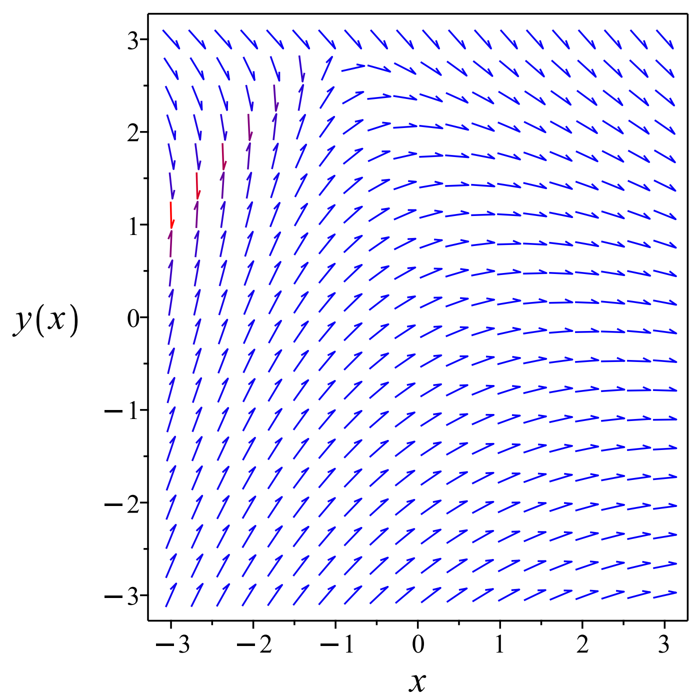

Figure 174: Slope field plot

Verification of solutions

$$\frac{x(x+2y-4)}{2} - \frac{y^2}{2} + 4y = c_1$$

Verified OK.

5.11.5 Maple step by step solution

Let's solve

$y+(x-y+4)\,y'=-x+2$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$

  ◦ Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

  ◦ Evaluate derivatives

    $1=1$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int(x+y-2)\,dx+f_1(y)$

- Evaluate integral

  $F(x,y)=\frac{x^2}{2}+xy-2x+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $x-y+4=x+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=-y+4$

- Solve for $f_1(y)$

  $f_1(y)=-\frac{1}{2}y^2+4y$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$F(x, y) = \frac{1}{2}x^2 + xy - 2x - \frac{1}{2}y^2 + 4y$

- Substitute $F(x, y)$ into the solution of the ODE

  $\frac{1}{2}x^2 + xy - 2x - \frac{1}{2}y^2 + 4y = c_1$

- Solve for y

  $\left\{y = x + 4 - \sqrt{2x^2 - 2c_1 + 4x + 16}, y = x + 4 + \sqrt{2x^2 - 2c_1 + 4x + 16}\right\}$

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{y + (x - y - 2)\, y' = -x}$$

5.12.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-y - x}{x - y - 2} \tag{1}$$

Which becomes

$$(-y - 2)\, dy = (-x)\, dy + (-y - x)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + (-y - x)\, dx = d\left(-\frac{1}{2}x^2 - xy\right)$$

Hence (2) becomes

$$(-y-2)\,dy = d\left(-\frac{1}{2}x^2 - xy\right)$$

Integrating both sides gives gives these solutions

$$y = x - 2 + \sqrt{2x^2 - 2c_1 - 4x + 4} + c_1$$
$$y = x - 2 - \sqrt{2x^2 - 2c_1 - 4x + 4} + c_1$$

Summary

The solution(s) found are the following

$$y = x - 2 + \sqrt{2x^2 - 2c_1 - 4x + 4} + c_1 \tag{1}$$
$$y = x - 2 - \sqrt{2x^2 - 2c_1 - 4x + 4} + c_1 \tag{2}$$

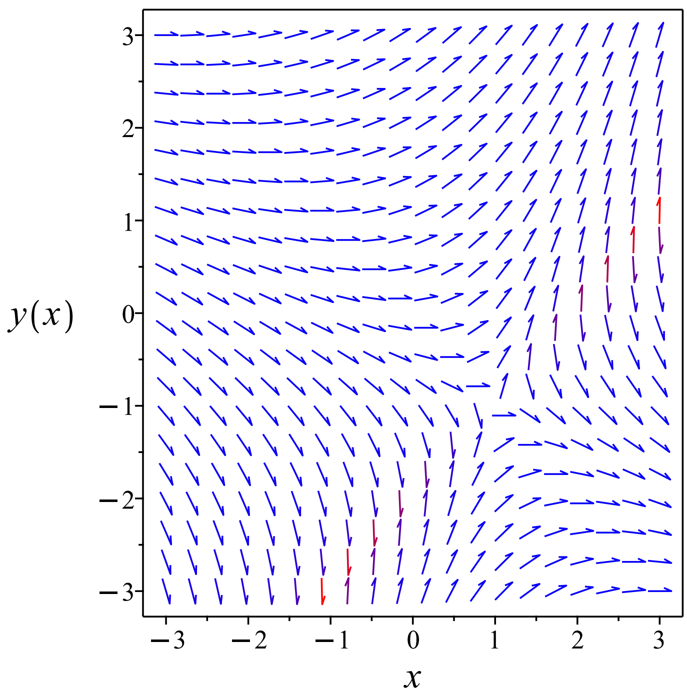

Figure 175: Slope field plot

Verification of solutions

$$y = x - 2 + \sqrt{2x^2 - 2c_1 - 4x + 4} + c_1$$

Verified OK.

$$y = x - 2 - \sqrt{2x^2 - 2c_1 - 4x + 4} + c_1$$

Verified OK.

5.12.2 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = \frac{Y(X) + y_0 + X + x_0}{-X - x_0 + Y(X) + y_0 + 2}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$\begin{aligned} x_0 &= 1 \\ y_0 &= -1 \end{aligned}$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = \frac{Y(X) + X}{-X + Y(X)}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X, Y) \\ &= \frac{Y + X}{-X + Y} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X, Y)$ and $N(X, Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X, Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X, Y)$$

In this case, it can be seen that both $M = -Y - X$ and $N = X - Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\begin{aligned} \frac{\mathrm{d}u}{\mathrm{d}X}X + u &= \frac{u+1}{u-1} \\ \frac{\mathrm{d}u}{\mathrm{d}X} &= \frac{\frac{u(X)+1}{u(X)-1} - u(X)}{X} \end{aligned}$$

Or

$$\frac{d}{dX}u(X) - \frac{\frac{u(X)+1}{u(X)-1} - u(X)}{X} = 0$$

Or

$$\left(\frac{d}{dX}u(X)\right) X u(X) - \left(\frac{d}{dX}u(X)\right) X + u(X)^2 - 2u(X) - 1 = 0$$

Or

$$X(u(X)-1)\left(\frac{d}{dX}u(X)\right) + u(X)^2 - 2u(X) - 1 = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X,u) \\ &= f(X)g(u) \\ &= -\frac{u^2-2u-1}{X(u-1)} \end{aligned}$$

Where $f(X) = -\frac{1}{X}$ and $g(u) = \frac{u^2-2u-1}{u-1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2-2u-1}{u-1}}\, du = -\frac{1}{X}\, dX$$

$$\int \frac{1}{\frac{u^2-2u-1}{u-1}}\, du = \int -\frac{1}{X}\, dX$$

$$\frac{\ln(u^2-2u-1)}{2} = -\ln(X) + c_2$$

Raising both side to exponential gives

$$\sqrt{u^2-2u-1} = \mathrm{e}^{-\ln(X)+c_2}$$

Which simplifies to

$$\sqrt{u^2-2u-1} = \frac{c_3}{X}$$

Which simplifies to

$$\sqrt{u(X)^2-2u(X)-1} = \frac{c_3 \mathrm{e}^{c_2}}{X}$$

The solution is

$$\sqrt{u(X)^2-2u(X)-1} = \frac{c_3 \mathrm{e}^{c_2}}{X}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\sqrt{\frac{Y(X)^2}{X^2} - \frac{2Y(X)}{X} - 1} = \frac{c_3 e^{c_2}}{X}$$

Using the solution for $Y(X)$

$$\sqrt{\frac{Y(X)^2 - 2Y(X)X - X^2}{X^2}} = \frac{c_3 e^{c_2}}{X}$$

And replacing back terms in the above solution using

$$Y = y + y_0$$
$$X = x + x_0$$

Or

$$Y = y - 1$$
$$X = x + 1$$

Then the solution in y becomes

$$\sqrt{\frac{(y+1)^2 - 2(y+1)(x-1) - (x-1)^2}{(x-1)^2}} = \frac{c_3 e^{c_2}}{x-1}$$

<u>Summary</u>
The solution(s) found are the following

$$\sqrt{\frac{(y+1)^2 - 2(y+1)(x-1) - (x-1)^2}{(x-1)^2}} = \frac{c_3 e^{c_2}}{x-1} \tag{1}$$

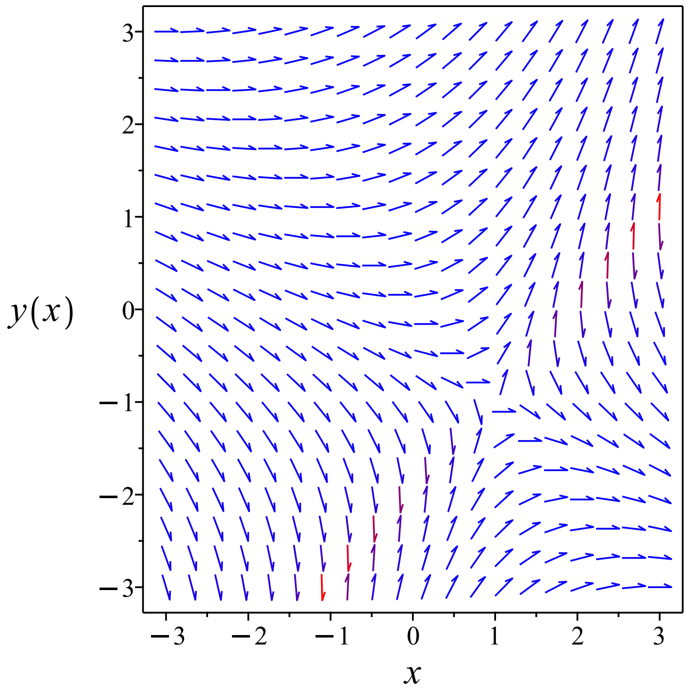

Figure 176: Slope field plot

Verification of solutions

$$\sqrt{\frac{(y+1)^2 - 2(y+1)(x-1) - (x-1)^2}{(x-1)^2}} = \frac{c_3 e^{c_2}}{x-1}$$

Verified OK.

5.12.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{y+x}{-x+y+2}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}&b_2 + \frac{(y+x)(b_3-a_2)}{-x+y+2} - \frac{(y+x)^2 a_3}{(-x+y+2)^2} \\ &- \left(\frac{1}{-x+y+2} + \frac{y+x}{(-x+y+2)^2}\right)(xa_2 + ya_3 + a_1) \\ &- \left(\frac{1}{-x+y+2} - \frac{y+x}{(-x+y+2)^2}\right)(xb_2 + yb_3 + b_1) = 0\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^2a_2 - x^2a_3 + 3x^2b_2 - x^2b_3 - 2xya_2 - 2xya_3 - 2xyb_2 + 2xyb_3 - y^2a_2 - 3y^2a_3 + y^2b_2 + y^2b_3 - 4xa_2 + 2x}{(x-y-2)^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned}&x^2a_2 - x^2a_3 + 3x^2b_2 - x^2b_3 - 2xya_2 - 2xya_3 - 2xyb_2 + 2xyb_3 \\ &- y^2a_2 - 3y^2a_3 + y^2b_2 + y^2b_3 - 4xa_2 + 2xb_1 - 6xb_2 + 2xb_3 \\ &- 2ya_1 - 2ya_2 - 2ya_3 + 4yb_2 - 2a_1 - 2b_1 + 4b_2 = 0\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}&a_2v_1^2 - 2a_2v_1v_2 - a_2v_2^2 - a_3v_1^2 - 2a_3v_1v_2 - 3a_3v_2^2 + 3b_2v_1^2 - 2b_2v_1v_2 \\ &+ b_2v_2^2 - b_3v_1^2 + 2b_3v_1v_2 + b_3v_2^2 - 2a_1v_2 - 4a_2v_1 - 2a_2v_2 \\ &- 2a_3v_2 + 2b_1v_1 - 6b_2v_1 + 4b_2v_2 + 2b_3v_1 - 2a_1 - 2b_1 + 4b_2 = 0\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(a_2-a_3+3b_2-b_3) v_1^2+(-2a_2-2a_3-2b_2+2b_3) v_1 v_2+(-4a_2+2b_1-6b_2+2b_3) v_1 \\ +(-a_2-3a_3+b_2+b_3) v_2^2+(-2a_1-2a_2-2a_3+4b_2) v_2-2a_1-2b_1+4b_2=0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-2a_1-2b_1+4b_2&=0\\
-2a_1-2a_2-2a_3+4b_2&=0\\
-4a_2+2b_1-6b_2+2b_3&=0\\
-2a_2-2a_3-2b_2+2b_3&=0\\
-a_2-3a_3+b_2+b_3&=0\\
a_2-a_3+3b_2-b_3&=0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1&=3b_2-b_3\\
a_2&=-2b_2+b_3\\
a_3&=b_2\\
b_1&=-b_2+b_3\\
b_2&=b_2\\
b_3&=b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi&=x-1\\
\eta&=y+1
\end{aligned}$$

Shifting is now applied to make $\xi=0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta&=\eta-\omega(x,y)\,\xi\\
&=y+1-\left(\frac{y+x}{-x+y+2}\right)(x-1)\\
&=\frac{x^2+2xy-y^2-4y-2}{x-y-2}\\
\xi&=0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2+2xy-y^2-4y-2}{x-y-2}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln(-x^2 - 2xy + y^2 + 4y + 2)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y + x}{-x + y + 2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y + x}{-y^2 + (2x - 4) y + x^2 - 2} \\ S_y &= \frac{x - y - 2}{-y^2 + (2x - 4) y + x^2 - 2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln\left(y^2 + (-2x+4)\,y - x^2 + 2\right)}{2} = c_1$$

Which simplifies to

$$\frac{\ln\left(y^2 + (-2x+4)\,y - x^2 + 2\right)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y+x}{-x+y+2}$ 	$R = x$ $S = \frac{\ln\left(y^2 + (-2x+4)\,y\right.}{2}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln \left(y^{2}+\left(-2 x+4\right) y-x^{2}+2\right)}{2}=c_{1} \tag{1}$$

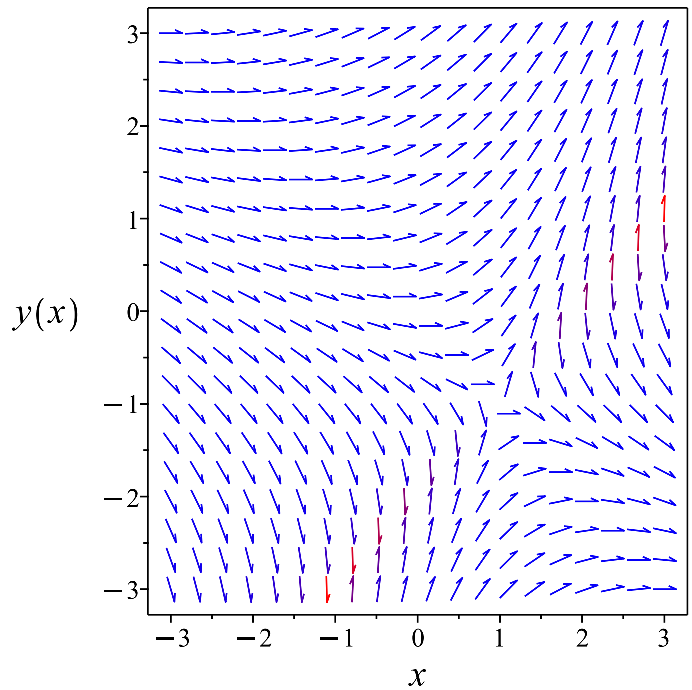

Figure 177: Slope field plot

Verification of solutions

$$\frac{\ln \left(y^{2}+\left(-2 x+4\right) y-x^{2}+2\right)}{2}=c_{1}$$

Verified OK.

5.12.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(x-y-2)\,\mathrm{d}y&=(-y-x)\,\mathrm{d}x\\ (y+x)\,\mathrm{d}x+(x-y-2)\,\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=y+x\\ N(x,y)&=x-y-2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(y+x)\\ &=1\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x - y - 2) \\
&= 1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int y + x \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{x(x + 2y)}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x - y - 2$. Therefore equation (4) becomes

$$
x - y - 2 = x + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -y - 2
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int (-y - 2) \, \mathrm{d}y \\
f(y) &= -\frac{1}{2}y^2 - 2y + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x(x+2y)}{2} - \frac{y^2}{2} - 2y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x(x+2y)}{2} - \frac{y^2}{2} - 2y$$

Summary

The solution(s) found are the following

$$\frac{x(x+2y)}{2} - \frac{y^2}{2} - 2y = c_1 \tag{1}$$

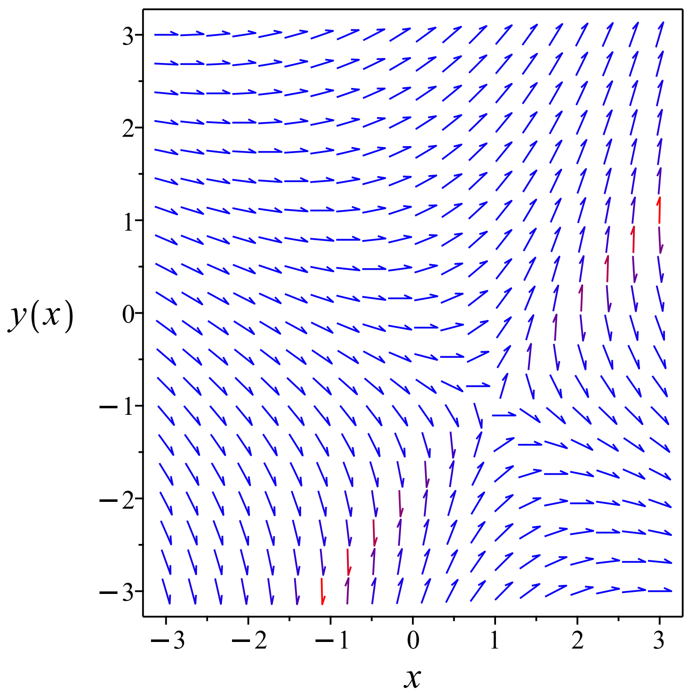

Figure 178: Slope field plot

Verification of solutions

$$\frac{x(x+2y)}{2} - \frac{y^2}{2} - 2y = c_1$$

Verified OK.

5.12.5 Maple step by step solution

Let's solve

$y + (x - y - 2)\, y' = -x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  ◦ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

  ◦ Evaluate derivatives

    $1 = 1$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\,, N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (y + x)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = xy + \frac{x^2}{2} + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

  $x - y - 2 = x + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = -y - 2$

- Solve for $f_1(y)$

  $f_1(y) = -\frac{1}{2}y^2 - 2y$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$F(x, y) = xy + \frac{1}{2}x^2 - \frac{1}{2}y^2 - 2y$

- Substitute $F(x, y)$ into the solution of the ODE

  $xy + \frac{1}{2}x^2 - \frac{1}{2}y^2 - 2y = c_1$

- Solve for y

  $\left\{y = x - 2 - \sqrt{2x^2 - 2c_1 - 4x + 4}, y = x - 2 + \sqrt{2x^2 - 2c_1 - 4x + 4}\right\}$

Section: Section 5. Homogeneous equations. Exercises page 44
Problem number: 112.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeMapleC", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{3y + (3x + 2y - 5)\, y' = -2x + 5}$$

5.13.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-2x - 3y + 5}{3x + 2y - 5} \tag{1}$$

Which becomes

$$(-5 + 2y)\, dy = (-3x)\, dy + (-2x - 3y + 5)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-3x)\, dy + (-2x - 3y + 5)\, dx = d\left(-x^2 - 3xy + 5x\right)$$

Hence (2) becomes

$$(-5+2y)\,dy = d\left(-x^2-3xy+5x\right)$$

Integrating both sides gives gives these solutions

$$y = -\frac{3x}{2}+\frac{5}{2}+\frac{\sqrt{5x^2+4c_1-10x+25}}{2}+c_1$$
$$y = -\frac{3x}{2}+\frac{5}{2}-\frac{\sqrt{5x^2+4c_1-10x+25}}{2}+c_1$$

Summary
The solution(s) found are the following

$$y = -\frac{3x}{2}+\frac{5}{2}+\frac{\sqrt{5x^2+4c_1-10x+25}}{2}+c_1 \tag{1}$$
$$y = -\frac{3x}{2}+\frac{5}{2}-\frac{\sqrt{5x^2+4c_1-10x+25}}{2}+c_1 \tag{2}$$

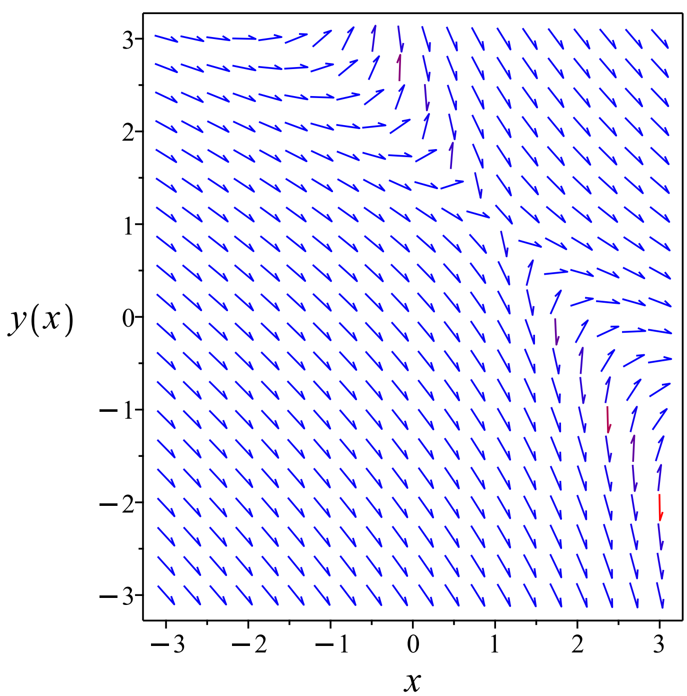

Figure 179: Slope field plot

Verification of solutions

$$y = -\frac{3x}{2} + \frac{5}{2} + \frac{\sqrt{5x^2 + 4c_1 - 10x + 25}}{2} + c_1$$

Verified OK.

$$y = -\frac{3x}{2} + \frac{5}{2} - \frac{\sqrt{5x^2 + 4c_1 - 10x + 25}}{2} + c_1$$

Verified OK.

5.13.2 Solving as homogeneousTypeMapleC ode

Let $Y = y + y_0$ and $X = x + x_0$ then the above is transformed to new ode in $Y(X)$

$$\frac{d}{dX}Y(X) = -\frac{2X + 2x_0 + 3Y(X) + 3y_0 - 5}{3X + 3x_0 + 2Y(X) + 2y_0 - 5}$$

Solving for possible values of x_0 and y_0 which makes the above ode a homogeneous ode results in

$$\begin{aligned} x_0 &= 1 \\ y_0 &= 1 \end{aligned}$$

Using these values now it is possible to easily solve for $Y(X)$. The above ode now becomes

$$\frac{d}{dX}Y(X) = -\frac{2X + 3Y(X)}{3X + 2Y(X)}$$

In canonical form, the ODE is

$$\begin{aligned} Y' &= F(X,Y) \\ &= -\frac{2X + 3Y}{3X + 2Y} \end{aligned} \tag{1}$$

An ode of the form $Y' = \frac{M(X,Y)}{N(X,Y)}$ is called homogeneous if the functions $M(X,Y)$ and $N(X,Y)$ are both homogeneous functions and of the same order. Recall that a function $f(X,Y)$ is homogeneous of order n if

$$f(t^n X, t^n Y) = t^n f(X,Y)$$

In this case, it can be seen that both $M = -2X - 3Y$ and $N = 3X + 2Y$ are both homogeneous and of the same order $n = 1$. Therefore this is a homogeneous ode. Since this ode is homogeneous, it is converted to separable ODE using the substitution $u = \frac{Y}{X}$, or $Y = uX$. Hence

$$\frac{\mathrm{d}Y}{\mathrm{d}X} = \frac{\mathrm{d}u}{\mathrm{d}X}X + u$$

Applying the transformation $Y = uX$ to the above ODE in (1) gives

$$\frac{\mathrm{d}u}{\mathrm{d}X}X + u = \frac{-3u-2}{2u+3}$$
$$\frac{\mathrm{d}u}{\mathrm{d}X} = \frac{\frac{-3u(X)-2}{2u(X)+3} - u(X)}{X}$$

Or

$$\frac{d}{dX}u(X) - \frac{\frac{-3u(X)-2}{2u(X)+3} - u(X)}{X} = 0$$

Or

$$2\left(\frac{d}{dX}u(X)\right)Xu(X) + 3\left(\frac{d}{dX}u(X)\right)X + 2u(X)^2 + 6u(X) + 2 = 0$$

Or

$$2 + X(2u(X)+3)\left(\frac{d}{dX}u(X)\right) + 2u(X)^2 + 6u(X) = 0$$

Which is now solved as separable in $u(X)$. Which is now solved in $u(X)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(X,u) \\ &= f(X)g(u) \\ &= -\frac{2(u^2+3u+1)}{X\,(2u+3)} \end{aligned}$$

Where $f(X) = -\frac{2}{X}$ and $g(u) = \frac{u^2+3u+1}{2u+3}$. Integrating both sides gives

$$\frac{1}{\frac{u^2+3u+1}{2u+3}}\,du = -\frac{2}{X}\,dX$$
$$\int \frac{1}{\frac{u^2+3u+1}{2u+3}}\,du = \int -\frac{2}{X}\,dX$$
$$\ln\left(u^2+3u+1\right) = -2\ln(X) + c_2$$

Raising both side to exponential gives

$$u^2 + 3u + 1 = \mathrm{e}^{-2\ln(X)+c_2}$$

Which simplifies to

$$u^2 + 3u + 1 = \frac{c_3}{X^2}$$

Which simplifies to

$$u(X)^2 + 3u(X) + 1 = \frac{c_3 e^{c_2}}{X^2}$$

The solution is

$$u(X)^2 + 3u(X) + 1 = \frac{c_3 e^{c_2}}{X^2}$$

Now u in the above solution is replaced back by Y using $u = \frac{Y}{X}$ which results in the solution

$$\frac{Y(X)^2}{X^2} + \frac{3Y(X)}{X} + 1 = \frac{c_3 e^{c_2}}{X^2}$$

Which simplifies to

$$Y(X)^2 + 3Y(X)\,X + X^2 = c_3 e^{c_2}$$

Using the solution for $Y(X)$

$$Y(X)^2 + 3Y(X)\,X + X^2 = c_3 e^{c_2}$$

And replacing back terms in the above solution using

$$\begin{aligned} Y &= y + y_0 \\ X &= x + x_0 \end{aligned}$$

Or

$$\begin{aligned} Y &= y + 1 \\ X &= x + 1 \end{aligned}$$

Then the solution in y becomes

$$(y-1)^2 + 3(y-1)(x-1) + (x-1)^2 = c_3 e^{c_2}$$

Summary

The solution(s) found are the following

$$(y-1)^2 + 3(y-1)(x-1) + (x-1)^2 = c_3 e^{c_2} \tag{1}$$

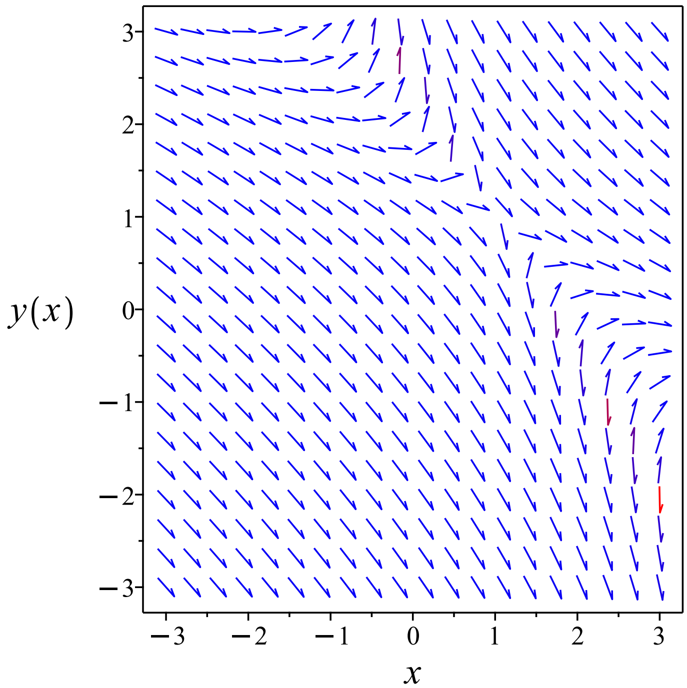

Figure 180: Slope field plot

Verification of solutions

$$(y-1)^2+3(y-1)(x-1)+(x-1)^2=c_3\mathrm{e}^{c_2}$$

Verified OK.

5.13.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{2x+3y-5}{3x+2y-5}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(2x+3y-5)(b_3-a_2)}{3x+2y-5} - \frac{(2x+3y-5)^2 a_3}{(3x+2y-5)^2} - \left(-\frac{2}{3x+2y-5} + \frac{6x+9y-15}{(3x+2y-5)^2}\right)(xa_2+ya_3+a_1) - \left(-\frac{3}{3x+2y-5} + \frac{4x+6y-10}{(3x+2y-5)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{6x^2a_2 - 4x^2a_3 + 14x^2b_2 - 6x^2b_3 + 8xya_2 - 12xya_3 + 12xyb_2 - 8xyb_3 + 6y^2a_2 - 14y^2a_3 + 4y^2b_2 - 6y^2b_3 -}{}$$

$$= 0$$

Setting the numerator to zero gives

$$6x^2a_2 - 4x^2a_3 + 14x^2b_2 - 6x^2b_3 + 8xya_2 - 12xya_3 + 12xyb_2 - 8xyb_3 + 6y^2a_2 - 14y^2a_3 + 4y^2b_2 - 6y^2b_3 - 20xa_2 + 20xa_3 + 5xb_1 - 35xb_2 + 25xb_3 - 5ya_1 - 25ya_2 + 35ya_3 - 20yb_2 + 20yb_3 + 5a_1 + 25a_2 - 25a_3 - 5b_1 + 25b_2 - 25b_3 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$6a_2v_1^2 + 8a_2v_1v_2 + 6a_2v_2^2 - 4a_3v_1^2 - 12a_3v_1v_2 - 14a_3v_2^2 + 14b_2v_1^2 + 12b_2v_1v_2 + 4b_2v_2^2 - 6b_3v_1^2 - 8b_3v_1v_2 - 6b_3v_2^2 - 5a_1v_2 - 20a_2v_1 - 25a_2v_2 + 20a_3v_1 + 35a_3v_2 + 5b_1v_1 - 35b_2v_1 - 20b_2v_2 + 25b_3v_1 + 20b_3v_2 + 5a_1 + 25a_2 - 25a_3 - 5b_1 + 25b_2 - 25b_3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(6a_2 - 4a_3 + 14b_2 - 6b_3) v_1^2 + (8a_2 - 12a_3 + 12b_2 - 8b_3) v_1 v_2 \\
&+ (-20a_2 + 20a_3 + 5b_1 - 35b_2 + 25b_3) v_1 + (6a_2 - 14a_3 + 4b_2 - 6b_3) v_2^2 \\
&+ (-5a_1 - 25a_2 + 35a_3 - 20b_2 + 20b_3) v_2 + 5a_1 \\
&+ 25a_2 - 25a_3 - 5b_1 + 25b_2 - 25b_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
6a_2 - 14a_3 + 4b_2 - 6b_3 &= 0 \\
6a_2 - 4a_3 + 14b_2 - 6b_3 &= 0 \\
8a_2 - 12a_3 + 12b_2 - 8b_3 &= 0 \\
-5a_1 - 25a_2 + 35a_3 - 20b_2 + 20b_3 &= 0 \\
-20a_2 + 20a_3 + 5b_1 - 35b_2 + 25b_3 &= 0 \\
5a_1 + 25a_2 - 25a_3 - 5b_1 + 25b_2 - 25b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 4b_2 - b_3 \\
a_2 &= -3b_2 + b_3 \\
a_3 &= -b_2 \\
b_1 &= -b_2 - b_3 \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x - 1 \\
\eta &= y - 1
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - 1 - \left(-\frac{2x+3y-5}{3x+2y-5}\right)(x-1) \\
&= \frac{2x^2 + 6xy + 2y^2 - 10x - 10y + 10}{3x+2y-5} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{2x^2+6xy+2y^2-10x-10y+10}{3x+2y-5}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(x^2 + 3xy + y^2 - 5x - 5y + 5)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{2x+3y-5}{3x+2y-5}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{2x+3y-5}{2x^2+(6y-10)\,x+2y^2-10y+10} \\
S_y &= \frac{3x+2y-5}{2x^2+(6y-10)\,x+2y^2-10y+10}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\ln\left(5+x^2+(3y-5)\,x+y^2-5y\right)}{2} = c_1
$$

Which simplifies to

$$
\frac{\ln\left(5+x^2+(3y-5)\,x+y^2-5y\right)}{2} = c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2x+3y-5}{3x+2y-5}$ 	$R = x$ $S = \frac{\ln(5 + x^2 + (3y - 5)}{2}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(5 + x^2 + (3y - 5)x + y^2 - 5y)}{2} = c_1 \tag{1}$$

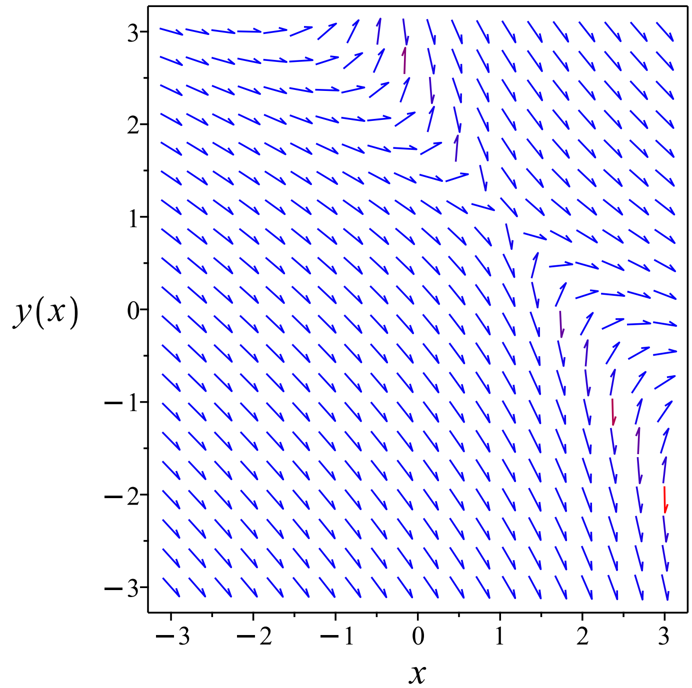

Figure 181: Slope field plot

Verification of solutions

$$\frac{\ln\left(5+x^2+(3y-5)\,x+y^2-5y\right)}{2}=c_1$$

Verified OK.

5.13.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\,\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(3x + 2y - 5)\,\mathrm{d}y &= (-2x - 3y + 5)\,\mathrm{d}x\\ (2x + 3y - 5)\,\mathrm{d}x + (3x + 2y - 5)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 2x + 3y - 5\\ N(x,y) &= 3x + 2y - 5\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2x + 3y - 5)\\ &= 3\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(3x + 2y - 5)\\ &= 3\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int 2x + 3y - 5 \,\mathrm{d}x$$
$$\phi = x(x + 3y - 5) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 3x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3x + 2y - 5$. Therefore equation (4) becomes

$$3x + 2y - 5 = 3x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -5 + 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (-5 + 2y) \,\mathrm{d}y$$
$$f(y) = y^2 - 5y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(x + 3y - 5) + y^2 - 5y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(x + 3y - 5) + y^2 - 5y$$

Summary

The solution(s) found are the following

$$x(x + 3y - 5) + y^2 - 5y = c_1 \tag{1}$$

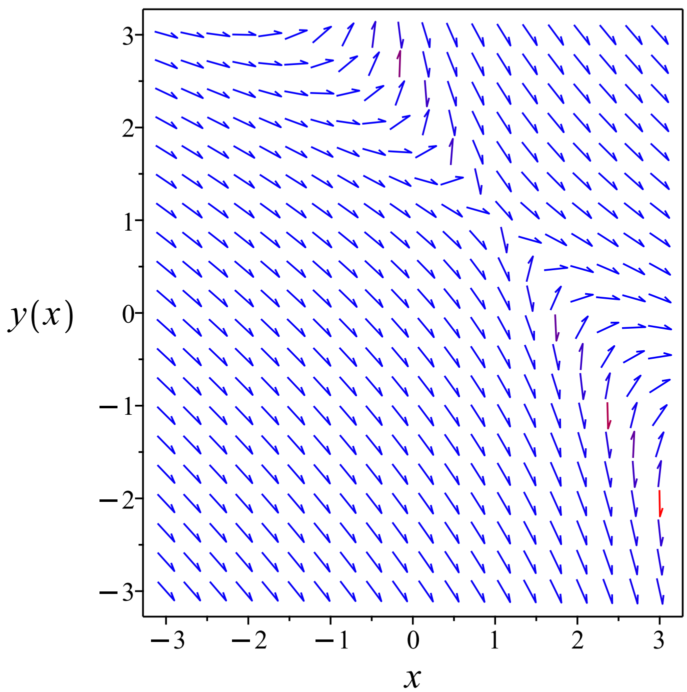

Figure 182: Slope field plot

Verification of solutions

$$x(x + 3y - 5) + y^2 - 5y = c_1$$

Verified OK.

5.13.5 Maple step by step solution

Let's solve

$3y + (3x + 2y - 5)\, y' = -2x + 5$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y) = 0$

  - Compute derivative of lhs

    $F'(x,y) + \left(\frac{\partial}{\partial y}F(x,y)\right) y' = 0$

  - Evaluate derivatives

    $3 = 3$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y)\,, N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int (2x + 3y - 5)\, dx + f_1(y)$

- Evaluate integral

  $F(x,y) = x^2 + 3xy - 5x + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $3x + 2y - 5 = 3x + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = -5 + 2y$

- Solve for $f_1(y)$

  $f_1(y) = y^2 - 5y$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$$F(x,y) = x^2 + 3xy + y^2 - 5x - 5y$$

- Substitute $F(x,y)$ into the solution of the ODE

$$x^2 + 3xy + y^2 - 5x - 5y = c_1$$

- Solve for y

$$\left\{y = -\frac{3x}{2} + \frac{5}{2} - \frac{\sqrt{5x^2+4c_1-10x+25}}{2}, y = -\frac{3x}{2} + \frac{5}{2} + \frac{\sqrt{5x^2+4c_1-10x+25}}{2}\right\}$$

Section: Section 5. Homogeneous equations. Exercises page 44
Problem number: 113.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{4y + (4x + 2y + 1)\, y' = -8x - 1}$$

5.14.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-8x - 4y - 1}{4x + 2y + 1} \tag{1}$$

Which becomes

$$(2y + 1)\, dy = (-4x)\, dy + (-8x - 4y - 1)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-4x)\, dy + (-8x - 4y - 1)\, dx = d\big(-4x^2 - 4xy - x\big)$$

Hence (2) becomes

$$(2y+1)\,dy = d\left(-4x^2 - 4xy - x\right)$$

Integrating both sides gives gives these solutions

$$y = -2x - \frac{1}{2} + \frac{\sqrt{4c_1 + 4x + 1}}{2} + c_1$$
$$y = -2x - \frac{1}{2} - \frac{\sqrt{4c_1 + 4x + 1}}{2} + c_1$$

Summary
The solution(s) found are the following

$$y = -2x - \frac{1}{2} + \frac{\sqrt{4c_1 + 4x + 1}}{2} + c_1 \tag{1}$$
$$y = -2x - \frac{1}{2} - \frac{\sqrt{4c_1 + 4x + 1}}{2} + c_1 \tag{2}$$

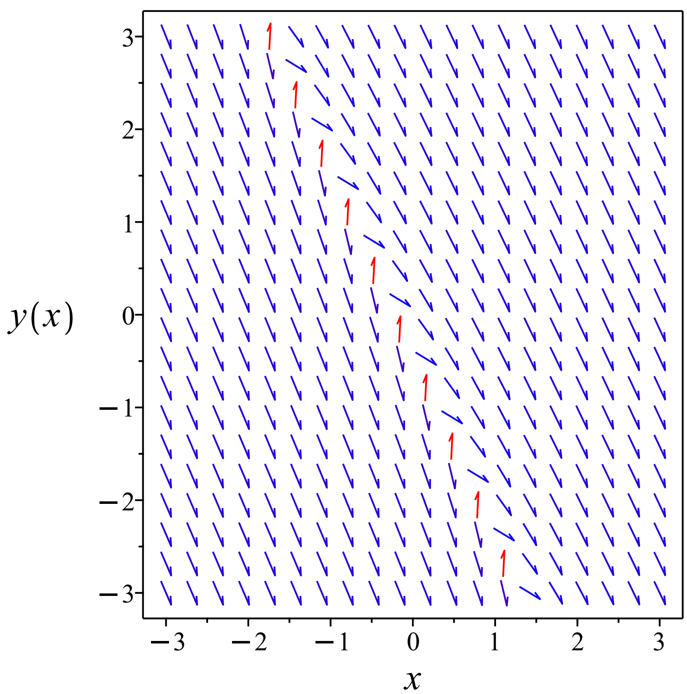

Figure 183: Slope field plot

Verification of solutions

$$y = -2x - \frac{1}{2} + \frac{\sqrt{4c_1 + 4x + 1}}{2} + c_1$$

Verified OK.

$$y = -2x - \frac{1}{2} - \frac{\sqrt{4c_1 + 4x + 1}}{2} + c_1$$

Verified OK.

5.14.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{8x + 4y + 1}{4x + 2y + 1}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(8x + 4y + 1)(b_3 - a_2)}{4x + 2y + 1} - \frac{(8x + 4y + 1)^2 a_3}{(4x + 2y + 1)^2} - \left(-\frac{8}{4x + 2y + 1} + \frac{32x + 16y + 4}{(4x + 2y + 1)^2}\right)(x a_2 + y a_3 + a_1) - \left(-\frac{4}{4x + 2y + 1} + \frac{16x + 8y + 2}{(4x + 2y + 1)^2}\right)(x b_2 + y b_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{32x^2a_2 - 64x^2a_3 + 16x^2b_2 - 32x^2b_3 + 32xya_2 - 64xya_3 + 16xyb_2 - 32xyb_3 + 8y^2a_2 - 16y^2a_3 + 4y^2b_2 - 8}{(4x + 2y}$$
$= 0$

Setting the numerator to zero gives

$$32x^2a_2 - 64x^2a_3 + 16x^2b_2 - 32x^2b_3 + 32xya_2 - 64xya_3 + 16xyb_2 - 32xyb_3 + 8y^2a_2 - 16y^2a_3 + 4y^2b_2 - 8y^2b_3 + 16xa_2 - 16xa_3 + 10xb_2 - 12xb_3 + 6ya_2 - 4ya_3 + 4yb_2 - 4yb_3 + 4a_1 + a_2 - a_3 + 2b_1 + b_2 - b_3 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$32a_2v_1^2 + 32a_2v_1v_2 + 8a_2v_2^2 - 64a_3v_1^2 - 64a_3v_1v_2 - 16a_3v_2^2 + 16b_2v_1^2 + 16b_2v_1v_2 + 4b_2v_2^2 - 32b_3v_1^2 - 32b_3v_1v_2 - 8b_3v_2^2 + 16a_2v_1 + 6a_2v_2 - 16a_3v_1 - 4a_3v_2 + 10b_2v_1 + 4b_2v_2 - 12b_3v_1 - 4b_3v_2 + 4a_1 + a_2 - a_3 + 2b_1 + b_2 - b_3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(32a_2 - 64a_3 + 16b_2 - 32b_3)\, v_1^2 + (32a_2 - 64a_3 + 16b_2 - 32b_3)\, v_1v_2 + (16a_2 - 16a_3 + 10b_2 - 12b_3)\, v_1 + (8a_2 - 16a_3 + 4b_2 - 8b_3)\, v_2^2 + (6a_2 - 4a_3 + 4b_2 - 4b_3)\, v_2 + 4a_1 + a_2 - a_3 + 2b_1 + b_2 - b_3 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}6a_2 - 4a_3 + 4b_2 - 4b_3 &= 0\\ 8a_2 - 16a_3 + 4b_2 - 8b_3 &= 0\\ 16a_2 - 16a_3 + 10b_2 - 12b_3 &= 0\\ 32a_2 - 64a_3 + 16b_2 - 32b_3 &= 0\\ 4a_1 + a_2 - a_3 + 2b_1 + b_2 - b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= a_1\\ a_2 &= 8a_1 + 4b_1\\ a_3 &= a_3\\ b_1 &= b_1\\ b_2 &= -8a_1 - 4b_1 - 2a_3\\ b_3 &= 4a_1 - 3a_3 + 2b_1\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= y\\ \eta &= -2x - 3y\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi\\ &= -2x - 3y - \left(-\frac{8x + 4y + 1}{4x + 2y + 1}\right)(y)\\ &= \frac{-8x^2 - 8xy - 2y^2 - 2x - 2y}{4x + 2y + 1}\\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\frac{-8x^2-8xy-2y^2-2x-2y}{4x+2y+1}} dy\end{aligned}$$

Which results in

$$S = -\frac{\ln\left(4x^2+4xy+y^2+x+y\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x+\omega(x,y)S_y}{R_x+\omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{8x+4y+1}{4x+2y+1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1\\ R_y &= 0\\ S_x &= \frac{-8x-4y-1}{8x^2+(8y+2)\,x+2y^2+2y}\\ S_y &= \frac{-4x-2y-1}{8x^2+(8y+2)\,x+2y^2+2y}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{\ln\left(y^2+(4x+1)\,y+4x^2+x\right)}{2} = c_1$$

Which simplifies to

$$-\frac{\ln\left(y^2+(4x+1)\,y+4x^2+x\right)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{8x+4y+1}{4x+2y+1}$ 	$R = x$ $S = -\frac{\ln\left(y^2+(4x+1)\,y\right.}{2}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$-\frac{\ln\left(y^2+(4x+1)\,y+4x^2+x\right)}{2} = c_1 \tag{1}$$

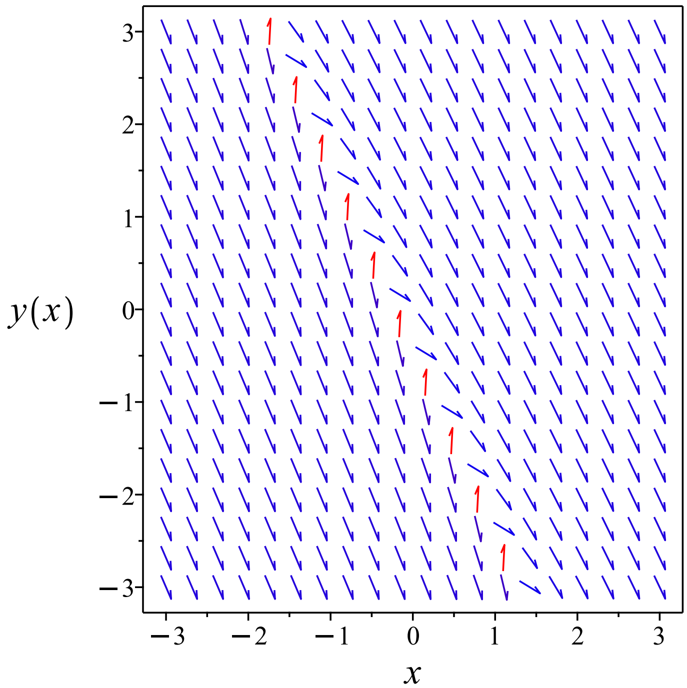

Figure 184: Slope field plot

Verification of solutions

$$
-\frac{\ln \left(y^{2}+\left(4 x+1\right) y+4 x^{2}+x\right)}{2}=c_{1}
$$

Verified OK.

5.14.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}
$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x,y)=0
$$

Hence

$$
\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}
$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(4x + 2y + 1)\,\mathrm{d}y &= (-8x - 4y - 1)\,\mathrm{d}x \\
(8x + 4y + 1)\,\mathrm{d}x + (4x + 2y + 1)\,\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= 8x + 4y + 1 \\
N(x, y) &= 4x + 2y + 1
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(8x + 4y + 1) \\
&= 4
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(4x + 2y + 1) \\
&= 4
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int M \, dx$$

$$\int \frac{\partial \phi}{\partial x} \, dx = \int 8x + 4y + 1 \, dx$$

$$\phi = x(4x + 4y + 1) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 4x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 4x + 2y + 1$. Therefore equation (4) becomes

$$4x + 2y + 1 = 4x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y + 1$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int (2y + 1) \, dy$$

$$f(y) = y^2 + y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(4x + 4y + 1) + y^2 + y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(4x + 4y + 1) + y^2 + y$$

Summary
The solution(s) found are the following

$$x(4x + 4y + 1) + y^2 + y = c_1 \tag{1}$$

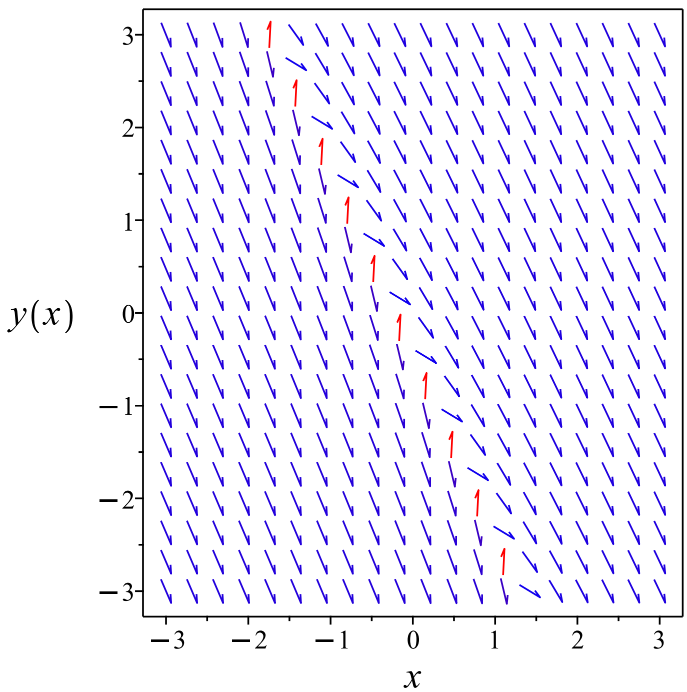

Figure 185: Slope field plot

Verification of solutions

$$x(4x + 4y + 1) + y^2 + y = c_1$$

Verified OK.

5.14.4 Maple step by step solution

Let's solve

$4y + (4x + 2y + 1)\, y' = -8x - 1$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ∘ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  - ∘ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

  - ∘ Evaluate derivatives

    $4 = 4$

  - ∘ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\, , N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (8x + 4y + 1)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = 4x^2 + 4xy + x + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $4x + 2y + 1 = 4x + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = 2y + 1$

- Solve for $f_1(y)$

  $f_1(y) = y^2 + y$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$$F(x,y) = 4x^2 + 4xy + y^2 + x + y$$

- Substitute $F(x,y)$ into the solution of the ODE

$$4x^2 + 4xy + y^2 + x + y = c_1$$

- Solve for y

$$\left\{y = -2x - \frac{1}{2} - \frac{\sqrt{4c_1 + 4x + 1}}{2}, y = -2x - \frac{1}{2} + \frac{\sqrt{4c_1 + 4x + 1}}{2}\right\}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{-2y+(3x-6y+2)\,y'=1-x}$$

5.15.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{-x+2y+1}{-3x+6y-2} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 - \frac{(-x+2y+1)(b_3-a_2)}{-3x+6y-2} - \frac{(-x+2y+1)^2 a_3}{(-3x+6y-2)^2} \\
& - \left(\frac{1}{-3x+6y-2} - \frac{3(-x+2y+1)}{(-3x+6y-2)^2}\right)(xa_2+ya_3+a_1) \\
& - \left(-\frac{2}{-3x+6y-2} + \frac{-6x+12y+6}{(-3x+6y-2)^2}\right)(xb_2+yb_3+b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
\frac{3x^2a_2 - x^2a_3 + 9x^2b_2 - 3x^2b_3 - 12xya_2 + 4xya_3 - 36xyb_2 + 12xyb_3 + 12y^2a_2 - 4y^2a_3 + 36y^2b_2 - 12y^2b_3}{(3x - 6y + 2}
$$

$= 0$

Setting the numerator to zero gives

$$
\begin{aligned}
& 3x^2a_2 - x^2a_3 + 9x^2b_2 - 3x^2b_3 - 12xya_2 + 4xya_3 - 36xyb_2 + 12xyb_3 \\
& + 12y^2a_2 - 4y^2a_3 + 36y^2b_2 - 12y^2b_3 + 4xa_2 + 2xa_3 + 2xb_2 + xb_3 \\
& + 2ya_2 + ya_3 - 24yb_2 - 12yb_3 + 5a_1 - 2a_2 - a_3 - 10b_1 + 4b_2 + 2b_3 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\{x, y\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\{x = v_1, y = v_2\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
& 3a_2v_1^2 - 12a_2v_1v_2 + 12a_2v_2^2 - a_3v_1^2 + 4a_3v_1v_2 - 4a_3v_2^2 + 9b_2v_1^2 - 36b_2v_1v_2 \\
& + 36b_2v_2^2 - 3b_3v_1^2 + 12b_3v_1v_2 - 12b_3v_2^2 + 4a_2v_1 + 2a_2v_2 + 2a_3v_1 + a_3v_2 \\
& + 2b_2v_1 - 24b_2v_2 + b_3v_1 - 12b_3v_2 + 5a_1 - 2a_2 - a_3 - 10b_1 + 4b_2 + 2b_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}(3a_2 - a_3 + 9b_2 - 3b_3)\, v_1^2 + (-12a_2 + 4a_3 - 36b_2 + 12b_3)\, v_1 v_2 \\ + (4a_2 + 2a_3 + 2b_2 + b_3)\, v_1 + (12a_2 - 4a_3 + 36b_2 - 12b_3)\, v_2^2 \\ + (2a_2 + a_3 - 24b_2 - 12b_3)\, v_2 + 5a_1 - 2a_2 - a_3 - 10b_1 + 4b_2 + 2b_3 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}-12a_2 + 4a_3 - 36b_2 + 12b_3 &= 0 \\ 2a_2 + a_3 - 24b_2 - 12b_3 &= 0 \\ 3a_2 - a_3 + 9b_2 - 3b_3 &= 0 \\ 4a_2 + 2a_3 + 2b_2 + b_3 &= 0 \\ 12a_2 - 4a_3 + 36b_2 - 12b_3 &= 0 \\ 5a_1 - 2a_2 - a_3 - 10b_1 + 4b_2 + 2b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= 2b_1 \\ a_2 &= -3b_2 \\ a_3 &= 6b_2 \\ b_1 &= b_1 \\ b_2 &= b_2 \\ b_3 &= -2b_2\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= 2 \\ \eta &= 1\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x, y)\, \xi \\ &= 1 - \left(-\frac{-x + 2y + 1}{-3x + 6y - 2}\right)(2) \\ &= \frac{5x - 10y}{3x - 6y + 2} \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{5x-10y}{3x-6y+2}} dy \end{aligned}$$

Which results in

$$S = \frac{3y}{5} - \frac{\ln(2y - x)}{5}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{-x + 2y + 1}{-3x + 6y - 2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{1}{5x - 10y} \\ S_y &= \frac{3}{5} + \frac{2}{5x - 10y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{5} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{5}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{R}{5} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{3y}{5} - \frac{\ln(-x+2y)}{5} = -\frac{x}{5} + c_1$$

Which simplifies to

$$\frac{3y}{5} - \frac{\ln(-x+2y)}{5} = -\frac{x}{5} + c_1$$

Which gives

$$y = \frac{\mathrm{e}^{-\operatorname{LambertW}\left(-\frac{3\,\mathrm{e}^{\frac{5x}{2}-5c_1}}{2}\right)+\frac{5x}{2}-5c_1}}{2} + \frac{x}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-x+2y+1}{-3x+6y-2}$ 	$R = x$ $S = \frac{3y}{5} - \frac{\ln(2y-x)}{5}$	$\frac{dS}{dR} = -\frac{1}{5}$ 
Summary

The solution(s) found are the following

$$y = \frac{e^{-\operatorname{LambertW}\left(-\frac{3\,e^{\frac{5x}{2}-5c_1}}{2}\right)+\frac{5x}{2}-5c_1}}{2} + \frac{x}{2} \tag{1}$$

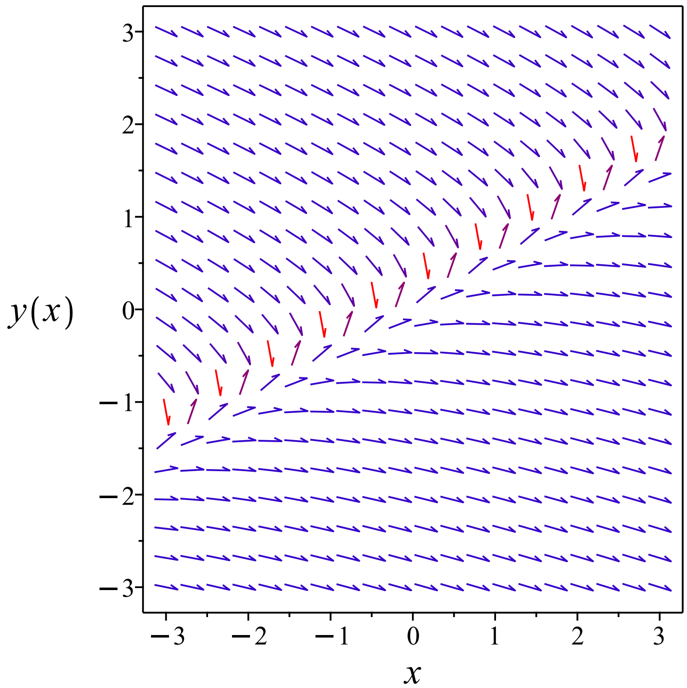

Figure 186: Slope field plot

Verification of solutions

$$y = \frac{e^{-\operatorname{LambertW}\left(-\frac{3\,e^{\frac{5x}{2}-5c_1}}{2}\right)+\frac{5x}{2}-5c_1}}{2} + \frac{x}{2}$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{y + (y - 1 + x)\, y' = -x}$$

5.16.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-y - x}{y - 1 + x} \tag{1}$$

Which becomes

$$(y - 1)\, dy = (-x)\, dy + (-y - x)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + (-y - x)\, dx = d\left(-\frac{1}{2}x^2 - xy\right)$$

Hence (2) becomes

$$(y-1)\,dy = d\left(-\frac{1}{2}x^2 - xy\right)$$

Integrating both sides gives gives these solutions

$$y = -x + 1 + \sqrt{2c_1 - 2x + 1} + c_1$$
$$y = -x + 1 - \sqrt{2c_1 - 2x + 1} + c_1$$

Summary

The solution(s) found are the following

$$y = -x + 1 + \sqrt{2c_1 - 2x + 1} + c_1 \tag{1}$$
$$y = -x + 1 - \sqrt{2c_1 - 2x + 1} + c_1 \tag{2}$$

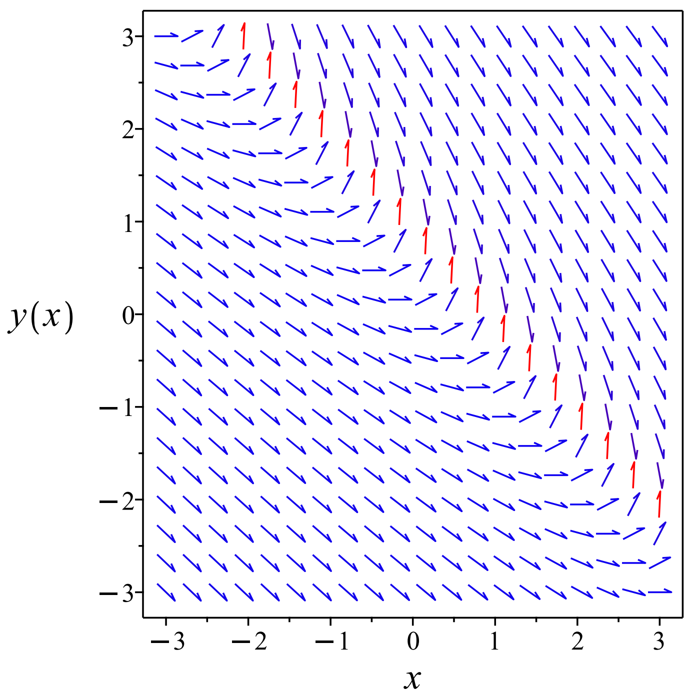

Figure 187: Slope field plot

Verification of solutions

$$y = -x + 1 + \sqrt{2c_1 - 2x + 1} + c_1$$

Verified OK.

$$y = -x + 1 - \sqrt{2c_1 - 2x + 1} + c_1$$

Verified OK.

5.16.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{y+x}{x-1+y} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 - \frac{(y+x)(b_3 - a_2)}{x-1+y} - \frac{(y+x)^2 a_3}{(x-1+y)^2} \\
& - \left(-\frac{1}{x-1+y} + \frac{y+x}{(x-1+y)^2}\right)(x a_2 + y a_3 + a_1) \\
& - \left(-\frac{1}{x-1+y} + \frac{y+x}{(x-1+y)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
\frac{x^2 a_2 - x^2 a_3 + x^2 b_2 - x^2 b_3 + 2xya_2 - 2xya_3 + 2xyb_2 - 2xyb_3 + y^2 a_2 - y^2 a_3 + y^2 b_2 - y^2 b_3 - 2xa_2 - 3xb_2}{(x-1+y)^2}
$$

$= 0$

Setting the numerator to zero gives

$$
\begin{aligned}
& x^2 a_2 - x^2 a_3 + x^2 b_2 - x^2 b_3 + 2xya_2 - 2xya_3 + 2xyb_2 - 2xyb_3 + y^2 a_2 - y^2 a_3 + y^2 b_2 \\
& - y^2 b_3 - 2xa_2 - 3xb_2 + xb_3 - ya_2 - ya_3 - 2yb_2 - a_1 - b_1 + b_2 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$a_2 v_1^2 + 2a_2 v_1 v_2 + a_2 v_2^2 - a_3 v_1^2 - 2a_3 v_1 v_2 - a_3 v_2^2 + b_2 v_1^2 + 2b_2 v_1 v_2 + b_2 v_2^2 - b_3 v_1^2 - 2b_3 v_1 v_2 - b_3 v_2^2 - 2a_2 v_1 - a_2 v_2 - a_3 v_2 - 3b_2 v_1 - 2b_2 v_2 + b_3 v_1 - a_1 - b_1 + b_2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(a_2 - a_3 + b_2 - b_3) v_1^2 + (2a_2 - 2a_3 + 2b_2 - 2b_3) v_1 v_2 + (-2a_2 - 3b_2 + b_3) v_1 + (a_2 - a_3 + b_2 - b_3) v_2^2 + (-a_2 - a_3 - 2b_2) v_2 - a_1 - b_1 + b_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-a_1 - b_1 + b_2 &= 0 \\
-2a_2 - 3b_2 + b_3 &= 0 \\
-a_2 - a_3 - 2b_2 &= 0 \\
a_2 - a_3 + b_2 - b_3 &= 0 \\
2a_2 - 2a_3 + 2b_2 - 2b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= -b_1 + b_2 \\
a_2 &= -a_3 - 2b_2 \\
a_3 &= a_3 \\
b_1 &= b_1 \\
b_2 &= b_2 \\
b_3 &= -2a_3 - b_2
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -1 \\
\eta &= 1
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 1 - \left(-\frac{y+x}{x-1+y}\right)(-1) \\
&= -\frac{1}{x-1+y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{-\frac{1}{x-1+y}} dy
\end{aligned}
$$

Which results in

$$
S = -xy + y - \frac{1}{2}y^2
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y+x}{x-1+y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -y \\ S_y &= -x+1-y \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{y(2x+y-2)}{2} = \frac{x^2}{2} + c_1$$

Which simplifies to

$$-\frac{y(2x+y-2)}{2} = \frac{x^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y+x}{x-1+y}$ 	$R = x$ $S = -\frac{y(2x+y-2)}{2}$	$\frac{dS}{dR} = R$ 
Summary

The solution(s) found are the following

$$-\frac{y(2x+y-2)}{2} = \frac{x^2}{2} + c_1 \tag{1}$$

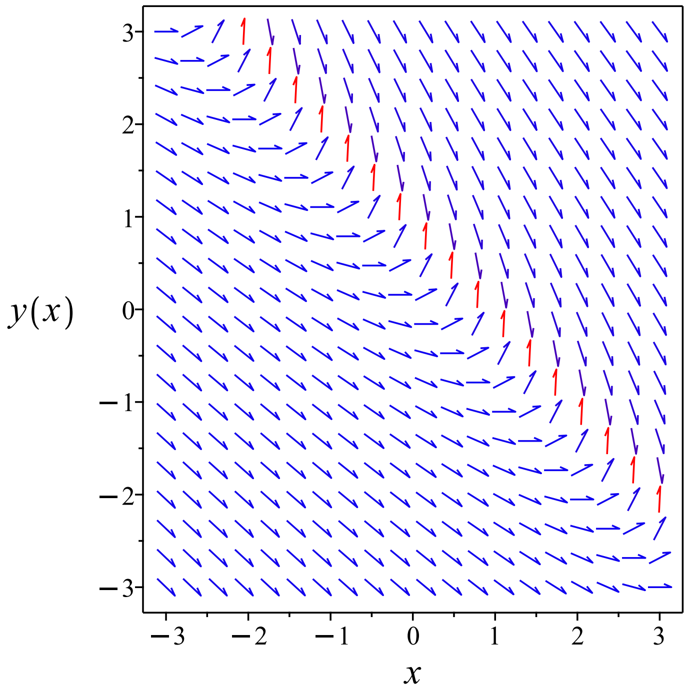

Figure 188: Slope field plot

Verification of solutions

$$-\frac{y(2x+y-2)}{2}=\frac{x^2}{2}+c_1$$

Verified OK.

5.16.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x - 1 + y)\, \mathrm{d}y = (-y - x)\, \mathrm{d}x$$
$$(y + x)\, \mathrm{d}x + (x - 1 + y)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = y + x$$
$$N(x, y) = x - 1 + y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y + x) \\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x - 1 + y) \\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int y + x \, \mathrm{d}x$$

$$\phi = \frac{x(x + 2y)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x - 1 + y$. Therefore equation (4) becomes

$$x - 1 + y = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y - 1$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (y - 1) \, \mathrm{d}y$$

$$f(y) = \frac{1}{2}y^2 - y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x(x + 2y)}{2} + \frac{y^2}{2} - y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x(x+2y)}{2} + \frac{y^2}{2} - y$$

Summary
The solution(s) found are the following

$$\frac{x(x+2y)}{2} + \frac{y^2}{2} - y = c_1 \tag{1}$$

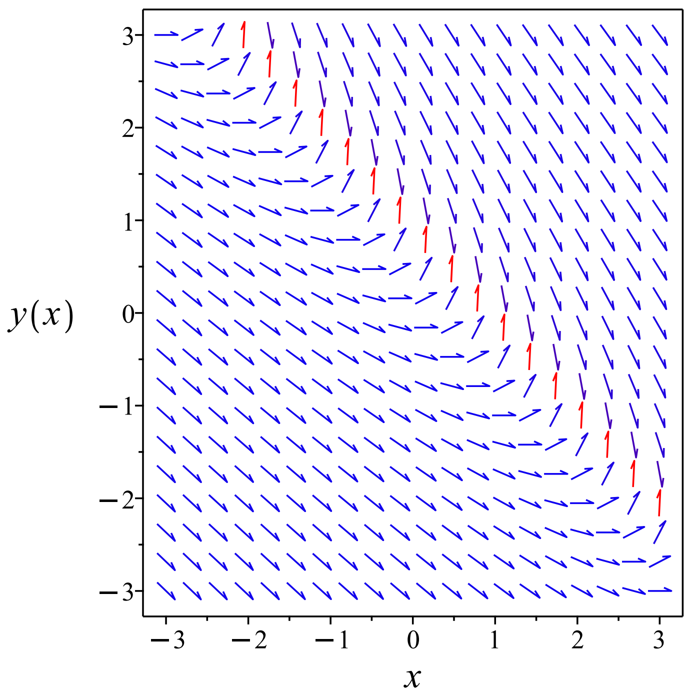

Figure 189: Slope field plot

Verification of solutions

$$\frac{x(x+2y)}{2} + \frac{y^2}{2} - y = c_1$$

Verified OK.

5.16.4 Maple step by step solution

Let's solve

$y + (y - 1 + x)\, y' = -x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  ◦ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

  ◦ Evaluate derivatives

    $1 = 1$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\, , N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (y + x)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = xy + \frac{x^2}{2} + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $x - 1 + y = x + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = y - 1$

- Solve for $f_1(y)$

  $f_1(y) = \frac{1}{2} y^2 - y$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$$F(x,y) = xy + \frac{1}{2}x^2 + \frac{1}{2}y^2 - y$$

- Substitute $F(x,y)$ into the solution of the ODE

$$xy + \frac{1}{2}x^2 + \frac{1}{2}y^2 - y = c_1$$

- Solve for y

$$\left\{y = -x + 1 - \sqrt{2c_1 - 2x + 1}, y = -x + 1 + \sqrt{2c_1 - 2x + 1}\right\}$$

The type(s) of ODE detected by this program : **"exactByInspection", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{2xy'(-y^2+x)+y^3=0}$$

5.17.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{y^3}{2x(y^2-x)} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 + \frac{y^3(b_3 - a_2)}{2x\,(y^2 - x)} - \frac{y^6 a_3}{4x^2\,(y^2 - x)^2} \\ & - \left(-\frac{y^3}{2x^2\,(y^2 - x)} + \frac{y^3}{2x\,(y^2 - x)^2}\right)(x a_2 + y a_3 + a_1) \\ & - \left(\frac{3y^2}{2x\,(y^2 - x)} - \frac{y^4}{x\,(y^2 - x)^2}\right)(x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{2x^2y^4b_2 + y^6a_3 - 2x^3y^2b_2 - 2x^2y^3a_2 + 4x^2y^3b_3 - 4x\,y^4a_3 - 2x\,y^4b_1 + 2y^5a_1 + 4x^4b_2 + 6x^2y^2b_1 - 4x\,y^3a_1}{4x^2\,(-y^2 + x)^2} = 0$$

Setting the numerator to zero gives

$$\begin{aligned} & 2x^2y^4b_2 + y^6a_3 - 2x^3y^2b_2 - 2x^2y^3a_2 + 4x^2y^3b_3 - 4x\,y^4a_3 \\ & - 2x\,y^4b_1 + 2y^5a_1 + 4x^4b_2 + 6x^2y^2b_1 - 4x\,y^3a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & a_3v_2^6 + 2b_2v_1^2v_2^4 + 2a_1v_2^5 - 2a_2v_1^2v_2^3 - 4a_3v_1v_2^4 - 2b_1v_1v_2^4 \\ & - 2b_2v_1^3v_2^2 + 4b_3v_1^2v_2^3 - 4a_1v_1v_2^3 + 6b_1v_1^2v_2^2 + 4b_2v_1^4 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$4b_2v_1^4 - 2b_2v_1^3v_2^2 + 2b_2v_1^2v_2^4 + (-2a_2 + 4b_3)\, v_1^2v_2^3 + 6b_1v_1^2v_2^2 \\ + (-4a_3 - 2b_1)\, v_1v_2^4 - 4a_1v_1v_2^3 + a_3v_2^6 + 2a_1v_2^5 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_3 &= 0 \\ -4a_1 &= 0 \\ 2a_1 &= 0 \\ 6b_1 &= 0 \\ -2b_2 &= 0 \\ 2b_2 &= 0 \\ 4b_2 &= 0 \\ -2a_2 + 4b_3 &= 0 \\ -4a_3 - 2b_1 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 2b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 2x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{y^3}{2x\,(y^2 - x)}\right)(2x) \\
&= \frac{xy}{-y^2 + x} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{xy}{-y^2+x}} dy
\end{aligned}$$

Which results in

$$S = -\frac{y^2}{2x} + \ln(y)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y^3}{2x\,(y^2 - x)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{y^2}{2x^2} \\
S_y &= \frac{-y^2 + x}{xy}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{2 \ln (y) x - y^2}{2x} = c_1
$$

Which simplifies to

$$
\frac{2 \ln (y) x - y^2}{2x} = c_1
$$

Which gives

$$
y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{2c_1}}{x}\right)}{2} + c_1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y^3}{2x(y^2-x)}$  	$R = x$ $S = \frac{2\ln(y)\,x - y^2}{2x}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{\operatorname{LambertW}\left(-\frac{\mathrm{e}^{2c_1}}{x}\right)}{2}+c_1} \tag{1}$$

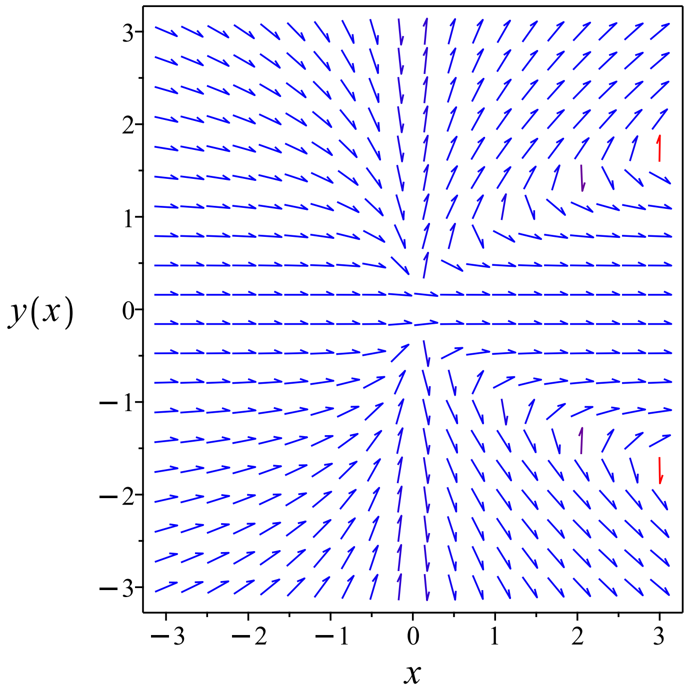

Figure 190: Slope field plot

Verification of solutions

$$y = e^{-\frac{\text{LambertW}\left(-\frac{e^{2c_1}}{x}\right)}{2}+c_1}$$

Verified OK.

5.17.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(2x\left(-y^2+x\right)\right)\mathrm{d}y &= \left(-y^3\right)\mathrm{d}x \\
\left(y^3\right)\mathrm{d}x + \left(2x\left(-y^2+x\right)\right)\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= y^3 \\
N(x,y) &= 2x\left(-y^2+x\right)
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y^3\right) \\
&= 3y^2
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(2x\left(-y^2+x\right)\right) \\
&= -2y^2+4x
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. By inspection $\frac{1}{x^2 y}$ is an integrating factor. Therefore by multiplying $M = y^3$ and $N = 2x(-y^2 + x)$ by this integrating factor the ode becomes exact. The new M, N are

$$M = \frac{y^2}{x^2}$$
$$N = \frac{-2y^2 + 2x}{yx}$$

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{-2y^2+2x}{xy}\right)\mathrm{d}y = \left(-\frac{y^2}{x^2}\right)\mathrm{d}x$$

$$\left(\frac{y^2}{x^2}\right)\mathrm{d}x + \left(\frac{-2y^2+2x}{xy}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{y^2}{x^2}$$
$$N(x,y) = \frac{-2y^2+2x}{xy}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y^2}{x^2}\right)\\ &= \frac{2y}{x^2}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{-2y^2+2x}{xy}\right)\\ &= \frac{2y}{x^2}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{y^2}{x^2}\,\mathrm{d}x$$

$$\phi = -\frac{y^2}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{2y}{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-2y^2+2x}{xy}$. Therefore equation (4) becomes

$$\frac{-2y^2 + 2x}{xy} = -\frac{2y}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{2}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{2}{y}\right) \mathrm{d}y$$

$$f(y) = 2\ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{y^2}{x} + 2\ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{y^2}{x} + 2\ln(y)$$

The solution becomes

$$y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{c_1}}{x}\right)}{2} + \frac{c_1}{2}}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{\mathrm{LambertW}\left(-\frac{\mathrm{e}^{c_1}}{x}\right)}{2} + \frac{c_1}{2}} \tag{1}$$

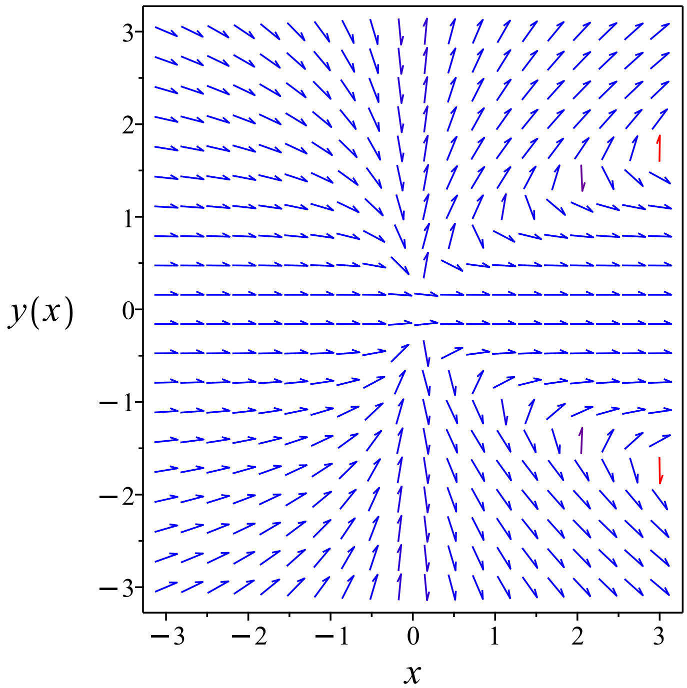

Figure 191: Slope field plot

Verification of solutions

$$y = e^{-\frac{\mathrm{LambertW}\left(-\frac{e^{c_1}}{x}\right)}{2}+\frac{c_1}{2}}$$

Verified OK.

The type(s) of ODE detected by this program : **"bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Bernoulli]
```

$$\boxed{4y^6 - 6y^5xy' = -x^3}$$

5.18.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{4y^6 + x^3}{6x\,y^5}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 151: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{x^4}{y^5}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^4}{y^5}} dy \end{aligned}$$

Which results in

$$S = \frac{y^6}{6x^4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{4y^6 + x^3}{6x\, y^5}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2y^6}{3x^5} \\ S_y &= \frac{y^5}{x^4} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{6x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{6R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{1}{6R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^6}{6x^4} = -\frac{1}{6x} + c_1$$

Which simplifies to

$$\frac{y^6}{6x^4} = -\frac{1}{6x} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{4y^6+x^3}{6x\,y^5}$ 	$R = x$ $S = \frac{y^6}{6x^4}$	$\frac{dS}{dR} = \frac{1}{6R^2}$ 
Summary

The solution(s) found are the following

$$\frac{y^6}{6x^4} = -\frac{1}{6x} + c_1 \tag{1}$$

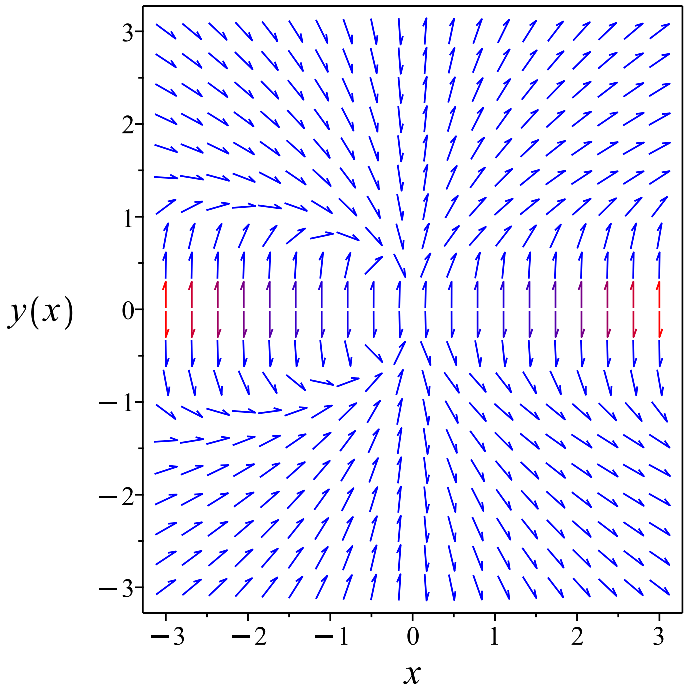

Figure 192: Slope field plot

Verification of solutions

$$\frac{y^6}{6x^4} = -\frac{1}{6x} + c_1$$

Verified OK.

5.18.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{4y^6 + x^3}{6x\,y^5} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{2}{3x}y + \frac{x^2}{6}\frac{1}{y^5} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= \frac{2}{3x} \\
f_1(x) &= \frac{x^2}{6} \\
n &= -5
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y^5}$ gives

$$
y'y^5 = \frac{2y^6}{3x} + \frac{x^2}{6} \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= y^6 \qquad (5)
\end{aligned}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = 6y^5y' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
\frac{w'(x)}{6} &= \frac{2w(x)}{3x} + \frac{x^2}{6} \\
w' &= \frac{4w}{x} + x^2 \qquad (7)
\end{aligned}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{4}{x} \\
q(x) &= x^2
\end{aligned}
$$

Hence the ode is

$$w'(x) - \frac{4w(x)}{x} = x^2$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{4}{x}dx} \\ &= \frac{1}{x^4}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)\left(x^2\right) \\ \frac{d}{dx}\left(\frac{w}{x^4}\right) &= \left(\frac{1}{x^4}\right)\left(x^2\right) \\ d\left(\frac{w}{x^4}\right) &= \frac{1}{x^2}\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^4} &= \int \frac{1}{x^2}\, dx \\ \frac{w}{x^4} &= -\frac{1}{x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^4}$ results in

$$w(x) = c_1 x^4 - x^3$$

Replacing w in the above by y^6 using equation (5) gives the final solution.

$$y^6 = c_1 x^4 - x^3$$

Solving for y gives

$$\begin{aligned}y(x) &= \left(x^3(c_1 x - 1)\right)^{\frac{1}{6}} \\ y(x) &= \frac{\left(1 + i\sqrt{3}\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \\ y(x) &= \frac{\left(i\sqrt{3} - 1\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \\ y(x) &= -\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}} \\ y(x) &= -\frac{\left(1 + i\sqrt{3}\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \\ y(x) &= -\frac{\left(i\sqrt{3} - 1\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(x^3(c_1 x - 1)\right)^{\frac{1}{6}} \tag{1}$$

$$y = \frac{\left(1 + i\sqrt{3}\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \tag{2}$$

$$y = \frac{\left(i\sqrt{3} - 1\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \tag{3}$$

$$y = -\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}} \tag{4}$$

$$y = -\frac{\left(1 + i\sqrt{3}\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \tag{5}$$

$$y = -\frac{\left(i\sqrt{3} - 1\right)\left(x^3(c_1 x - 1)\right)^{\frac{1}{6}}}{2} \tag{6}$$

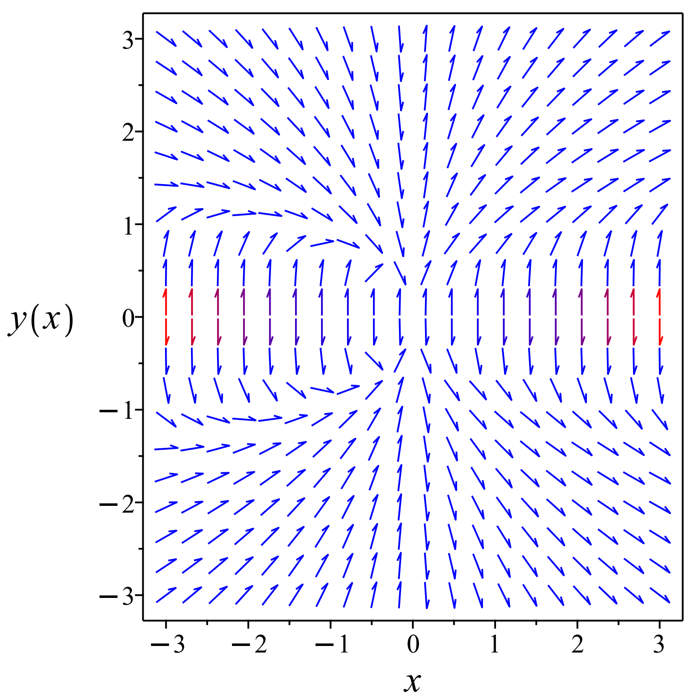

Figure 193: Slope field plot

Verification of solutions

$$y = \left(x^3(c_1x-1)\right)^{\frac{1}{6}}$$

Verified OK.

$$y = \frac{\left(1+i\sqrt{3}\right)\left(x^3(c_1x-1)\right)^{\frac{1}{6}}}{2}$$

Verified OK.

$$y = \frac{\left(i\sqrt{3}-1\right)\left(x^3(c_1x-1)\right)^{\frac{1}{6}}}{2}$$

Verified OK.

$$y = -\left(x^3(c_1x-1)\right)^{\frac{1}{6}}$$

Verified OK.

$$y = -\frac{\left(1+i\sqrt{3}\right)\left(x^3(c_1x-1)\right)^{\frac{1}{6}}}{2}$$

Verified OK.

$$y = -\frac{\left(i\sqrt{3}-1\right)\left(x^3(c_1x-1)\right)^{\frac{1}{6}}}{2}$$

Verified OK.

5.18.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
(-6x\,y^5)\,\mathrm{d}y &= (-4y^6 - x^3)\,\mathrm{d}x \\
(4y^6 + x^3)\,\mathrm{d}x + (-6x\,y^5)\,\mathrm{d}y &= 0
\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 4y^6 + x^3$$
$$N(x, y) = -6x\,y^5$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(4y^6 + x^3) \\
&= 24y^5
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-6x\,y^5) \\
&= -6y^5
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= -\frac{1}{6y^5 x}\left(\left(24y^5\right) - \left(-6y^5\right)\right) \\ &= -\frac{5}{x} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\frac{5}{x} \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-5\ln(x)} \\ &= \frac{1}{x^5} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{x^5}\left(4y^6 + x^3\right) \\ &= \frac{4y^6 + x^3}{x^5} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{x^5}\left(-6x\,y^5\right) \\ &= -\frac{6y^5}{x^4} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{4y^6 + x^3}{x^5}\right) + \left(-\frac{6y^5}{x^4}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{4y^6 + x^3}{x^5} \mathrm{d}x$$
$$\phi = \frac{-y^6 - x^3}{x^4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{6y^5}{x^4} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{6y^5}{x^4}$. Therefore equation (4) becomes

$$-\frac{6y^5}{x^4} = -\frac{6y^5}{x^4} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{-y^6 - x^3}{x^4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{-y^6 - x^3}{x^4}$$

Summary

The solution(s) found are the following

$$\frac{-y^6 - x^3}{x^4} = c_1 \tag{1}$$

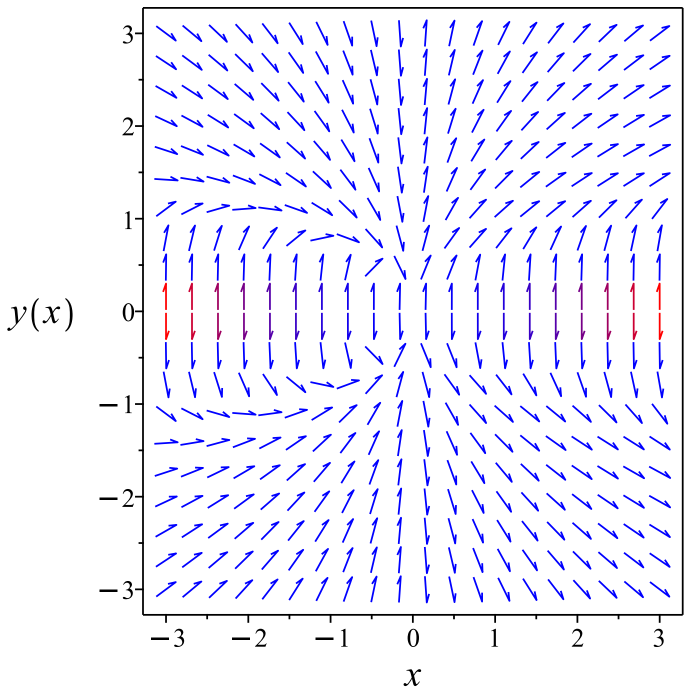

Figure 194: Slope field plot

Verification of solutions

$$\frac{-y^6 - x^3}{x^4} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`]]
```

$$\boxed{y\left(1+\sqrt{y^4x^2+1}\right)+2y'x=0}$$

5.19.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{y\left(1+\sqrt{x^2y^4+1}\right)}{2x}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 - \frac{y\left(1+\sqrt{x^2y^4+1}\right)(b_3-a_2)}{2x} - \frac{y^2\left(1+\sqrt{x^2y^4+1}\right)^2 a_3}{4x^2} \\ &- \left(-\frac{y^5}{2\sqrt{x^2y^4+1}} + \frac{y\left(1+\sqrt{x^2y^4+1}\right)}{2x^2}\right)(xa_2+ya_3+a_1) \\ &- \left(-\frac{1+\sqrt{x^2y^4+1}}{2x} - \frac{x\,y^4}{\sqrt{x^2y^4+1}}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-6x^4y^4b_2 - 2x^3y^5a_2 - 4x^3y^5b_3 + 2x^2y^6a_3 - 6x^3y^4b_1 + (x^2y^4+1)^{\frac{3}{2}}\,y^2a_3 - 6b_2\sqrt{x^2y^4+1}\,x^2 + 3y^2a_3\sqrt{x^2}}{4\sqrt{x^2y^4+1}\,x^2}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &6x^4y^4b_2 + 2x^3y^5a_2 + 4x^3y^5b_3 - 2x^2y^6a_3 + 6x^3y^4b_1 - \left(x^2y^4+1\right)^{\frac{3}{2}} y^2a_3 \\ &+ 6b_2\sqrt{x^2y^4+1}\,x^2 - 3y^2a_3\sqrt{x^2y^4+1} + 2\sqrt{x^2y^4+1}\,xb_1 \\ &- 2\sqrt{x^2y^4+1}\,ya_1 + 2x^2b_2 - 4y^2a_3 + 2xb_1 - 2ya_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &4x^4y^4b_2 + 2x^3y^5a_2 + 4x^3y^5b_3 + 2x^2y^6a_3 + 4x^3y^4b_1 + 2x^2y^5a_1 \\ &- \left(x^2y^4+1\right)^{\frac{3}{2}} y^2a_3 + 2\left(x^2y^4+1\right)x^2b_2 - 4\left(x^2y^4+1\right)y^2a_3 \\ &+ 2\left(x^2y^4+1\right)xb_1 - 2\left(x^2y^4+1\right)ya_1 + 6b_2\sqrt{x^2y^4+1}\,x^2 \\ &- 3y^2a_3\sqrt{x^2y^4+1} + 2\sqrt{x^2y^4+1}\,xb_1 - 2\sqrt{x^2y^4+1}\,ya_1 = 0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned} &-x^2\sqrt{x^2y^4+1}\,y^6a_3 + 6x^4y^4b_2 + 2x^3y^5a_2 + 4x^3y^5b_3 - 2x^2y^6a_3 \\ &+ 6x^3y^4b_1 + 6b_2\sqrt{x^2y^4+1}\,x^2 - 4y^2a_3\sqrt{x^2y^4+1} + 2x^2b_2 \\ &+ 2\sqrt{x^2y^4+1}\,xb_1 - 2\sqrt{x^2y^4+1}\,ya_1 - 4y^2a_3 + 2xb_1 - 2ya_1 = 0 \end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{x^2y^4+1}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{x^2y^4+1} = v_3\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned}-v_1^2v_3v_2^6a_3 + 2v_1^3v_2^5a_2 - 2v_1^2v_2^6a_3 + 6v_1^4v_2^4b_2 + 4v_1^3v_2^5b_3 + 6v_1^3v_2^4b_1 - 4v_2^2a_3v_3 \\ + 6b_2v_3v_1^2 - 2v_3v_2a_1 - 4v_2^2a_3 + 2v_3v_1b_1 + 2v_1^2b_2 - 2v_2a_1 + 2v_1b_1 = 0\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$\begin{aligned}6v_1^4v_2^4b_2 + (2a_2 + 4b_3)\,v_1^3v_2^5 + 6v_1^3v_2^4b_1 - v_1^2v_3v_2^6a_3 - 2v_1^2v_2^6a_3 + 6b_2v_3v_1^2 \\ + 2v_1^2b_2 + 2v_3v_1b_1 + 2v_1b_1 - 4v_2^2a_3v_3 - 4v_2^2a_3 - 2v_3v_2a_1 - 2v_2a_1 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}-2a_1 &= 0 \\ -4a_3 &= 0 \\ -2a_3 &= 0 \\ -a_3 &= 0 \\ 2b_1 &= 0 \\ 6b_1 &= 0 \\ 2b_2 &= 0 \\ 6b_2 &= 0 \\ 2a_2 + 4b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0\\
a_2 &= -2b_3\\
a_3 &= 0\\
b_1 &= 0\\
b_2 &= 0\\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -2x\\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi\\
&= y - \left(-\frac{y\left(1+\sqrt{x^2y^4+1}\right)}{2x}\right)(-2x)\\
&= -y\sqrt{x^2y^4+1}\\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy\\
&= \int \frac{1}{-y\sqrt{x^2y^4+1}} dy
\end{aligned}
$$

Which results in

$$S = \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{x^2 y^4+1}}\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y\left(1+\sqrt{x^2 y^4+1}\right)}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{1}{2x\sqrt{x^2 y^4+1}} \\
S_y &= -\frac{1}{y\sqrt{x^2 y^4+1}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{2x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{2R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\ln(R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{y^4x^2+1}}\right)}{2} = \frac{\ln(x)}{2} + c_1$$

Which simplifies to

$$\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{y^4x^2+1}}\right)}{2} = \frac{\ln(x)}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y\left(1+\sqrt{x^2y^4+1}\right)}{2x}$ 	$R = x$ $S = \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{x^2y^4+1}}\right)}{2}$	$\frac{dS}{dR} = \frac{1}{2R}$ 
Summary

The solution(s) found are the following

$$\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{y^4x^2+1}}\right)}{2} = \frac{\ln(x)}{2} + c_1 \tag{1}$$

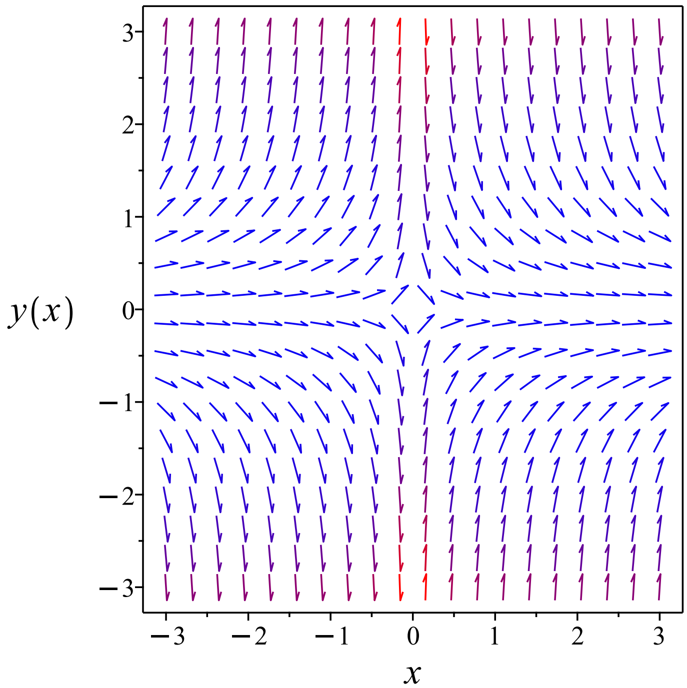

Figure 195: Slope field plot

Verification of solutions

$$\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{y^4x^2+1}}\right)}{2} = \frac{\ln(x)}{2} + c_1$$

Verified OK.

Problem number: 119.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{y^3+3(y^3-x)\,y^2y'=-x}$$

5.20.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{y^3+x}{3\,(y^3-x)\,y^2} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 - \frac{(y^3+x)(b_3-a_2)}{3(y^3-x)y^2} - \frac{(y^3+x)^2 a_3}{9(y^3-x)^2 y^4} \\
& - \left(-\frac{1}{3(y^3-x)y^2} - \frac{y^3+x}{3(y^3-x)^2 y^2}\right)(xa_2+ya_3+a_1) \\
& - \left(-\frac{1}{y^3-x} + \frac{y^3+x}{(y^3-x)^2} + \frac{\frac{2y^3}{3}+\frac{2x}{3}}{y^3(y^3-x)}\right)(xb_2+yb_3+b_1) = 0
\end{aligned}
\tag{5E}
$$

Putting the above in normal form gives

$$\frac{9y^{10}b_2 - 24x\,y^7b_2 + 3y^8a_2 - 9y^8b_3 - 6y^7b_1 - 9x^2y^4b_2 + 6x\,y^5a_2 - 18x\,y^5b_3 + 5y^6a_3 - 18x\,y^4b_1 + 6y^5a_1 + \cdots}{9(-y^3+x)^2 y^4} = 0$$

Setting the numerator to zero gives

$$
\begin{aligned}
& 9y^{10}b_2 - 24x\,y^7b_2 + 3y^8a_2 - 9y^8b_3 - 6y^7b_1 - 9x^2y^4b_2 + 6x\,y^5a_2 - 18x\,y^5b_3 + 5y^6a_3 \\
& - 18x\,y^4b_1 + 6y^5a_1 + 6x^3yb_2 - 3x^2y^2a_2 + 9x^2y^2b_3 - 2x\,y^3a_3 + 6x^2yb_1 - x^2a_3 = 0
\end{aligned}
\tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
& 9b_2v_2^{10} + 3a_2v_2^8 - 24b_2v_1v_2^7 - 9b_3v_2^8 - 6b_1v_2^7 + 6a_2v_1v_2^5 + 5a_3v_2^6 - 9b_2v_1^2v_2^4 \\
& - 18b_3v_1v_2^5 + 6a_1v_2^5 - 18b_1v_1v_2^4 - 3a_2v_1^2v_2^2 - 2a_3v_1v_2^3 + 6b_2v_1^3v_2 + 9b_3v_1^2v_2^2 \\
& + 6b_1v_1^2v_2 - a_3v_1^2 = 0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} &6b_2v_1^3v_2 - 9b_2v_1^2v_2^4 + (-3a_2 + 9b_3)\, v_1^2v_2^2 + 6b_1v_1^2v_2 - a_3v_1^2 \\ &- 24b_2v_1v_2^7 + (6a_2 - 18b_3)\, v_1v_2^5 - 18b_1v_1v_2^4 - 2a_3v_1v_2^3 \\ &+ 9b_2v_2^{10} + (3a_2 - 9b_3)\, v_2^8 - 6b_1v_2^7 + 5a_3v_2^6 + 6a_1v_2^5 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} 6a_1 &= 0 \\ -2a_3 &= 0 \\ -a_3 &= 0 \\ 5a_3 &= 0 \\ -18b_1 &= 0 \\ -6b_1 &= 0 \\ 6b_1 &= 0 \\ -24b_2 &= 0 \\ -9b_2 &= 0 \\ 6b_2 &= 0 \\ 9b_2 &= 0 \\ -3a_2 + 9b_3 &= 0 \\ 3a_2 - 9b_3 &= 0 \\ 6a_2 - 18b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 3b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = 3x$$
$$\eta = y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{y^3 + x}{3\,(y^3 - x)\,y^2}\right)(3x) \\
&= \frac{-y^6 - x^2}{-y^5 + y^2 x} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-y^6 - x^2}{-y^5 + y^2 x}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(y^6 + x^2)}{6} - \frac{\arctan\left(\frac{y^3}{x}\right)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y^3+x}{3\left(y^3-x\right)y^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y^3+x}{3y^6+3x^2} \\ S_y &= -\frac{\left(-y^3+x\right)y^2}{y^6+x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln\left(y^6+x^2\right)}{6} - \frac{\arctan\left(\frac{y^3}{x}\right)}{3} = c_1$$

Which simplifies to

$$\frac{\ln\left(y^6+x^2\right)}{6} - \frac{\arctan\left(\frac{y^3}{x}\right)}{3} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y^3+x}{3(y^3-x)y^2}$ 	$R = x$ $S = \frac{\ln(y^6+x^2)}{6} - \frac{\text{arctan}}{3}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln\left(y^6+x^2\right)}{6} - \frac{\arctan\left(\frac{y^3}{x}\right)}{3} = c_1 \tag{1}$$

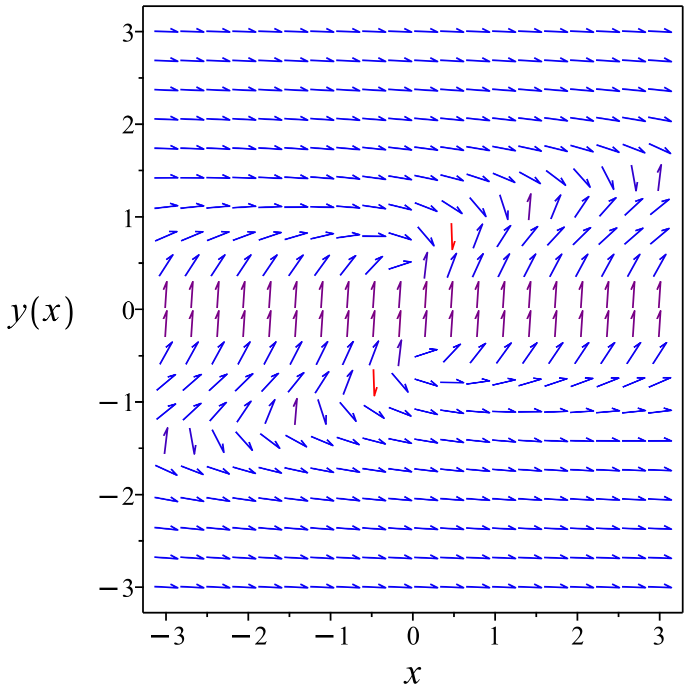

Figure 196: Slope field plot

Verification of solutions

$$\frac{\ln\left(y^6+x^2\right)}{6}-\frac{\arctan\left(\frac{y^3}{x}\right)}{3}=c_1$$

Verified OK.

Problem number: 125.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' + 2y = e^{-x}}$$

6.1.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2$$
$$q(x) = e^{-x}$$

Hence the ode is

$$y' + 2y = e^{-x}$$

The integrating factor μ is

$$\mu = e^{\int 2dx}$$
$$= e^{2x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(e^{-x}\right)$$
$$\frac{d}{dx}\left(y\, e^{2x}\right) = \left(e^{2x}\right)\left(e^{-x}\right)$$
$$d\left(y\, e^{2x}\right) = e^{x}\, dx$$

Integrating gives

$$y\, e^{2x} = \int e^{x}\, dx$$
$$y\, e^{2x} = e^{x} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{2x}$ results in

$$y = e^{-2x} e^{x} + c_1 e^{-2x}$$

which simplifies to

$$y = e^{-x} + c_1 e^{-2x}$$

Summary
The solution(s) found are the following

$$y = e^{-x} + c_1 e^{-2x} \tag{1}$$

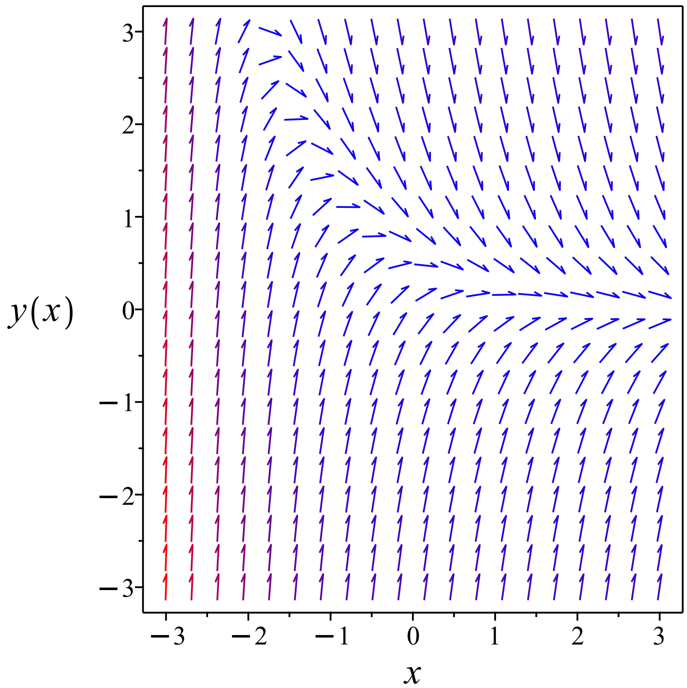

Figure 197: Slope field plot

Verification of solutions

$$y = e^{-x} + c_1 e^{-2x}$$

Verified OK.

6.1.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -2y + e^{-x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 153: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0

polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-2x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-2x}} dy \end{aligned}$$

Which results in

$$S = y\, e^{2x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -2y + e^{-x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= 2y\, e^{2x} \\ S_y &= e^{2x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = e^{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = e^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = e^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\, e^{2x} = e^{x} + c_1$$

Which simplifies to

$$y\, e^{2x} = e^{x} + c_1$$

Which gives

$$y = (e^{x} + c_1)\, e^{-2x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -2y + e^{-x}$ 	$R = x$ $S = y\, e^{2x}$	$\frac{dS}{dR} = e^{R}$ 
<u>Summary</u>
The solution(s) found are the following

$$y = (e^{x} + c_1)\, e^{-2x} \tag{1}$$

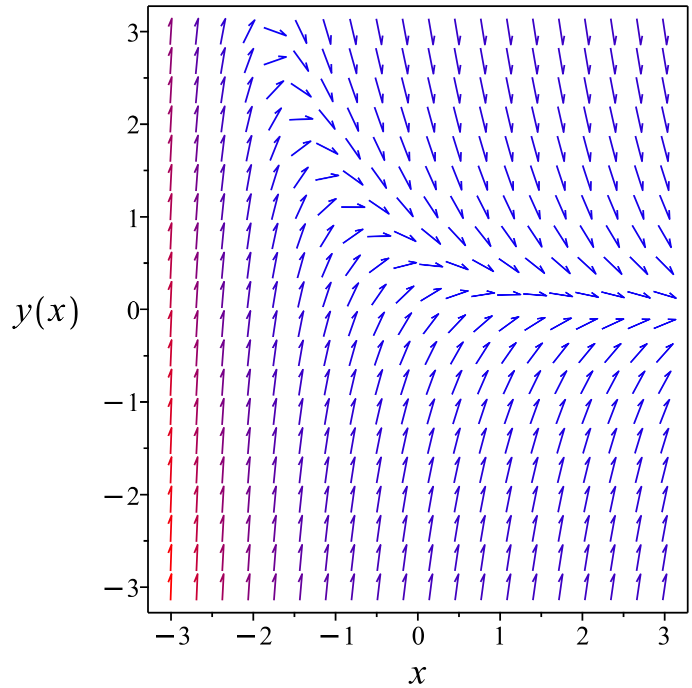

Figure 198: Slope field plot

Verification of solutions

$$y = (e^x + c_1) e^{-2x}$$

Verified OK.

6.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= \left(-2y + \mathrm{e}^{-x}\right)\mathrm{d}x\\ \left(2y - \mathrm{e}^{-x}\right)\mathrm{d}x + \mathrm{d}y &= 0 \qquad (2\mathrm{A})\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 2y - \mathrm{e}^{-x}\\ N(x, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2y - \mathrm{e}^{-x}\right)\\ &= 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((2) - (0)) \\ &= 2 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int 2 \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{2x} \\ &= \mathrm{e}^{2x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{2x}\left(2y - \mathrm{e}^{-x}\right) \\ &= 2y\,\mathrm{e}^{2x} - \mathrm{e}^{x} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{2x}(1) \\ &= \mathrm{e}^{2x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(2y\,\mathrm{e}^{2x} - \mathrm{e}^{x}\right) + \left(\mathrm{e}^{2x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int 2y \,\mathrm{e}^{2x} - \mathrm{e}^{x} \mathrm{d}x$$
$$\phi = y \,\mathrm{e}^{2x} - \mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{2x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{2x}$. Therefore equation (4) becomes

$$\mathrm{e}^{2x} = \mathrm{e}^{2x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = y \,\mathrm{e}^{2x} - \mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y \,\mathrm{e}^{2x} - \mathrm{e}^{x}$$

The solution becomes

$$y = (\mathrm{e}^{x} + c_1) \,\mathrm{e}^{-2x}$$

Summary

The solution(s) found are the following

$$y = (\mathrm{e}^{x} + c_1) \,\mathrm{e}^{-2x} \tag{1}$$

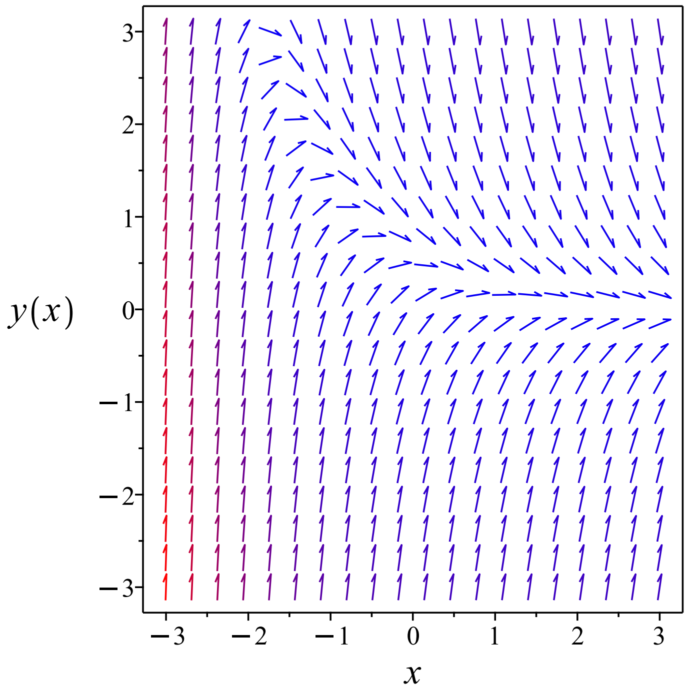

Figure 199: Slope field plot

Verification of solutions

$$y = (e^{x} + c_1)\, e^{-2x}$$

Verified OK.

6.1.4 Maple step by step solution

Let's solve

$y' + 2y = e^{-x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -2y + e^{-x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + 2y = e^{-x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' + 2y) = \mu(x)\, e^{-x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y'+2y)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x)=2\mu(x)$

- Solve to find the integrating factor

  $\mu(x)=\mathrm{e}^{2x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int \mu(x)\,\mathrm{e}^{-x}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y=\int \mu(x)\,\mathrm{e}^{-x}dx+c_1$

- Solve for y

  $y=\frac{\int \mu(x)\mathrm{e}^{-x}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\mathrm{e}^{2x}$

  $y=\frac{\int \mathrm{e}^{-x}\mathrm{e}^{2x}dx+c_1}{\mathrm{e}^{2x}}$

- Evaluate the integrals on the rhs

  $y=\frac{\mathrm{e}^{x}+c_1}{\mathrm{e}^{2x}}$

- Simplify

  $y=(\mathrm{e}^{x}+c_1)\,\mathrm{e}^{-2x}$

The type(s) of ODE detected by this program : **"exact", "linear", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{-y'x - y = -x^2}$$

With initial conditions

$$[y(1) = 0]$$

6.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= x \end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = x$$

The domain of $p(x) = \frac{1}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

6.2.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int \frac{1}{x} dx} \\ &= x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(x) \\ \frac{\mathrm{d}}{\mathrm{d}x}(xy) &= (x)(x) \\ \mathrm{d}(xy) &= x^2\, \mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} xy &= \int x^2\, \mathrm{d}x \\ xy &= \frac{x^3}{3} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{x^2}{3} + \frac{c_1}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1 + \frac{1}{3}$$

$$c_1 = -\frac{1}{3}$$

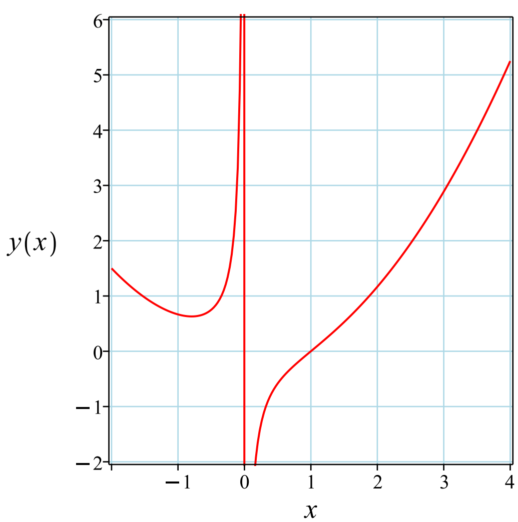
Substituting c_1 found above in the general solution gives

$$y = \frac{x^3 - 1}{3x}$$

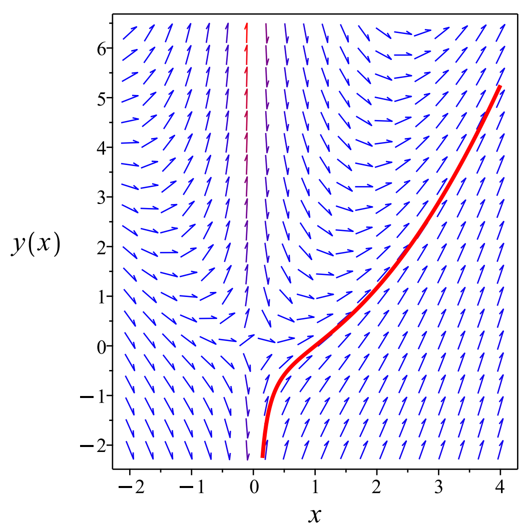
Summary

The solution(s) found are the following

$$y = \frac{x^3 - 1}{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{x^3 - 1}{3x}$$

Verified OK.

6.2.3 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{-x^2 + y}{x} \tag{1}$$

Which becomes

$$0 = (-x)\, dy + \left(x^2 - y\right) dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\, dy + \left(x^2 - y\right) dx = d\left(\frac{1}{3}x^3 - xy\right)$$

Hence (2) becomes

$$0 = d\left(\frac{1}{3}x^3 - xy\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{x^3 + 3c_1}{3x} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = 2c_1 + \frac{1}{3}$$

$$c_1 = -\frac{1}{6}$$

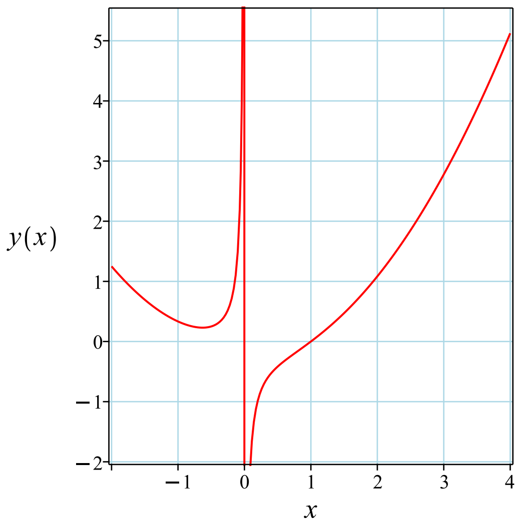
Substituting c_1 found above in the general solution gives

$$y = \frac{2x^3 - x - 1}{6x}$$

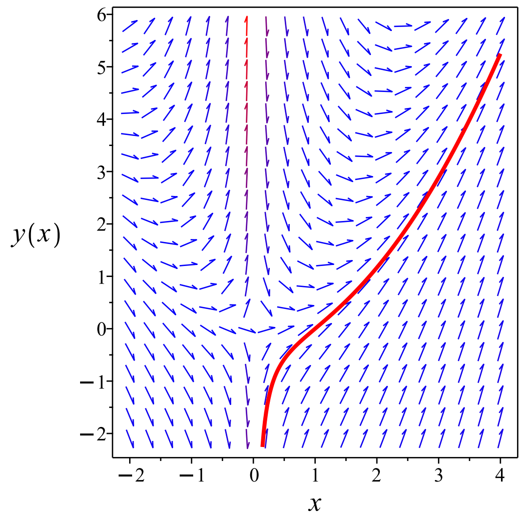
Summary

The solution(s) found are the following

$$y = \frac{2x^3 - x - 1}{6x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{2x^3 - x - 1}{6x}$$

Warning, solution could not be verified

6.2.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-x^2 + y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 156: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{-x^2 + y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^3}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = \frac{x^3}{3} + c_1$$

Which simplifies to

$$yx = \frac{x^3}{3} + c_1$$

Which gives

$$y = \frac{x^3 + 3c_1}{3x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-x^2+y}{x}$ 	$R = x$ $S = xy$	$\frac{dS}{dR} = R^2$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1 + \frac{1}{3}$$

$$c_1 = -\frac{1}{3}$$

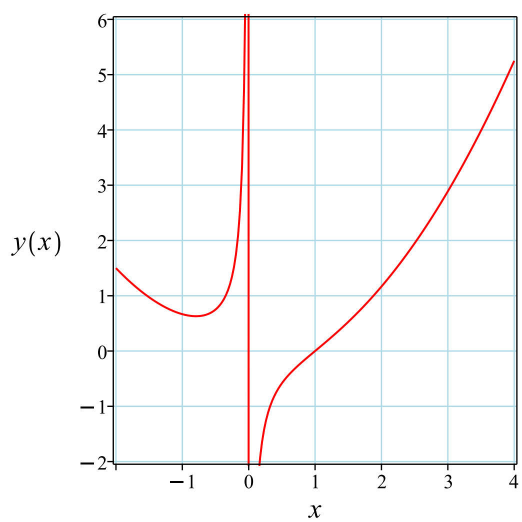
Substituting c_1 found above in the general solution gives

$$y = \frac{x^3 - 1}{3x}$$

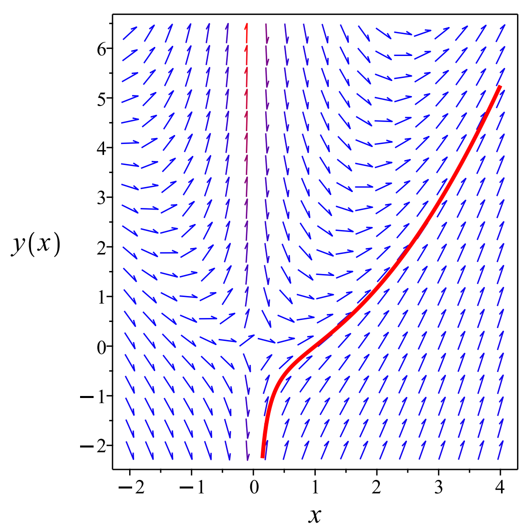
Summary

The solution(s) found are the following

$$y = \frac{x^3 - 1}{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{x^3 - 1}{3x}$$

Verified OK.

6.2.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-x)\,\mathrm{d}y &= \left(-x^2 + y\right)\mathrm{d}x\\ \left(x^2 - y\right)\mathrm{d}x + (-x)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= x^2 - y\\ N(x,y) &= -x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^2 - y)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-x)\\ &= -1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int x^2 - y\,\mathrm{d}x\\ \phi &= \frac{1}{3}x^3 - xy + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -x$. Therefore equation (4) becomes

$$-x = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{3}x^3 - xy + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{3}x^3 - xy$$

The solution becomes

$$y = -\frac{-x^3 + 3c_1}{3x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \frac{1}{3} - c_1$$

$$c_1 = \frac{1}{3}$$

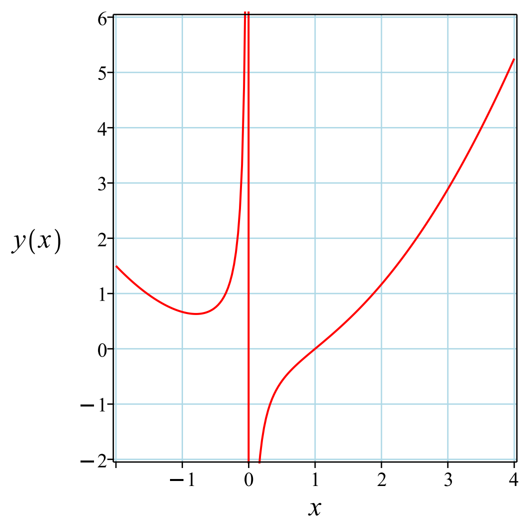
Substituting c_1 found above in the general solution gives

$$y = \frac{x^3 - 1}{3x}$$

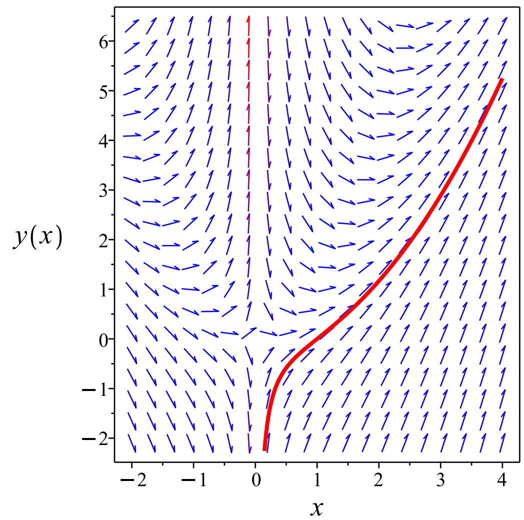
Summary

The solution(s) found are the following

$$y = \frac{x^3 - 1}{3x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{x^3 - 1}{3x}$$

Verified OK.

6.2.6 Maple step by step solution

Let's solve

$[-y'x - y = -x^2, y(1) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{x} + x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{x} = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu(x)\, x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{x}$
- Solve to find the integrating factor

  $\mu(x) = x$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x) y)\right) dx = \int \mu(x) x dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x) y = \int \mu(x) x dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x) x dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = x$

  $y = \frac{\int x^2 dx + c_1}{x}$
- Evaluate the integrals on the rhs

  $y = \frac{\frac{x^3}{3} + c_1}{x}$
- Simplify

  $y = \frac{x^3 + 3c_1}{3x}$
- Use initial condition $y(1) = 0$

  $0 = c_1 + \frac{1}{3}$
- Solve for c_1

  $c_1 = -\frac{1}{3}$
- Substitute $c_1 = -\frac{1}{3}$ into general solution and simplify

  $y = \frac{x^3 - 1}{3x}$
- Solution to the IVP

  $y = \frac{x^3 - 1}{3x}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 127.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - 2yx = 2x\,e^{x^2}}$$

6.3.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2x \\ q(x) &= 2x\,e^{x^2} \end{aligned}$$

Hence the ode is

$$y' - 2yx = 2x\,e^{x^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -2x dx} \\ &= e^{-x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(2x\, e^{x^2}\right) \\ \frac{d}{dx}\left(e^{-x^2} y\right) &= \left(e^{-x^2}\right)\left(2x\, e^{x^2}\right) \\ d\left(e^{-x^2} y\right) &= (2x)\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-x^2} y &= \int 2x\, dx \\ e^{-x^2} y &= x^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x^2}$ results in

$$y = x^2 e^{x^2} + c_1 e^{x^2}$$

which simplifies to

$$y = e^{x^2}\left(x^2 + c_1\right)$$

Summary

The solution(s) found are the following

$$y = e^{x^2}\left(x^2 + c_1\right) \tag{1}$$

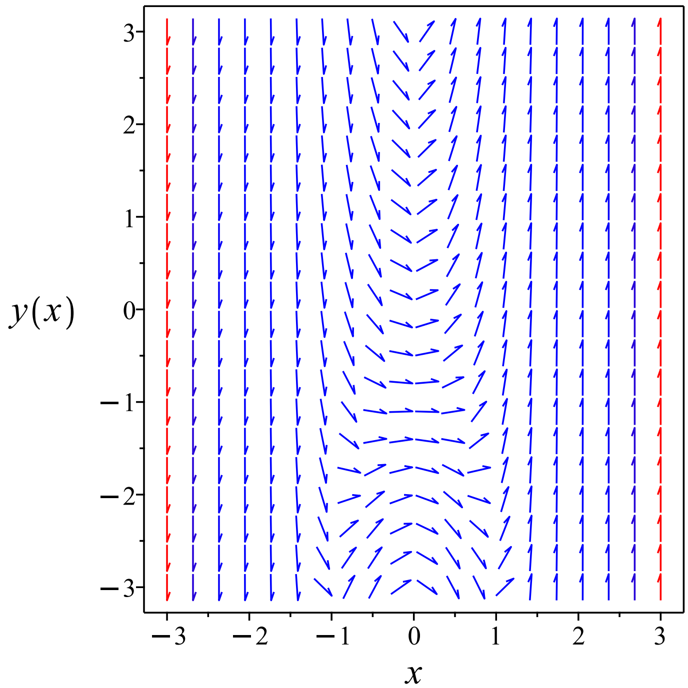

Figure 204: Slope field plot

Verification of solutions

$$y = e^{x^2}(x^2 + c_1)$$

Verified OK.

6.3.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = 2xy + 2x\,e^{x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 159: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \mathrm{e}^{x^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{x^2}} dy \end{aligned}$$

Which results in

$$S = e^{-x^2} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = 2xy + 2x e^{x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -2x e^{-x^2} y \\ S_y &= e^{-x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-x^2} y = x^2 + c_1$$

Which simplifies to

$$e^{-x^2} y = x^2 + c_1$$

Which gives

$$y = e^{x^2} \left(x^2 + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2xy + 2x\,e^{x^2}$ 	$R = x$ $S = e^{-x^2} y$	$\frac{dS}{dR} = 2R$ 
Summary

The solution(s) found are the following

$$y = e^{x^2} \left(x^2 + c_1\right) \tag{1}$$

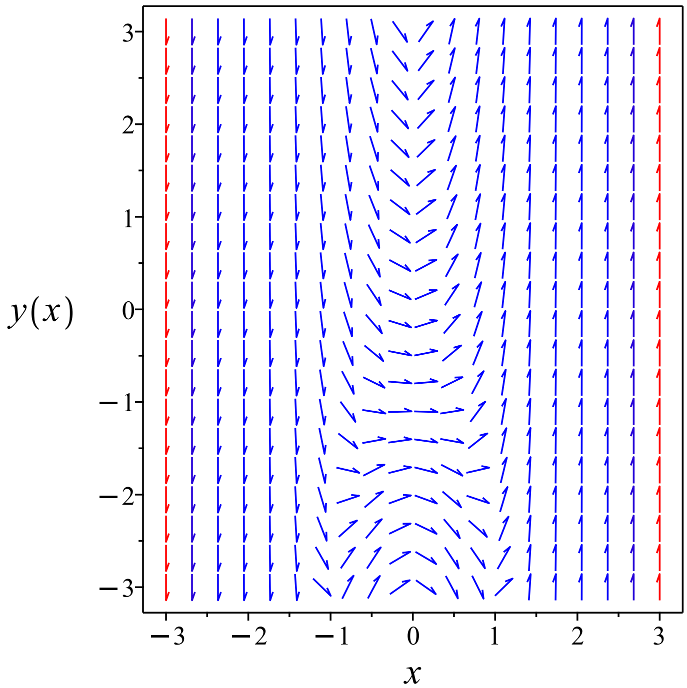

Figure 205: Slope field plot

Verification of solutions

$$y = e^{x^2}(x^2 + c_1)$$

Verified OK.

6.3.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(2xy + 2x\,\mathrm{e}^{x^2}\right)\mathrm{d}x$$
$$\left(-2xy - 2x\,\mathrm{e}^{x^2}\right)\mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -2xy - 2x\,\mathrm{e}^{x^2}$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-2xy - 2x\,\mathrm{e}^{x^2}\right)\\ &= -2x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-2x) - (0)) \\ &= -2x \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -2x \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-x^2} \\ &= \mathrm{e}^{-x^2} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-x^2}\left(-2xy - 2x\,\mathrm{e}^{x^2}\right) \\ &= -2x\left(1 + \mathrm{e}^{-x^2} y\right) \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-x^2}(1) \\ &= \mathrm{e}^{-x^2} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(-2x\left(1 + \mathrm{e}^{-x^2} y\right)\right) + \left(\mathrm{e}^{-x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -2x\left(1 + \mathrm{e}^{-x^2} y\right) \mathrm{d}x$$

$$\phi = -x^2 + \mathrm{e}^{-x^2} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x^2}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x^2} = \mathrm{e}^{-x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 + \mathrm{e}^{-x^2} y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 + \mathrm{e}^{-x^2} y$$

The solution becomes

$$y = e^{x^2}(x^2 + c_1)$$

Summary

The solution(s) found are the following

$$y = e^{x^2}(x^2 + c_1) \tag{1}$$

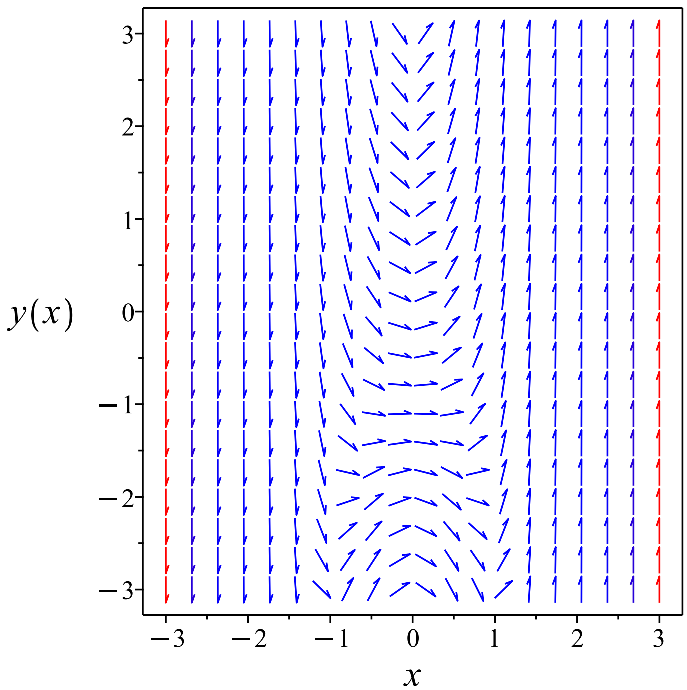

Figure 206: Slope field plot

Verification of solutions

$$y = e^{x^2}(x^2 + c_1)$$

Verified OK.

6.3.4 Maple step by step solution

Let's solve

$y' - 2yx = 2x\,e^{x^2}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2yx + 2x\,e^{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - 2yx = 2x\,e^{x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - 2yx) = 2\mu(x)\,x\,e^{x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' - 2yx) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -2\mu(x)\,x$

- Solve to find the integrating factor

  $\mu(x) = e^{-x^2}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int 2\mu(x)\,x\,e^{x^2} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int 2\mu(x)\,x\,e^{x^2} dx + c_1$

- Solve for y

  $y = \frac{\int 2\mu(x)x\,e^{x^2} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = e^{-x^2}$

  $y = \frac{\int 2x\,e^{x^2} e^{-x^2} dx + c_1}{e^{-x^2}}$

- Evaluate the integrals on the rhs

  $y = \frac{x^2 + c_1}{e^{-x^2}}$

- Simplify

$$y = e^{x^2}(x^2 + c_1)$$

Problem number: 128.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' + 2yx = e^{-x^2}}$$

6.4.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 2x$$
$$q(x) = e^{-x^2}$$

Hence the ode is

$$y' + 2yx = e^{-x^2}$$

The integrating factor μ is

$$\mu = e^{\int 2x dx}$$
$$= e^{x^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(e^{-x^2}\right)$$
$$\frac{d}{dx}\left(e^{x^2} y\right) = \left(e^{x^2}\right)\left(e^{-x^2}\right)$$
$$d\left(e^{x^2} y\right) = dx$$

Integrating gives

$$e^{x^2} y = \int dx$$
$$e^{x^2} y = x + c_1$$

Dividing both sides by the integrating factor $\mu = e^{x^2}$ results in

$$y = x\,e^{-x^2} + c_1 e^{-x^2}$$

which simplifies to

$$y = e^{-x^2}(x + c_1)$$

Summary
The solution(s) found are the following

$$y = e^{-x^2}(x + c_1) \tag{1}$$

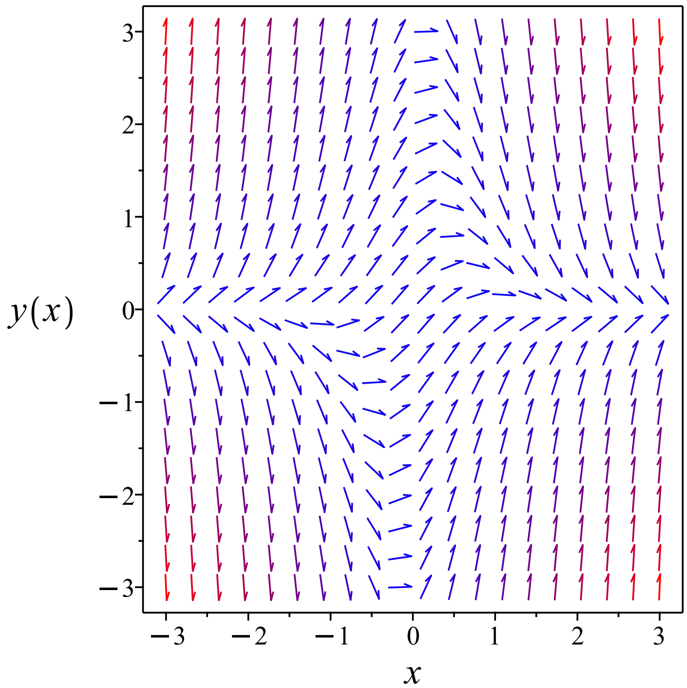

Figure 207: Slope field plot

Verification of solutions

$$y = e^{-x^2}(x + c_1)$$

Verified OK.

6.4.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -2xy + e^{-x^2} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 162: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-x^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-x^2}} dy \end{aligned}$$

Which results in

$$S = e^{x^2} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -2xy + e^{-x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= 2x\, e^{x^2} y \\ S_y &= e^{x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,\mathrm{e}^{x^2} = x + c_1$$

Which simplifies to

$$y\,\mathrm{e}^{x^2} = x + c_1$$

Which gives

$$y = \mathrm{e}^{-x^2}(x + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -2xy + \mathrm{e}^{-x^2}$ 	$R = x$ $S = \mathrm{e}^{x^2} y$	$\frac{dS}{dR} = 1$ 
Summary
The solution(s) found are the following

$$y = \mathrm{e}^{-x^2}(x + c_1) \tag{1}$$

Verification of solutions

$$y = e^{-x^2}(x + c_1)$$

Verified OK.

6.4.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-2xy + \mathrm{e}^{-x^2}\right) \mathrm{d}x$$
$$\left(2xy - \mathrm{e}^{-x^2}\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 2xy - \mathrm{e}^{-x^2}$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2xy - \mathrm{e}^{-x^2}\right)\\ &= 2x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((2x) - (0)) \\
&= 2x
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int 2x \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{x^2} \\
&= \mathrm{e}^{x^2}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{x^2}\left(2xy - \mathrm{e}^{-x^2}\right) \\
&= 2x\,\mathrm{e}^{x^2} y - 1
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{x^2}(1) \\
&= \mathrm{e}^{x^2}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(2x\,\mathrm{e}^{x^2} y - 1\right) + \left(\mathrm{e}^{x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int 2x\,\mathrm{e}^{x^2}y - 1\,\mathrm{d}x$$

$$\phi = -x + \mathrm{e}^{x^2}y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \mathrm{e}^{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \mathrm{e}^{x^2}$. Therefore equation (4) becomes

$$\mathrm{e}^{x^2} = \mathrm{e}^{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x + \mathrm{e}^{x^2}y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x + \mathrm{e}^{x^2}y$$

The solution becomes

$$y = e^{-x^2}(x + c_1)$$

Summary

The solution(s) found are the following

$$y = e^{-x^2}(x + c_1) \tag{1}$$

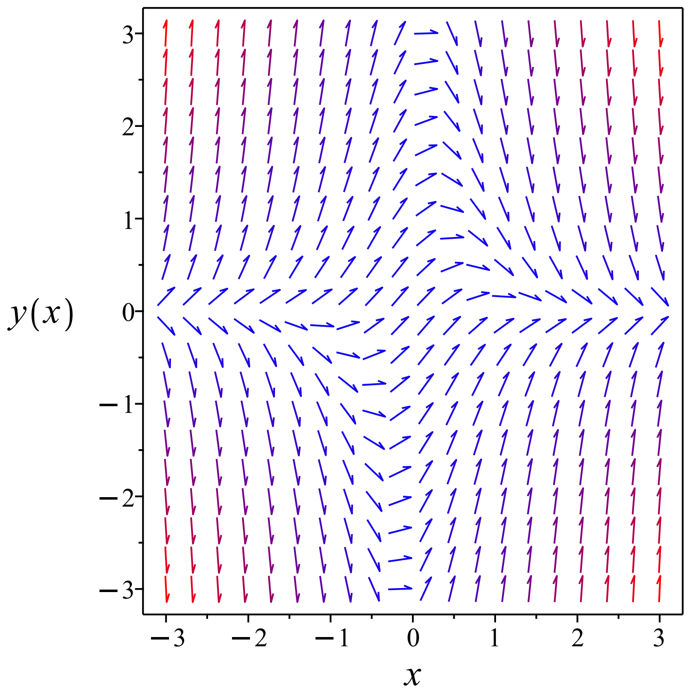

Figure 209: Slope field plot

Verification of solutions

$$y = e^{-x^2}(x + c_1)$$

Verified OK.

6.4.4 Maple step by step solution

Let's solve

$y' + 2yx = \mathrm{e}^{-x^2}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -2yx + \mathrm{e}^{-x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + 2yx = \mathrm{e}^{-x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' + 2yx) = \mu(x)\,\mathrm{e}^{-x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' + 2yx) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = 2\mu(x)\,x$

- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{x^2}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,\mathrm{e}^{-x^2} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,\mathrm{e}^{-x^2} dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x)\mathrm{e}^{-x^2} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \mathrm{e}^{x^2}$

  $y = \frac{\int \mathrm{e}^{-x^2}\mathrm{e}^{x^2} dx + c_1}{\mathrm{e}^{x^2}}$

- Evaluate the integrals on the rhs

  $y = \frac{x + c_1}{\mathrm{e}^{x^2}}$

- Simplify

$$y = e^{-x^2}(x + c_1)$$

Problem number: 129.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\cos(x)\, y' - \sin(x)\, y = 2x}$$

With initial conditions

$$[y(0) = 0]$$

6.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\tan(x)$$
$$q(x) = 2x\sec(x)$$

Hence the ode is

$$y' - \tan(x)\,y = 2x\sec(x)$$

The domain of $p(x) = -\tan(x)$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z815 \lor \frac{1}{2}\pi + \pi\_Z815 < x\right\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 2x\sec(x)$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z815 \lor \frac{1}{2}\pi + \pi\_Z815 < x\right\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

6.5.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\tan(x)dx}\\ &= \cos(x)\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(2x\sec(x))\\ \frac{d}{dx}(\cos(x)\,y) &= (\cos(x))(2x\sec(x))\\ d(\cos(x)\,y) &= (2x)\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\cos(x)\,y &= \int 2x\,dx\\ \cos(x)\,y &= x^2 + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \cos(x)$ results in

$$y = \sec(x)\,x^2 + c_1\sec(x)$$

which simplifies to

$$y = \sec(x)\left(x^2 + c_1\right)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

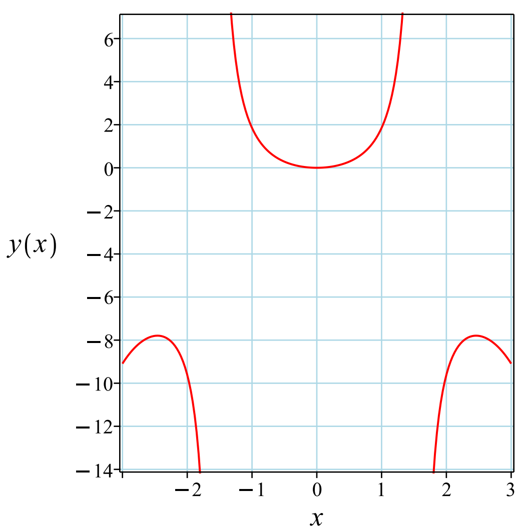
Substituting c_1 found above in the general solution gives

$$y = \sec(x)\, x^2$$

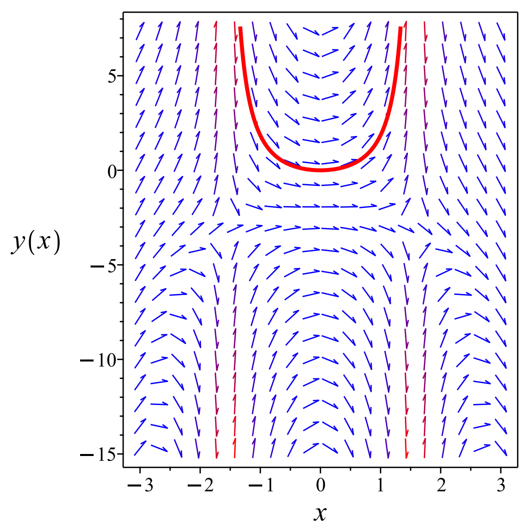
Summary

The solution(s) found are the following

$$y = \sec(x)\, x^2 \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sec(x)\, x^2$$

Verified OK.

6.5.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{\sin(x)\,y + 2x}{\cos(x)} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 165: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{1}{\cos(x)}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{1}{\cos(x)}} dy
\end{aligned}
$$

Which results in

$$
S = \cos(x)\, y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{\sin(x)\, y + 2x}{\cos(x)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\sin(x)\,y \\
S_y &= \cos(x)
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 2x \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 2R
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = R^2 + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
y\cos(x) = x^2 + c_1
$$

Which simplifies to

$$
y\cos(x) = x^2 + c_1
$$

Which gives

$$
y = \frac{x^2 + c_1}{\cos(x)}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\sin(x)y+2x}{\cos(x)}$ 	$R = x$ $S = \cos(x)\, y$	$\frac{dS}{dR} = 2R$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

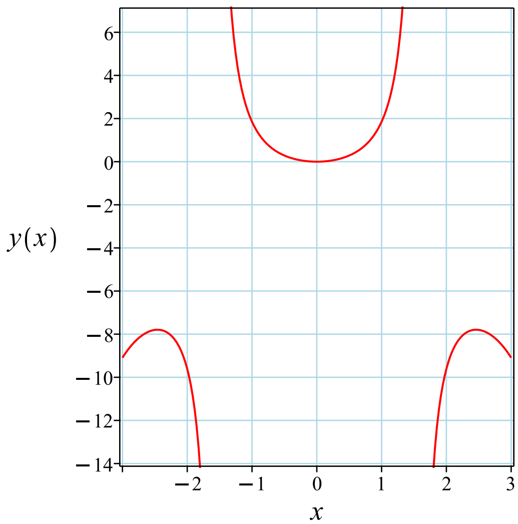
Substituting c_1 found above in the general solution gives

$$y = \frac{x^2}{\cos(x)}$$

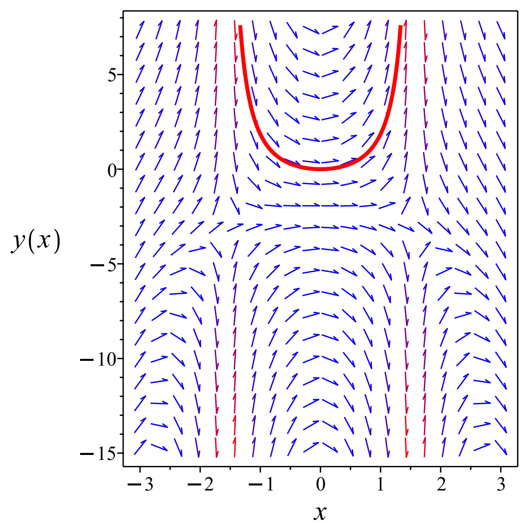
Summary

The solution(s) found are the following

$$y = \frac{x^2}{\cos(x)} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{x^2}{\cos(x)}$$

Verified OK.

6.5.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} (\cos(x)) \, \mathrm{d}y &= (\sin(x) \, y + 2x) \, \mathrm{d}x \\ (-\sin(x) \, y - 2x) \, \mathrm{d}x + (\cos(x)) \, \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= -\sin(x) \, y - 2x \\ N(x, y) &= \cos(x) \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\sin(x) \, y - 2x) \\ &= -\sin(x) \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(x)) \\ &= -\sin(x) \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\sin(x) y - 2x \, \mathrm{d}x$$
$$\phi = -x^2 + \cos(x) y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \cos(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \cos(x)$. Therefore equation (4) becomes

$$\cos(x) = \cos(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 + \cos(x) y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 + \cos(x) y$$

The solution becomes

$$y = \frac{x^2 + c_1}{\cos(x)}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

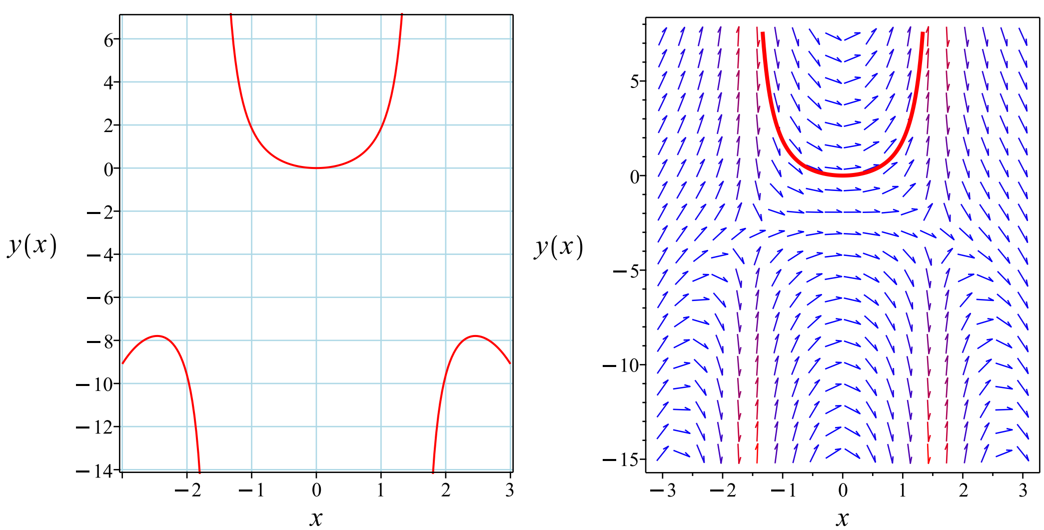
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \frac{x^2}{\cos(x)}$$

Summary
The solution(s) found are the following

$$y = \frac{x^2}{\cos(x)} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{x^2}{\cos(x)}$$

Verified OK.

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y'x - 2y = \cos(x)\, x^3}$$

6.6.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{2}{x}$$
$$q(x) = \cos(x)\, x^2$$

Hence the ode is

$$y' - \frac{2y}{x} = \cos(x)\, x^2$$

The integrating factor μ is

$$\mu = e^{\int -\frac{2}{x}dx}$$
$$= \frac{1}{x^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\cos(x)\, x^2\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^2}\right) = \left(\frac{1}{x^2}\right)\left(\cos(x)\, x^2\right)$$
$$d\left(\frac{y}{x^2}\right) = \cos(x)\, dx$$

Integrating gives

$$\frac{y}{x^2} = \int \cos(x)\, dx$$
$$\frac{y}{x^2} = \sin(x) + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$y = \sin(x)\, x^2 + c_1 x^2$$

which simplifies to

$$y = x^2(\sin(x) + c_1)$$

Summary
The solution(s) found are the following

$$y = x^2(\sin(x) + c_1) \tag{1}$$

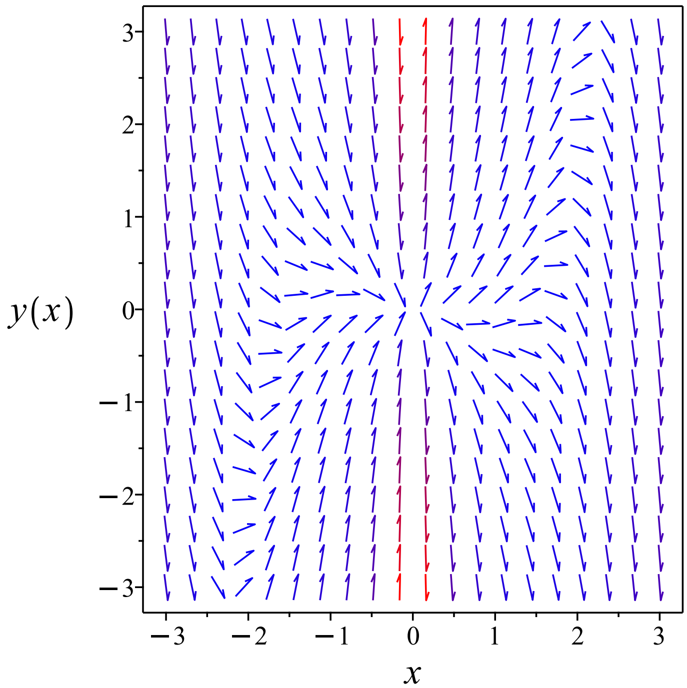

Figure 213: Slope field plot

Verification of solutions

$$y = x^2(\sin(x) + c_1)$$

Verified OK.

6.6.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{2y + \cos(x)\, x^3}{x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 168: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= x^2 \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x^2} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2y + \cos(x)\, x^3}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2y}{x^3} \\ S_y &= \frac{1}{x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cos(x) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cos(R)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \sin(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x^2} = \sin(x) + c_1$$

Which simplifies to

$$\frac{y}{x^2} = \sin(x) + c_1$$

Which gives

$$y = x^2(\sin(x) + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{2y+\cos(x)x^3}{x}$ 	$R = x$ $S = \frac{y}{x^2}$	$\frac{dS}{dR} = \cos(R)$ 
Summary

The solution(s) found are the following

$$y = x^2(\sin(x) + c_1) \tag{1}$$

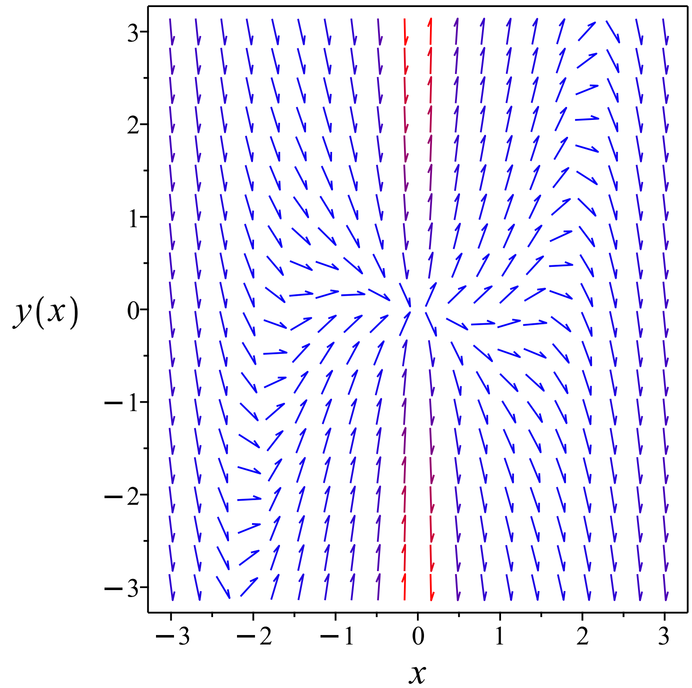

Figure 214: Slope field plot

Verification of solutions

$$y = x^2(\sin(x) + c_1)$$

Verified OK.

6.6.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x)\,\mathrm{d}y = \left(2y + \cos(x)\,x^3\right)\mathrm{d}x$$
$$\left(-2y - \cos(x)\,x^3\right)\mathrm{d}x + (x)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -2y - \cos(x)\,x^3$$
$$N(x, y) = x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-2y - \cos(x)\,x^3\right)$$
$$= -2$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(x)$$
$$= 1$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x}((-2) - (1)) \\
&= -\frac{3}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\frac{3}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-3\ln(x)} \\
&= \frac{1}{x^3}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^3}\left(-2y - \cos(x)\, x^3\right) \\
&= \frac{-2y - \cos(x)\, x^3}{x^3}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^3}(x) \\
&= \frac{1}{x^2}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{-2y - \cos(x)\, x^3}{x^3}\right) + \left(\frac{1}{x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{-2y - \cos(x)\, x^3}{x^3} \mathrm{d}x$$

$$\phi = -\sin(x) + \frac{y}{x^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{1}{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{x^2}$. Therefore equation (4) becomes

$$\frac{1}{x^2} = \frac{1}{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sin(x) + \frac{y}{x^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sin(x) + \frac{y}{x^2}$$

The solution becomes

$$y = x^2(\sin(x) + c_1)$$

Summary

The solution(s) found are the following

$$y = x^2(\sin(x) + c_1) \tag{1}$$

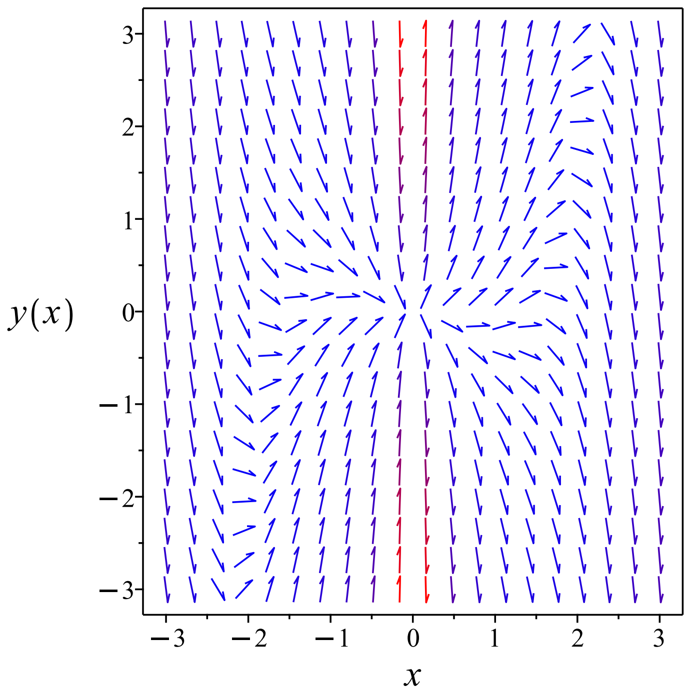

Figure 215: Slope field plot

Verification of solutions

$$y = x^2(\sin(x) + c_1)$$

Verified OK.

6.6.4 Maple step by step solution

Let's solve

$y'x - 2y = \cos(x)\, x^3$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{2y}{x} + \cos(x)\, x^2$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{2y}{x} = \cos(x)\, x^2$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x) \left(y' - \frac{2y}{x}\right) = \mu(x) \cos(x)\, x^2$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x) \left(y' - \frac{2y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{2\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{x^2}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x) \cos(x)\, x^2 dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \mu(x) \cos(x)\, x^2 dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x) \cos(x) x^2 dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{x^2}$

  $y = x^2 \left(\int \cos(x)\, dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = x^2 (\sin(x) + c_1)$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - \tan(x)\, y = \frac{1}{\cos(x)^3}}$$

With initial conditions

$$[y(0) = 0]$$

6.7.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\tan(x)\\ q(x) &= \sec(x)^3\end{aligned}$$

Hence the ode is

$$y' - \tan(x)\, y = \sec(x)^3$$

The domain of $p(x) = -\tan(x)$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z815 \vee \frac{1}{2}\pi + \pi\_Z815 < x\right\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \sec(x)^3$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z815 \vee \frac{1}{2}\pi + \pi\_Z815 < x\right\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

6.7.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\tan(x)dx}\\ &= \cos(x)\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\sec(x)^3\right)\\ \frac{d}{dx}(\cos(x)\, y) &= (\cos(x))\left(\sec(x)^3\right)\\ d(\cos(x)\, y) &= \sec(x)^2\, dx\end{aligned}$$

Integrating gives

$$\cos(x) y = \int \sec(x)^2 \, dx$$

$$\cos(x) y = \tan(x) + c_1$$

Dividing both sides by the integrating factor $\mu = \cos(x)$ results in

$$y = \sec(x)\tan(x) + c_1 \sec(x)$$

which simplifies to

$$y = \sec(x)(\tan(x) + c_1)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

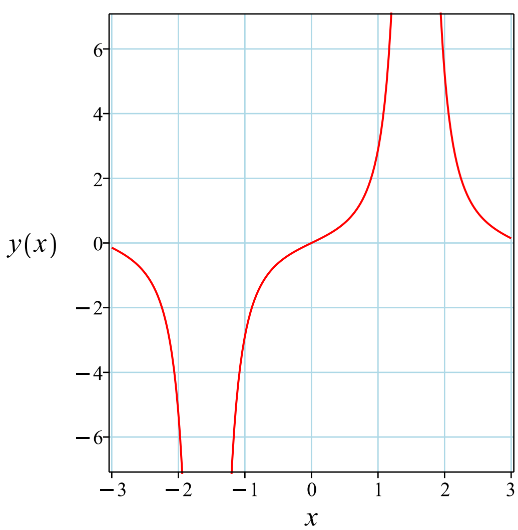
Substituting c_1 found above in the general solution gives

$$y = \sec(x)\tan(x)$$

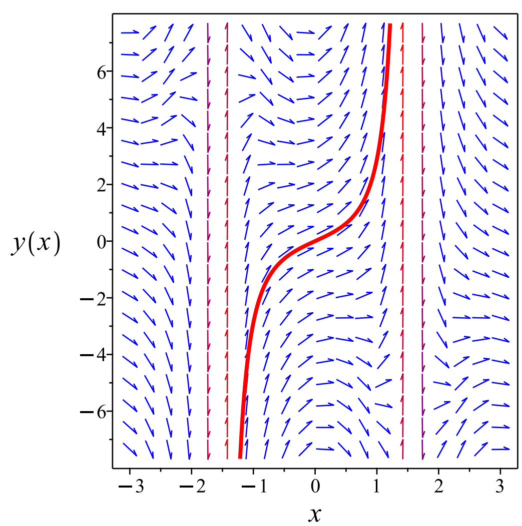
Summary

The solution(s) found are the following

$$y = \sec(x)\tan(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sec(x)\tan(x)$$

Verified OK.

6.7.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{\tan(x)\, y \cos(x)^3 + 1}{\cos(x)^3}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 171: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{\cos(x)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{\cos(x)}} dy \end{aligned}$$

Which results in

$$S = \cos(x)\, y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\tan(x)\, y \cos(x)^3 + 1}{\cos(x)^3}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\sin(x)\, y \\ S_y &= \cos(x) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \sec(x)^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \sec(R)^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \tan(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\cos(x) = \tan(x) + c_1$$

Which simplifies to

$$y\cos(x) = \tan(x) + c_1$$

Which gives

$$y = \frac{\tan(x) + c_1}{\cos(x)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{\tan(x)y\cos(x)^3+1}{\cos(x)^3}$ 	$R = x$ $S = \cos(x)\, y$	$\frac{dS}{dR} = \sec(R)^2$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = \sec(x)\tan(x)$$

Summary

The solution(s) found are the following

$$y = \sec(x)\tan(x) \tag{1}$$

6.7.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y} \frac{d y}{d x}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned} \frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N \end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \mathrm{d} x+N(x, y) \mathrm{d} y=0 \tag{1A}$$

Therefore

$$\mathrm{d} y=\left(\tan (x) y+\frac{1}{\cos (x)^3}\right) \mathrm{d} x$$

$$\left(-\tan (x) y-\frac{1}{\cos (x)^3}\right) \mathrm{d} x+\mathrm{d} y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= -\tan (x) y-\frac{1}{\cos (x)^3} \\ N(x, y) &= 1 \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\tan (x) y-\frac{1}{\cos (x)^3}\right) \\ &= -\tan (x) \end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1((-\tan(x)) - (0)) \\
&= -\tan(x)
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\tan(x) \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{\ln(\cos(x))} \\
&= \cos(x)
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \cos(x)\left(-\tan(x)\, y - \frac{1}{\cos(x)^3}\right) \\
&= -\sin(x)\, y - \sec(x)^2
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \cos(x)(1) \\
&= \cos(x)
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\sin(x)\, y - \sec(x)^2\right) + (\cos(x))\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\sin(x)\, y - \sec(x)^2 \, \mathrm{d}x$$

$$\phi = -\tan(x) + \cos(x)\, y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \cos(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \cos(x)$. Therefore equation (4) becomes

$$\cos(x) = \cos(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\tan(x) + \cos(x)\, y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\tan(x) + \cos(x)\, y$$

The solution becomes

$$y = \frac{\tan(x) + c_1}{\cos(x)}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

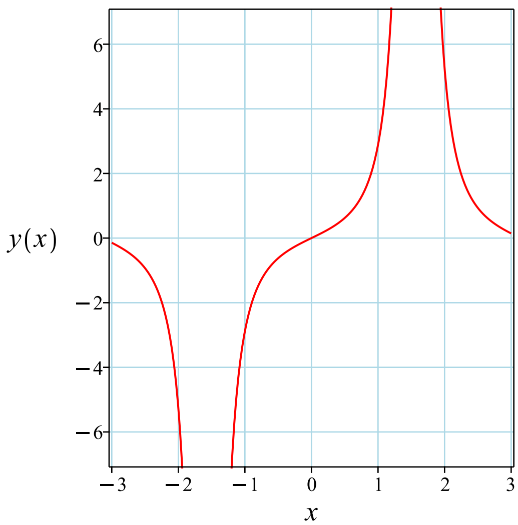
Substituting c_1 found above in the general solution gives

$$y = \sec(x) \tan(x)$$

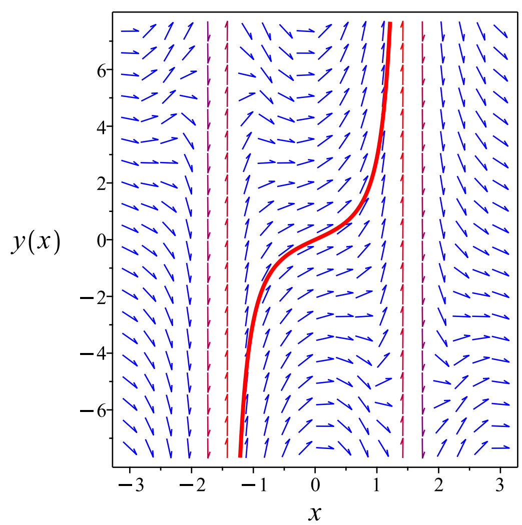
Summary

The solution(s) found are the following

$$y = \sec(x) \tan(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \sec(x) \tan(x)$$

Verified OK.

6.7.5 Maple step by step solution

Let's solve

$\left[y' - \tan(x)\, y = \frac{1}{\cos(x)^3}, y(0) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \tan(x)\, y + \frac{1}{\cos(x)^3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \tan(x)\, y = \frac{1}{\cos(x)^3}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \tan(x)\, y\right) = \frac{\mu(x)}{\cos(x)^3}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' - \tan(x)\, y\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)\tan(x)$

- Solve to find the integrating factor

  $\mu(x) = \cos(x)$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)}{\cos(x)^3} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)}{\cos(x)^3} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)}{\cos(x)^3} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \cos(x)$

  $y = \frac{\int \frac{1}{\cos(x)^2} dx + c_1}{\cos(x)}$

- Evaluate the integrals on the rhs

  $y = \frac{\tan(x) + c_1}{\cos(x)}$

- Simplify

  $y = \sec(x)(\tan(x) + c_1)$

- Use initial condition $y(0) = 0$

  $0 = c_1$

- Solve for c_1

  $c_1 = 0$

- Substitute $c_1 = 0$ into general solution and simplify

  $y = \sec(x)\tan(x)$

- Solution to the IVP

  $y = \sec(x)\tan(x)$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 132.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{x \ln(x) y' - y = 3x^3 \ln(x)^2}$$

6.8.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x \ln(x)}$$
$$q(x) = 3x^2 \ln(x)$$

Hence the ode is

$$y' - \frac{y}{x \ln(x)} = 3x^2 \ln(x)$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x \ln(x)}dx}$$
$$= \frac{1}{\ln(x)}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(3x^2 \ln(x)\right)$$
$$\frac{d}{dx}\left(\frac{y}{\ln(x)}\right) = \left(\frac{1}{\ln(x)}\right)\left(3x^2 \ln(x)\right)$$
$$d\left(\frac{y}{\ln(x)}\right) = \left(3x^2\right) dx$$

Integrating gives

$$\frac{y}{\ln(x)} = \int 3x^2 \, dx$$
$$\frac{y}{\ln(x)} = x^3 + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{\ln(x)}$ results in

$$y = x^3 \ln(x) + c_1 \ln(x)$$

which simplifies to

$$y = \ln(x)\left(x^3 + c_1\right)$$

Summary

The solution(s) found are the following

$$y = \ln(x)\left(x^3 + c_1\right) \tag{1}$$

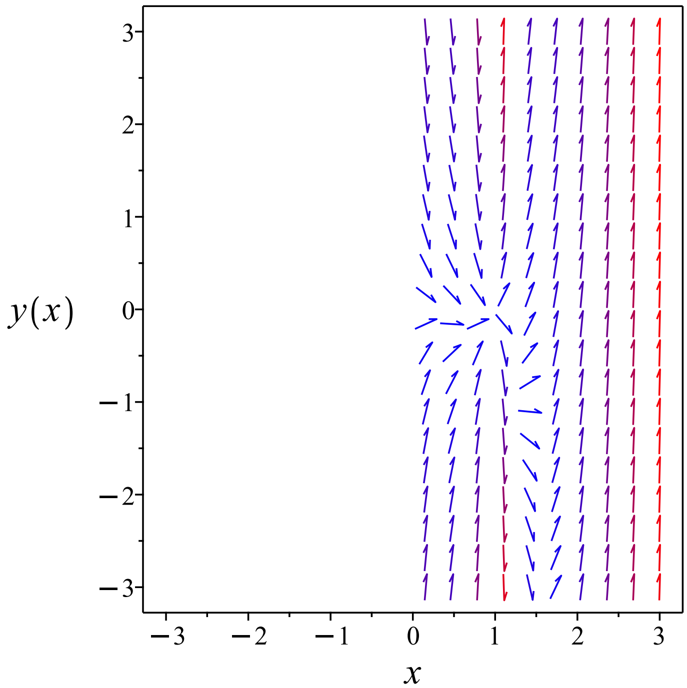

Figure 219: Slope field plot

Verification of solutions

$$y = \ln(x)\left(x^3 + c_1\right)$$

Verified OK.

6.8.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y + 3x^3 \ln(x)^2}{x \ln(x)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 174: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \ln(x) \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\ln(x)} dy \end{aligned}$$

Which results in

$$S = \frac{y}{\ln(x)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y + 3x^3 \ln(x)^2}{x \ln(x)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{\ln(x)^2 x} \\ S_y &= \frac{1}{\ln(x)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 3x^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 3R^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^3 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{\ln(x)} = x^3 + c_1$$

Which simplifies to

$$\frac{y}{\ln(x)} = x^3 + c_1$$

Which gives

$$y = x^3 \ln(x) + c_1 \ln(x)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y+3x^3\ln(x)^2}{x\ln(x)}$ 	$R = x$ $S = \frac{y}{\ln(x)}$	$\frac{dS}{dR} = 3R^2$ 
Summary
The solution(s) found are the following

$$y = x^3 \ln(x) + c_1 \ln(x) \tag{1}$$

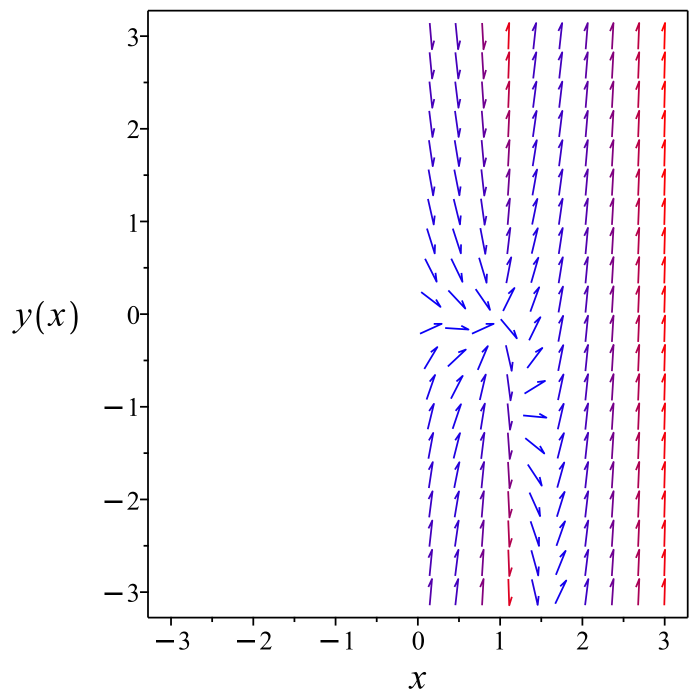

Figure 220: Slope field plot

Verification of solutions

$$y = x^3 \ln(x) + c_1 \ln(x)$$

Verified OK.

6.8.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx} \phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y} \frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x \ln (x))\,\mathrm{d}y &= \left(y + 3x^3 \ln (x)^2\right)\mathrm{d}x\\ \left(-y - 3x^3 \ln (x)^2\right)\mathrm{d}x + (x \ln (x))\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -y - 3x^3 \ln (x)^2\\ N(x, y) &= x \ln (x)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y - 3x^3 \ln (x)^2\right)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x \ln (x))\\ &= \ln (x) + 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{x\ln(x)}((-1) - (\ln(x) + 1)) \\ &= \frac{-2 - \ln(x)}{x\ln(x)} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A\,\mathrm{d}x} \\ &= e^{\int \frac{-2-\ln(x)}{x\ln(x)}\,\mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-\ln(x) - 2\ln(\ln(x))} \\ &= \frac{1}{\ln(x)^2 x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{\ln(x)^2 x}\left(-y - 3x^3\ln(x)^2\right) \\ &= \frac{-y - 3x^3\ln(x)^2}{\ln(x)^2 x} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{\ln(x)^2 x}(x\ln(x)) \\ &= \frac{1}{\ln(x)} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{-y - 3x^3\ln(x)^2}{\ln(x)^2 x}\right) + \left(\frac{1}{\ln(x)}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \frac{-y - 3x^3\ln(x)^2}{\ln(x)^2 x}\,\mathrm{d}x$$
$$\phi = -x^3 + \frac{y}{\ln(x)} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \frac{1}{\ln(x)} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \frac{1}{\ln(x)}$. Therefore equation (4) becomes

$$\frac{1}{\ln(x)} = \frac{1}{\ln(x)} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^3 + \frac{y}{\ln(x)} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^3 + \frac{y}{\ln(x)}$$

The solution becomes

$$y = x^3 \ln(x) + c_1 \ln(x)$$

Summary

The solution(s) found are the following

$$y = x^3 \ln(x) + c_1 \ln(x) \tag{1}$$

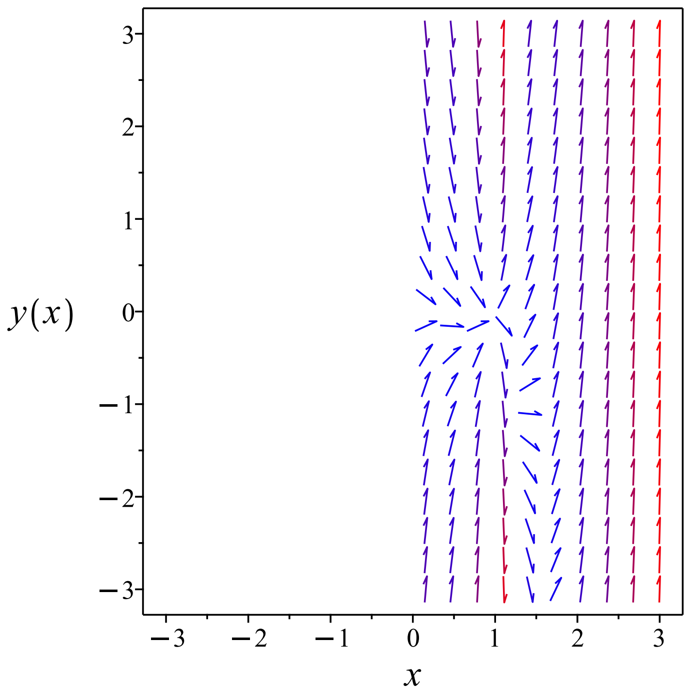

Figure 221: Slope field plot

Verification of solutions

$$y = x^3 \ln(x) + c_1 \ln(x)$$

Verified OK.

6.8.4 Maple step by step solution

Let's solve

$x \ln (x) y' - y = 3x^3 \ln (x)^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y}{x \ln(x)} + 3x^2 \ln (x)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{x \ln(x)} = 3x^2 \ln (x)$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x) \left(y' - \frac{y}{x \ln(x)}\right) = 3\mu(x) x^2 \ln (x)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x) y)$

  $\mu(x) \left(y' - \frac{y}{x \ln(x)}\right) = \mu'(x) y + \mu(x) y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)}{x \ln(x)}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{\ln(x)}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x) y)\right) dx = \int 3\mu(x) x^2 \ln (x) dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x) y = \int 3\mu(x) x^2 \ln (x) dx + c_1$

- Solve for y

  $y = \frac{\int 3\mu(x)x^2 \ln(x)dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{\ln(x)}$

  $y = \ln (x) \left(\int 3x^2 dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = \ln (x) (x^3 + c_1)$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{(-y^2 + 2x)\, y' - 2y = 0}$$

6.9.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{2y}{y^2 - 2x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{2y(b_3 - a_2)}{y^2 - 2x} - \frac{4y^2 a_3}{(y^2 - 2x)^2} + \frac{4y(x a_2 + y a_3 + a_1)}{(y^2 - 2x)^2} - \left(-\frac{2}{y^2 - 2x} + \frac{4y^2}{(y^2 - 2x)^2}\right)(x b_2 + y b_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-y^4 b_2 + 6x\, y^2 b_2 - 2y^3 a_2 + 4y^3 b_3 + 2y^2 b_1 + 4x b_1 - 4y a_1}{(-y^2 + 2x)^2} = 0$$

Setting the numerator to zero gives

$$y^4 b_2 - 6x\, y^2 b_2 + 2y^3 a_2 - 4y^3 b_3 - 2y^2 b_1 - 4x b_1 + 4y a_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$b_2 v_2^4 + 2a_2 v_2^3 - 6b_2 v_1 v_2^2 - 4b_3 v_2^3 - 2b_1 v_2^2 + 4a_1 v_2 - 4b_1 v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$-6b_2 v_1 v_2^2 - 4b_1 v_1 + b_2 v_2^4 + (2a_2 - 4b_3)\, v_2^3 - 2b_1 v_2^2 + 4a_1 v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
b_2 &= 0 \\
4a_1 &= 0 \\
-4b_1 &= 0 \\
-2b_1 &= 0 \\
-6b_2 &= 0 \\
2a_2 - 4b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= 2b_3 \\
a_3 &= a_3 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= y \\
\eta &= 0
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= 0 - \left(-\frac{2y}{y^2 - 2x}\right)(y) \\
&= -\frac{2y^2}{-y^2 + 2x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{-\frac{2y^2}{-y^2+2x}} dy
\end{aligned}$$

Which results in

$$S = \frac{y}{2} + \frac{x}{y}$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{2y}{y^2-2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{y} \\
S_y &= \frac{1}{2} - \frac{x}{y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x,y in terms of R,S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{2} + \frac{x}{y} = c_1$$

Which simplifies to

$$\frac{y}{2} + \frac{x}{y} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2y}{y^2-2x}$ 	$R = x$ $S = \frac{y}{2} + \frac{x}{y}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{y}{2} + \frac{x}{y} = c_1 \tag{1}$$

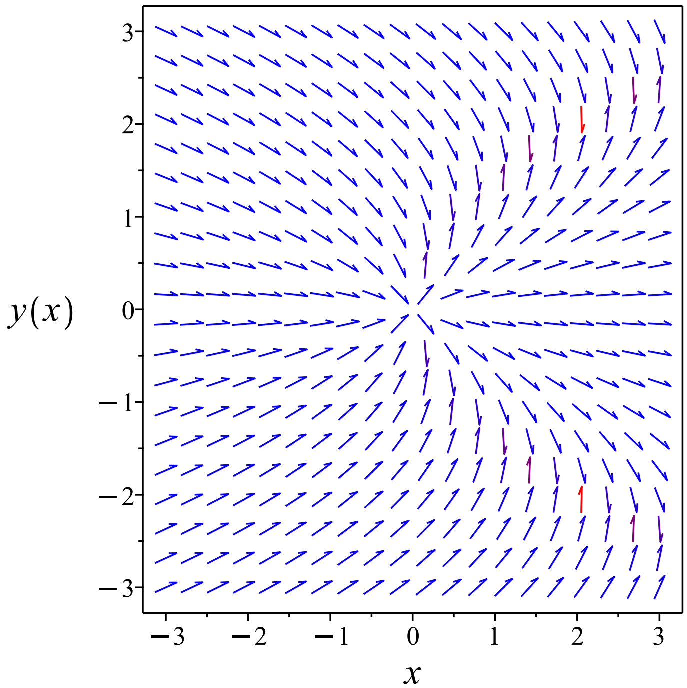

Figure 222: Slope field plot

Verification of solutions

$$\frac{y}{2}+\frac{x}{y}=c_1$$

Verified OK.

6.9.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\,\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-y^2 + 2x\right) \mathrm{d}y = (2y) \, \mathrm{d}x$$
$$(-2y) \, \mathrm{d}x + \left(-y^2 + 2x\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -2y$$
$$N(x, y) = -y^2 + 2x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(-2y)$$
$$= -2$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(-y^2 + 2x\right)$$
$$= 2$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{-y^2 + 2x}((-2) - (2)) \\
&= -\frac{4}{-y^2 + 2x}
\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= -\frac{1}{2y}((2) - (-2)) \\
&= -\frac{2}{y}
\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}
\mu &= e^{\int B \, \mathrm{d}y} \\
&= e^{\int -\frac{2}{y} \, \mathrm{d}y}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{-2\ln(y)} \\
&= \frac{1}{y^2}
\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{y^2}(-2y) \\
&= -\frac{2}{y}
\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{y^2}(-y^2 + 2x) \\
&= \frac{-y^2 + 2x}{y^2}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\frac{2}{y}\right) + \left(\frac{-y^2 + 2x}{y^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{2}{y}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{2x}{y} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \frac{2x}{y^2} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-y^2+2x}{y^2}$. Therefore equation (4) becomes

$$
\frac{-y^2 + 2x}{y^2} = \frac{2x}{y^2} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -1$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (-1)\,\mathrm{d}y$$
$$f(y) = -y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{2x}{y} - y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{2x}{y} - y$$

Summary

The solution(s) found are the following

$$-\frac{2x}{y} - y = c_1 \tag{1}$$

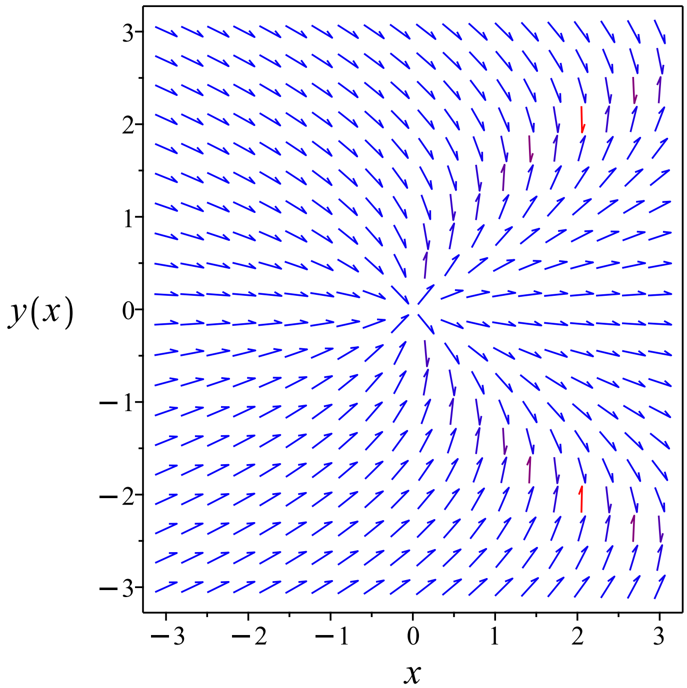

Figure 223: Slope field plot

Verification of solutions

$$-\frac{2x}{y} - y = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' + y\cos(x) = \cos(x)}$$

With initial conditions

$$[y(0) = 1]$$

6.10.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \cos(x) \\ q(x) &= \cos(x) \end{aligned}$$

Hence the ode is

$$y' + y\cos(x) = \cos(x)$$

The domain of $p(x) = \cos(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \cos(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

6.10.2 Solving as separable ode

In canonical form the ODE is

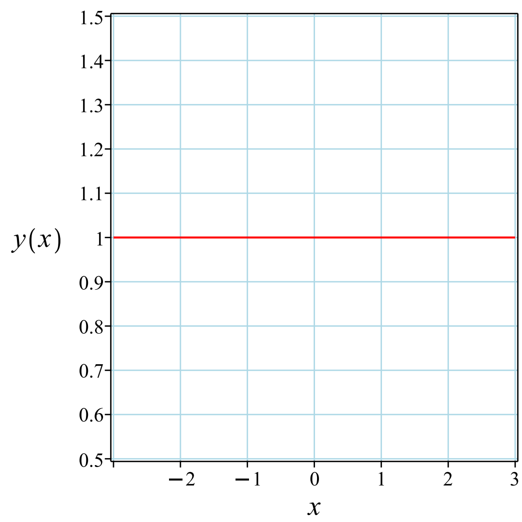
$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= \cos(x)(1 - y) \end{aligned}$$

Where $f(x) = \cos(x)$ and $g(y) = 1 - y$. Since unique solution exists and $g(y)$ evaluated at $y_0 = 1$ is zero, then the solution is

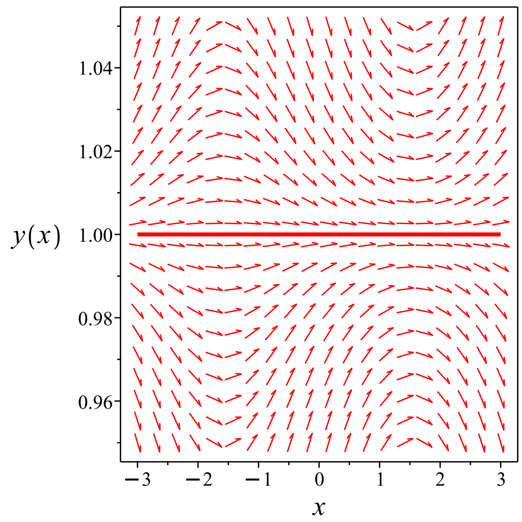
$$\begin{aligned} y &= y_0 \\ &= 1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = 1 \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = 1$$

Verified OK.

6.10.3 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \cos(x)dx} \\ &= e^{\sin(x)}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(\cos(x)) \\ \frac{d}{dx}\left(e^{\sin(x)}y\right) &= \left(e^{\sin(x)}\right)(\cos(x)) \\ d\left(e^{\sin(x)}y\right) &= \left(\cos(x)\, e^{\sin(x)}\right)\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{\sin(x)}y &= \int \cos(x)\, e^{\sin(x)}\, dx \\ e^{\sin(x)}y &= e^{\sin(x)} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{\sin(x)}$ results in

$$y = e^{-\sin(x)} e^{\sin(x)} + c_1 e^{-\sin(x)}$$

which simplifies to

$$y = 1 + c_1 e^{-\sin(x)}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 1 + c_1$$

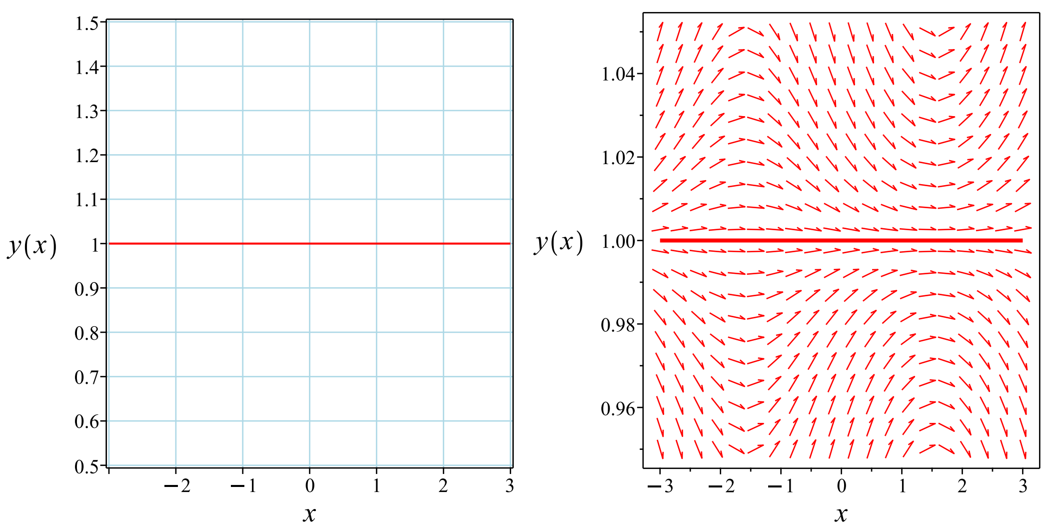
$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = 1$$

Summary
The solution(s) found are the following

$$y = 1 \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = 1$$

Verified OK.

6.10.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\cos(x)\, y+\cos(x) \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 177: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y'=f(x)y(x)+g(x)$	0	$e^{\int f dx}$
separable ode	$y'=f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y'=f(x)$	0	1
quadrature ode	$y'=g(y)$	1	0
homogeneous ODEs of Class A	$y'=f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y'=(a+bx+cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y'=\frac{y}{x}+g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y'=g(x)\,e^{h(x)+by}+f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y'=\frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y'=f(x)\,y+g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y'=f_1(x)\,y+f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \mathrm{e}^{-\sin(x)}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{\mathrm{e}^{-\sin(x)}} dy\end{aligned}$$

Which results in

$$S = \mathrm{e}^{\sin(x)} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\cos(x)\, y + \cos(x)$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1\\ R_y &= 0\\ S_x &= \cos(x)\, \mathrm{e}^{\sin(x)} y\\ S_y &= \mathrm{e}^{\sin(x)}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cos(x)\, e^{\sin(x)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cos(R)\, e^{\sin(R)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = e^{\sin(R)} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{\sin(x)} y = e^{\sin(x)} + c_1$$

Which simplifies to

$$e^{\sin(x)} y = e^{\sin(x)} + c_1$$

Which gives

$$y = e^{-\sin(x)} \left(e^{\sin(x)} + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\cos(x)\, y + \cos(x)$ 	$R = x$ $S = \mathrm{e}^{\sin(x)} y$	$\frac{dS}{dR} = \cos(R)\, \mathrm{e}^{\sin(R)}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 1 + c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$y = 1$$

Summary

The solution(s) found are the following

$$y = 1 \tag{1}$$

<u>Verification of solutions</u>

$$y = 1$$

Verified OK.

6.10.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{1-y}\right)\mathrm{d}y &= (\cos(x))\,\mathrm{d}x\\ (-\cos(x))\,\mathrm{d}x + \left(\frac{1}{1-y}\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -\cos(x)\\ N(x, y) &= \frac{1}{1-y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cos(x))\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{1-y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\cos(x) \mathrm{d}x$$
$$\phi = -\sin(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{1-y}$. Therefore equation (4) becomes

$$\frac{1}{1-y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y-1}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(-\frac{1}{y-1}\right) \mathrm{d}y$$
$$f(y) = -\ln(y-1) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sin(x) - \ln(y-1) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sin(x) - \ln(y - 1)$$

The solution becomes

$$y = e^{-\sin(x) - c_1} + 1$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

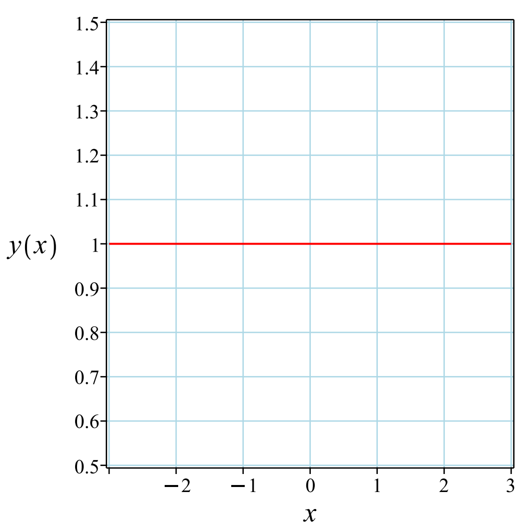
$$1 = e^{-c_1} + 1$$

Unable to solve for constant of integration. Since $\lim_{c_1 \to \infty}$ gives $y = e^{-\sin(x) - c_1} + 1 = y = 1$ and this result satisfies the given initial condition.

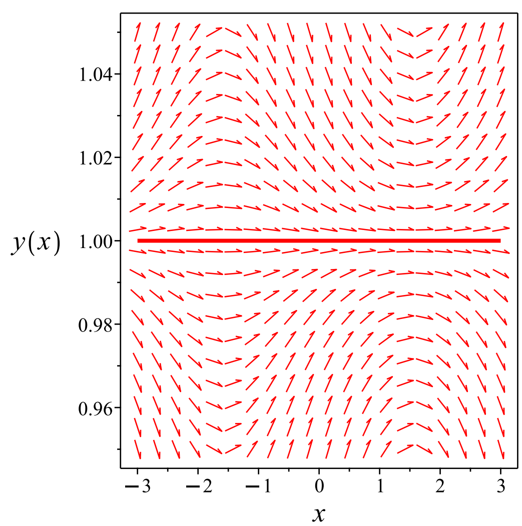
Summary

The solution(s) found are the following

$$y = 1$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 1$$

Verified OK.

6.10.6 Maple step by step solution

Let's solve

$[y' + y\cos(x) = \cos(x), y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y-1} = -\cos(x)$

- Integrate both sides with respect to x

  $\int \frac{y'}{y-1}dx = \int -\cos(x)\,dx + c_1$

- Evaluate integral

  $\ln(y-1) = -\sin(x) + c_1$

- Solve for y

  $y = e^{-\sin(x)+c_1} + 1$

- Use initial condition $y(0) = 1$

  $1 = 1 + e^{c_1}$

- Solution does not satisfy initial condition

The type(s) of ODE detected by this program : **"exact", "differentialType", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries]]
```

$$\boxed{y' - \frac{y}{2\ln(y)\, y + y - x} = 0}$$

6.11.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{y}{2\ln(y)\, y + y - x} \tag{1}$$

Which becomes

$$(2\ln(y)\, y + y)\, dy = (x)\, dy + (y)\, dx \tag{2}$$

But the RHS is complete differential because

$$(x)\, dy + (y)\, dx = d(xy)$$

Hence (2) becomes

$$(2\ln(y)\, y + y)\, dy = d(xy)$$

Integrating both sides gives gives the solution as

$$\ln(y)\, y^2 = yx + c_1$$

Summary

The solution(s) found are the following

$$\ln(y)\, y^2 = yx + c_1 \tag{1}$$

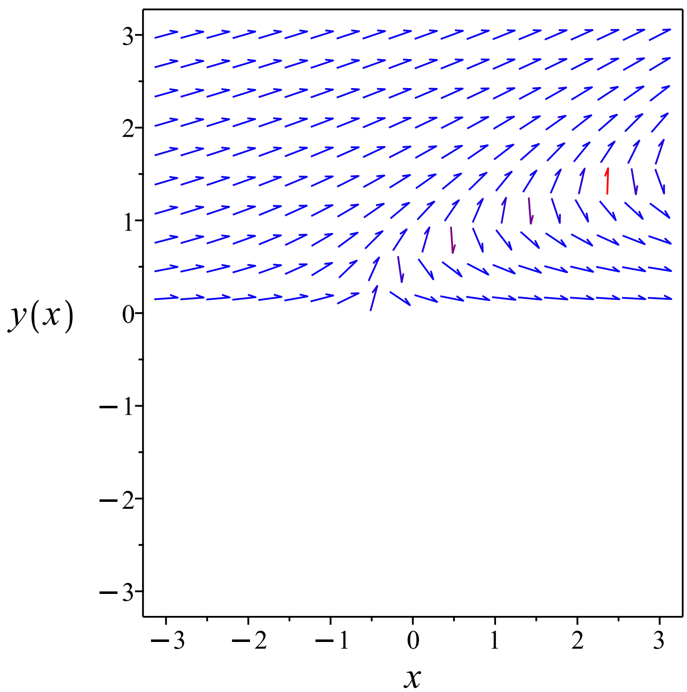

Figure 228: Slope field plot

Verification of solutions

$$\ln(y)\, y^2 = yx + c_1$$

Verified OK.

6.11.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{y}{2\ln(y)\,y + y - x} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
b_2 + \frac{y(b_3 - a_2)}{2\ln(y)\,y + y - x} - \frac{y^2 a_3}{(2\ln(y)\,y + y - x)^2} - \frac{y(x a_2 + y a_3 + a_1)}{(2\ln(y)\,y + y - x)^2} \\
- \left(\frac{1}{2\ln(y)\,y + y - x} - \frac{y(3 + 2\ln(y))}{(2\ln(y)\,y + y - x)^2}\right)(x b_2 + y b_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
\frac{4\ln(y)^2 y^2 b_2 - 4\ln(y)\,x y b_2 - 2\ln(y)\,y^2 a_2 + 4\ln(y)\,y^2 b_2 + 2\ln(y)\,y^2 b_3 + 2x^2 b_2 - y^2 a_2 - 2y^2 a_3 + y^2 b_2 + 3}{(2\ln(y)\,y + y - x)^2} = 0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
4\ln(y)^2 y^2 b_2 - 4\ln(y)\,x y b_2 - 2\ln(y)\,y^2 a_2 + 4\ln(y)\,y^2 b_2 + 2\ln(y)\,y^2 b_3 \\
+ 2x^2 b_2 - y^2 a_2 - 2y^2 a_3 + y^2 b_2 + 3y^2 b_3 + x b_1 - y a_1 + 2y b_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, \ln(y)\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, \ln(y) = v_3\}$$

The above PDE (6E) now becomes

$$4v_3^2v_2^2b_2 - 2v_3v_2^2a_2 - 4v_3v_1v_2b_2 + 4v_3v_2^2b_2 + 2v_3v_2^2b_3 - v_2^2a_2 - 2v_2^2a_3 + 2v_1^2b_2 + v_2^2b_2 + 3v_2^2b_3 - v_2a_1 + v_1b_1 + 2v_2b_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$2v_1^2b_2 - 4v_3v_1v_2b_2 + v_1b_1 + 4v_3^2v_2^2b_2 + (-2a_2 + 4b_2 + 2b_3)\,v_2^2v_3 + (-a_2 - 2a_3 + b_2 + 3b_3)\,v_2^2 + (-a_1 + 2b_1)\,v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} b_1 &= 0 \\ -4b_2 &= 0 \\ 2b_2 &= 0 \\ 4b_2 &= 0 \\ -a_1 + 2b_1 &= 0 \\ -2a_2 + 4b_2 + 2b_3 &= 0 \\ -a_2 - 2a_3 + b_2 + 3b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= b_3 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = y + x$$
$$\eta = y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{y}{2\ln(y)\,y + y - x}\right)(y + x) \\
&= \frac{2\ln(y)\,y^2 - 2xy}{2\ln(y)\,y + y - x} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{2\ln(y)y^2 - 2xy}{2\ln(y)y + y - x}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(\ln(y)\,y^2 - xy)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y}{2\ln(y)\, y + y - x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{-2\ln(y)\, y + 2x} \\ S_y &= \frac{2\ln(y)\, y + y - x}{2y\,(\ln(y)\, y - x)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y)}{2} + \frac{\ln(\ln(y)\, y - x)}{2} = c_1$$

Which simplifies to

$$\frac{\ln(y)}{2} + \frac{\ln(\ln(y)\, y - x)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y}{2\ln(y)y+y-x}$ 	$R = x$ $S = \frac{\ln(y)}{2} + \frac{\ln(\ln(y)y -}{2}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(y)}{2} + \frac{\ln(\ln(y)\, y - x)}{2} = c_1 \tag{1}$$

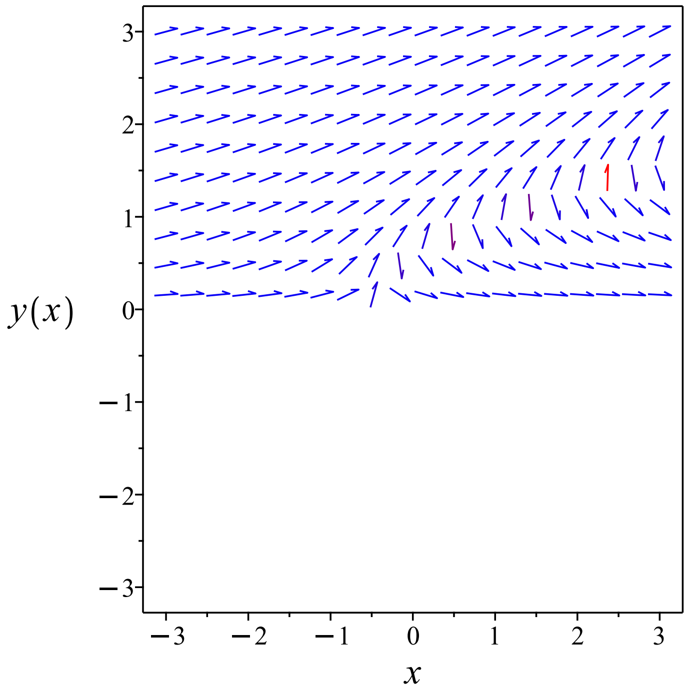

Figure 229: Slope field plot

Verification of solutions

$$\frac{\ln(y)}{2}+\frac{\ln(\ln(y)\,y-x)}{2}=c_1$$

Verified OK.

6.11.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(2 \ln (y) y + y - x) \,\mathrm{d}y &= (y) \,\mathrm{d}x \\
(-y) \,\mathrm{d}x + (2 \ln (y) y + y - x) \,\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -y \\
N(x, y) &= 2 \ln (y) y + y - x
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-y) \\
&= -1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2 \ln (y) y + y - x) \\
&= -1
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int -y \,\mathrm{d}x$$
$$\phi = -xy + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2\ln(y)\,y + y - x$. Therefore equation (4) becomes

$$2\ln(y)\,y + y - x = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2\ln(y)\,y + y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int ((2\ln(y) + 1)\,y) \,\mathrm{d}y$$
$$f(y) = \ln(y)\,y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \ln(y)\,y^2 - xy + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \ln(y)\, y^2 - xy$$

Summary
The solution(s) found are the following

$$\ln(y)\, y^2 - yx = c_1 \tag{1}$$

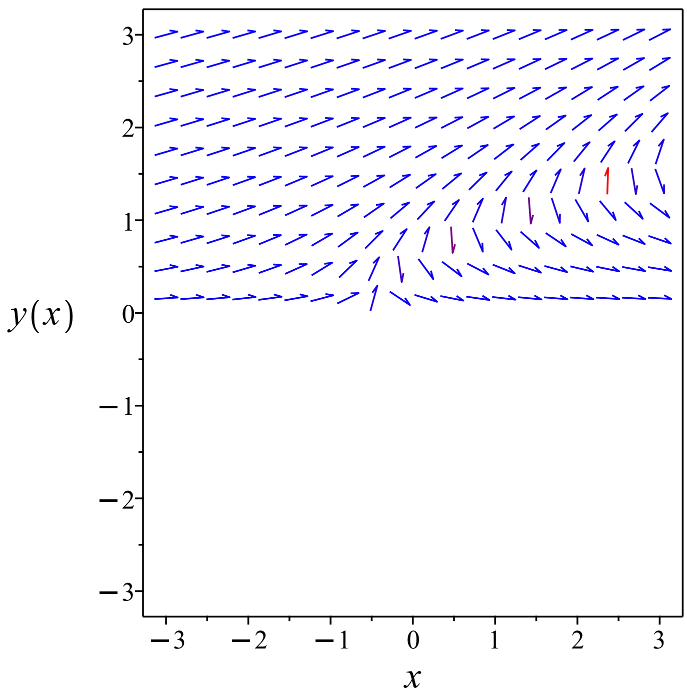

Figure 230: Slope field plot

Verification of solutions

$$\ln(y)\, y^2 - yx = c_1$$

Verified OK.

$$\boxed{\left(\frac{e^{-y^2}}{2} - yx\right) y' = 1}$$

6.12.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{\mathrm{e}^{-y^2}}{2} - xy\right)\mathrm{d}y &= \mathrm{d}x\\ -\mathrm{d}x + \left(\frac{\mathrm{e}^{-y^2}}{2} - xy\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -1\\ N(x, y) &= \frac{\mathrm{e}^{-y^2}}{2} - xy\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-1)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{\mathrm{e}^{-y^2}}{2} - xy\right) \\ &= -y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{2}{-2xy + \mathrm{e}^{-y^2}}((0) - (-y)) \\ &= \frac{2y}{-2xy + \mathrm{e}^{-y^2}}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= -1((-y) - (0)) \\ &= y\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}\mu &= e^{\int B \, \mathrm{d}y} \\ &= e^{\int y \, \mathrm{d}y}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\frac{y^2}{2}} \\ &= \mathrm{e}^{\frac{y^2}{2}}\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{\frac{y^2}{2}}(-1) \\ &= -\mathrm{e}^{\frac{y^2}{2}}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{\frac{y^2}{2}}\left(\frac{\mathrm{e}^{-y^2}}{2} - xy\right) \\
&= -y\,\mathrm{e}^{\frac{y^2}{2}} x + \frac{\mathrm{e}^{-\frac{y^2}{2}}}{2}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{\frac{y^2}{2}}\right) + \left(-y\,\mathrm{e}^{\frac{y^2}{2}} x + \frac{\mathrm{e}^{-\frac{y^2}{2}}}{2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\mathrm{e}^{\frac{y^2}{2}}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\mathrm{e}^{\frac{y^2}{2}} x + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -y\,\mathrm{e}^{\frac{y^2}{2}} x + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y\,\mathrm{e}^{\frac{y^2}{2}} x + \frac{\mathrm{e}^{-\frac{y^2}{2}}}{2}$. Therefore equation (4) becomes

$$
-y\,\mathrm{e}^{\frac{y^2}{2}} x + \frac{\mathrm{e}^{-\frac{y^2}{2}}}{2} = -y\,\mathrm{e}^{\frac{y^2}{2}} x + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{e^{-\frac{y^2}{2}}}{2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,dy = \int \left(\frac{e^{-\frac{y^2}{2}}}{2}\right) dy$$

$$f(y) = \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{y\sqrt{2}}{2}\right)}{4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -e^{\frac{y^2}{2}} x + \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{y\sqrt{2}}{2}\right)}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -e^{\frac{y^2}{2}} x + \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{y\sqrt{2}}{2}\right)}{4}$$

Summary

The solution(s) found are the following

$$-e^{\frac{y^2}{2}} x + \frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{y\sqrt{2}}{2}\right)}{4} = c_1 \tag{1}$$

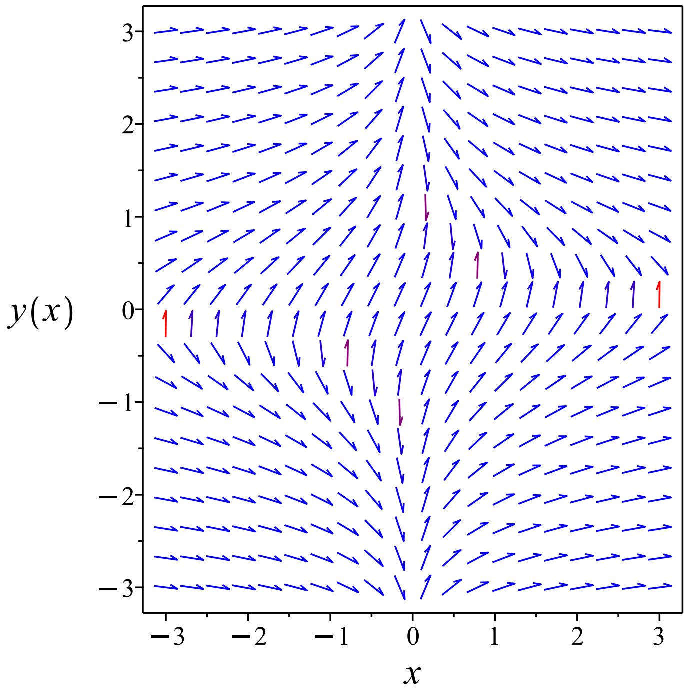

Figure 231: Slope field plot

Verification of solutions

$$-e^{\frac{y^2}{2}}x+\frac{\sqrt{\pi}\,\sqrt{2}\,\mathrm{erf}\left(\frac{y\sqrt{2}}{2}\right)}{4}=c_1$$

Verified OK.

Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 137.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - y\,e^{x} = 2x\,e^{e^{x}}}$$

6.13.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -e^{x} \\ q(x) &= 2x\,e^{e^{x}} \end{aligned}$$

Hence the ode is

$$y' - y\,e^{x} = 2x\,e^{e^{x}}$$

The integrating factor μ is

$$\mu = e^{\int -e^x dx}$$
$$= e^{-e^x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(2x\, e^{e^x}\right)$$
$$\frac{d}{dx}\left(e^{-e^x} y\right) = \left(e^{-e^x}\right)\left(2x\, e^{e^x}\right)$$
$$d\left(e^{-e^x} y\right) = (2x)\, dx$$

Integrating gives

$$e^{-e^x} y = \int 2x\, dx$$
$$e^{-e^x} y = x^2 + c_1$$

Dividing both sides by the integrating factor $\mu = e^{-e^x}$ results in

$$y = e^{e^x} x^2 + c_1 e^{e^x}$$

which simplifies to

$$y = e^{e^x}\left(x^2 + c_1\right)$$

Summary
The solution(s) found are the following

$$y = e^{e^x}\left(x^2 + c_1\right) \tag{1}$$

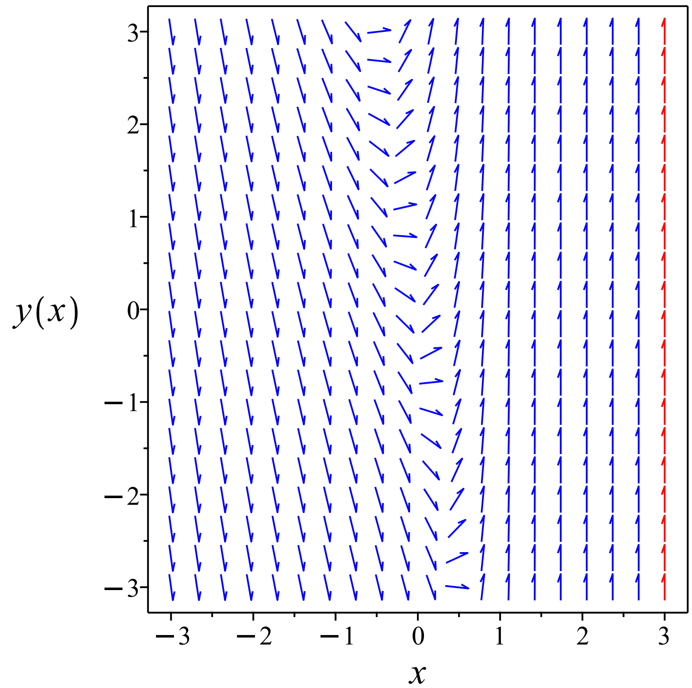

Figure 232: Slope field plot

<u>Verification of solutions</u>

$$y = \mathrm{e}^{\mathrm{e}^{x}} \left(x^{2}+c_{1}\right)$$

Verified OK.

6.13.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \mathrm{e}^{x} y + 2x\,\mathrm{e}^{\mathrm{e}^{x}} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 180: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= 0\\ \eta(x,y) &= \mathrm{e}^{\mathrm{e}^{x}}\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{\mathrm{e}^x}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{-\mathrm{e}^x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \mathrm{e}^x y + 2x\,\mathrm{e}^{\mathrm{e}^x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -y\,\mathrm{e}^{x-\mathrm{e}^x} \\ S_y &= \mathrm{e}^{-\mathrm{e}^x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-e^x} y = x^2 + c_1$$

Which simplifies to

$$e^{-e^x} y = x^2 + c_1$$

Which gives

$$y = e^{e^x} (x^2 + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = e^x y + 2x\,e^{e^x}$ 	$R = x$ $S = e^{-e^x} y$	$\frac{dS}{dR} = 2R$ 
Summary
The solution(s) found are the following

$$y = e^{e^x} (x^2 + c_1) \tag{1}$$

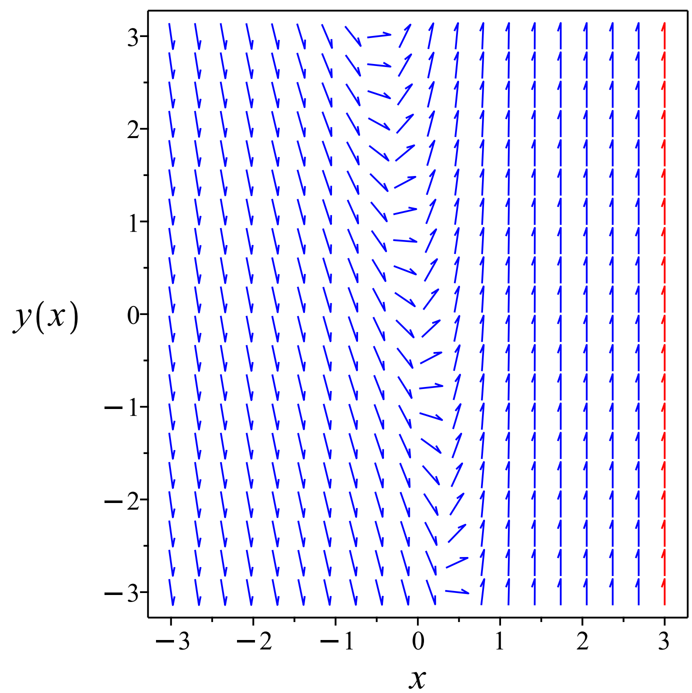

Figure 233: Slope field plot

Verification of solutions

$$y = e^{e^x}(x^2 + c_1)$$

Verified OK.

6.13.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(\mathrm{e}^x y + 2x\,\mathrm{e}^{\mathrm{e}^x}\right) \mathrm{d}x$$
$$\left(-\mathrm{e}^x y - 2x\,\mathrm{e}^{\mathrm{e}^x}\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\mathrm{e}^x y - 2x\,\mathrm{e}^{\mathrm{e}^x}$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\mathrm{e}^x y - 2x\,\mathrm{e}^{\mathrm{e}^x}\right)$$
$$= -\mathrm{e}^x$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(1)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-\mathrm{e}^{x}) - (0)) \\ &= -\mathrm{e}^{x} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \,\mathrm{d}x} \\ &= e^{\int -\mathrm{e}^{x} \,\mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-\mathrm{e}^{x}} \\ &= \mathrm{e}^{-\mathrm{e}^{x}} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-\mathrm{e}^{x}}\left(-\mathrm{e}^{x} y - 2x\,\mathrm{e}^{\mathrm{e}^{x}}\right) \\ &= -y\,\mathrm{e}^{x-\mathrm{e}^{x}} - 2x \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-\mathrm{e}^{x}}(1) \\ &= \mathrm{e}^{-\mathrm{e}^{x}} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(-y\,\mathrm{e}^{x-\mathrm{e}^{x}} - 2x\right) + \left(\mathrm{e}^{-\mathrm{e}^{x}}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -y \, \mathrm{e}^{x-\mathrm{e}^{x}} - 2x \, \mathrm{d}x$$
$$\phi = -x^2 + \mathrm{e}^{-\mathrm{e}^{x}} y + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-\mathrm{e}^{x}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-\mathrm{e}^{x}}$. Therefore equation (4) becomes

$$\mathrm{e}^{-\mathrm{e}^{x}} = \mathrm{e}^{-\mathrm{e}^{x}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^2 + \mathrm{e}^{-\mathrm{e}^{x}} y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^2 + \mathrm{e}^{-\mathrm{e}^{x}} y$$

The solution becomes

$$y = \mathrm{e}^{\mathrm{e}^{x}} (x^2 + c_1)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\mathrm{e}^{x}} (x^2 + c_1) \tag{1}$$

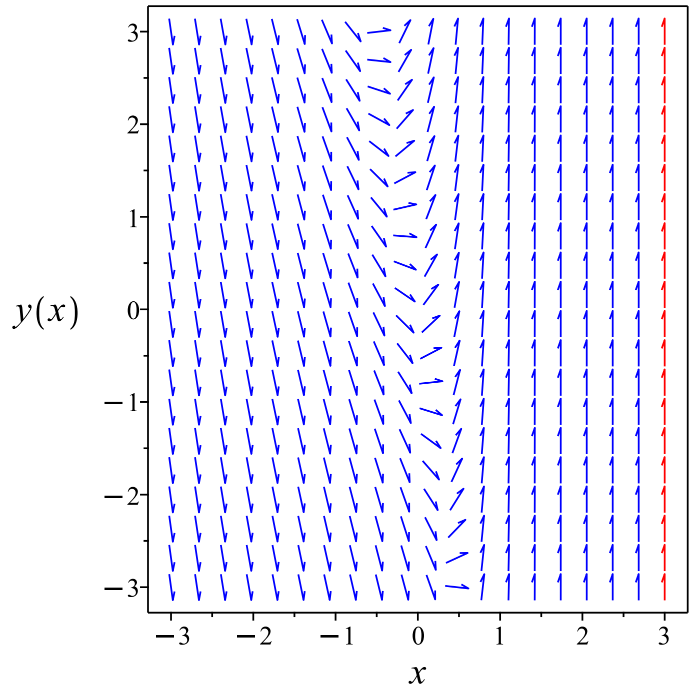

Figure 234: Slope field plot

Verification of solutions

$$y = e^{e^x}(x^2 + c_1)$$

Verified OK.

6.13.4 Maple step by step solution

Let's solve

$y' - y\,e^x = 2x\,e^{e^x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = y\,e^x + 2x\,e^{e^x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y\,e^x = 2x\,e^{e^x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - y\,e^x) = 2\mu(x)\,x\,e^{e^x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y'-y\,\mathrm{e}^{x})=\mu'(x)\,y+\mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x)=-\mu(x)\,\mathrm{e}^{x}$
- Solve to find the integrating factor

  $\mu(x)=\mathrm{e}^{-\mathrm{e}^{x}}$
- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int 2\mu(x)\,x\,\mathrm{e}^{\mathrm{e}^{x}}dx+c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y=\int 2\mu(x)\,x\,\mathrm{e}^{\mathrm{e}^{x}}dx+c_1$
- Solve for y

  $y=\frac{\int 2\mu(x)x\,\mathrm{e}^{\mathrm{e}^{x}}dx+c_1}{\mu(x)}$
- Substitute $\mu(x)=\mathrm{e}^{-\mathrm{e}^{x}}$

  $y=\frac{\int 2x\,\mathrm{e}^{\mathrm{e}^{x}}\mathrm{e}^{-\mathrm{e}^{x}}dx+c_1}{\mathrm{e}^{-\mathrm{e}^{x}}}$
- Evaluate the integrals on the rhs

  $y=\frac{x^2+c_1}{\mathrm{e}^{-\mathrm{e}^{x}}}$
- Simplify

  $y=\mathrm{e}^{\mathrm{e}^{x}}(x^2+c_1)$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 138.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' + yx\,\mathrm{e}^{x} = \mathrm{e}^{(1-x)\mathrm{e}^{x}}}$$

6.14.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = x\,\mathrm{e}^{x}$$
$$q(x) = \mathrm{e}^{-\mathrm{e}^{x}(x-1)}$$

Hence the ode is

$$y' + yx\,\mathrm{e}^{x} = \mathrm{e}^{-\mathrm{e}^{x}(x-1)}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int x\,e^{x}dx} \\
&= e^{e^{x}(x-1)}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(e^{-e^{x}(x-1)}\right) \\
\frac{d}{dx}\left(e^{e^{x}(x-1)}y\right) &= \left(e^{e^{x}(x-1)}\right)\left(e^{-e^{x}(x-1)}\right) \\
d\left(e^{e^{x}(x-1)}y\right) &= dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{e^{x}(x-1)}y &= \int dx \\
e^{e^{x}(x-1)}y &= x + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{e^{x}(x-1)}$ results in

$$
y = e^{-e^{x}(x-1)}x + c_1 e^{-e^{x}(x-1)}
$$

which simplifies to

$$
y = e^{-e^{x}(x-1)}(x + c_1)
$$

Summary
The solution(s) found are the following

$$
y = e^{-e^{x}(x-1)}(x + c_1) \tag{1}
$$

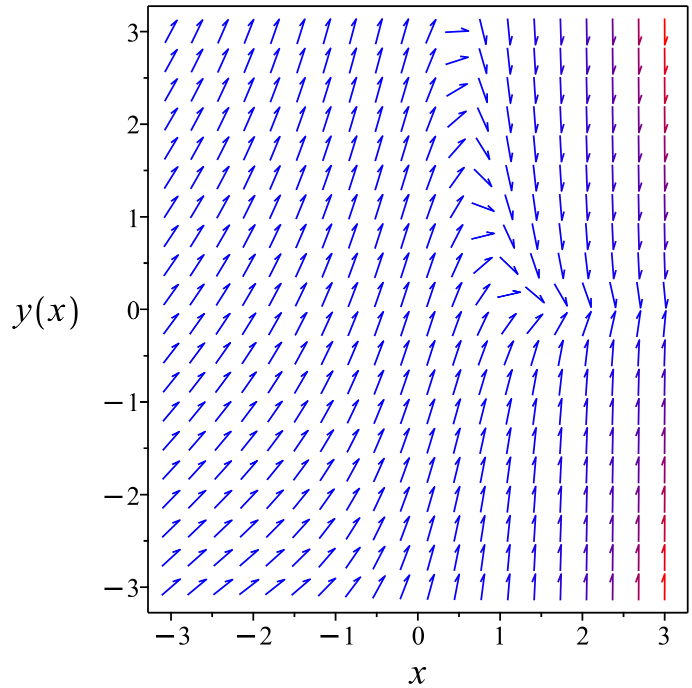

Figure 235: Slope field plot

Verification of solutions

$$y = e^{-e^x(x-1)}(x + c_1)$$

Verified OK.

6.14.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -x e^x y + e^{(1-x)e^x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 183: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \mathrm{e}^{-\mathrm{e}^{x}(x-1)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-\mathrm{e}^{x}(x-1)}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{\mathrm{e}^{x}(x-1)} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -x\,\mathrm{e}^{x} y + \mathrm{e}^{(1-x)\mathrm{e}^{x}}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= xy\,\mathrm{e}^{x+\mathrm{e}^{x}(x-1)} \\ S_y &= \mathrm{e}^{\mathrm{e}^{x}(x-1)} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{e^x(x-1)} y = x + c_1$$

Which simplifies to

$$e^{e^x(x-1)} y = x + c_1$$

Which gives

$$y = e^{-e^x(x-1)}(x + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -x\,e^x y + e^{(1-x)e^x}$ 	$R = x$ $S = e^{e^x(x-1)} y$	$\frac{dS}{dR} = 1$ 
Summary
The solution(s) found are the following

$$y = e^{-e^x(x-1)}(x + c_1) \tag{1}$$

Verification of solutions

$$y = e^{-e^x(x-1)}(x + c_1)$$

Verified OK.

6.14.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(-x\,\mathrm{e}^{x} y + \mathrm{e}^{(1-x)\mathrm{e}^{x}}\right) \mathrm{d}x$$
$$\left(x\,\mathrm{e}^{x} y - \mathrm{e}^{(1-x)\mathrm{e}^{x}}\right) \mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = x\,\mathrm{e}^{x} y - \mathrm{e}^{(1-x)\mathrm{e}^{x}}$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(x\,\mathrm{e}^{x} y - \mathrm{e}^{(1-x)\mathrm{e}^{x}}\right)$$
$$= x\,\mathrm{e}^{x}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(1)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((x\,\mathrm{e}^{x}) - (0)) \\ &= x\,\mathrm{e}^{x} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A\,\mathrm{d}x} \\ &= e^{\int x\,\mathrm{e}^{x}\,\mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\mathrm{e}^{x}(x-1)} \\ &= \mathrm{e}^{\mathrm{e}^{x}(x-1)} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{\mathrm{e}^{x}(x-1)}\left(x\,\mathrm{e}^{x}y - \mathrm{e}^{(1-x)\mathrm{e}^{x}}\right) \\ &= xy\,\mathrm{e}^{x+\mathrm{e}^{x}(x-1)} - 1 \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{\mathrm{e}^{x}(x-1)}(1) \\ &= \mathrm{e}^{\mathrm{e}^{x}(x-1)} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(xy\,\mathrm{e}^{x+\mathrm{e}^{x}(x-1)} - 1\right) + \left(\mathrm{e}^{\mathrm{e}^{x}(x-1)}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int xy \, \mathrm{e}^{x+\mathrm{e}^x(x-1)} - 1 \mathrm{d}x \\
\phi &= -x + \mathrm{e}^{\mathrm{e}^x(x-1)} y + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{\mathrm{e}^x(x-1)} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{\mathrm{e}^x(x-1)}$. Therefore equation (4) becomes

$$
\mathrm{e}^{\mathrm{e}^x(x-1)} = \mathrm{e}^{\mathrm{e}^x(x-1)} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$
\phi = -x + \mathrm{e}^{\mathrm{e}^x(x-1)} y + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$
c_1 = -x + \mathrm{e}^{\mathrm{e}^x(x-1)} y
$$

The solution becomes

$$
y = \mathrm{e}^{-\mathrm{e}^x(x-1)}(x + c_1)
$$

Summary
The solution(s) found are the following

$$y = e^{-e^x(x-1)}(x + c_1) \tag{1}$$

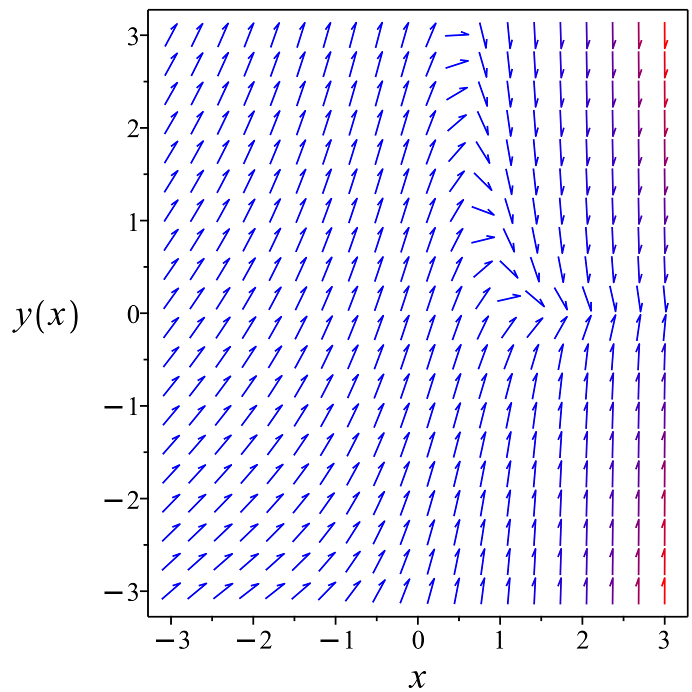

Figure 237: Slope field plot

Verification of solutions

$$y = e^{-e^x(x-1)}(x + c_1)$$

Verified OK.

6.14.4 Maple step by step solution

Let's solve

$y' + yx\,e^x = e^{(1-x)e^x}$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -yx\,e^x + e^{-e^x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + yx\,\mathrm{e}^{x} = \mathrm{e}^{-\mathrm{e}^{x}(x-1)}$
- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + yx\,\mathrm{e}^{x}\right) = \mu(x)\,\mathrm{e}^{-\mathrm{e}^{x}(x-1)}$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' + yx\,\mathrm{e}^{x}\right) = \mu'(x)\,y + \mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)\,x\,\mathrm{e}^{x}$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{\mathrm{e}^{x}(x-1)}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,\mathrm{e}^{-\mathrm{e}^{x}(x-1)} dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,\mathrm{e}^{-\mathrm{e}^{x}(x-1)} dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x)\mathrm{e}^{-\mathrm{e}^{x}(x-1)} dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{\mathrm{e}^{x}(x-1)}$

  $y = \frac{\int \mathrm{e}^{-\mathrm{e}^{x}(x-1)}\mathrm{e}^{\mathrm{e}^{x}(x-1)} dx + c_1}{\mathrm{e}^{\mathrm{e}^{x}(x-1)}}$
- Evaluate the integrals on the rhs

  $y = \frac{x + c_1}{\mathrm{e}^{\mathrm{e}^{x}(x-1)}}$
- Simplify

  $y = \mathrm{e}^{-\mathrm{e}^{x}(x-1)}(x + c_1)$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y\ln(2) = 2^{\sin(x)}(\cos(x) - 1)\ln(2)}$$

6.15.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\ln(2) \\ q(x) &= 2^{\sin(x)}(\cos(x) - 1)\ln(2) \end{aligned}$$

Hence the ode is

$$y' - y\ln(2) = 2^{\sin(x)}(\cos(x) - 1)\ln(2)$$

The integrating factor μ is

$$\mu = e^{\int -\ln(2)dx}$$
$$= e^{-\ln(2)x}$$

Which simplifies to

$$\mu = 2^{-x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(2^{\sin(x)}(\cos(x)-1)\ln(2)\right)$$
$$\frac{d}{dx}\left(2^{-x}y\right) = \left(2^{-x}\right)\left(2^{\sin(x)}(\cos(x)-1)\ln(2)\right)$$
$$d\left(2^{-x}y\right) = \left(2^{\sin(x)-x}(\cos(x)-1)\ln(2)\right)\, dx$$

Integrating gives

$$2^{-x}y = \int 2^{\sin(x)-x}(\cos(x)-1)\ln(2)\, dx$$
$$2^{-x}y = \frac{\tan\left(\frac{x}{2}\right)^2 e^{\left(\frac{2\tan\left(\frac{x}{2}\right)}{1+\tan\left(\frac{x}{2}\right)^2}-x\right)\ln(2)} + e^{\left(\frac{2\tan\left(\frac{x}{2}\right)}{1+\tan\left(\frac{x}{2}\right)^2}-x\right)\ln(2)}}{1+\tan\left(\frac{x}{2}\right)^2} + c_1$$

Dividing both sides by the integrating factor $\mu = 2^{-x}$ results in

$$y = \frac{2^x\left(\tan\left(\frac{x}{2}\right)^2 e^{\left(\frac{2\tan\left(\frac{x}{2}\right)}{1+\tan\left(\frac{x}{2}\right)^2}-x\right)\ln(2)} + e^{\left(\frac{2\tan\left(\frac{x}{2}\right)}{1+\tan\left(\frac{x}{2}\right)^2}-x\right)\ln(2)}\right)}{1+\tan\left(\frac{x}{2}\right)^2} + c_1 2^x$$

which simplifies to

$$y = c_1 2^x + 2^{\sin(x)}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 2^x + 2^{\sin(x)} \tag{1}$$

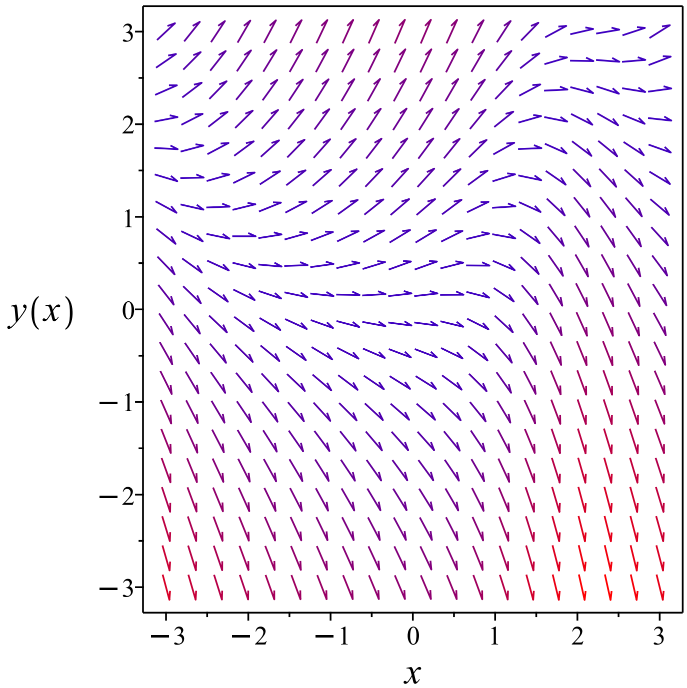

Figure 238: Slope field plot

Verification of solutions

$$y = c_1 2^x + 2^{\sin(x)}$$

Verified OK.

6.15.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = 2^{\sin(x)} \ln(2) \cos(x) - 2^{\sin(x)} \ln(2) + y \ln(2)$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 186: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= e^{\ln(2)x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{\ln(2)x}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{-\ln(2)x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = 2^{\sin(x)} \ln(2) \cos(x) - 2^{\sin(x)} \ln(2) + y \ln(2)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\ln(2)\, 2^{-x} y \\ S_y &= 2^{-x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2^{\sin(x)-x}(\cos(x) - 1)\ln(2) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2^{\sin(R)-R}(\cos(R) - 1)\ln(2)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 + 2^{-\frac{\tan\left(\frac{R}{2}\right)^2 R - 2\tan\left(\frac{R}{2}\right) + R}{1+\tan\left(\frac{R}{2}\right)^2}} \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$2^{-x} y = c_1 + 2^{-\frac{\tan\left(\frac{x}{2}\right)^2 x - 2\tan\left(\frac{x}{2}\right) + x}{1+\tan\left(\frac{x}{2}\right)^2}}$$

Which simplifies to

$$2^{-x} y - c_1 - 2^{\sin(x) - x} = 0$$

Which gives

$$y = 2^x \left(2^{\sin(x) - x} + c_1\right)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2^{\sin(x)} \ln(2) \cos(x) - 2^{\sin(x)} \ln(2) + y \ln(2)$ 	$R = x$ $S = 2^{-x} y$	$\frac{dS}{dR} = 2^{\sin(R) - R}(\cos(R) - 1) \ln(2)$ 
Summary
The solution(s) found are the following

$$y = 2^x \left(2^{\sin(x) - x} + c_1\right) \tag{1}$$

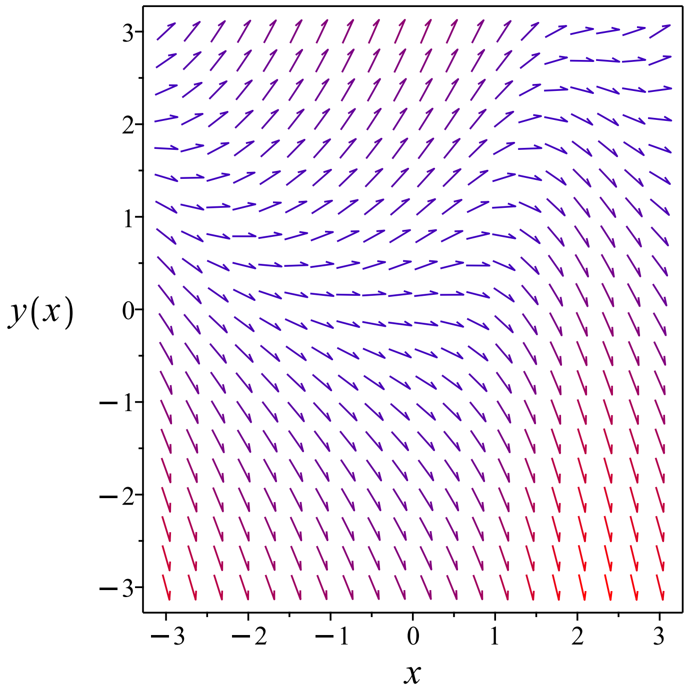

Figure 239: Slope field plot

Verification of solutions

$$y = 2^x \left(2^{\sin(x)-x} + c_1\right)$$

6.15.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\mathrm{d}y = \left(y \ln(2) + 2^{\sin(x)}(\cos(x) - 1)\ln(2)\right)\mathrm{d}x$$
$$\left(-y \ln(2) - 2^{\sin(x)}(\cos(x) - 1)\ln(2)\right)\mathrm{d}x + \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -y \ln(2) - 2^{\sin(x)}(\cos(x) - 1)\ln(2)$$
$$N(x, y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y \ln(2) - 2^{\sin(x)}(\cos(x) - 1)\ln(2)\right) \\ &= -\ln(2)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-\ln(2)) - (0)) \\ &= -\ln(2) \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\ln(2) \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-\ln(2)x} \\ &= 2^{-x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= 2^{-x}\left(-y\ln(2) - 2^{\sin(x)}(\cos(x) - 1)\ln(2)\right) \\ &= -\ln(2)\left(2^{\sin(x)}(\cos(x) - 1) + y\right)2^{-x} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= 2^{-x}(1) \\ &= 2^{-x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(-\ln(2)\left(2^{\sin(x)}(\cos(x) - 1) + y\right)2^{-x}\right) + \left(2^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\ln(2) \left(2^{\sin(x)}(\cos(x) - 1) + y\right) 2^{-x} \, \mathrm{d}x$$

$$\phi = 2^{-x}\left(-2^{\sin(x)} + y\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2^{-x}$. Therefore equation (4) becomes

$$2^{-x} = 2^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = 2^{-x}\left(-2^{\sin(x)} + y\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 2^{-x}\left(-2^{\sin(x)} + y\right)$$

The solution becomes

$$y = \left(2^{\sin(x)} 2^{-x} + c_1\right) 2^{x}$$

Summary

The solution(s) found are the following

$$y = \left(2^{\sin(x)}2^{-x} + c_1\right) 2^x \tag{1}$$

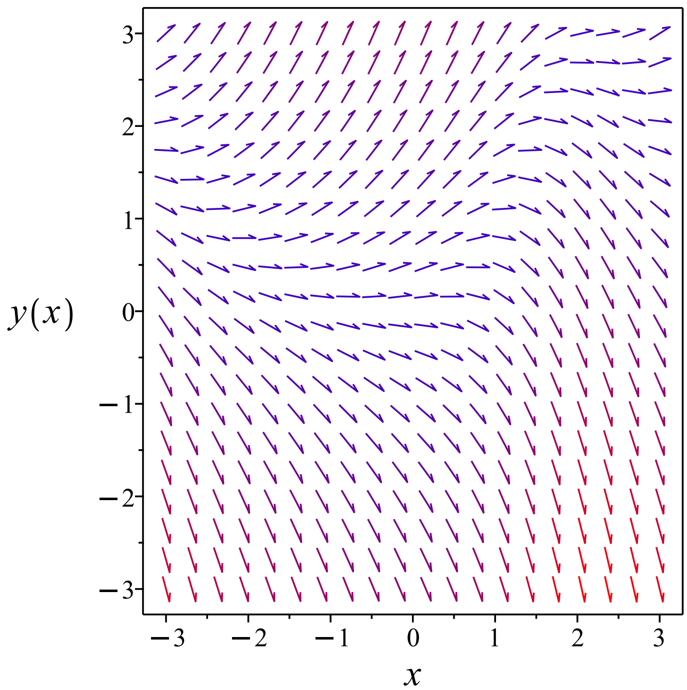

Figure 240: Slope field plot

Verification of solutions

$$y = \left(2^{\sin(x)}2^{-x} + c_1\right) 2^x$$

Verified OK.

6.15.4 Maple step by step solution

Let's solve

$y' - y\ln(2) = 2^{\sin(x)}(\cos(x) - 1)\ln(2)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = y\ln(2) + 2^{\sin(x)}(\cos(x) - 1)\ln(2)$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y\ln(2) = 2^{\sin(x)}(\cos(x) - 1)\ln(2)$
- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - y\ln(2)\right) = \mu(x)\,2^{\sin(x)}(\cos(x) - 1)\ln(2)$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' - y\ln(2)\right) = \mu'(x)\,y + \mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)\ln(2)$
- Solve to find the integrating factor

  $\mu(x) = \frac{1}{2^x}$
- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx = \int \mu(x)\,2^{\sin(x)}(\cos(x) - 1)\ln(2)\,dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,2^{\sin(x)}(\cos(x) - 1)\ln(2)\,dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x)2^{\sin(x)}(\cos(x)-1)\ln(2)dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \frac{1}{2^x}$

  $y = 2^x\left(\int \frac{2^{\sin(x)}(\cos(x)-1)\ln(2)}{2^x}dx + c_1\right)$
- Evaluate the integrals on the rhs

  $$y = 2^x\left(\frac{\tan\left(\frac{x}{2}\right)^2 \mathrm{e}^{\frac{2\tan\left(\frac{x}{2}\right)\ln(2)}{1+\tan\left(\frac{x}{2}\right)^2}} + \mathrm{e}^{\frac{2\tan\left(\frac{x}{2}\right)\ln(2)}{1+\tan\left(\frac{x}{2}\right)^2}}}{\mathrm{e}^{\ln(2)x}\left(1+\tan\left(\frac{x}{2}\right)^2\right)} + c_1\right)$$
- Simplify

  $y = c_1 2^x + 2^{\sin(x)}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = -2\,\mathrm{e}^{-x}}$$

With initial conditions

$$[y(\infty) = 0]$$

6.16.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = -2\,\mathrm{e}^{-x}$$

Hence the ode is

$$y' - y = -2\,e^{-x}$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

But the point $x_0 = \infty$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

6.16.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-1)dx} \\ &= e^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(-2\,e^{-x}\right) \\ \frac{d}{dx}\left(e^{-x}y\right) &= \left(e^{-x}\right)\left(-2\,e^{-x}\right) \\ d\left(e^{-x}y\right) &= \left(-2\,e^{-2x}\right)\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-x}y &= \int -2\,e^{-2x}\,dx \\ e^{-x}y &= e^{-2x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = e^{-2x}e^{x} + e^{x}c_1$$

which simplifies to

$$y = e^{-x} + e^{x}c_1$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \text{signum}\,(c_1)\,\infty$$

Solving for c_1 gives

$$c_1 = -\left(-y + \mathrm{e}^{-x}\right) \mathrm{e}^{-x}$$

Using given initial conditions results in $c_1 = 0$ Hence the solution is

$$y = \mathrm{e}^{-x}$$

Therefore the solution is

$$y = \mathrm{e}^{-x}$$

Summary
The solution(s) found are the following

$$y = \mathrm{e}^{-x} \tag{1}$$

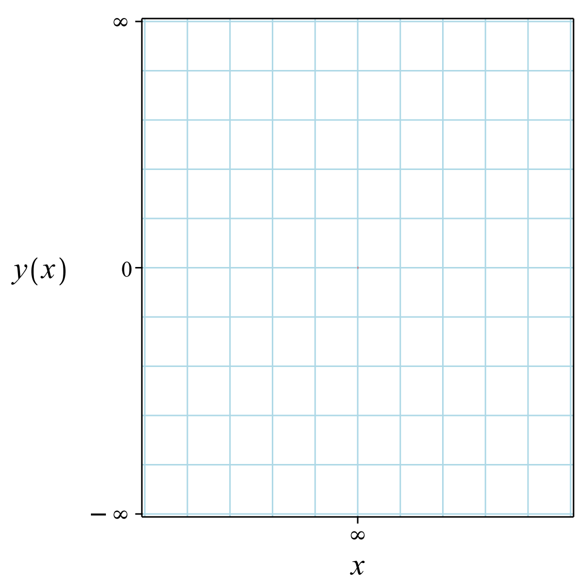

Figure 241: Solution plot

Verification of solutions

$$y = \mathrm{e}^{-x}$$

Verified OK.

6.16.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= y - 2\,\mathrm{e}^{-x} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 189: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= e^{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{e^{x}} dy
\end{aligned}
$$

Which results in

$$
S = e^{-x} y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = y - 2\,e^{-x}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -e^{-x} y \\
S_y &= e^{-x}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -2\,\mathrm{e}^{-2x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -2\,\mathrm{e}^{-2R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \mathrm{e}^{-2R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{-x} y = \mathrm{e}^{-2x} + c_1$$

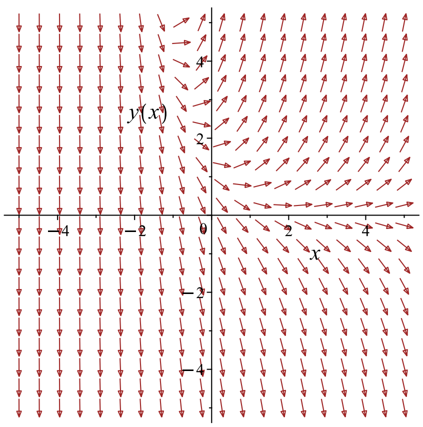
Which simplifies to

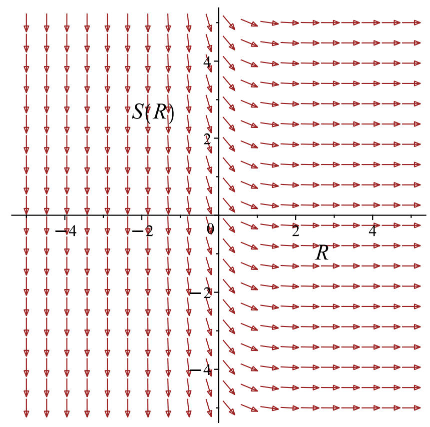
$$\mathrm{e}^{-x} y = \mathrm{e}^{-2x} + c_1$$

Which gives

$$y = \left(\mathrm{e}^{-2x} + c_1\right) \mathrm{e}^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = y - 2\,\mathrm{e}^{-x}$


</td><td>$R = x$
$S = \mathrm{e}^{-x} y$</td><td>$\frac{dS}{dR} = -2\,\mathrm{e}^{-2R}$


</td></tr>
</table>

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \mathrm{signum}\,(c_1)\,\infty$$

Solving for c_1 gives

$$c_1 = \mathrm{e}^{-x} y - \mathrm{e}^{-2x}$$

Using given initial conditions results in $c_1 = 0$ Hence the solution is

$$y = \mathrm{e}^{-2x} \mathrm{e}^{x}$$

Therefore the solution is

$$y = \mathrm{e}^{-2x} \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-2x} \mathrm{e}^{x} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-2x} \mathrm{e}^{x}$$

Verified OK.

6.16.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= \left(y - 2\,\mathrm{e}^{-x}\right)\mathrm{d}x\\ \left(-y + 2\,\mathrm{e}^{-x}\right)\mathrm{d}x + \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -y + 2\,\mathrm{e}^{-x}\\ N(x,y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y + 2\,\mathrm{e}^{-x}\right)\\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= 1((-1) - (0))\\ &= -1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int -1\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-x}\\ &= \mathrm{e}^{-x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{-x}\left(-y + 2\,\mathrm{e}^{-x}\right)\\ &= -\mathrm{e}^{-x}\left(y - 2\,\mathrm{e}^{-x}\right)\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-x}(1) \\
&= \mathrm{e}^{-x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\mathrm{e}^{-x}\left(y - 2\,\mathrm{e}^{-x}\right)\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\mathrm{e}^{-x}\left(y - 2\,\mathrm{e}^{-x}\right)\mathrm{d}x \\
\phi &= \mathrm{e}^{-x}y - \mathrm{e}^{-2x} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$
\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = e^{-x}y - e^{-2x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = e^{-x}y - e^{-2x}$$

The solution becomes

$$y = \left(e^{-2x} + c_1\right) e^{x}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = \operatorname{signum}(c_1) \infty$$

Solving for c_1 gives

$$c_1 = e^{-x}y - e^{-2x}$$

Using given initial conditions results in $c_1 = 0$ Hence the solution is

$$y = e^{-2x} e^{x}$$

Therefore the solution is

$$y = e^{-2x} e^{x}$$

Summary
The solution(s) found are the following

$$y = e^{-2x} e^{x} \tag{1}$$

Verification of solutions

$$y = e^{-2x} e^{x}$$

Verified OK.

6.16.5 Maple step by step solution

Let's solve

$[y' - y = -2\,\mathrm{e}^{-x}, y(\infty) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = y - 2\,\mathrm{e}^{-x}$

Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 150.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

Unable to solve or complete the solution.

$$\boxed{y' \sin(x) - y \cos(x) = -\frac{\sin(x)^2}{x^2}}$$

With initial conditions

$$[y(\infty) = 0]$$

6.17.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\cot(x) \\ q(x) &= -\frac{\sin(x)}{x^2} \end{aligned}$$

Hence the ode is

$$y' - y\cot(x) = -\frac{\sin(x)}{x^2}$$

The domain of $p(x) = -\cot(x)$ is

$$\{x < \pi\_Z796 \lor \pi\_Z796 < x\}$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = -\frac{\sin(x)}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

6.17.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\cot(x)dx} \\ &= \frac{1}{\sin(x)} \end{aligned}$$

Which simplifies to

$$\mu = \csc(x)$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(-\frac{\sin(x)}{x^2}\right) \\ \frac{d}{dx}(\csc(x)\, y) &= (\csc(x))\left(-\frac{\sin(x)}{x^2}\right) \\ d(\csc(x)\, y) &= \left(-\frac{1}{x^2}\right) dx \end{aligned}$$

Integrating gives

$$\csc(x)\, y = \int -\frac{1}{x^2}\, \mathrm{d}x$$
$$\csc(x)\, y = \frac{1}{x} + c_1$$

Dividing both sides by the integrating factor $\mu = \csc(x)$ results in

$$y = \frac{\sin(x)}{x} + \sin(x)\, c_1$$

which simplifies to

$$y = \sin(x)\left(\frac{1}{x} + c_1\right)$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -|c_1|..|c_1|$$

Unable to solve for constant of integration. Verification of solutions N/A

6.17.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-\cos(x)\, y\, x^2 + \sin(x)^2}{\sin(x)\, x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 192: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \sin(x) \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\sin(x)} dy \end{aligned}$$

Which results in

$$S = \frac{y}{\sin(x)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-\cos(x)\, y\, x^2 + \sin(x)^2}{\sin(x)\, x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\csc(x)\cot(x)\, y \\ S_y &= \csc(x) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\csc(x)\, y = \frac{1}{x} + c_1$$

Which simplifies to

$$\csc(x)\, y = \frac{1}{x} + c_1$$

Which gives

$$y = \frac{c_1 x + 1}{\csc(x)\, x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-\cos(x) y\, x^2 + \sin(x)^2}{\sin(x) x^2}$ 	$R = x$ $S = \csc(x)\, y$	$\frac{dS}{dR} = -\frac{1}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$
0 = -|c_1|..|c_1|
$$

Unable to solve for constant of integration. Verification of solutions N/A

6.17.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}
$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x,y) = 0
$$

Hence

$$
\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}
$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$(\sin(x))\,\mathrm{d}y = \left(\cos(x)\,y - \frac{\sin(x)^2}{x^2}\right)\mathrm{d}x$$

$$\left(-\cos(x)\,y + \frac{\sin(x)^2}{x^2}\right)\mathrm{d}x + (\sin(x))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= -\cos(x)\,y + \frac{\sin(x)^2}{x^2} \\ N(x,y) &= \sin(x) \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\cos(x)\,y + \frac{\sin(x)^2}{x^2}\right) \\ &= -\cos(x) \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\sin(x)) \\ &= \cos(x) \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \csc(x)\left((-\cos(x)) - (\cos(x))\right) \\ &= -2\cot(x) \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A\,\mathrm{d}x} \\ &= e^{\int -2\cot(x)\,\mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(\sin(x))}\\ &= \csc(x)^2\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \csc(x)^2\left(-\cos(x)\,y+\frac{\sin(x)^2}{x^2}\right)\\ &= -\csc(x)\cot(x)\,y+\frac{1}{x^2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \csc(x)^2(\sin(x))\\ &= \csc(x)\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(-\csc(x)\cot(x)\,y+\frac{1}{x^2}\right)+(\csc(x))\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x\\ \int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int-\csc(x)\cot(x)\,y+\frac{1}{x^2}\,\mathrm{d}x\end{aligned}$$

$$\phi = -\frac{1}{x}+\csc(x)\,y+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \csc(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \csc(x)$. Therefore equation (4) becomes

$$\csc(x) = \csc(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{x} + \csc(x)\,y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{x} + \csc(x)\,y$$

The solution becomes

$$y = \frac{c_1 x + 1}{\csc(x)\,x}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -|c_1|..|c_1|$$

Unable to solve for constant of integration. Verification of solutions N/A

6.17.5 Maple step by step solution

Let's solve

$\left[y' \sin(x) - y\cos(x) = -\frac{\sin(x)^2}{x^2}, y(\infty) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y\cos(x)}{\sin(x)} - \frac{\sin(x)}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y\cos(x)}{\sin(x)} = -\frac{\sin(x)}{x^2}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{y\cos(x)}{\sin(x)}\right) = -\frac{\mu(x)\sin(x)}{x^2}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' - \frac{y\cos(x)}{\sin(x)}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)\cos(x)}{\sin(x)}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{\sin(x)}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right)dx = \int -\frac{\mu(x)\sin(x)}{x^2}dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int -\frac{\mu(x)\sin(x)}{x^2}dx + c_1$

- Solve for y

  $y = \frac{\int -\frac{\mu(x)\sin(x)}{x^2}dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{\sin(x)}$

  $y = \sin(x)\left(\int -\frac{1}{x^2}dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = \sin(x)\left(\frac{1}{x} + c_1\right)$

- Simplify

  $y = \frac{\sin(x)(c_1x+1)}{x}$
- Use initial condition $y(\infty) = 0$

  $0 = \mathit{undefined}(c_1\infty + 1)$
- Solution does not satisfy initial condition

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{x^2y'\cos\left(\frac{1}{x}\right)-y\sin\left(\frac{1}{x}\right)=-1}$$

With initial conditions

$$[y(\infty)=1]$$

6.18.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{\tan\left(\frac{1}{x}\right)}{x^2}\\ q(x) &= -\frac{\sec\left(\frac{1}{x}\right)}{x^2}\end{aligned}$$

Hence the ode is

$$y' - \frac{\tan\left(\frac{1}{x}\right)y}{x^2} = -\frac{\sec\left(\frac{1}{x}\right)}{x^2}$$

The domain of $p(x) = -\frac{\tan\left(\frac{1}{x}\right)}{x^2}$ is

$$\left\{-\infty \leq x < 0, 0 < x < \frac{2}{\pi\left(1+2\_Z818\right)}, \frac{2}{\pi\left(1+2\_Z818\right)} < x \leq \infty\right\}$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = -\frac{\sec\left(\frac{1}{x}\right)}{x^2}$ is

$$\left\{-\infty \leq x < 0, 0 < x < \frac{2}{\pi\left(1+2\_Z818\right)}, \frac{2}{\pi\left(1+2\_Z818\right)} < x \leq \infty\right\}$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

6.18.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{\tan\left(\frac{1}{x}\right)}{x^2}dx}\\ &= \frac{1}{\cos\left(\frac{1}{x}\right)}\end{aligned}$$

Which simplifies to

$$\mu = \sec\left(\frac{1}{x}\right)$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-\frac{\sec\left(\frac{1}{x}\right)}{x^2}\right)$$

$$\frac{d}{dx}\left(\sec\left(\frac{1}{x}\right)y\right) = \left(\sec\left(\frac{1}{x}\right)\right)\left(-\frac{\sec\left(\frac{1}{x}\right)}{x^2}\right)$$

$$d\left(\sec\left(\frac{1}{x}\right)y\right) = \left(-\frac{\sec\left(\frac{1}{x}\right)^2}{x^2}\right) dx$$

Integrating gives

$$\sec\left(\frac{1}{x}\right)y = \int -\frac{\sec\left(\frac{1}{x}\right)^2}{x^2}\, dx$$

$$\sec\left(\frac{1}{x}\right)y = \tan\left(\frac{1}{x}\right) + c_1$$

Dividing both sides by the integrating factor $\mu = \sec\left(\frac{1}{x}\right)$ results in

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + c_1\cos\left(\frac{1}{x}\right)$$

which simplifies to

$$y = c_1\cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$y = \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)$$

Summary

The solution(s) found are the following

$$y = \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right) \tag{1}$$

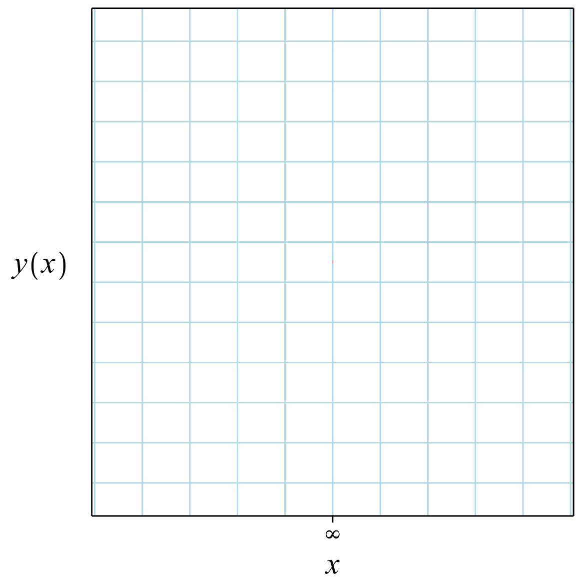

Figure 242: Solution plot

Verification of solutions

$$y = \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)$$

Verified OK.

6.18.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y\sin\left(\frac{1}{x}\right) - 1}{x^2\cos\left(\frac{1}{x}\right)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 195: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \cos\left(\frac{1}{x}\right) \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\cos\left(\frac{1}{x}\right)} dy \end{aligned}$$

Which results in

$$S = \frac{y}{\cos\left(\frac{1}{x}\right)}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y \sin\left(\frac{1}{x}\right) - 1}{x^2 \cos\left(\frac{1}{x}\right)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{\sec\left(\frac{1}{x}\right) \tan\left(\frac{1}{x}\right) y}{x^2} \\ S_y &= \sec\left(\frac{1}{x}\right) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{\sec\left(\frac{1}{x}\right)^2}{x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{\sec\left(\frac{1}{R}\right)^2}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \tan\left(\frac{1}{R}\right) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\sec\left(\frac{1}{x}\right) y = \tan\left(\frac{1}{x}\right) + c_1$$

Which simplifies to

$$\sec\left(\frac{1}{x}\right) y = \tan\left(\frac{1}{x}\right) + c_1$$

Which gives

$$y = \frac{\tan\left(\frac{1}{x}\right) + c_1}{\sec\left(\frac{1}{x}\right)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y \sin\left(\frac{1}{x}\right) - 1}{x^2 \cos\left(\frac{1}{x}\right)}$ 	$R = x$ $S = \sec\left(\frac{1}{x}\right) y$	$\frac{dS}{dR} = -\frac{\sec\left(\frac{1}{R}\right)^2}{R^2}$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + \cos\left(\frac{1}{x}\right)$$

Summary

The solution(s) found are the following

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + \cos\left(\frac{1}{x}\right) \tag{1}$$

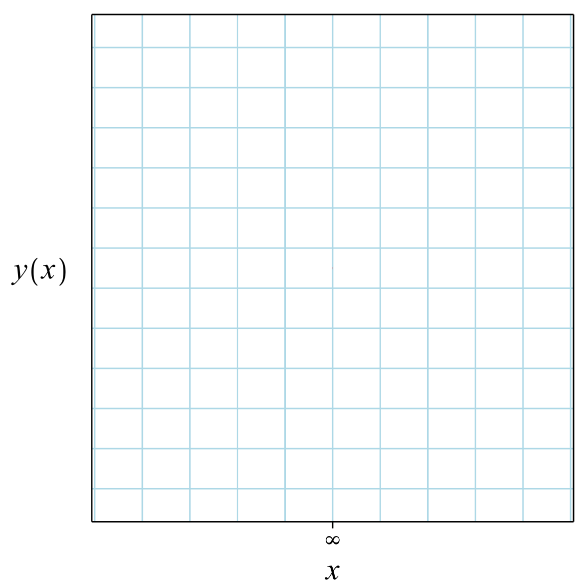

Figure 243: Solution plot

Verification of solutions

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + \cos\left(\frac{1}{x}\right)$$

Verified OK.

6.18.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x^2\cos\left(\frac{1}{x}\right)\right)\mathrm{d}y&=\left(y\sin\left(\frac{1}{x}\right)-1\right)\mathrm{d}x\\ \left(-y\sin\left(\frac{1}{x}\right)+1\right)\mathrm{d}x+\left(x^2\cos\left(\frac{1}{x}\right)\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -y\sin\left(\frac{1}{x}\right) + 1$$
$$N(x,y) = x^2\cos\left(\frac{1}{x}\right)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y\sin\left(\frac{1}{x}\right) + 1\right)\\ &= -\sin\left(\frac{1}{x}\right)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x^2\cos\left(\frac{1}{x}\right)\right)\\ &= 2x\cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{\sec\left(\frac{1}{x}\right)}{x^2}\left(\left(-\sin\left(\frac{1}{x}\right)\right) - \left(2x\cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)\right)\right)\\ &= \frac{-2\tan\left(\frac{1}{x}\right) - 2x}{x^2}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int \frac{-2\tan\left(\frac{1}{x}\right)-2x}{x^2}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{2\ln\left(\frac{1}{x}\right)-2\ln\left(\cos\left(\frac{1}{x}\right)\right)} \\
&= \frac{1}{\cos\left(\frac{1}{x}\right)^{2} x^{2}}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{\cos\left(\frac{1}{x}\right)^{2} x^{2}}\left(-y\sin\left(\frac{1}{x}\right)+1\right) \\
&= \frac{\sec\left(\frac{1}{x}\right)^{2}\left(-y\sin\left(\frac{1}{x}\right)+1\right)}{x^{2}}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{\cos\left(\frac{1}{x}\right)^{2} x^{2}}\left(x^{2}\cos\left(\frac{1}{x}\right)\right) \\
&= \sec\left(\frac{1}{x}\right)
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{\sec\left(\frac{1}{x}\right)^{2}\left(-y\sin\left(\frac{1}{x}\right)+1\right)}{x^{2}}\right) + \left(\sec\left(\frac{1}{x}\right)\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x
$$

$$
\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \frac{\sec\left(\frac{1}{x}\right)^{2}\left(-y\sin\left(\frac{1}{x}\right)+1\right)}{x^{2}}\,\mathrm{d}x
$$

$$
\phi = -\tan\left(\frac{1}{x}\right) + \sec\left(\frac{1}{x}\right)y + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \sec\left(\frac{1}{x}\right) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \sec\left(\frac{1}{x}\right)$. Therefore equation (4) becomes

$$\sec\left(\frac{1}{x}\right) = \sec\left(\frac{1}{x}\right) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\tan\left(\frac{1}{x}\right) + \sec\left(\frac{1}{x}\right) y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\tan\left(\frac{1}{x}\right) + \sec\left(\frac{1}{x}\right) y$$

The solution becomes

$$y = \frac{\tan\left(\frac{1}{x}\right) + c_1}{\sec\left(\frac{1}{x}\right)}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = c_1$$

$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + \cos\left(\frac{1}{x}\right)$$

Summary

The solution(s) found are the following

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + \cos\left(\frac{1}{x}\right) \tag{1}$$

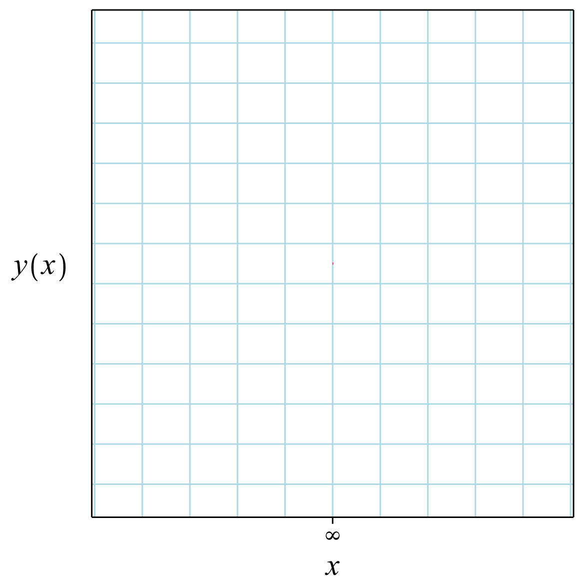

Figure 244: Solution plot

Verification of solutions

$$y = \cos\left(\frac{1}{x}\right)\tan\left(\frac{1}{x}\right) + \cos\left(\frac{1}{x}\right)$$

Verified OK.

6.18.5 Maple step by step solution

Let's solve

$\left[x^2 y' \cos\left(\frac{1}{x}\right) - y \sin\left(\frac{1}{x}\right) = -1, y(\infty) = 1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$$y' = \frac{\sin\left(\frac{1}{x}\right) y}{x^2 \cos\left(\frac{1}{x}\right)} - \frac{1}{x^2 \cos\left(\frac{1}{x}\right)}$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

$$y' - \frac{\sin\left(\frac{1}{x}\right) y}{x^2 \cos\left(\frac{1}{x}\right)} = -\frac{1}{x^2 \cos\left(\frac{1}{x}\right)}$$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$$\mu(x) \left(y' - \frac{\sin\left(\frac{1}{x}\right) y}{x^2 \cos\left(\frac{1}{x}\right)}\right) = -\frac{\mu(x)}{x^2 \cos\left(\frac{1}{x}\right)}$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

$$\mu(x) \left(y' - \frac{\sin\left(\frac{1}{x}\right) y}{x^2 \cos\left(\frac{1}{x}\right)}\right) = \mu'(x)\, y + \mu(x)\, y'$$

- Isolate $\mu'(x)$

$$\mu'(x) = -\frac{\mu(x) \sin\left(\frac{1}{x}\right)}{x^2 \cos\left(\frac{1}{x}\right)}$$

- Solve to find the integrating factor

$$\mu(x) = \frac{1}{\cos\left(\frac{1}{x}\right)}$$

- Integrate both sides with respect to x

$$\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int -\frac{\mu(x)}{x^2 \cos\left(\frac{1}{x}\right)} dx + c_1$$

- Evaluate the integral on the lhs

$$\mu(x)\, y = \int -\frac{\mu(x)}{x^2 \cos\left(\frac{1}{x}\right)} dx + c_1$$

- Solve for y

$$y = \frac{\int -\frac{\mu(x)}{x^2 \cos\left(\frac{1}{x}\right)} dx + c_1}{\mu(x)}$$

- Substitute $\mu(x) = \frac{1}{\cos\left(\frac{1}{x}\right)}$

$$y = \cos\left(\frac{1}{x}\right) \left(\int -\frac{1}{\cos\left(\frac{1}{x}\right)^2 x^2} dx + c_1\right)$$

- Evaluate the integrals on the rhs

$$y = \cos\left(\frac{1}{x}\right) \left(\tan\left(\frac{1}{x}\right) + c_1\right)$$

- Simplify

$$y = c_1 \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)$$

- Use initial condition $y(\infty) = 1$

$$1 = c_1$$

- Solve for c_1

  $c_1 = 1$

- Substitute $c_1 = 1$ into general solution and simplify

  $y = \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)$

- Solution to the IVP

  $y = \cos\left(\frac{1}{x}\right) + \sin\left(\frac{1}{x}\right)$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

Unable to solve or complete the solution.

$$\boxed{2y'x - y = 1 - \frac{2}{\sqrt{x}}}$$

With initial conditions

$$[y(\infty) = -1]$$

6.19.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{2x} \\ q(x) &= \frac{\sqrt{x}-2}{2x^{\frac{3}{2}}} \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{2x} = \frac{\sqrt{x}-2}{2x^{\frac{3}{2}}}$$

The domain of $p(x) = -\frac{1}{2x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = \infty$ is inside this domain. The domain of $q(x) = \frac{\sqrt{x}-2}{2x^{\frac{3}{2}}}$ is

$$\{0 < x\}$$

And the point $x_0 = \infty$ is also inside this domain. Hence solution exists and is unique.

6.19.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{2x}dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{\sqrt{x}-2}{2x^{\frac{3}{2}}}\right) \\ \frac{d}{dx}\left(\frac{y}{\sqrt{x}}\right) &= \left(\frac{1}{\sqrt{x}}\right)\left(\frac{\sqrt{x}-2}{2x^{\frac{3}{2}}}\right) \\ d\left(\frac{y}{\sqrt{x}}\right) &= \left(\frac{\sqrt{x}-2}{2x^2}\right) dx \end{aligned}$$

Integrating gives

$$\frac{y}{\sqrt{x}} = \int \frac{\sqrt{x}-2}{2x^2}\, \mathrm{d}x$$
$$\frac{y}{\sqrt{x}} = -\frac{1}{\sqrt{x}} + \frac{1}{x} + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{\sqrt{x}}$ results in

$$y = \sqrt{x}\left(-\frac{1}{\sqrt{x}} + \frac{1}{x}\right) + c_1\sqrt{x}$$

which simplifies to

$$y = \frac{c_1 x^{\frac{3}{2}} + \sqrt{x} - x}{x}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \operatorname{signum}(c_1)\,\infty$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

6.19.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y\sqrt{x} + \sqrt{x} - 2}{2x^{\frac{3}{2}}}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 198: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \sqrt{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\sqrt{x}} dy \end{aligned}$$

Which results in

$$S = \frac{y}{\sqrt{x}}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y\sqrt{x} + \sqrt{x} - 2}{2x^{\frac{3}{2}}}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{2x^{\frac{3}{2}}} \\ S_y &= \frac{1}{\sqrt{x}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{x - 2\sqrt{x}}{2x^{\frac{5}{2}}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R - 2\sqrt{R}}{2R^{\frac{5}{2}}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{1}{\sqrt{R}} + \frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{\sqrt{x}} = -\frac{1}{\sqrt{x}} + \frac{1}{x} + c_1$$

Which simplifies to

$$\frac{y}{\sqrt{x}} = -\frac{1}{\sqrt{x}} + \frac{1}{x} + c_1$$

Which gives

$$y = \frac{c_1 x^{\frac{3}{2}} + \sqrt{x} - x}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y\sqrt{x}+\sqrt{x}-2}{2x^{\frac{3}{2}}}$ 	$R = x$ $S = \frac{y}{\sqrt{x}}$	$\frac{dS}{dR} = \frac{R-2\sqrt{R}}{2R^{\frac{5}{2}}}$ 
Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \operatorname{signum}(c_1)\,\infty$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

6.19.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$
\begin{aligned}
(2x)\, \mathrm{d}y &= \left(y + 1 - \frac{2}{\sqrt{x}}\right) \mathrm{d}x \\
\left(-y - 1 + \frac{2}{\sqrt{x}}\right) \mathrm{d}x + (2x)\, \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= -y - 1 + \frac{2}{\sqrt{x}} \\
N(x,y) &= 2x
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-y - 1 + \frac{2}{\sqrt{x}}\right) \\
&= -1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x) \\
&= 2
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{2x}((-1) - (2)) \\
&= -\frac{3}{2x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \,\mathrm{d}x} \\
&= e^{\int -\frac{3}{2x} \,\mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-\frac{3\ln(x)}{2}} \\ &= \frac{1}{x^{\frac{3}{2}}}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \frac{1}{x^{\frac{3}{2}}}\left(-y-1+\frac{2}{\sqrt{x}}\right) \\ &= \frac{2+(-y-1)\sqrt{x}}{x^2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \frac{1}{x^{\frac{3}{2}}}(2x) \\ &= \frac{2}{\sqrt{x}}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{2+(-y-1)\sqrt{x}}{x^2}\right)+\left(\frac{2}{\sqrt{x}}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x \\ \int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\frac{2+(-y-1)\sqrt{x}}{x^2}\,\mathrm{d}x\end{aligned}$$

$$\phi = \frac{(2y+2)\,x-2\sqrt{x}}{x^{\frac{3}{2}}}+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{2}{\sqrt{x}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2}{\sqrt{x}}$. Therefore equation (4) becomes

$$\frac{2}{\sqrt{x}} = \frac{2}{\sqrt{x}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(2y+2)\,x - 2\sqrt{x}}{x^{\frac{3}{2}}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(2y+2)\,x - 2\sqrt{x}}{x^{\frac{3}{2}}}$$

The solution becomes

$$y = \frac{c_1 x^{\frac{3}{2}} + 2\sqrt{x} - 2x}{2x}$$

Initial conditions are used to solve for c_1. Substituting $x = \infty$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \operatorname{signum}(c_1)\,\infty$$

Warning: Unable to solve for constant of integration.

Verification of solutions N/A

6.19.5 Maple step by step solution

Let's solve

$\left[2y'x-y=1-\frac{2}{\sqrt{x}}, y(\infty)=-1\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y'=\frac{y}{2x}+\frac{\sqrt{x}-2}{2x^{\frac{3}{2}}}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y'-\frac{y}{2x}=\frac{\sqrt{x}-2}{2x^{\frac{3}{2}}}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y'-\frac{y}{2x}\right)=\frac{\mu(x)(\sqrt{x}-2)}{2x^{\frac{3}{2}}}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y'-\frac{y}{2x}\right)=\mu'(x)\,y+\mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x)=-\frac{\mu(x)}{2x}$

- Solve to find the integrating factor

  $\mu(x)=\frac{1}{\sqrt{x}}$

- Integrate both sides with respect to x

  $\int\left(\frac{d}{dx}(\mu(x)\,y)\right)dx=\int\frac{\mu(x)(\sqrt{x}-2)}{2x^{\frac{3}{2}}}dx+c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y=\int\frac{\mu(x)(\sqrt{x}-2)}{2x^{\frac{3}{2}}}dx+c_1$

- Solve for y

  $y=\frac{\int\frac{\mu(x)(\sqrt{x}-2)}{2x^{\frac{3}{2}}}dx+c_1}{\mu(x)}$

- Substitute $\mu(x)=\frac{1}{\sqrt{x}}$

  $y=\sqrt{x}\left(\int\frac{\sqrt{x}-2}{2x^2}dx+c_1\right)$

- Evaluate the integrals on the rhs

$$y = \sqrt{x}\left(-\frac{1}{\sqrt{x}} + \frac{1}{x} + c_1\right)$$

- Simplify

$$y = \frac{c_1 x^{\frac{3}{2}} + \sqrt{x} - x}{x}$$

- Use initial condition $y(\infty) = -1$

$$-1 = 0$$

- Solution does not satisfy initial condition

Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 153.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2y'x + y = (x^2 + 1)\,e^x}$$

With initial conditions

$$[y(-\infty) = 1]$$

6.20.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{2x}$$
$$q(x) = \frac{e^x(x^2 + 1)}{2x}$$

Hence the ode is

$$y' + \frac{y}{2x} = \frac{e^{x}(x^2+1)}{2x}$$

The domain of $p(x) = \frac{1}{2x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = -\infty$ is inside this domain. The domain of $q(x) = \frac{e^{x}(x^2+1)}{2x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = -\infty$ is also inside this domain. Hence solution exists and is unique.

6.20.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{1}{2x}dx} \\ &= \sqrt{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{e^{x}(x^2+1)}{2x}\right) \\ \frac{d}{dx}(y\sqrt{x}) &= (\sqrt{x})\left(\frac{e^{x}(x^2+1)}{2x}\right) \\ d(y\sqrt{x}) &= \left(\frac{e^{x}(x^2+1)}{2\sqrt{x}}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}y\sqrt{x} &= \int \frac{e^{x}(x^2+1)}{2\sqrt{x}} dx \\ y\sqrt{x} &= \frac{x^{\frac{3}{2}}e^{x}}{2} - \frac{3\sqrt{x}\,e^{x}}{4} + \frac{7\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{8} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \sqrt{x}$ results in

$$y = \frac{\frac{x^{\frac{3}{2}}e^{x}}{2} - \frac{3\sqrt{x}\,e^{x}}{4} + \frac{7\sqrt{\pi}\,\operatorname{erfi}(\sqrt{x})}{8}}{\sqrt{x}} + \frac{c_1}{\sqrt{x}}$$

which simplifies to

$$y = \frac{4x^{\frac{3}{2}} \mathrm{e}^{x} - 6\sqrt{x}\, \mathrm{e}^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 8c_1}{8\sqrt{x}}$$

Initial conditions are used to solve for c_1. Substituting $x = -\infty$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 0$$

This shows that no solution exist.

Summary

The solution(s) found are the following

$$y = \frac{4x^{\frac{3}{2}} \mathrm{e}^{x} - 6\sqrt{x}\, \mathrm{e}^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 8c_1}{8\sqrt{x}}$$

Verification of solutions

$$y = \frac{4x^{\frac{3}{2}} \mathrm{e}^{x} - 6\sqrt{x}\, \mathrm{e}^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 8c_1}{8\sqrt{x}}$$

Warning, solution could not be verified

6.20.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= \frac{x^2 \mathrm{e}^{x} + \mathrm{e}^{x} - y}{2x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 201: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= 0 \\ \eta(x, y) &= \frac{1}{\sqrt{x}} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{\sqrt{x}}} dy \end{aligned}$$

Which results in

$$S = y\sqrt{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{x^2 e^x + e^x - y}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y}{2\sqrt{x}} \\ S_y &= \sqrt{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{e^x (x^2 + 1)}{2\sqrt{x}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{e^R (R^2 + 1)}{2\sqrt{R}}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\mathrm{e}^{R} R^{\frac{3}{2}}}{2} - \frac{3\,\mathrm{e}^{R}\sqrt{R}}{4} + \frac{7\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{R}\right)}{8} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\sqrt{x} = \frac{x^{\frac{3}{2}}\mathrm{e}^{x}}{2} - \frac{3\sqrt{x}\,\mathrm{e}^{x}}{4} + \frac{7\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{8} + c_1$$

Which simplifies to

$$y\sqrt{x} = \frac{x^{\frac{3}{2}}\mathrm{e}^{x}}{2} - \frac{3\sqrt{x}\,\mathrm{e}^{x}}{4} + \frac{7\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right)}{8} + c_1$$

Which gives

$$y = \frac{4x^{\frac{3}{2}}\mathrm{e}^{x} - 6\sqrt{x}\,\mathrm{e}^{x} + 7\sqrt{\pi}\,\operatorname{erfi}\left(\sqrt{x}\right) + 8c_1}{8\sqrt{x}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2\mathrm{e}^{x}+\mathrm{e}^{x}-y}{2x}$ 	$R = x$ $S = y\sqrt{x}$	$\frac{dS}{dR} = \frac{\mathrm{e}^{R}(R^2+1)}{2\sqrt{R}}$ 
Initial conditions are used to solve for c_1. Substituting $x = -\infty$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 0$$

This shows that no solution exist.

Summary

The solution(s) found are the following

$$y = \frac{4x^{\frac{3}{2}} e^{x} - 6\sqrt{x}\, e^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 8c_1}{8\sqrt{x}}$$

Verification of solutions

$$y = \frac{4x^{\frac{3}{2}} e^{x} - 6\sqrt{x}\, e^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 8c_1}{8\sqrt{x}}$$

Warning, solution could not be verified

6.20.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(2x)\,\mathrm{d}y &= \left(-y+\left(x^2+1\right)\mathrm{e}^x\right)\mathrm{d}x\\ \left(y-\left(x^2+1\right)\mathrm{e}^x\right)\mathrm{d}x+(2x)\,\mathrm{d}y &= 0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= y-\left(x^2+1\right)\mathrm{e}^x\\ N(x,y) &= 2x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y-\left(x^2+1\right)\mathrm{e}^x\right)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x)\\ &= 2\end{aligned}$$

Since $\frac{\partial M}{\partial y}\neq\frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x}((1)-(2))\\ &= -\frac{1}{2x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int -\frac{1}{2x}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-\frac{\ln(x)}{2}}\\ &= \frac{1}{\sqrt{x}}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{\sqrt{x}}\left(y - \left(x^2+1\right)\mathrm{e}^x\right)\\ &= -\frac{x^2\mathrm{e}^x + \mathrm{e}^x - y}{\sqrt{x}}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{\sqrt{x}}(2x)\\ &= 2\sqrt{x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(-\frac{x^2\mathrm{e}^x + \mathrm{e}^x - y}{\sqrt{x}}\right) + \left(2\sqrt{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\frac{x^2 \mathrm{e}^x + \mathrm{e}^x - y}{\sqrt{x}} \, \mathrm{d}x$$

$$\phi = -x^{\frac{3}{2}} \mathrm{e}^x - \frac{7\sqrt{\pi}\, \mathrm{erfi}\left(\sqrt{x}\right)}{4} + 2\left(y + \frac{3\,\mathrm{e}^x}{4}\right)\sqrt{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2\sqrt{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2\sqrt{x}$. Therefore equation (4) becomes

$$2\sqrt{x} = 2\sqrt{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^{\frac{3}{2}} \mathrm{e}^x - \frac{7\sqrt{\pi}\, \mathrm{erfi}\left(\sqrt{x}\right)}{4} + 2\left(y + \frac{3\,\mathrm{e}^x}{4}\right)\sqrt{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^{\frac{3}{2}} \mathrm{e}^x - \frac{7\sqrt{\pi}\, \mathrm{erfi}\left(\sqrt{x}\right)}{4} + 2\left(y + \frac{3\,\mathrm{e}^x}{4}\right)\sqrt{x}$$

The solution becomes

$$y = \frac{4x^{\frac{3}{2}} \mathrm{e}^x - 6\sqrt{x}\, \mathrm{e}^x + 7\sqrt{\pi}\, \mathrm{erfi}\left(\sqrt{x}\right) + 4c_1}{8\sqrt{x}}$$

Initial conditions are used to solve for c_1. Substituting $x = -\infty$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 0$$

This shows that no solution exist.

Summary

The solution(s) found are the following

$$y = \frac{4x^{\frac{3}{2}} e^{x} - 6\sqrt{x}\, e^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 4c_1}{8\sqrt{x}}$$

Verification of solutions

$$y = \frac{4x^{\frac{3}{2}} e^{x} - 6\sqrt{x}\, e^{x} + 7\sqrt{\pi}\, \operatorname{erfi}\left(\sqrt{x}\right) + 4c_1}{8\sqrt{x}}$$

Problem number: 154.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y'x + y = 2x}$$

6.21.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = 2$$

Hence the ode is

$$y' + \frac{y}{x} = 2$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{1}{x}dx} \\
&= x
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(2) \\
\frac{\mathrm{d}}{\mathrm{d}x}(xy) &= (x)(2) \\
\mathrm{d}(xy) &= (2x)\ \mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
xy &= \int 2x\,\mathrm{d}x \\
xy &= x^2 + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = x + \frac{c_1}{x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = x + \frac{c_1}{x} \tag{1}$$

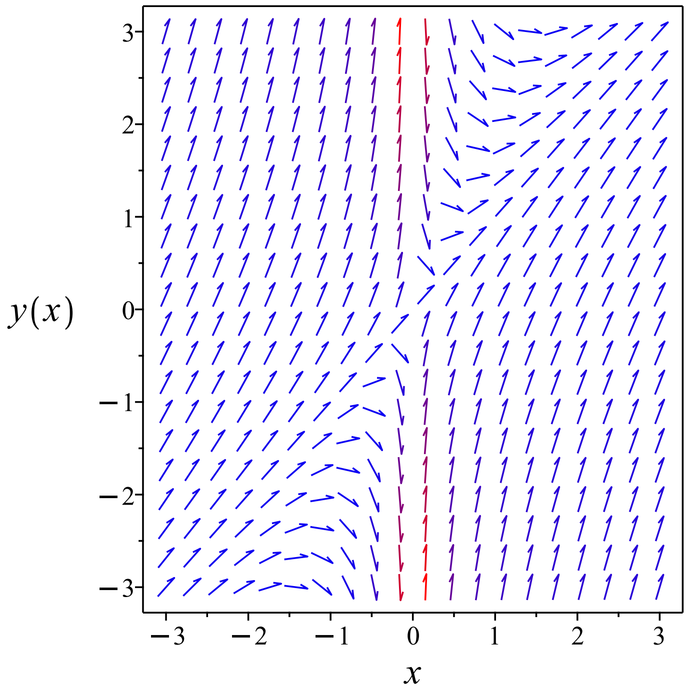

Figure 245: Slope field plot

Verification of solutions

$$y = x + \frac{c_1}{x}$$

Verified OK.

6.21.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$(u'(x)\,x + u(x))\,x + u(x)\,x = 2x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{-2u+2}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = -2u + 2$. Integrating both sides gives

$$\frac{1}{-2u+2}\,du = \frac{1}{x}\,dx$$

$$\int \frac{1}{-2u+2}\,du = \int \frac{1}{x}\,dx$$

$$-\frac{\ln(u-1)}{2} = \ln(x) + c_2$$

Raising both side to exponential gives

$$\frac{1}{\sqrt{u-1}} = \mathrm{e}^{\ln(x)+c_2}$$

Which simplifies to

$$\frac{1}{\sqrt{u-1}} = c_3 x$$

Therefore the solution y is

$$\begin{aligned} y &= ux \\ &= \frac{\left(c_3^2 \mathrm{e}^{2c_2} x^2 + 1\right) \mathrm{e}^{-2c_2}}{x\, c_3^2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(c_3^2 \mathrm{e}^{2c_2} x^2 + 1\right) \mathrm{e}^{-2c_2}}{x\, c_3^2} \tag{1}$$

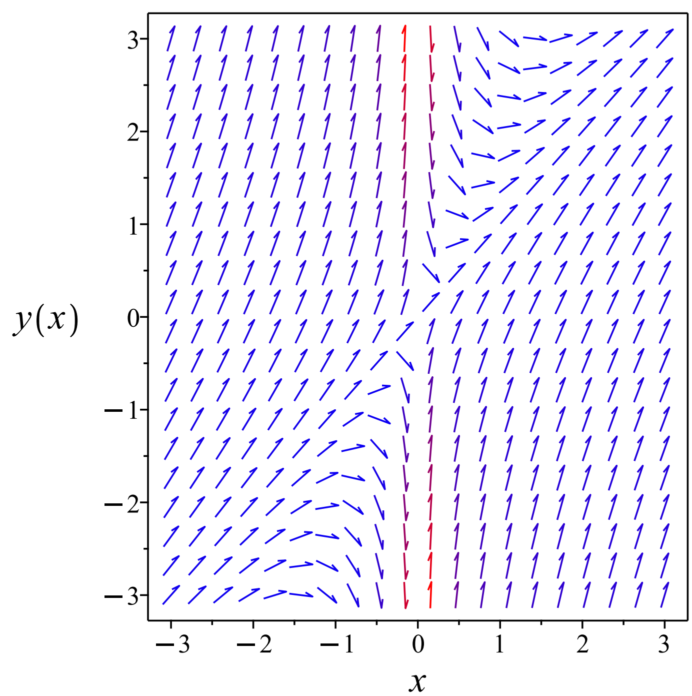

Figure 246: Slope field plot

Verification of solutions

$$y = \frac{(c_3^2 e^{2c_2} x^2 + 1) e^{-2c_2}}{x c_3^2}$$

Verified OK.

6.21.3 Solving as differentialType ode

Writing the ode as

$$y' = \frac{2x - y}{x} \tag{1}$$

Which becomes

$$0 = (-x) dy + (2x - y) dx \tag{2}$$

But the RHS is complete differential because

$$(-x) dy + (2x - y) dx = d(x^2 - xy)$$

Hence (2) becomes

$$0 = d(x^2 - xy)$$

Integrating both sides gives gives these solutions

$$y = \frac{x^2 + c_1}{x} + c_1$$

Summary
The solution(s) found are the following

$$y = \frac{x^2 + c_1}{x} + c_1 \tag{1}$$

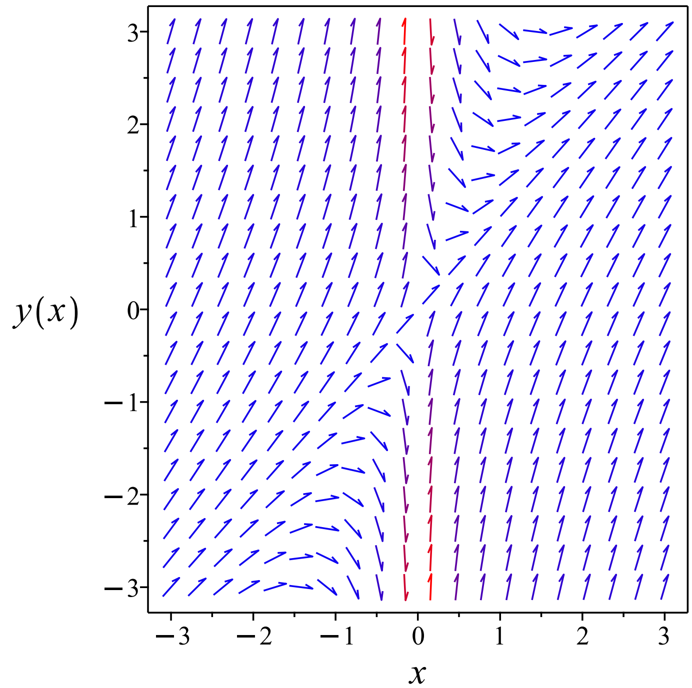

Figure 247: Slope field plot

Verification of solutions

$$y = \frac{x^2 + c_1}{x} + c_1$$

Verified OK.

6.21.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{-2x + y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 203: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-2x + y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = R^2 + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = x^2 + c_1$$

Which simplifies to

$$yx = x^2 + c_1$$

Which gives

$$y = \frac{x^2 + c_1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>

</td></tr>
</table>

Summary

The solution(s) found are the following

$$y = \frac{x^2 + c_1}{x} \tag{1}$$

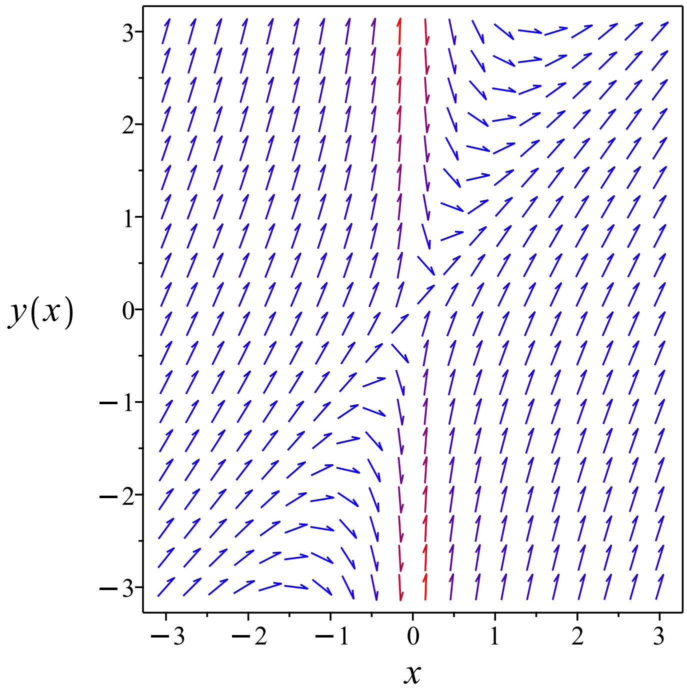

Figure 248: Slope field plot

Verification of solutions

$$y = \frac{x^2 + c_1}{x}$$

Verified OK.

6.21.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y &= (2x-y)\,\mathrm{d}x\\ (-2x+y)\,\mathrm{d}x + (x)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -2x+y\\ N(x,y) &= x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-2x+y)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x)\\ &= 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -2x + y \, \mathrm{d}x$$

$$\phi = -x(-y + x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x$. Therefore equation (4) becomes

$$x = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x(-y + x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x(-y + x)$$

The solution becomes

$$y = \frac{x^2 + c_1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2 + c_1}{x} \tag{1}$$

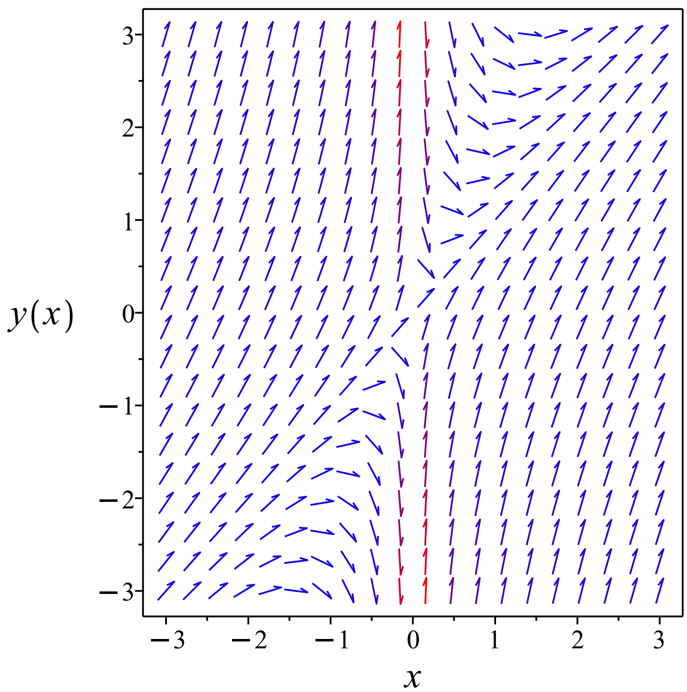

Figure 249: Slope field plot

Verification of solutions

$$y = \frac{x^2 + c_1}{x}$$

Verified OK.

6.21.6 Maple step by step solution

Let's solve

$y'x + y = 2x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = 2 - \frac{y}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{x} = 2$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = 2\mu(x)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = x$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int 2\mu(x)\,dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int 2\mu(x)\,dx + c_1$

- Solve for y

  $y = \frac{\int 2\mu(x)dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = x$

  $y = \frac{\int 2xdx + c_1}{x}$

- Evaluate the integrals on the rhs

  $y = \frac{x^2 + c_1}{x}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 155.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' \sin (x) + y \cos (x) = 1}$$

6.22.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \cot (x)$$
$$q(x) = \csc (x)$$

Hence the ode is

$$y' + y \cot (x) = \csc (x)$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \cot(x)dx} \\
&= \sin(x)
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)(\csc(x)) \\
\frac{d}{dx}(\sin(x)\, y) &= (\sin(x))(\csc(x)) \\
d(\sin(x)\, y) &= dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\sin(x)\, y &= \int dx \\
\sin(x)\, y &= x + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \sin(x)$ results in

$$
y = \csc(x)\, x + c_1 \csc(x)
$$

which simplifies to

$$
y = \csc(x)(x + c_1)
$$

Summary

The solution(s) found are the following

$$
y = \csc(x)(x + c_1) \tag{1}
$$

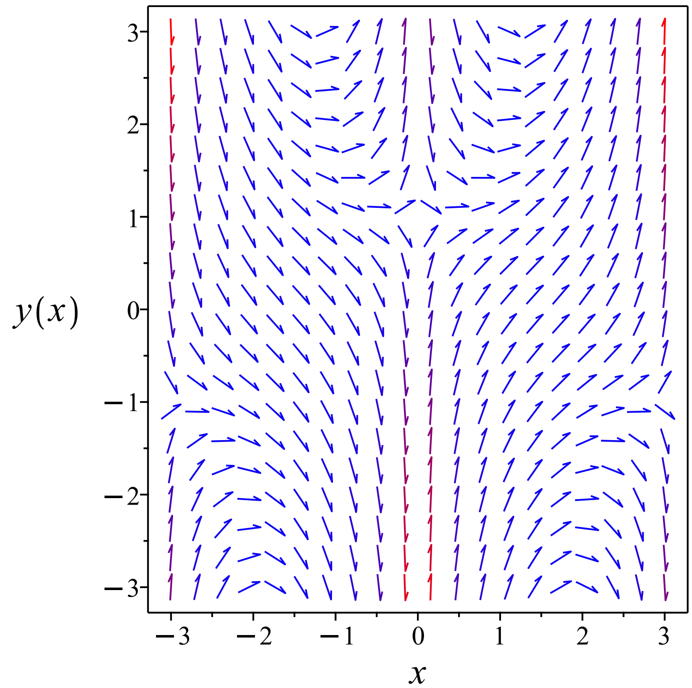

Figure 250: Slope field plot

Verification of solutions

$$y = \csc(x)(x + c_1)$$

Verified OK.

6.22.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{\cos(x)\, y - 1}{\sin(x)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 206: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{\sin(x)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{\sin(x)}} dy \end{aligned}$$

Which results in

$$S = \sin(x)\, y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{\cos(x)\, y - 1}{\sin(x)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \cos(x)\, y \\ S_y &= \sin(x) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\sin(x) y = x + c_1$$

Which simplifies to

$$\sin(x) y = x + c_1$$

Which gives

$$y = \frac{x + c_1}{\sin(x)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{\cos(x)y-1}{\sin(x)}$ 	$R = x$ $S = \sin(x) y$	$\frac{dS}{dR} = 1$ 
Summary

The solution(s) found are the following

$$y = \frac{x + c_1}{\sin(x)} \tag{1}$$

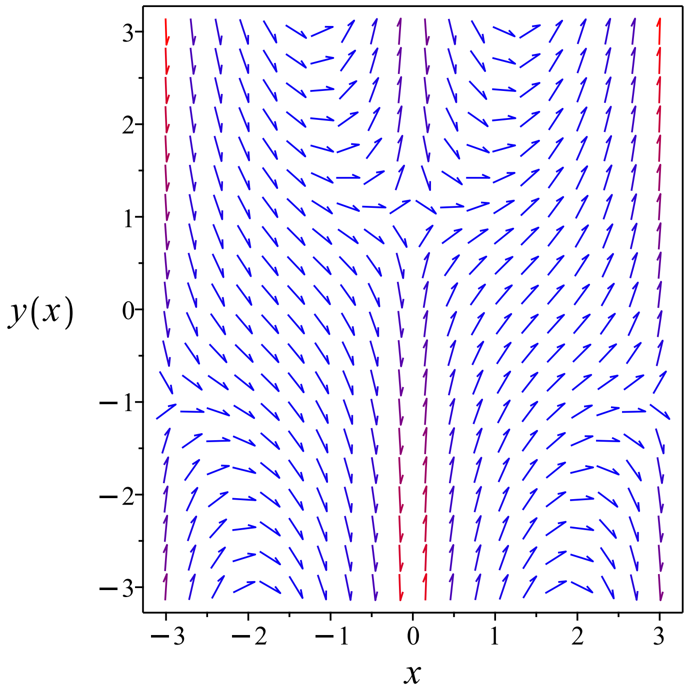

Figure 251: Slope field plot

Verification of solutions

$$y = \frac{x + c_1}{\sin(x)}$$

Verified OK.

6.22.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(\sin(x))\,\mathrm{d}y = (-\cos(x)\,y + 1)\,\mathrm{d}x$$
$$(\cos(x)\,y - 1)\,\mathrm{d}x + (\sin(x))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = \cos(x)\,y - 1$$
$$N(x, y) = \sin(x)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\cos(x)\,y - 1) \\ &= \cos(x)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\sin(x)) \\ &= \cos(x)\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$
$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int \cos(x)\,y-1\,\mathrm{d}x$$
$$\phi=-x+\sin(x)\,y+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=\sin(x)+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=\sin(x)$. Therefore equation (4) becomes

$$\sin(x)=\sin(x)+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=0$$

Therefore

$$f(y)=c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi=-x+\sin(x)\,y+c_1$$

But since ϕ itself is a constant function, then let $\phi=c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1=-x+\sin(x)\,y$$

The solution becomes

$$y = \frac{x + c_1}{\sin(x)}$$

Summary

The solution(s) found are the following

$$y = \frac{x + c_1}{\sin(x)} \tag{1}$$

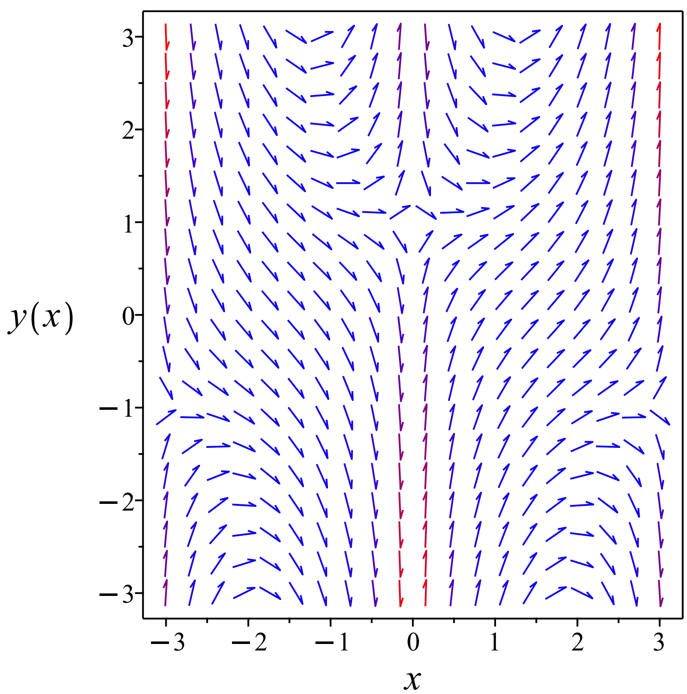

Figure 252: Slope field plot

Verification of solutions

$$y = \frac{x + c_1}{\sin(x)}$$

6.22.4 Maple step by step solution

Let's solve

$y' \sin(x) + y \cos(x) = 1$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y \cos(x)}{\sin(x)} + \frac{1}{\sin(x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y \cos(x)}{\sin(x)} = \frac{1}{\sin(x)}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y \cos(x)}{\sin(x)}\right) = \frac{\mu(x)}{\sin(x)}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{y \cos(x)}{\sin(x)}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x) \cos(x)}{\sin(x)}$

- Solve to find the integrating factor

  $\mu(x) = \sin(x)$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)}{\sin(x)} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)}{\sin(x)} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)}{\sin(x)} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \sin(x)$

  $y = \frac{\int 1 dx + c_1}{\sin(x)}$

- Evaluate the integrals on the rhs

  $y = \frac{x + c_1}{\sin(x)}$

- Simplify

  $y = \csc(x)(x + c_1)$

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{\cos(x)\,y' - \sin(x)\,y = -\sin(2x)}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 0\right]$$

6.23.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\tan(x)$$
$$q(x) = -2\sin(x)$$

Hence the ode is

$$y' - \tan(x) y = -2 \sin(x)$$

The domain of $p(x) = -\tan(x)$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z815 \vee \frac{1}{2}\pi + \pi\_Z815 < x\right\}$$

But the point $x_0 = \frac{\pi}{2}$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

6.23.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\tan(x) dx} \\ &= \cos(x)\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(-2\sin(x)) \\ \frac{d}{dx}(\cos(x) y) &= (\cos(x))(-2\sin(x)) \\ d(\cos(x) y) &= (-\sin(2x))\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\cos(x) y &= \int -\sin(2x)\, dx \\ \cos(x) y &= \frac{\cos(2x)}{2} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \cos(x)$ results in

$$y = \frac{\sec(x)\cos(2x)}{2} + c_1 \sec(x)$$

which simplifies to

$$y = \cos(x) - \frac{\sec(x)}{2} + c_1 \sec(x)$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration. Solving for c_1 gives

$$c_1 = -\frac{2\cos(x) - \sec(x) - 2y}{2\sec(x)}$$

Using given initial conditions results in $c_1 = \frac{1}{2}$ Hence the solution is

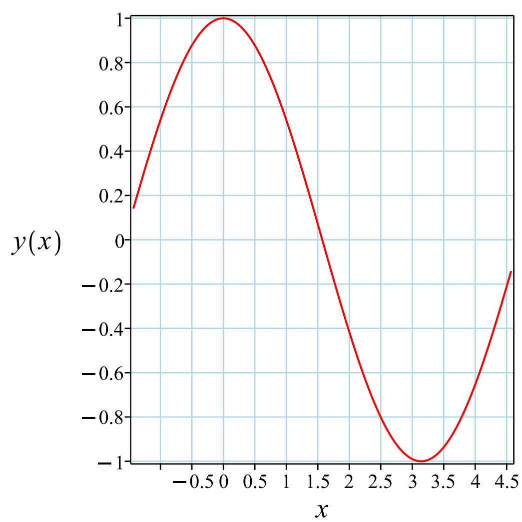
$$y = \cos(x)$$

Therefore the solution is

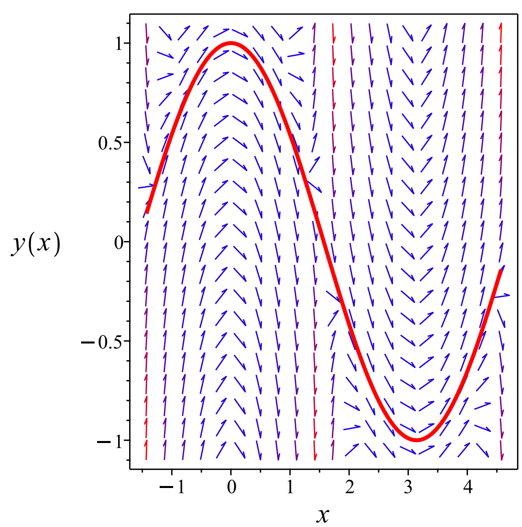
$$y = \cos(x)$$

Summary
The solution(s) found are the following

$$y = \cos(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \cos(x)$$

Verified OK.

6.23.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-\sin(x)\, y + \sin(2x)}{\cos(x)} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 209: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x + b_1y + c_1}{a_2x + b_2y + c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \frac{1}{\cos(x)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{\cos(x)}} dy \end{aligned}$$

Which results in

$$S = \cos(x)\, y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-\sin(x)\, y + \sin(2x)}{\cos(x)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\sin(x)\, y \\
S_y &= \cos(x)
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\sin(2x) \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\sin(2R)
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{\cos(2R)}{2} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
y\cos(x) = \frac{\cos(2x)}{2} + c_1
$$

Which simplifies to

$$
y\cos(x) = \frac{\cos(2x)}{2} + c_1
$$

Which gives

$$
y = \frac{\cos(2x) + 2c_1}{2\cos(x)}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-\sin(x)y+\sin(2x)}{\cos(x)}$  	$R = x$ $S = \cos(x)\, y$	$\frac{dS}{dR} = -\sin(2R)$ 
Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration. Solving for c_1 gives

$$c_1 = -\cos(x)^2 + \cos(x)\, y + \frac{1}{2}$$

Using given initial conditions results in $c_1 = \frac{1}{2}$ Hence the solution is

$$y = \frac{1 + \cos(2x)}{2\cos(x)}$$

Therefore the solution is

$$y = \frac{1 + \cos(2x)}{2\cos(x)}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{1 + \cos(2x)}{2\cos(x)} \tag{1}$$

<u>Verification of solutions</u>

$$y = \frac{1 + \cos(2x)}{2\cos(x)}$$

Verified OK.

6.23.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\cos(x))\,\mathrm{d}y &= (\sin(x)\,y - \sin(2x))\,\mathrm{d}x\\ (-\sin(x)\,y + \sin(2x))\,\mathrm{d}x + (\cos(x))\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -\sin(x)\,y + \sin(2x)\\ N(x, y) &= \cos(x)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\sin(x)\,y + \sin(2x))\\ &= -\sin(x)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(x))\\ &= -\sin(x)\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\sin(x) y + \sin(2x) \mathrm{d}x$$

$$\phi = -\cos(x)^2 + \cos(x) y + \frac{1}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \cos(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \cos(x)$. Therefore equation (4) becomes

$$\cos(x) = \cos(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\cos(x)^2 + \cos(x) y + \frac{1}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\cos(x)^2 + \cos(x) y + \frac{1}{2}$$

The solution becomes

$$y = \frac{2\cos(x)^2 - 1 + 2c_1}{2\cos(x)}$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{2}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration. Solving for c_1 gives

$$c_1 = -\cos(x)^2 + \cos(x) y + \frac{1}{2}$$

Using given initial conditions results in $c_1 = \frac{1}{2}$ Hence the solution is

$$y = \cos(x)$$

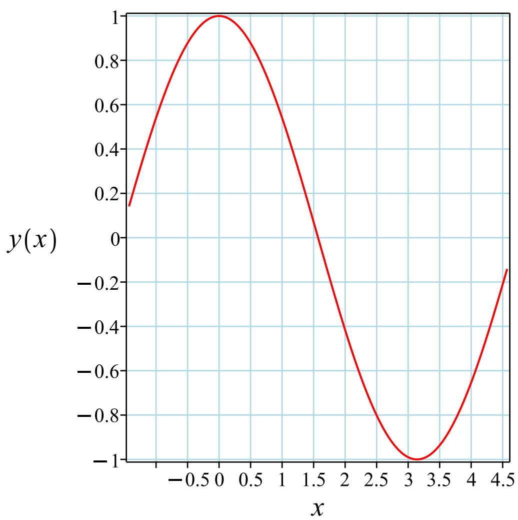
Therefore the solution is

$$y = \cos(x)$$

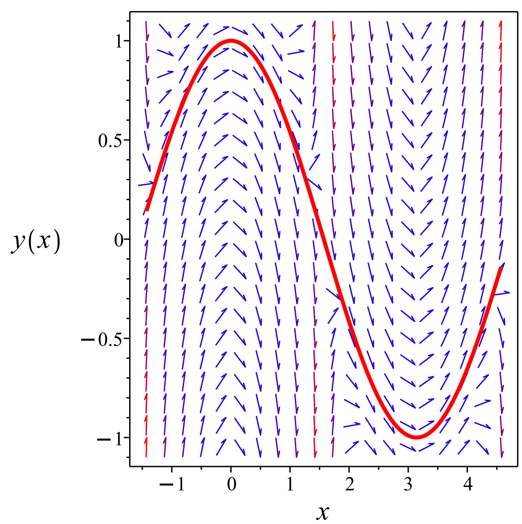
Summary

The solution(s) found are the following

$$y = \cos(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \cos(x)$$

Problem number: 157.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' + 2yx - 2y^2x = 0}$$

6.24.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= 2xy(y-1) \end{aligned}$$

Where $f(x) = 2x$ and $g(y) = y(y-1)$. Integrating both sides gives

$$\frac{1}{y\,(y-1)}\,dy = 2x\,dx$$

$$\int \frac{1}{y\,(y-1)}\,dy = \int 2x\,dx$$
$$\ln\left(y-1\right)-\ln\left(y\right) = x^2 + c_1$$

Raising both side to exponential gives

$$e^{\ln(y-1)-\ln(y)} = e^{x^2+c_1}$$

Which simplifies to

$$\frac{y-1}{y} = c_2 e^{x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{-1+c_2 e^{x^2}} \tag{1}$$

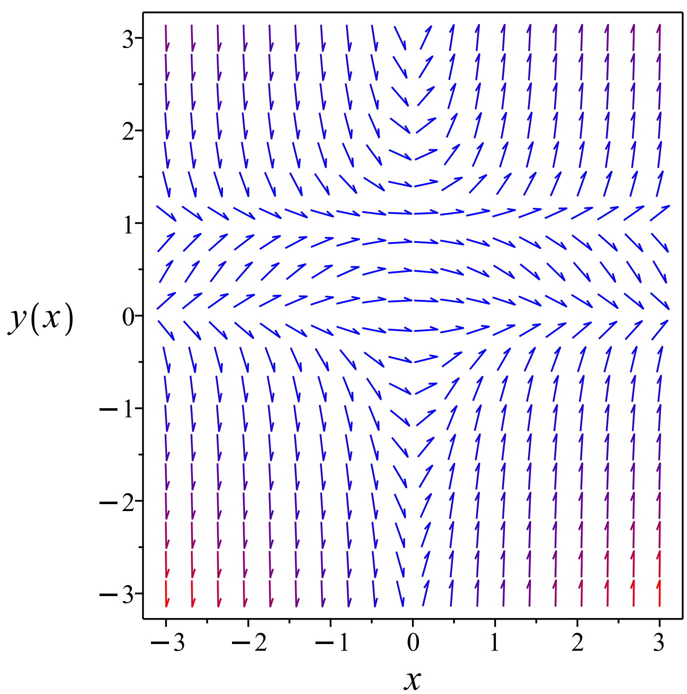

Figure 256: Slope field plot

6.24.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned}y' &= 2y^2x - 2xy \\ y' &= \omega(x,y)\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 211: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{2x} \\
\eta(x,y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{2x}} dx
\end{aligned}
$$

Which results in

$$
S = x^2
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = 2y^2 x - 2xy
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= 2x \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y\,(y-1)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R\,(R-1)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \ln(R-1) - \ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x^2 = \ln(y-1) - \ln(y) + c_1$$

Which simplifies to

$$x^2 = \ln(y-1) - \ln(y) + c_1$$

Which gives

$$y = \frac{e^{-x^2+c_1}}{-1+e^{-x^2+c_1}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2y^2x - 2xy$ 	$R = y$ $S = x^2$	$\frac{dS}{dR} = \frac{1}{R(R-1)}$ 
Summary

The solution(s) found are the following

$$y = \frac{e^{-x^2+c_1}}{-1 + e^{-x^2+c_1}} \tag{1}$$

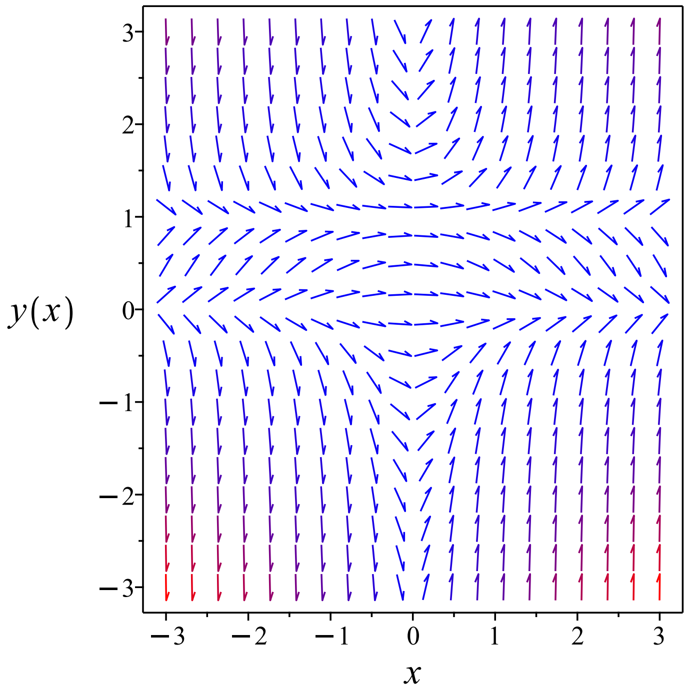

Figure 257: Slope field plot

Verification of solutions

$$y = \frac{e^{-x^2+c_1}}{-1+e^{-x^2+c_1}}$$

Verified OK.

6.24.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= 2y^2x - 2xy \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -2xy + 2xy^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -2x \\ f_1(x) &= 2x \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y' \frac{1}{y^2} = -\frac{2x}{y} + 2x \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = -\frac{1}{y^2} y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(x) &= -2w(x)\, x + 2x \\ w' &= 2xw - 2x \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2x \\ q(x) &= -2x \end{aligned}$$

Hence the ode is

$$w'(x) - 2w(x)\, x = -2x$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -2x dx} \\
&= e^{-x^2}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu w) &= (\mu)(-2x) \\
\frac{d}{dx}\left(e^{-x^2} w\right) &= \left(e^{-x^2}\right)(-2x) \\
d\left(e^{-x^2} w\right) &= \left(-2x\, e^{-x^2}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
e^{-x^2} w &= \int -2x\, e^{-x^2}\, dx \\
e^{-x^2} w &= e^{-x^2} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{-x^2}$ results in

$$
w(x) = e^{-x^2} e^{x^2} + c_1 e^{x^2}
$$

which simplifies to

$$
w(x) = 1 + c_1 e^{x^2}
$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$
\frac{1}{y} = 1 + c_1 e^{x^2}
$$

Or

$$
y = \frac{1}{1 + c_1 e^{x^2}}
$$

Summary

The solution(s) found are the following

$$
y = \frac{1}{1 + c_1 e^{x^2}} \tag{1}
$$

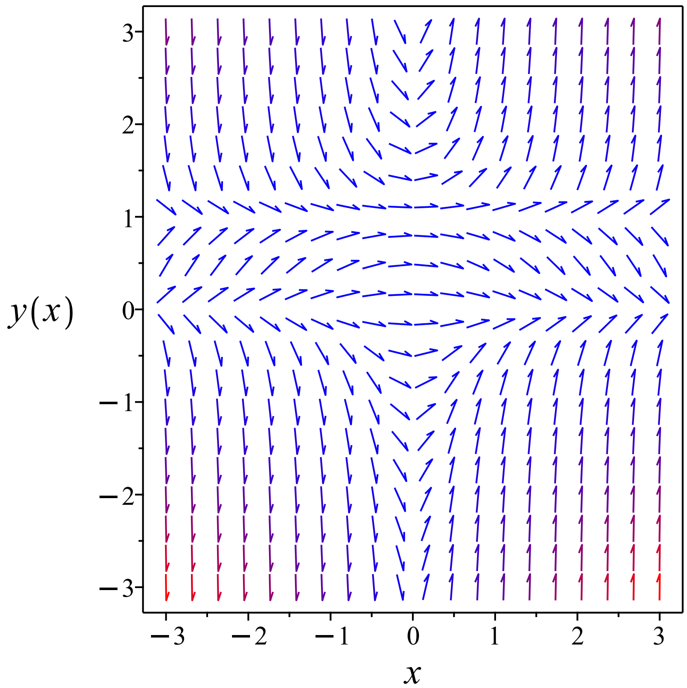

Figure 258: Slope field plot

Verification of solutions

$$y = \frac{1}{1 + c_1 e^{x^2}}$$

Verified OK.

6.24.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{2y\,(y-1)}\right)\mathrm{d}y &= (x)\,\mathrm{d}x \\
(-x)\,\mathrm{d}x + \left(\frac{1}{2y\,(y-1)}\right)\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= -x \\
N(x,y) &= \frac{1}{2y\,(y-1)}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x) \\
&= 0
\end{aligned}
$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2y\left(y-1\right)}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x = \int M\, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x = \int -x\, \mathrm{d}x$$

$$\phi = -\frac{x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2y(y-1)}$. Therefore equation (4) becomes

$$\frac{1}{2y\left(y-1\right)} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{2y\left(y-1\right)}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{2y\,(y-1)}\right) \mathrm{d}y$$

$$f(y) = \frac{\ln(y-1)}{2} - \frac{\ln(y)}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} + \frac{\ln(y-1)}{2} - \frac{\ln(y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} + \frac{\ln(y-1)}{2} - \frac{\ln(y)}{2}$$

The solution becomes

$$y = -\frac{1}{\mathrm{e}^{x^2+2c_1} - 1}$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{\mathrm{e}^{x^2+2c_1} - 1} \tag{1}$$

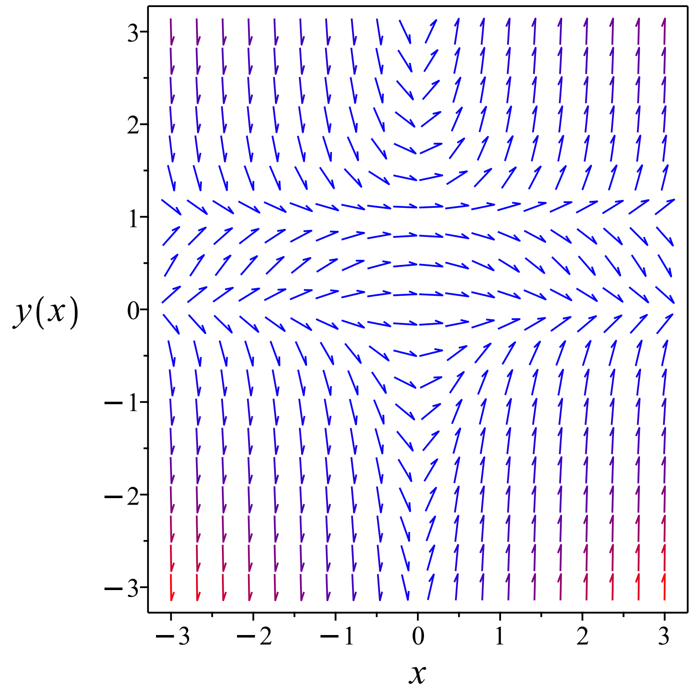

Figure 259: Slope field plot

Verification of solutions

$$y = -\frac{1}{e^{x^2+2c_1} - 1}$$

Verified OK.

6.24.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= 2y^2x - 2xy \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 2y^2x - 2xy$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = -2x$ and $f_2(x) = 2x$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{2xu} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 2 \\ f_1 f_2 &= -4x^2 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$2xu''(x) - \left(-4x^2 + 2\right) u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + c_2 \mathrm{e}^{-x^2}$$

The above shows that

$$u'(x) = -2c_2 x \, \mathrm{e}^{-x^2}$$

Using the above in (1) gives the solution

$$y = \frac{c_2 \mathrm{e}^{-x^2}}{c_1 + c_2 \mathrm{e}^{-x^2}}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\mathrm{e}^{-x^2}}{c_3 + \mathrm{e}^{-x^2}}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{-x^2}}{c_3 + e^{-x^2}} \tag{1}$$

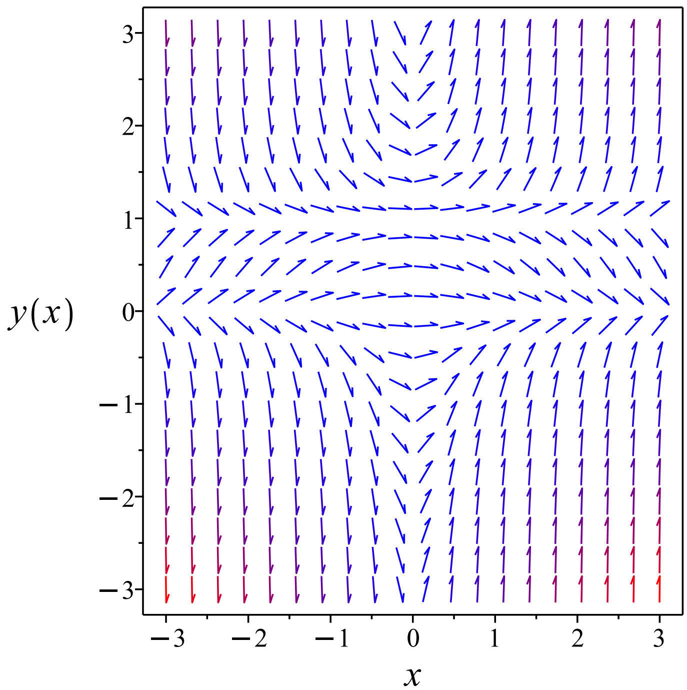

Figure 260: Slope field plot

Verification of solutions

$$y = \frac{e^{-x^2}}{c_3 + e^{-x^2}}$$

Verified OK.

6.24.6 Maple step by step solution

Let's solve

$y' + 2yx - 2y^2x = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

$\frac{y'}{y(y-1)} = 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y(y-1)}dx = \int 2x dx + c_1$

- Evaluate integral

  $\ln(y-1) - \ln(y) = x^2 + c_1$

- Solve for y

  $y = -\frac{1}{e^{x^2+c_1}-1}$

Problem number: 158.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, _Bernoulli]
```

$$\boxed{3y^2xy' - 2y^3 = x^3}$$

6.25.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$3u(x)^2\,x^3(u'(x)\,x + u(x)) - 2u(x)^3\,x^3 = x^3$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u^3 - 1}{3u^2x}
\end{aligned}$$

Where $f(x) = -\frac{1}{3x}$ and $g(u) = \frac{u^3-1}{u^2}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{u^3-1}{u^2}}\,du &= -\frac{1}{3x}\,dx \\
\int \frac{1}{\frac{u^3-1}{u^2}}\,du &= \int -\frac{1}{3x}\,dx \\
\frac{\ln(u^3-1)}{3} &= -\frac{\ln(x)}{3} + c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
(u^3-1)^{\frac{1}{3}} = \mathrm{e}^{-\frac{\ln(x)}{3}+c_2}
$$

Which simplifies to

$$
(u^3-1)^{\frac{1}{3}} = \frac{c_3}{x^{\frac{1}{3}}}
$$

Which simplifies to

$$
\left(u(x)^3-1\right)^{\frac{1}{3}} = \frac{c_3\mathrm{e}^{c_2}}{x^{\frac{1}{3}}}
$$

The solution is

$$
\left(u(x)^3-1\right)^{\frac{1}{3}} = \frac{c_3\mathrm{e}^{c_2}}{x^{\frac{1}{3}}}
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\left(\frac{y^3}{x^3}-1\right)^{\frac{1}{3}} &= \frac{c_3\mathrm{e}^{c_2}}{x^{\frac{1}{3}}} \\
\left(\frac{y^3-x^3}{x^3}\right)^{\frac{1}{3}} &= \frac{c_3\mathrm{e}^{c_2}}{x^{\frac{1}{3}}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\left(\frac{y^3-x^3}{x^3}\right)^{\frac{1}{3}} = \frac{c_3\mathrm{e}^{c_2}}{x^{\frac{1}{3}}} \tag{1}
$$

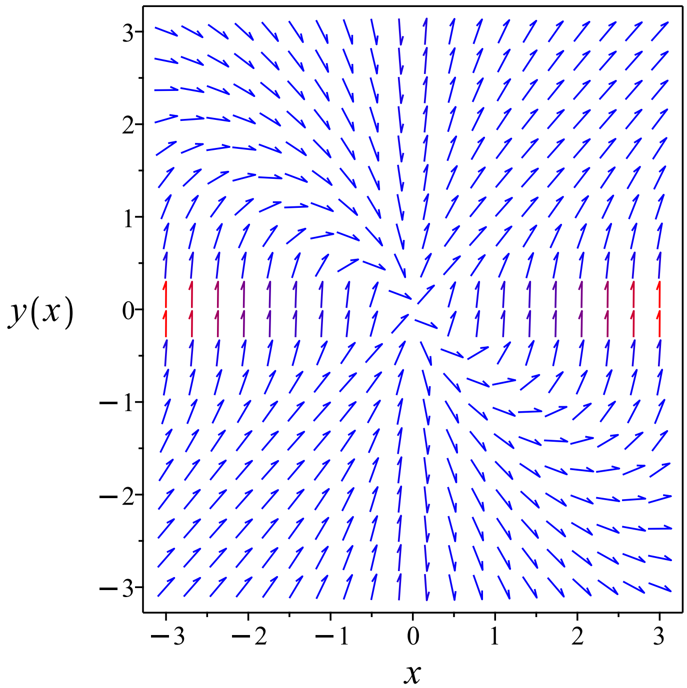

Figure 261: Slope field plot

Verification of solutions

$$\left(\frac{y^3 - x^3}{x^3}\right)^{\frac{1}{3}} = \frac{c_3 e^{c_2}}{x^{\frac{1}{3}}}$$

Verified OK.

6.25.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^3 + 2y^3}{3y^2 x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 214: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{x^2}{y^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2}{y^2}} dy \end{aligned}$$

Which results in

$$S = \frac{y^3}{3x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^3 + 2y^3}{3y^2 x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2y^3}{3x^3} \\ S_y &= \frac{y^2}{x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{3} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{3}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{R}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^3}{3x^2} = \frac{x}{3} + c_1$$

Which simplifies to

$$\frac{y^3}{3x^2} = \frac{x}{3} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^3+2y^3}{3y^2x}$ 	$R = x$ $S = \frac{y^3}{3x^2}$	$\frac{dS}{dR} = \frac{1}{3}$ 
Summary
The solution(s) found are the following

$$\frac{y^3}{3x^2} = \frac{x}{3} + c_1 \tag{1}$$

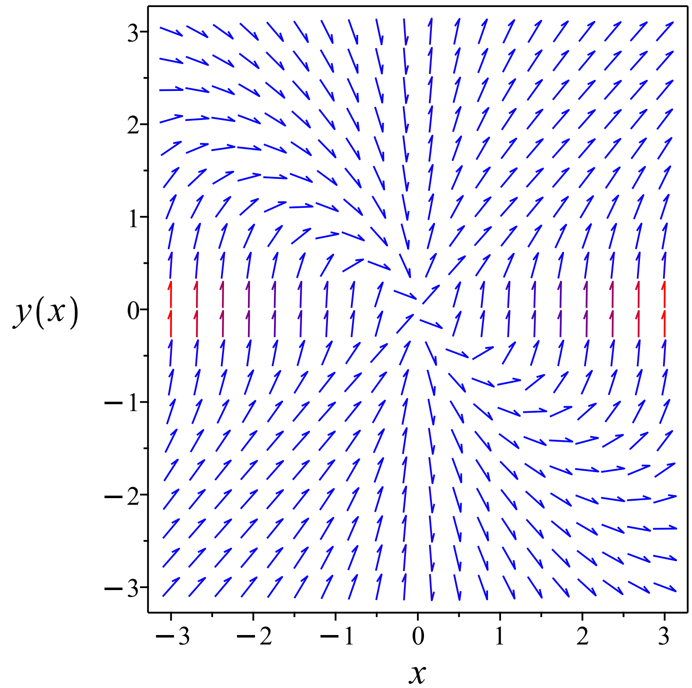

Figure 262: Slope field plot

Verification of solutions

$$\frac{y^3}{3x^2} = \frac{x}{3} + c_1$$

Verified OK.

6.25.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{x^3+2y^3}{3y^2x} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{2}{3x}y + \frac{x^2}{3}\frac{1}{y^2} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{2}{3x} \\ f_1(x) &= \frac{x^2}{3} \\ n &= -2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y^2}$ gives

$$y'y^2 = \frac{2y^3}{3x} + \frac{x^2}{3} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^3 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 3y^2y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{3} &= \frac{2w(x)}{3x} + \frac{x^2}{3} \\ w' &= \frac{2w}{x} + x^2 \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= x^2 \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{2w(x)}{x} = x^2$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)\left(x^2\right) \\ \frac{d}{dx}\left(\frac{w}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(x^2\right) \\ d\left(\frac{w}{x^2}\right) &= dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^2} &= \int dx \\ \frac{w}{x^2} &= x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$w(x) = c_1 x^2 + x^3$$

which simplifies to

$$w(x) = x^2(x + c_1)$$

Replacing w in the above by y^3 using equation (5) gives the final solution.

$$y^3 = x^2(x + c_1)$$

Solving for y gives

$$\begin{aligned}y(x) &= \left(x^2(x + c_1)\right)^{\frac{1}{3}} \\ y(x) &= \frac{\left(x^2(x + c_1)\right)^{\frac{1}{3}}\left(i\sqrt{3} - 1\right)}{2} \\ y(x) &= -\frac{\left(x^2(x + c_1)\right)^{\frac{1}{3}}\left(1 + i\sqrt{3}\right)}{2}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(x^2(x + c_1)\right)^{\frac{1}{3}} \tag{1}$$

$$y = \frac{\left(x^2(x + c_1)\right)^{\frac{1}{3}} \left(i\sqrt{3} - 1\right)}{2} \tag{2}$$

$$y = -\frac{\left(x^2(x + c_1)\right)^{\frac{1}{3}} \left(1 + i\sqrt{3}\right)}{2} \tag{3}$$

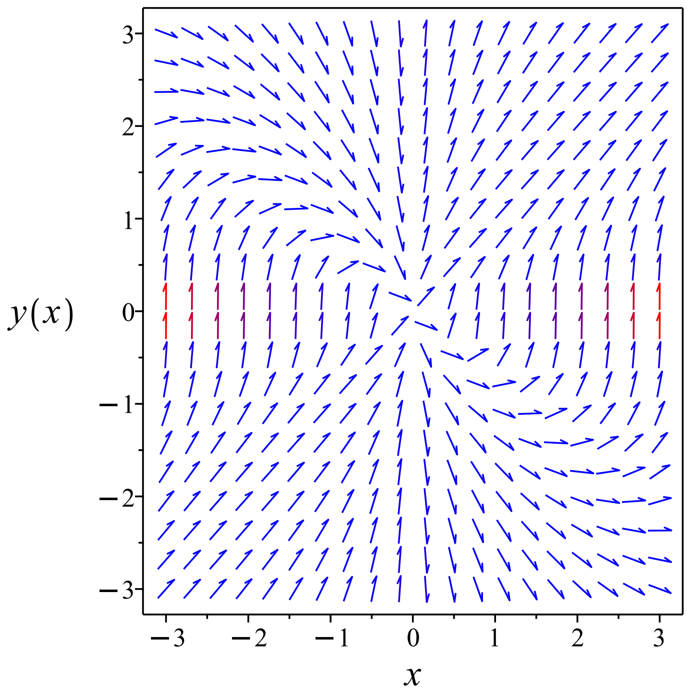

Figure 263: Slope field plot

Verification of solutions

$$y = \left(x^2(x+c_1)\right)^{\frac{1}{3}}$$

Verified OK.

$$y = \frac{\left(x^2(x+c_1)\right)^{\frac{1}{3}} \left(i\sqrt{3}-1\right)}{2}$$

Verified OK.

$$y = -\frac{\left(x^2(x+c_1)\right)^{\frac{1}{3}} \left(1+i\sqrt{3}\right)}{2}$$

Verified OK.

6.25.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition

$\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(3y^2x\right)\mathrm{d}y &= \left(x^3+2y^3\right)\mathrm{d}x\\ \left(-x^3-2y^3\right)\mathrm{d}x + \left(3y^2x\right)\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -x^3-2y^3\\ N(x,y) &= 3y^2x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^3-2y^3\right)\\ &= -6y^2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(3y^2x\right)\\ &= 3y^2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{3x\,y^2}\left(\left(-6y^2\right)-\left(3y^2\right)\right)\\ &= -\frac{3}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\frac{3}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-3\ln(x)} \\
&= \frac{1}{x^3}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^3}\left(-x^3 - 2y^3\right) \\
&= \frac{-x^3 - 2y^3}{x^3}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^3}\left(3y^2 x\right) \\
&= \frac{3y^2}{x^2}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{-x^3 - 2y^3}{x^3}\right) + \left(\frac{3y^2}{x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{-x^3 - 2y^3}{x^3} \mathrm{d}x$$
$$\phi = -x + \frac{y^3}{x^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{3y^2}{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{3y^2}{x^2}$. Therefore equation (4) becomes

$$\frac{3y^2}{x^2} = \frac{3y^2}{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x + \frac{y^3}{x^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x + \frac{y^3}{x^2}$$

Summary

The solution(s) found are the following

$$-x + \frac{y^3}{x^2} = c_1 \tag{1}$$

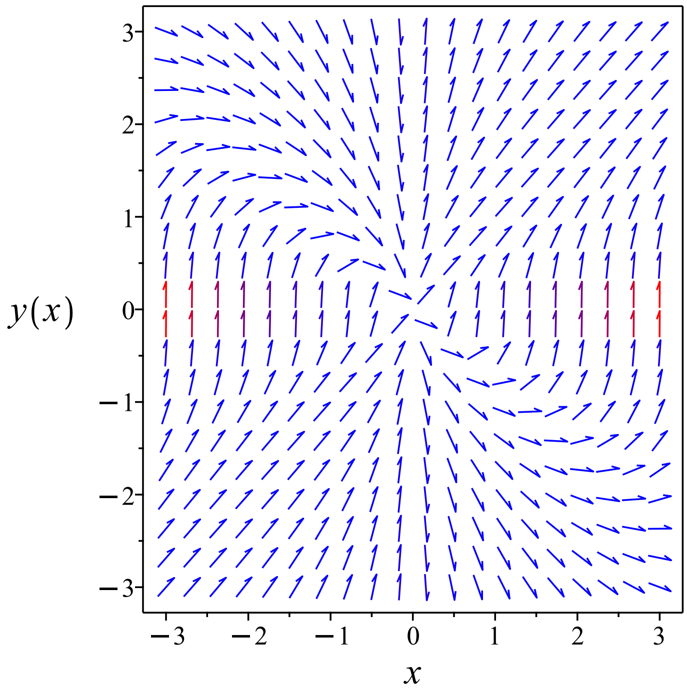

Figure 264: Slope field plot

Verification of solutions

$$-x+\frac{y^3}{x^2}=c_1$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries]]
```

$$\boxed{(x^3 + e^y)\, y' = 3x^2}$$

6.26.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{3x^2}{x^3 + e^y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{3x^2(b_3 - a_2)}{x^3 + e^y} - \frac{9x^4 a_3}{(x^3 + e^y)^2} - \left(\frac{6x}{x^3 + e^y} - \frac{9x^4}{(x^3 + e^y)^2}\right)(xa_2 + ya_3 + a_1) + \frac{3x^2 e^y (xb_2 + yb_3 + b_1)}{(x^3 + e^y)^2} = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^6 b_2 + 3x^5 b_3 + 3x^4 y a_3 + 5 e^y x^3 b_2 + 3 e^y x^2 y b_3 + 3x^4 a_1 - 9x^4 a_3 - 9 e^y x^2 a_2 + 3 e^y x^2 b_1 + 3 e^y x^2 b_3 - 6 e^y x y a_3}{(x^3 + e^y)^2} = 0$$

Setting the numerator to zero gives

$$x^6 b_2 + 3x^5 b_3 + 3x^4 y a_3 + 5 e^y x^3 b_2 + 3 e^y x^2 y b_3 + 3x^4 a_1 - 9x^4 a_3 - 9 e^y x^2 a_2 + 3 e^y x^2 b_1 + 3 e^y x^2 b_3 - 6 e^y x y a_3 + e^{2y} b_2 - 6 e^y x a_1 = 0 \tag{6E}$$

Simplifying the above gives

$$x^6 b_2 + 3x^5 b_3 + 3x^4 y a_3 + 5 e^y x^3 b_2 + 3 e^y x^2 y b_3 + 3x^4 a_1 - 9x^4 a_3 - 9 e^y x^2 a_2 + 3 e^y x^2 b_1 + 3 e^y x^2 b_3 - 6 e^y x y a_3 + e^{2y} b_2 - 6 e^y x a_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, e^y, e^{2y}\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, e^y = v_3, e^{2y} = v_4\}$$

The above PDE (6E) now becomes

$$v_1^6 b_2 + 3v_1^4 v_2 a_3 + 3v_1^5 b_3 + 3v_1^4 a_1 - 9v_1^4 a_3 + 5v_3 v_1^3 b_2 + 3v_3 v_1^2 v_2 b_3 - 9v_3 v_1^2 a_2 - 6v_3 v_1 v_2 a_3 + 3v_3 v_1^2 b_1 + 3v_3 v_1^2 b_3 - 6v_3 v_1 a_1 + v_4 b_2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$v_1^6 b_2 + 3v_1^5 b_3 + 3v_1^4 v_2 a_3 + (3a_1 - 9a_3) v_1^4 + 5v_3 v_1^3 b_2 + 3v_3 v_1^2 v_2 b_3 + (-9a_2 + 3b_1 + 3b_3) v_1^2 v_3 - 6v_3 v_1 v_2 a_3 - 6v_3 v_1 a_1 + v_4 b_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} b_2 &= 0 \\ -6a_1 &= 0 \\ -6a_3 &= 0 \\ 3a_3 &= 0 \\ 5b_2 &= 0 \\ 3b_3 &= 0 \\ 3a_1 - 9a_3 &= 0 \\ -9a_2 + 3b_1 + 3b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= a_2 \\ a_3 &= 0 \\ b_1 &= 3a_2 \\ b_2 &= 0 \\ b_3 &= 0 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= 3 \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 3 - \left(\frac{3x^2}{x^3 + \mathrm{e}^y}\right)(x) \\
&= \frac{3\,\mathrm{e}^y}{x^3 + \mathrm{e}^y} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{3\,\mathrm{e}^y}{x^3 + \mathrm{e}^y}} dy
\end{aligned}$$

Which results in

$$S = -\frac{x^3 \mathrm{e}^{-y}}{3} + \frac{\ln(\mathrm{e}^y)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{3x^2}{x^3 + \mathrm{e}^y}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -x^2 \mathrm{e}^{-y} \\
S_y &= \frac{x^3 \mathrm{e}^{-y}}{3} + \frac{1}{3}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\frac{x^3 \mathrm{e}^{-y}}{3} + \frac{y}{3} = c_1
$$

Which simplifies to

$$
-\frac{x^3 \mathrm{e}^{-y}}{3} + \frac{y}{3} = c_1
$$

Which gives

$$
y = \mathrm{LambertW}\left(x^3 \mathrm{e}^{-3c_1}\right) + 3c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{3x^2}{x^3+e^y}$ 	$R = x$ $S = -\frac{x^3 e^{-y}}{3} + \frac{y}{3}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \text{LambertW}\left(x^3 e^{-3c_1}\right) + 3c_1 \tag{1}$$

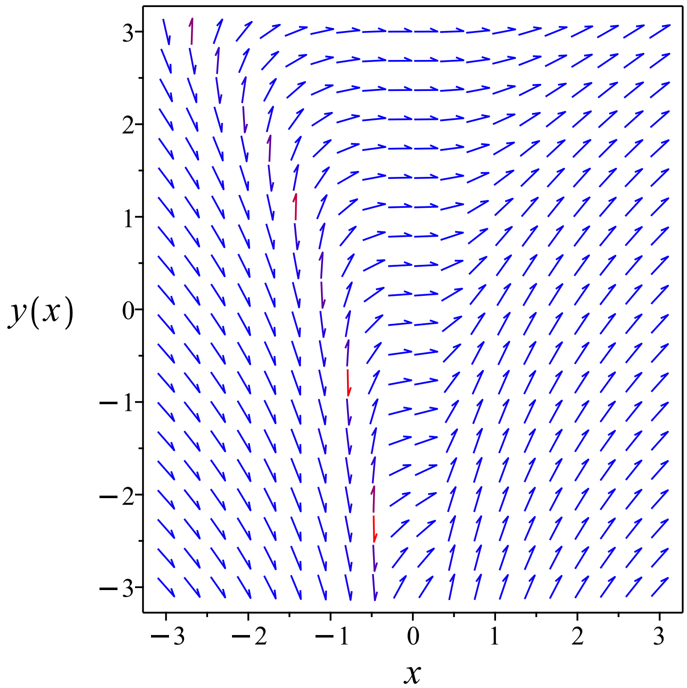

Figure 265: Slope field plot

Verification of solutions

$$y = \text{LambertW}\left(x^3 e^{-3c_1}\right) + 3c_1$$

Verified OK.

6.26.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(x^3+\mathrm{e}^y\right)\mathrm{d}y=\left(3x^2\right)\mathrm{d}x$$
$$\left(-3x^2\right)\mathrm{d}x+\left(x^3+\mathrm{e}^y\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y)=-3x^2$$
$$N(x,y)=x^3+\mathrm{e}^y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-3x^2\right)\\&=0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}\left(x^3+\mathrm{e}^y\right)\\&=3x^2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x^3 + \mathrm{e}^y}\left((0) - \left(3x^2\right)\right) \\
&= -\frac{3x^2}{x^3 + \mathrm{e}^y}
\end{aligned}
$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$
\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= -\frac{1}{3x^2}\left(\left(3x^2\right) - (0)\right) \\
&= -1
\end{aligned}
$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$
\begin{aligned}
\mu &= e^{\int B \, \mathrm{d}y} \\
&= e^{\int -1 \, \mathrm{d}y}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-y} \\
&= \mathrm{e}^{-y}
\end{aligned}
$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-y}\left(-3x^2\right) \\
&= -3x^2\mathrm{e}^{-y}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-y}\left(x^3 + \mathrm{e}^y\right) \\
&= 1 + x^3\mathrm{e}^{-y}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-3x^2\mathrm{e}^{-y}\right) + \left(1 + x^3\mathrm{e}^{-y}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -3x^2\mathrm{e}^{-y}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -x^3\mathrm{e}^{-y} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = x^3\mathrm{e}^{-y} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 1 + x^3\mathrm{e}^{-y}$. Therefore equation (4) becomes

$$
1 + x^3\mathrm{e}^{-y} = x^3\mathrm{e}^{-y} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 1
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\,\mathrm{d}y &= \int (1)\,\mathrm{d}y \\
f(y) &= y + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x^3 e^{-y} + y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x^3 e^{-y} + y$$

The solution becomes

$$y = \text{LambertW}\left(x^3 e^{-c_1}\right) + c_1$$

Summary

The solution(s) found are the following

$$y = \text{LambertW}\left(x^3 e^{-c_1}\right) + c_1 \tag{1}$$

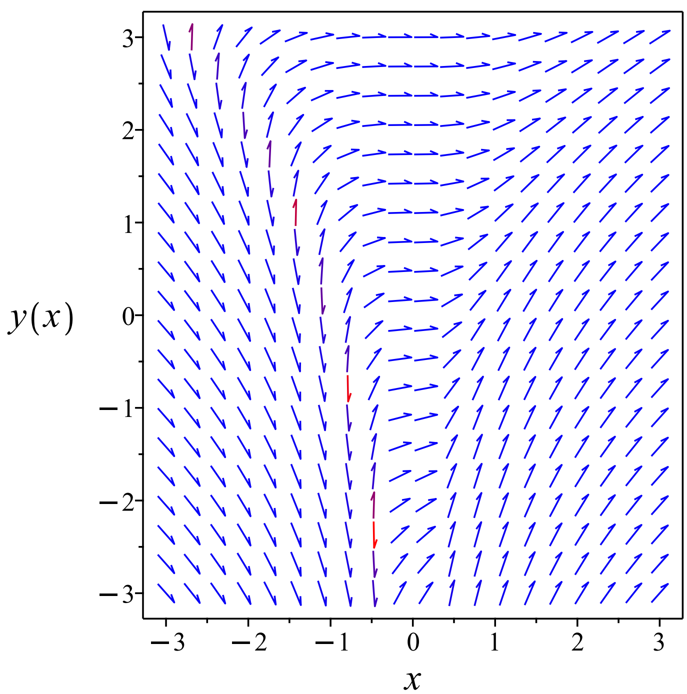

Figure 266: Slope field plot

Verification of solutions

$$y = \text{LambertW}\left(x^3 e^{-c_1}\right) + c_1$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' + 3yx - y\,\mathrm{e}^{x^2} = 0}$$

6.27.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= y\left(\mathrm{e}^{x^2} - 3x\right) \end{aligned}$$

Where $f(x) = e^{x^2} - 3x$ and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y} dy &= e^{x^2} - 3x\, dx \\
\int \frac{1}{y} dy &= \int e^{x^2} - 3x\, dx \\
\ln(y) &= -\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2} + c_1 \\
y &= e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2} + c_1} \\
&= c_1 e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}} \tag{1}
$$

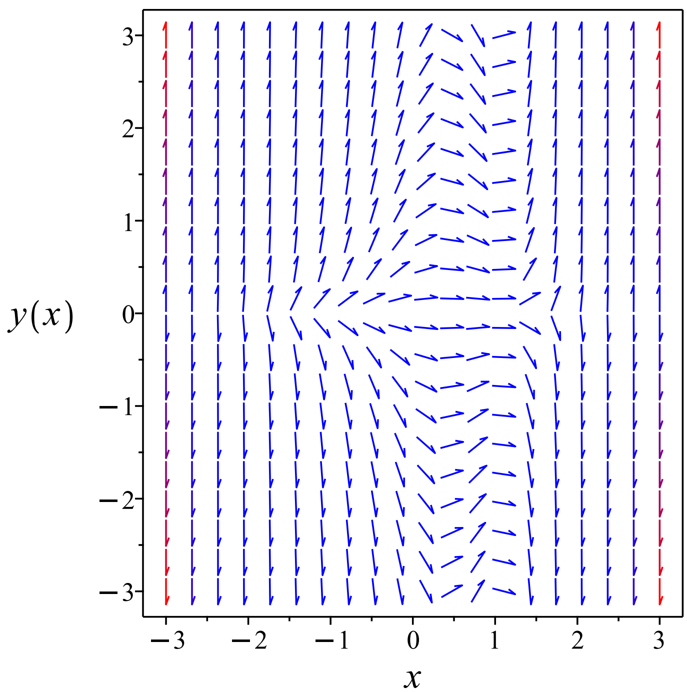

Figure 267: Slope field plot

Verification of solutions

$$
y = c_1 e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}}
$$

Verified OK.

6.27.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\mathrm{e}^{x^2} + 3x \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' + y\left(-\mathrm{e}^{x^2} + 3x\right) = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int \left(-\mathrm{e}^{x^2}+3x\right)dx} \\ &= \mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}\mu y &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} y\right) &= 0 \end{aligned}$$

Integrating gives

$$\mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} y = c_1$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}}$ results in

$$y = c_1 \mathrm{e}^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} \tag{1}$$

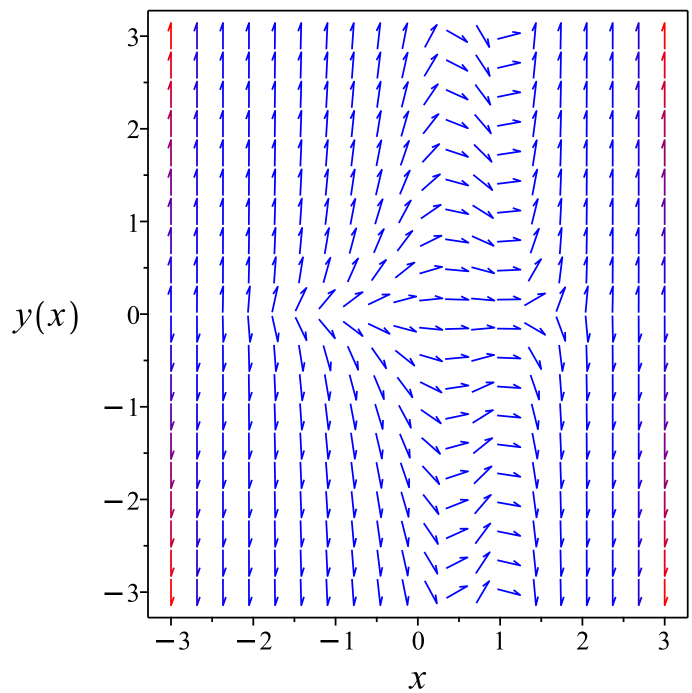

Figure 268: Slope field plot

Verification of solutions

$$y = c_1 e^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\operatorname{erfi}(x)}{2}}$$

Verified OK.

6.27.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x + u(x) + 3u(x)\,x^2 - u(x)\,x\,e^{x^2} = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u\left(x\,e^{x^2} - 3x^2 - 1\right)}{x} \end{aligned}$$

Where $f(x) = \frac{x\,e^{x^2}-3x^2-1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{x\,e^{x^2}-3x^2-1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{x\,e^{x^2}-3x^2-1}{x}\,dx \\
\ln(u) &= -\frac{3x^2}{2} - \ln(x) + \frac{\sqrt{\pi}\,\operatorname{erfi}(x)}{2} + c_2 \\
u &= e^{-\frac{3x^2}{2}-\ln(x)+\frac{\sqrt{\pi}\,\operatorname{erfi}(x)}{2}+c_2} \\
&= c_2 e^{-\frac{3x^2}{2}-\ln(x)+\frac{\sqrt{\pi}\,\operatorname{erfi}(x)}{2}}
\end{aligned}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= xu \\
&= x c_2 e^{-\frac{3x^2}{2}-\ln(x)+\frac{\sqrt{\pi}\,\operatorname{erfi}(x)}{2}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = x c_2 e^{-\frac{3x^2}{2}-\ln(x)+\frac{\sqrt{\pi}\,\operatorname{erfi}(x)}{2}} \tag{1}
$$

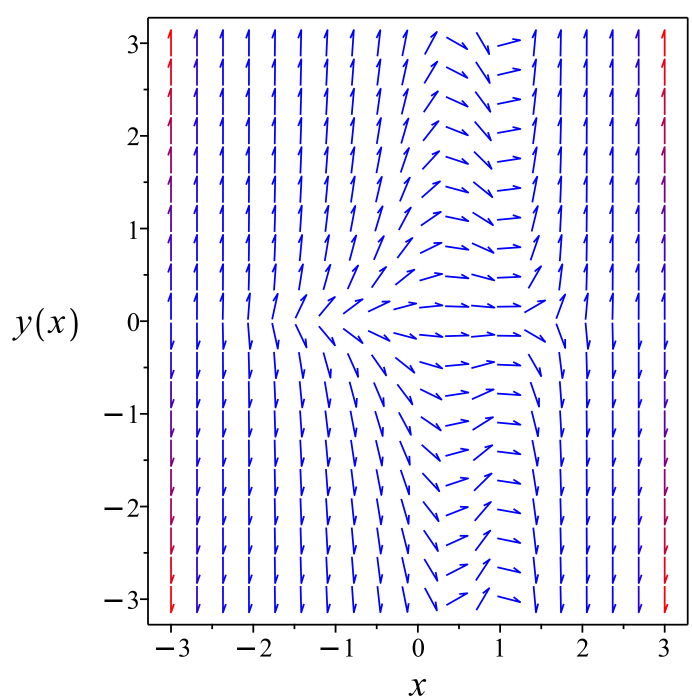

Figure 269: Slope field plot

Verification of solutions

$$y = xc_2 \mathrm{e}^{-\frac{3x^2}{2} - \ln(x) + \frac{\sqrt{\pi}\, \mathrm{erfi}(x)}{2}}$$

Verified OK.

6.27.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -3xy + \mathrm{e}^{x^2} y \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 216: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \mathrm{e}^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}}} dy \end{aligned}$$

Which results in

$$S = e^{\frac{3x^2}{2} - \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -3xy + e^{x^2} y$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \left(-e^{x^2} + 3x\right) e^{\frac{3x^2}{2} - \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}} y \\ S_y &= e^{\frac{3x^2}{2} - \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} y = c_1$$

Which simplifies to

$$\mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} y = c_1$$

Which gives

$$y = c_1 \mathrm{e}^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -3xy + \mathrm{e}^{x^2} y$ 	$R = x$ $S = \mathrm{e}^{\frac{3x^2}{2}-\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} y$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}} \tag{1}$$

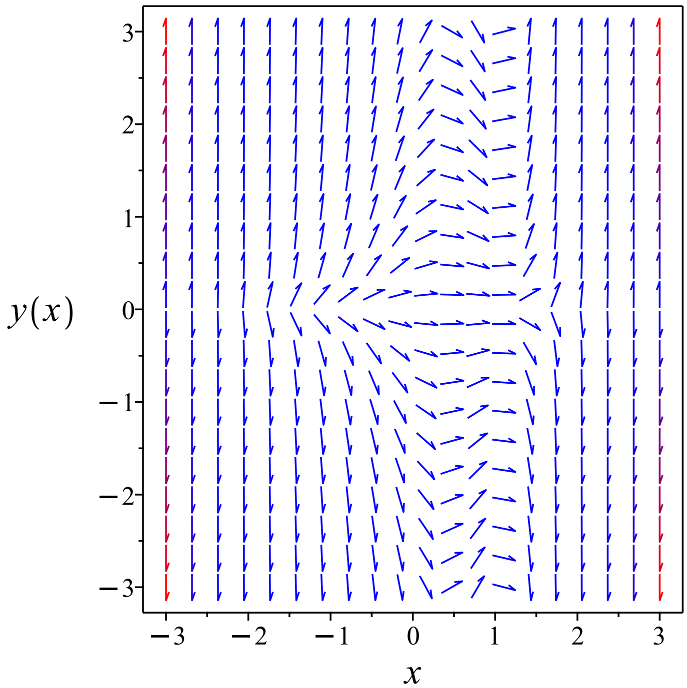

Figure 270: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2}}$$

Verified OK.

6.27.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y}\right)\mathrm{d}y=\left(\mathrm{e}^{x^2}-3x\right)\mathrm{d}x$$
$$\left(-\mathrm{e}^{x^2}+3x\right)\mathrm{d}x+\left(\frac{1}{y}\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y)=-\mathrm{e}^{x^2}+3x$$
$$N(x,y)=\frac{1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y}=\frac{\partial}{\partial y}\left(-\mathrm{e}^{x^2}+3x\right)$$
$$=0$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -\mathrm{e}^{x^2} + 3x \,\mathrm{d}x \\
\phi &= \frac{3x^2}{2} - \frac{\sqrt{\pi}\,\mathrm{erfi}\,(x)}{2} + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$
\frac{1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(\frac{1}{y}\right) \mathrm{d}y \\
f(y) &= \ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{3x^2}{2} - \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2} + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{3x^2}{2} - \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2} + \ln(y)$$

The solution becomes

$$y = e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2} + c_1}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{3x^2}{2} + \frac{\sqrt{\pi}\, \operatorname{erfi}(x)}{2} + c_1} \tag{1}$$

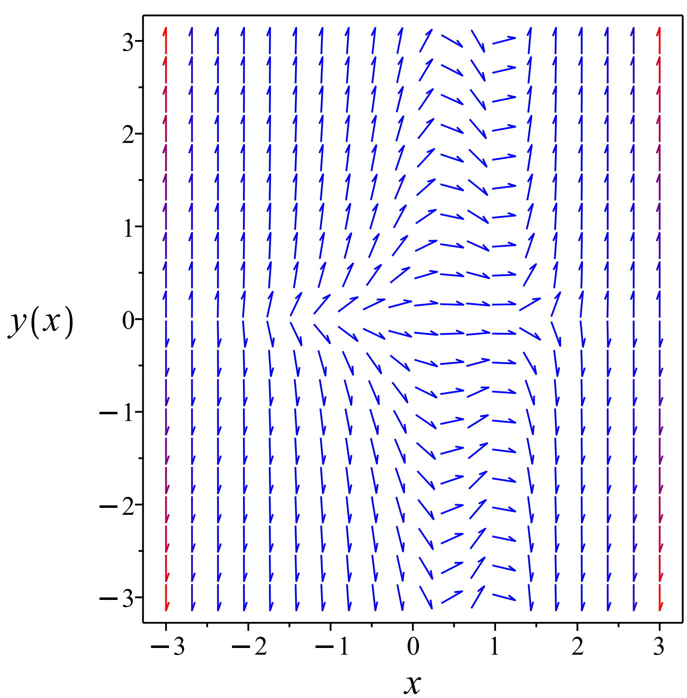

Figure 271: Slope field plot

Verification of solutions

$$y = e^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}+c_1}$$

Verified OK.

6.27.6 Maple step by step solution

Let's solve

$y' + 3yx - y\,e^{x^2} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = e^{x^2} - 3x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int \left(e^{x^2} - 3x\right)dx + c_1$

- Evaluate integral

  $\ln(y) = -\frac{3x^2}{2} + \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2} + c_1$

- Solve for y

  $y = e^{-\frac{3x^2}{2}+\frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{2}+c_1}$

The type(s) of ODE detected by this program : **"bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_Bernoulli]
```

$$\boxed{2y' \ln (x) + \frac{y}{x} - \frac{\cos (x)}{y} = 0}$$

6.29.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-y^2 + \cos (x)\, x}{2 \ln (x)\, xy}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 219: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{y \ln(x)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{y\ln(x)}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln(x)\, y^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{-y^2 + \cos(x)\, x}{2\ln(x)\, xy}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y^2}{2x} \\ S_y &= y\ln(x) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\cos(x)}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{\cos(R)}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{\sin(R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2 \ln(x)}{2} = \frac{\sin(x)}{2} + c_1$$

Which simplifies to

$$\frac{y^2 \ln(x)}{2} = \frac{\sin(x)}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{-y^2+\cos(x)x}{2\ln(x)xy}$ 	$R = x$ $S = \frac{\ln(x)\, y^2}{2}$	$\frac{dS}{dR} = \frac{\cos(R)}{2}$ 
Summary

The solution(s) found are the following

$$\frac{y^2 \ln(x)}{2} = \frac{\sin(x)}{2} + c_1 \tag{1}$$

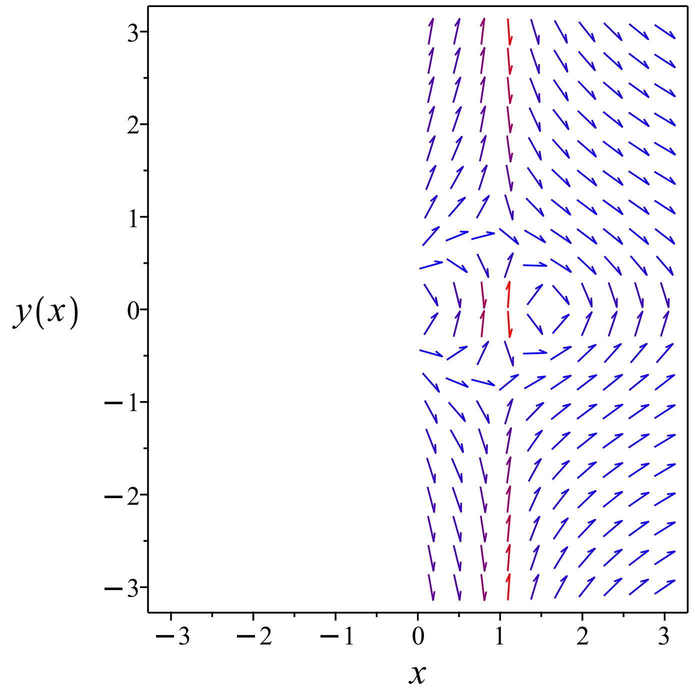

Figure 272: Slope field plot

Verification of solutions

$$\frac{y^2 \ln(x)}{2} = \frac{\sin(x)}{2} + c_1$$

Verified OK.

6.29.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{-y^2 + \cos(x) x}{2 \ln(x) x y} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{2x \ln(x)} y + \frac{\cos(x)}{2 \ln(x)} \frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x) y + f_1(x) y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{1}{2x\ln(x)} \\ f_1(x) &= \frac{\cos(x)}{2\ln(x)} \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = -\frac{y^2}{2x\ln(x)} + \frac{\cos(x)}{2\ln(x)} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= -\frac{w(x)}{2x\ln(x)} + \frac{\cos(x)}{2\ln(x)} \\ w' &= -\frac{w}{x\ln(x)} + \frac{\cos(x)}{\ln(x)} \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= \frac{1}{x \ln(x)} \\
q(x) &= \frac{\cos(x)}{\ln(x)}
\end{aligned}
$$

Hence the ode is

$$
w'(x) + \frac{w(x)}{x \ln(x)} = \frac{\cos(x)}{\ln(x)}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int \frac{1}{x \ln(x)} dx} \\
&= \ln(x)
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu w) &= (\mu) \left(\frac{\cos(x)}{\ln(x)}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}(\ln(x) w) &= (\ln(x)) \left(\frac{\cos(x)}{\ln(x)}\right) \\
\mathrm{d}(\ln(x) w) &= \cos(x) \, \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\ln(x) w &= \int \cos(x) \, \mathrm{d}x \\
\ln(x) w &= \sin(x) + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \ln(x)$ results in

$$
w(x) = \frac{\sin(x)}{\ln(x)} + \frac{c_1}{\ln(x)}
$$

which simplifies to

$$
w(x) = \frac{\sin(x) + c_1}{\ln(x)}
$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$
y^2 = \frac{\sin(x) + c_1}{\ln(x)}
$$

Solving for y gives

$$y(x) = \frac{\sqrt{\ln(x)(\sin(x)+c_1)}}{\ln(x)}$$
$$y(x) = -\frac{\sqrt{\ln(x)(\sin(x)+c_1)}}{\ln(x)}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{\sqrt{\ln(x)(\sin(x)+c_1)}}{\ln(x)} \tag{1}$$
$$y = -\frac{\sqrt{\ln(x)(\sin(x)+c_1)}}{\ln(x)} \tag{2}$$

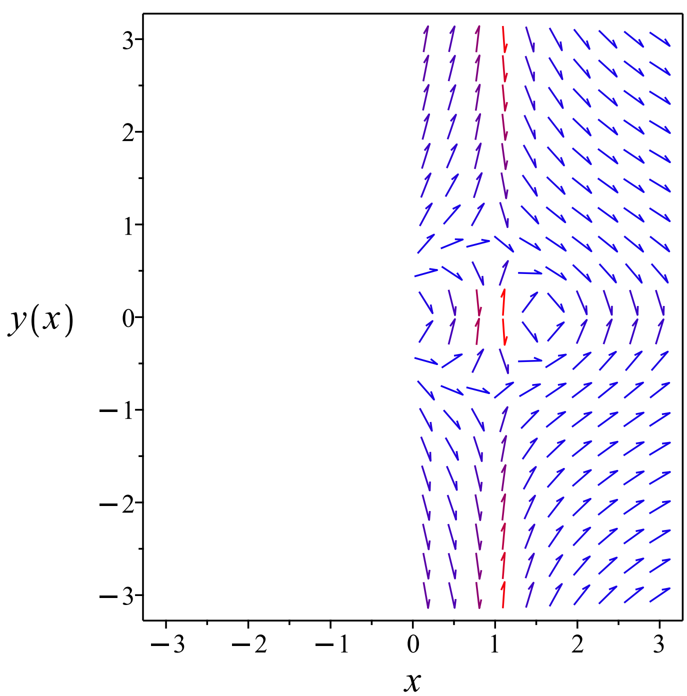

Figure 273: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{\ln (x) (\sin (x) + c_1)}}{\ln (x)}$$

Verified OK.

$$y = -\frac{\sqrt{\ln (x) (\sin (x) + c_1)}}{\ln (x)}$$

Verified OK.

6.29.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(2\ln(x))\,\mathrm{d}y = \left(-\frac{y}{x} + \frac{\cos(x)}{y}\right)\mathrm{d}x$$

$$\left(\frac{y}{x} - \frac{\cos(x)}{y}\right)\mathrm{d}x + (2\ln(x))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= \frac{y}{x} - \frac{\cos(x)}{y} \\ N(x, y) &= 2\ln(x) \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y}{x} - \frac{\cos(x)}{y}\right) \\ &= \frac{1}{x} + \frac{\cos(x)}{y^2} \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2\ln(x)) \\ &= \frac{2}{x} \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{2\ln(x)}\left(\left(\frac{1}{x} + \frac{\cos(x)}{y^2}\right) - \left(\frac{2}{x}\right)\right) \\ &= \frac{-\frac{1}{x} + \frac{\cos(x)}{y^2}}{2\ln(x)} \end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= -\frac{xy}{-y^2 + \cos(x)\,x}\left(\left(\frac{2}{x}\right) - \left(\frac{1}{x} + \frac{\cos(x)}{y^2}\right)\right) \\
&= \frac{1}{y}
\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}
\mu &= e^{\int B \, \mathrm{d}y} \\
&= e^{\int \frac{1}{y} \, \mathrm{d}y}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{\ln(y)} \\
&= y
\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= y\left(\frac{y}{x} - \frac{\cos(x)}{y}\right) \\
&= \frac{y^2 - \cos(x)\,x}{x}
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= y(2\ln(x)) \\
&= 2y\ln(x)
\end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{y^2 - \cos(x)\,x}{x}\right) + (2y\ln(x))\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{y^2 - \cos(x)\, x}{x} \mathrm{d}x$$

$$\phi = -\sin(x) + \ln(x)\, y^2 + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2y \ln(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2y \ln(x)$. Therefore equation (4) becomes

$$2y \ln(x) = 2y \ln(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sin(x) + \ln(x)\, y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sin(x) + \ln(x)\, y^2$$

Summary

The solution(s) found are the following

$$y^2 \ln(x) - \sin(x) = c_1 \tag{1}$$

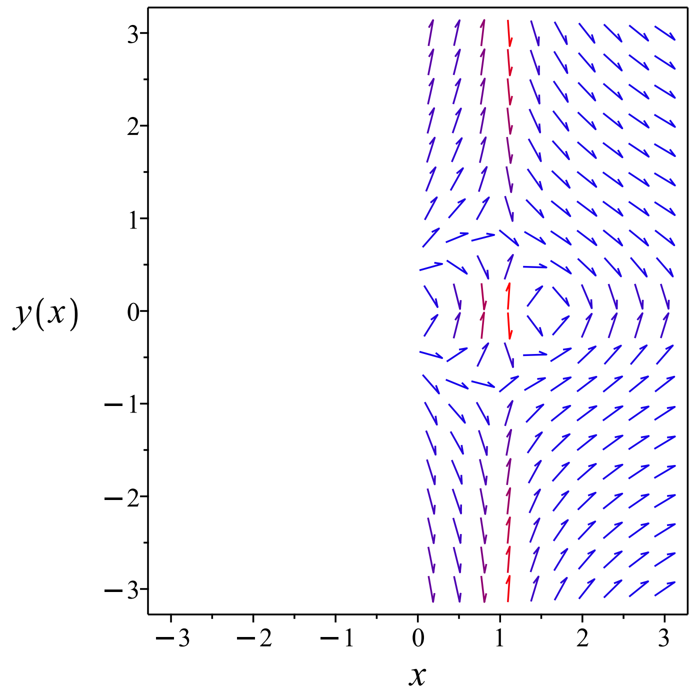

Figure 274: Slope field plot

Verification of solutions

$$y^2 \ln(x) - \sin(x) = c_1$$

Verified OK.

Problem number: 163.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"bernoulli", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_Bernoulli]`

$$\boxed{2y' \sin(x) + y \cos(x) - \sin(x)^2 y^3 = 0}$$

6.30.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y\left(-\sin(x)^2 y^2 + \cos(x)\right)}{2\sin(x)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 221: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \sin(x)\, y^3
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\sin(x)\, y^3} dy \end{aligned}$$

Which results in

$$S = -\frac{1}{2\sin(x)\, y^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y\left(-\sin(x)^2 y^2 + \cos(x)\right)}{2\sin(x)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{\csc(x)\cot(x)}{2y^2} \\ S_y &= \frac{\csc(x)}{y^3} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{\csc(x)}{2y^2} = \frac{x}{2} + c_1$$

Which simplifies to

$$-\frac{\csc(x)}{2y^2} = \frac{x}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y\left(-\sin(x)^2 y^2+\cos(x)\right)}{2\sin(x)}$ 	$R = x$ $S = -\frac{\csc(x)}{2y^2}$	$\frac{dS}{dR} = \frac{1}{2}$ 
Summary

The solution(s) found are the following

$$-\frac{\csc(x)}{2y^2} = \frac{x}{2} + c_1 \tag{1}$$

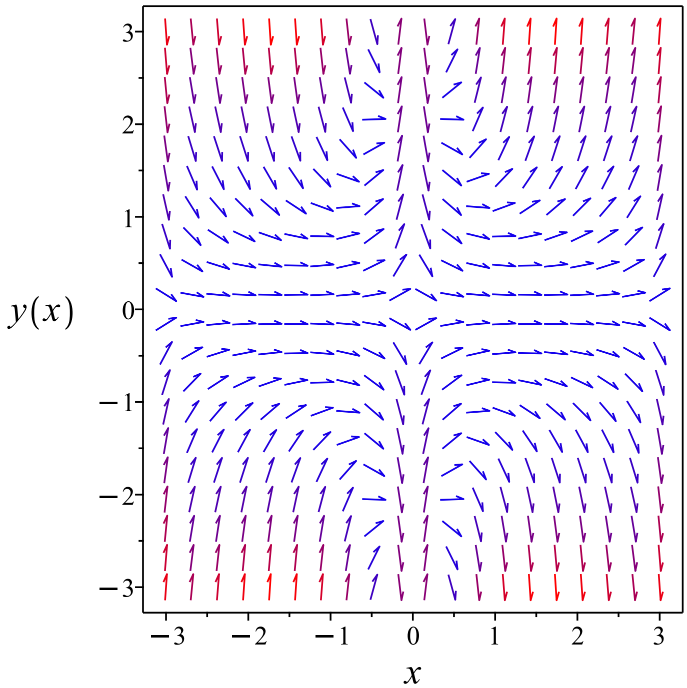

Figure 275: Slope field plot

Verification of solutions

$$-\frac{\csc(x)}{2y^2} = \frac{x}{2} + c_1$$

Verified OK.

6.30.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{y(-\sin(x)^2 y^2 + \cos(x))}{2\sin(x)} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{\cos(x)}{2\sin(x)}y + \frac{\sin(x)}{2}y^3 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned}
f_0(x) &= -\frac{\cos(x)}{2\sin(x)} \\
f_1(x) &= \frac{\sin(x)}{2} \\
n &= 3
\end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^3$ gives

$$y'\frac{1}{y^3} = -\frac{\cos(x)}{2\sin(x)\,y^2} + \frac{\sin(x)}{2} \tag{4}$$

Let

$$\begin{aligned}
w &= y^{1-n} \\
&= \frac{1}{y^2}
\end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = -\frac{2}{y^3}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned}
-\frac{w'(x)}{2} &= -\frac{\cos(x)\,w(x)}{2\sin(x)} + \frac{\sin(x)}{2} \\
w' &= \frac{\cos(x)\,w}{\sin(x)} - \sin(x)
\end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\cot(x) \\
q(x) &= -\sin(x)
\end{aligned}
$$

Hence the ode is

$$
w'(x) - \cot(x)\, w(x) = -\sin(x)
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -\cot(x)dx} \\
&= \frac{1}{\sin(x)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \csc(x)
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu w) &= (\mu)(-\sin(x)) \\
\frac{d}{dx}(\csc(x)\, w) &= (\csc(x))(-\sin(x)) \\
d(\csc(x)\, w) &= -1\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\csc(x)\, w &= \int -1\, dx \\
\csc(x)\, w &= -x + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \csc(x)$ results in

$$
w(x) = -x\sin(x) + \sin(x)\, c_1
$$

which simplifies to

$$
w(x) = \sin(x)(-x + c_1)
$$

Replacing w in the above by $\frac{1}{y^2}$ using equation (5) gives the final solution.

$$
\frac{1}{y^2} = \sin(x)(-x + c_1)
$$

Solving for y gives

$$y(x) = \frac{1}{\sqrt{\sin(x)(-x+c_1)}}$$
$$y(x) = -\frac{1}{\sqrt{\sin(x)(-x+c_1)}}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{\sqrt{\sin(x)(-x+c_1)}} \tag{1}$$
$$y = -\frac{1}{\sqrt{\sin(x)(-x+c_1)}} \tag{2}$$

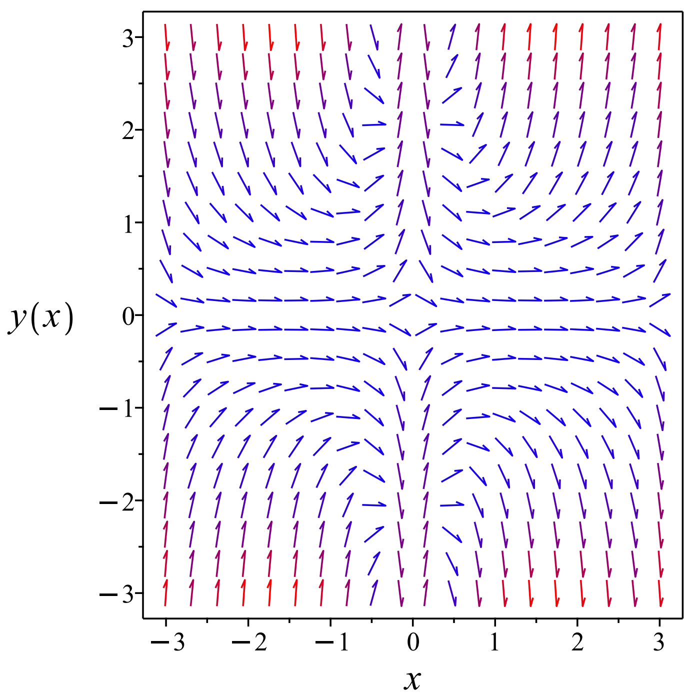

Figure 276: Slope field plot

Verification of solutions

$$y = \frac{1}{\sqrt{\sin(x)(-x+c_1)}}$$

Verified OK.

$$y = -\frac{1}{\sqrt{\sin(x)(-x+c_1)}}$$

Verified OK.

```

$$\boxed{\left(1+x^{2}+y^{2}\right) y'+yx=0}$$

6.31.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x^2+y^2+1\right)\mathrm{d}y&=(-xy)\,\mathrm{d}x\\(xy)\,\mathrm{d}x+\left(x^2+y^2+1\right)\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=xy\\N(x,y)&=x^2+y^2+1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}(xy)\\&=x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}\left(x^2+y^2+1\right)\\&=2x\end{aligned}$$

Since $\frac{\partial M}{\partial y}\neq\frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A&=\frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\&=\frac{1}{x^2+y^2+1}((x)-(2x))\\&=-\frac{x}{x^2+y^2+1}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= \frac{1}{xy}((2x) - (x)) \\ &= \frac{1}{y} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \, \mathrm{d}y} \\ &= e^{\int \frac{1}{y} \, \mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\ln(y)} \\ &= y \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= y(xy) \\ &= y^2 x \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= y\left(x^2 + y^2 + 1\right) \\ &= y\left(x^2 + y^2 + 1\right) \end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(y^2 x\right) + \left(y\left(x^2 + y^2 + 1\right)\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int y^2 x\,\mathrm{d}x$$
$$\phi = \frac{y^2x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = x^2y + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = y(x^2+y^2+1)$. Therefore equation (4) becomes

$$y(x^2+y^2+1) = x^2y + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y^3 + y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (y^3+y)\,\mathrm{d}y$$
$$f(y) = \frac{(y^2+1)^2}{4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{y^2x^2}{2} + \frac{(y^2+1)^2}{4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{y^2 x^2}{2} + \frac{(y^2+1)^2}{4}$$

Summary

The solution(s) found are the following

$$\frac{x^2 y^2}{2} + \frac{(1+y^2)^2}{4} = c_1 \tag{1}$$

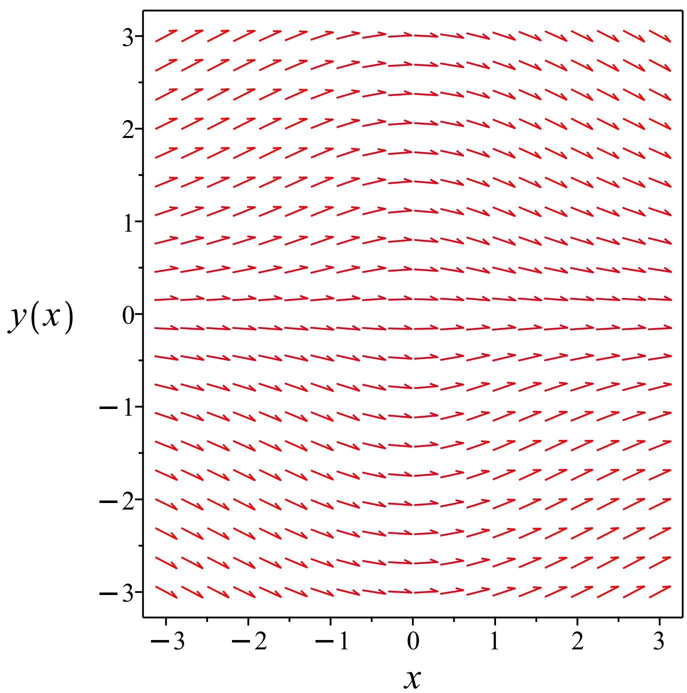

Figure 277: Slope field plot

Verification of solutions

$$\frac{x^2 y^2}{2} + \frac{(1+y^2)^2}{4} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "riccati", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y' - y\cos(x) - y^2\cos(x) = 0}$$

6.32.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \cos(x)\left(y^2+y\right) \end{aligned}$$

Where $f(x) = \cos(x)$ and $g(y) = y^2 + y$. Integrating both sides gives

$$\frac{1}{y^2+y}\,dy = \cos(x)\,dx$$

$$\int \frac{1}{y^2+y}\,dy = \int \cos(x)\,dx$$
$$-\ln(y+1)+\ln(y) = \sin(x)+c_1$$

Raising both side to exponential gives

$$e^{-\ln(y+1)+\ln(y)} = e^{\sin(x)+c_1}$$

Which simplifies to

$$\frac{y}{y+1} = c_2 e^{\sin(x)}$$

Summary

The solution(s) found are the following

$$y = -\frac{c_2 e^{\sin(x)}}{-1+c_2 e^{\sin(x)}} \tag{1}$$

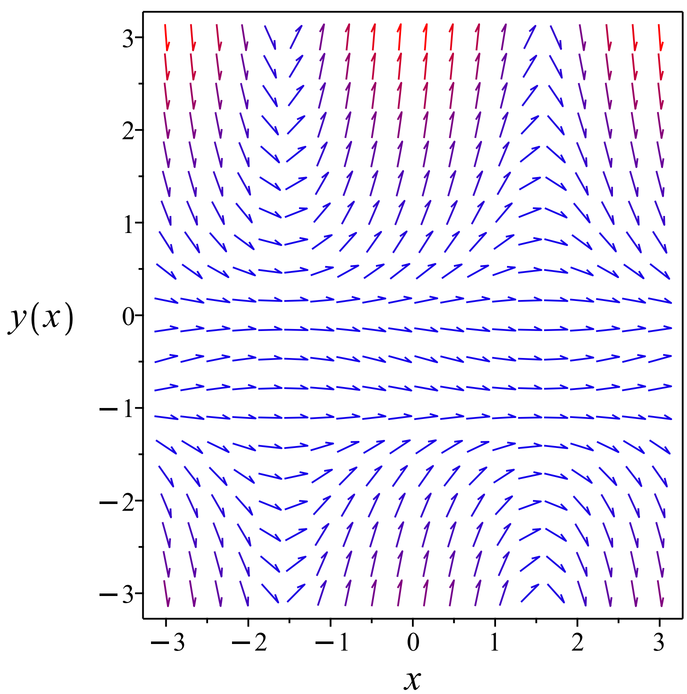

Figure 278: Slope field plot

Verification of solutions

$$y = -\frac{c_2 e^{\sin(x)}}{-1+c_2 e^{\sin(x)}}$$

Verified OK.

6.32.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \cos(x)\, y + \cos(x)\, y^2 \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 223: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= \frac{1}{\cos(x)} \\
\eta(x,y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$
R = y
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\xi} dx \\
&= \int \frac{1}{\frac{1}{\cos(x)}} dx
\end{aligned}
$$

Which results in

$$
S = \sin(x)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \cos(x)\, y + \cos(x)\, y^2
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \cos(x) \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{y(y+1)} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{R(R+1)}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\ln(R+1) + \ln(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\sin(x) = -\ln(y+1) + \ln(y) + c_1
$$

Which simplifies to

$$
\sin(x) = -\ln(y+1) + \ln(y) + c_1
$$

Which gives

$$
y = \frac{1}{e^{-\sin(x)+c_1} - 1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \cos(x)\, y + \cos(x)\, y^2$ 	$R = y$ $S = \sin(x)$	$\frac{dS}{dR} = \frac{1}{R(R+1)}$ 
Summary

The solution(s) found are the following

$$y = \frac{1}{e^{-\sin(x)+c_1} - 1} \tag{1}$$

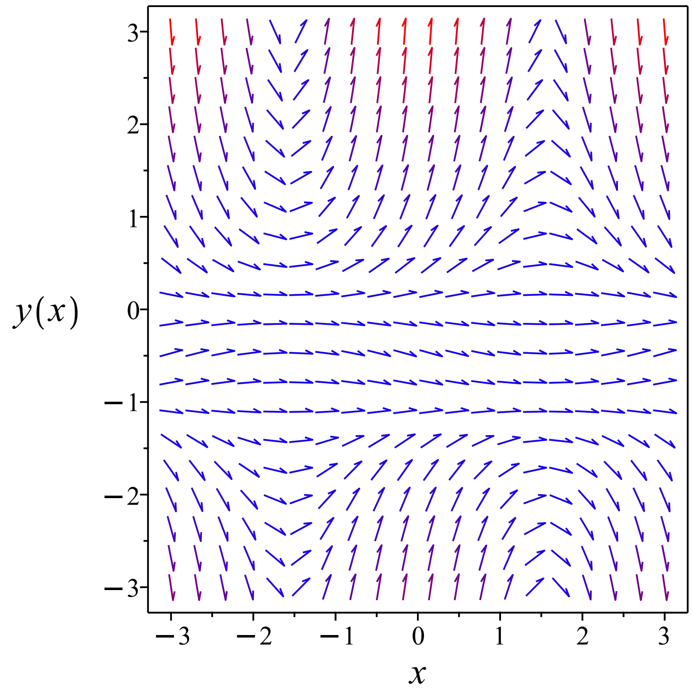

Figure 279: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{1}{\mathrm{e}^{-\sin(x)+c_1} - 1}$$

Verified OK.

6.32.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \cos\left(x\right) y+\cos\left(x\right) y^{2} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \cos\left(x\right) y+\cos\left(x\right) y^{2} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= \cos(x) \\
f_1(x) &= \cos(x) \\
n &= 2
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$
y'\frac{1}{y^2} = \frac{\cos(x)}{y} + \cos(x) \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= \frac{1}{y}
\end{aligned} \tag{5}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = -\frac{1}{y^2}y' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
-w'(x) &= \cos(x)\, w(x) + \cos(x) \\
w' &= -\cos(x)\, w - \cos(x)
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= \cos(x) \\
q(x) &= -\cos(x)
\end{aligned}
$$

Hence the ode is

$$
w'(x) + \cos(x)\, w(x) = -\cos(x)
$$

The integrating factor μ is

$$\mu = e^{\int \cos(x)dx}$$
$$= e^{\sin(x)}$$

The ode becomes

$$\frac{d}{dx}(\mu w) = (\mu)(-\cos(x))$$
$$\frac{d}{dx}\left(e^{\sin(x)}w\right) = \left(e^{\sin(x)}\right)(-\cos(x))$$
$$d\left(e^{\sin(x)}w\right) = \left(-\cos(x)\,e^{\sin(x)}\right)\,dx$$

Integrating gives

$$e^{\sin(x)}w = \int -\cos(x)\,e^{\sin(x)}\,dx$$
$$e^{\sin(x)}w = -e^{\sin(x)} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{\sin(x)}$ results in

$$w(x) = -e^{-\sin(x)}e^{\sin(x)} + c_1e^{-\sin(x)}$$

which simplifies to

$$w(x) = -1 + c_1e^{-\sin(x)}$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$\frac{1}{y} = -1 + c_1e^{-\sin(x)}$$

Or

$$y = \frac{1}{-1 + c_1e^{-\sin(x)}}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{-1 + c_1e^{-\sin(x)}} \tag{1}$$

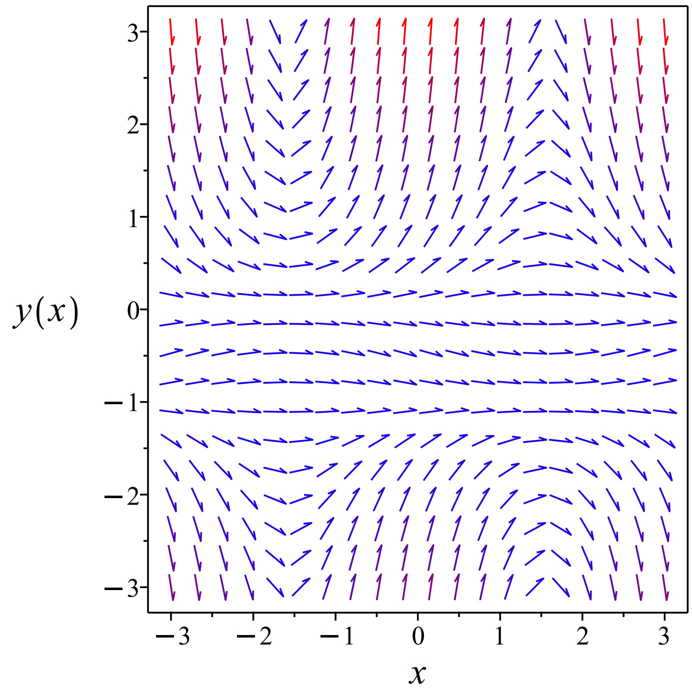

Figure 280: Slope field plot

Verification of solutions

$$y = \frac{1}{-1 + c_1 e^{-\sin(x)}}$$

Verified OK.

6.32.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y^2 + y}\right) \mathrm{d}y = (\cos(x))\,\mathrm{d}x$$
$$(-\cos(x))\,\mathrm{d}x + \left(\frac{1}{y^2 + y}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\cos(x)$$
$$N(x, y) = \frac{1}{y^2 + y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cos(x))\\ &= 0\end{aligned}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\frac{1}{y^2+y}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int -\cos(x)\,\mathrm{d}x$$
$$\phi = -\sin(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y^2+y}$. Therefore equation (4) becomes

$$\frac{1}{y^2+y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y(y+1)}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{y(y+1)}\right)\mathrm{d}y$$
$$f(y) = -\ln(y+1) + \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sin(x) - \ln(y+1) + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sin(x) - \ln(y+1) + \ln(y)$$

The solution becomes

$$y = -\frac{e^{\sin(x)+c_1}}{-1 + e^{\sin(x)+c_1}}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{\sin(x)+c_1}}{-1 + e^{\sin(x)+c_1}} \tag{1}$$

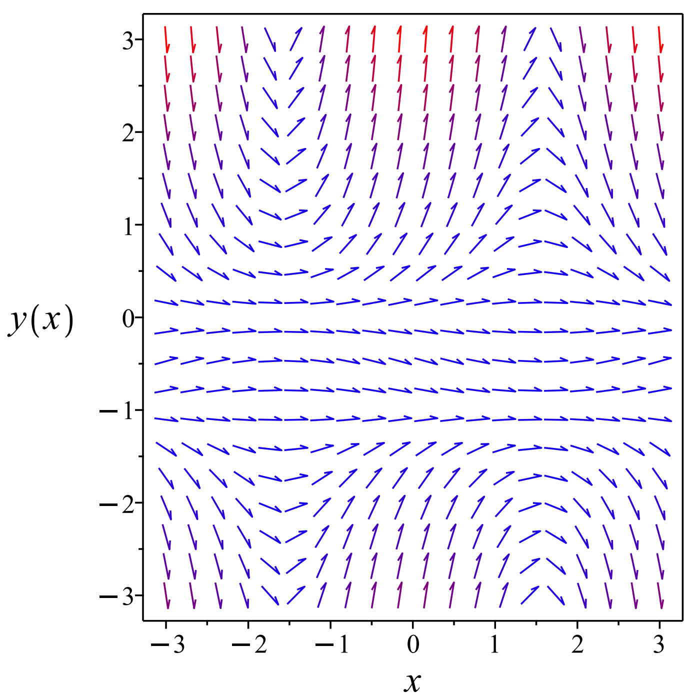

Figure 281: Slope field plot

Verification of solutions

$$y = -\frac{e^{\sin(x)+c_1}}{-1 + e^{\sin(x)+c_1}}$$

Verified OK.

6.32.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \cos(x) y + \cos(x) y^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \cos(x) y + \cos(x) y^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = \cos(x)$ and $f_2(x) = \cos(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\cos(x) u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\sin(x) \\ f_1 f_2 &= \cos(x)^2 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\cos(x) u''(x) - \left(\cos(x)^2 - \sin(x)\right) u'(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + c_2 \mathrm{e}^{\sin(x)}$$

The above shows that

$$u'(x) = c_2 \cos(x) \mathrm{e}^{\sin(x)}$$

Using the above in (1) gives the solution

$$y = -\frac{c_2 \mathrm{e}^{\sin(x)}}{c_1 + c_2 \mathrm{e}^{\sin(x)}}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\mathrm{e}^{\sin(x)}}{c_3 + \mathrm{e}^{\sin(x)}}$$

Summary

The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{\sin(x)}}{c_3 + \mathrm{e}^{\sin(x)}} \tag{1}$$

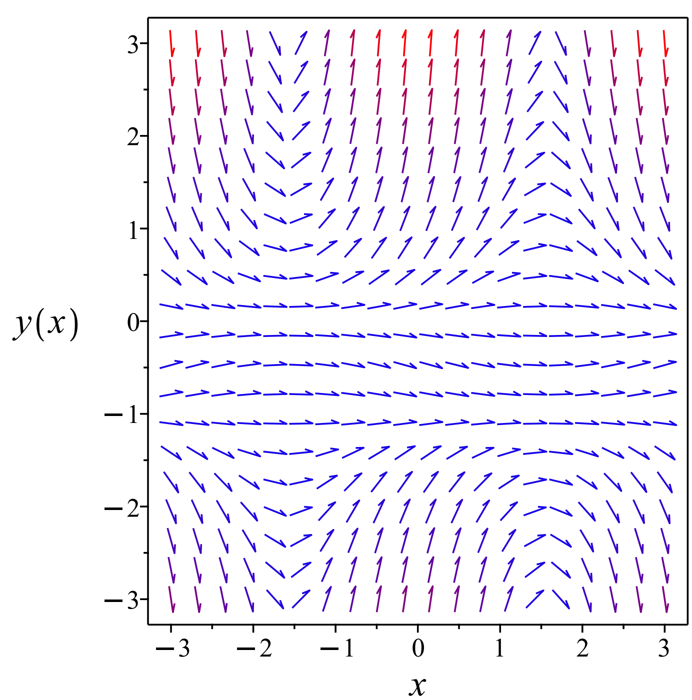

Figure 282: Slope field plot

Verification of solutions

$$y = -\frac{e^{\sin(x)}}{c_3 + e^{\sin(x)}}$$

Verified OK.

6.32.6 Maple step by step solution

Let's solve

$y' - y\cos(x) - y^2\cos(x) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y(y+1)} = \cos(x)$

- Integrate both sides with respect to x

  $\int \frac{y'}{y(y+1)}dx = \int \cos(x)\,dx + c_1$

- Evaluate integral

  $-\ln(y+1) + \ln(y) = \sin(x) + c_1$

- Solve for y

  $y = -\frac{e^{\sin(x)+c_1}}{-1+e^{\sin(x)+c_1}}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 6. Linear equations of the first order. The Bernoulli equation. Exercises page 54
Problem number: 166.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

```
[`y=_G(x,y')`]
```

$$\boxed{y' - \tan(y) - \frac{e^{x}}{\cos(y)} = 0}$$

6.33.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\cos(y))\,\mathrm{d}y &= (\tan(y)\cos(y) + \mathrm{e}^x)\,\mathrm{d}x \\ (-\tan(y)\cos(y) - \mathrm{e}^x)\,\mathrm{d}x + (\cos(y))\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -\tan(y)\cos(y) - \mathrm{e}^x \\ N(x, y) &= \cos(y)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\tan(y)\cos(y) - \mathrm{e}^x) \\ &= -\cos(y)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(y)) \\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \sec(y)\left(\left(-\left(\tan(y)^2 + 1\right)\cos(y) + \tan(y)\sin(y)\right) - (0)\right) \\
&= -1
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -1 \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-x} \\
&= \mathrm{e}^{-x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-x}(-\tan(y)\cos(y) - \mathrm{e}^{x}) \\
&= -\sin(y)\,\mathrm{e}^{-x} - 1
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-x}(\cos(y)) \\
&= \cos(y)\,\mathrm{e}^{-x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\sin(y)\,\mathrm{e}^{-x} - 1\right) + \left(\cos(y)\,\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \overline{M} \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int -\sin(y)\,\mathrm{e}^{-x} - 1 \,\mathrm{d}x$$

$$\phi = -x + \sin(y)\,\mathrm{e}^{-x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \cos(y)\,\mathrm{e}^{-x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \cos(y)\,\mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\cos(y)\,\mathrm{e}^{-x} = \cos(y)\,\mathrm{e}^{-x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x + \sin(y)\,\mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x + \sin(y)\,\mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$-x + \sin(y)\,\mathrm{e}^{-x} = c_1 \tag{1}$$

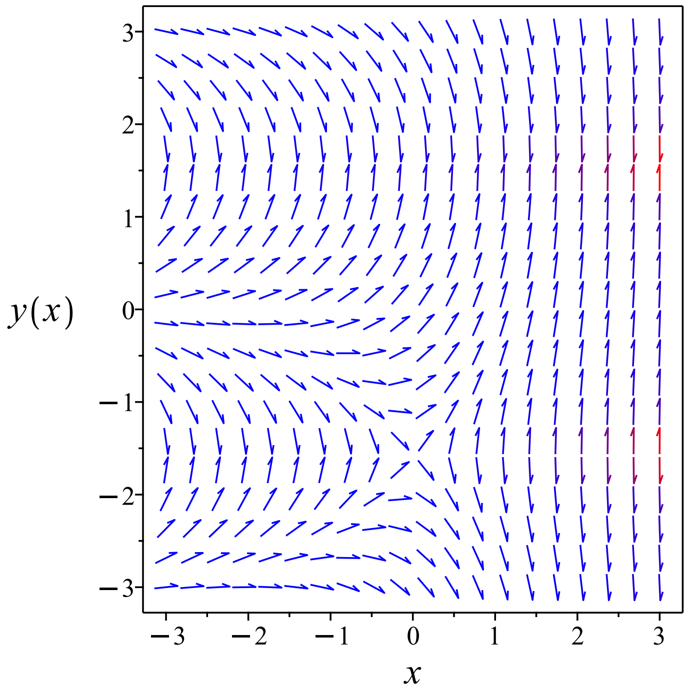

Figure 283: Slope field plot

<u>Verification of solutions</u>

$$-x + \sin(y)\,\mathrm{e}^{-x} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

`[[_1st_order, `_with_symmetry_[F(x),G(y)]`]]`

$$\boxed{\cos(y)\, y' + \sin(y) = x + 1}$$

6.35.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\cos(y))\,\mathrm{d}y &= (-\sin(y) + x + 1)\,\mathrm{d}x\\ (\sin(y) - x - 1)\,\mathrm{d}x + (\cos(y))\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= \sin(y) - x - 1\\ N(x, y) &= \cos(y)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\sin(y) - x - 1)\\ &= \cos(y)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(y))\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \sec(y)\,((\cos(y)) - (0))\\ &= 1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x} \\ &= e^{\int 1\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{x} \\ &= \mathrm{e}^{x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{x}(\sin(y) - x - 1) \\ &= (\sin(y) - x - 1)\,\mathrm{e}^{x}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{x}(\cos(y)) \\ &= \mathrm{e}^{x}\cos(y)\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ ((\sin(y) - x - 1)\,\mathrm{e}^{x}) + (\mathrm{e}^{x}\cos(y))\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\ \int \frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int (\sin(y) - x - 1)\,\mathrm{e}^{x}\,\mathrm{d}x \\ \phi &= (\sin(y) - x)\,\mathrm{e}^{x} + f(y)\end{aligned} \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = e^x \cos(y) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = e^x \cos(y)$. Therefore equation (4) becomes

$$e^x \cos(y) = e^x \cos(y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (\sin(y) - x) e^x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (\sin(y) - x) e^x$$

<u>Summary</u>

The solution(s) found are the following

$$(\sin(y) - x) e^x = c_1 \tag{1}$$

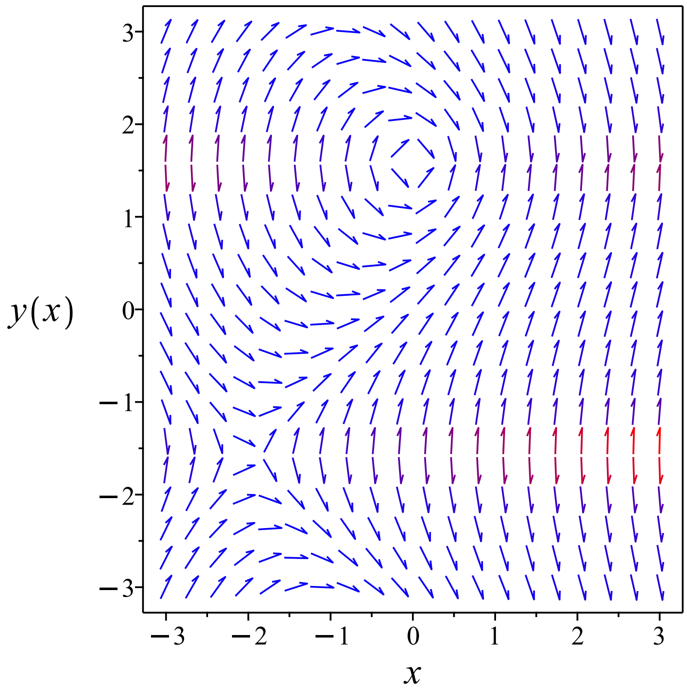

Figure 284: Slope field plot

Verification of solutions

$$(\sin(y) - x) e^{x} = c_1$$

7.1.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$x\left(2x^2+u(x)^2\,x^2\right)+u(x)\,x\left(x^2+2u(x)^2\,x^2\right)\left(u'(x)\,x+u(x)\right)=0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= -\frac{2(u^4+u^2+1)}{x\,(2u^3+u)}
\end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = \frac{u^4+u^2+1}{2u^3+u}$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{\frac{u^4+u^2+1}{2u^3+u}}\,du &= -\frac{2}{x}\,dx \\
\int \frac{1}{\frac{u^4+u^2+1}{2u^3+u}}\,du &= \int -\frac{2}{x}\,dx \\
\frac{\ln\left(u^4+u^2+1\right)}{2} &= -2\ln\left(x\right)+c_2
\end{aligned}
$$

Raising both side to exponential gives

$$
\sqrt{u^4+u^2+1} = \mathrm{e}^{-2\ln(x)+c_2}
$$

Which simplifies to

$$
\sqrt{u^4+u^2+1} = \frac{c_3}{x^2}
$$

Which simplifies to

$$
\sqrt{u\left(x\right)^4+u\left(x\right)^2+1} = \frac{c_3\mathrm{e}^{c_2}}{x^2}
$$

The solution is

$$
\sqrt{u\left(x\right)^4+u\left(x\right)^2+1} = \frac{c_3\mathrm{e}^{c_2}}{x^2}
$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$
\begin{aligned}
\sqrt{\frac{y^4}{x^4}+\frac{y^2}{x^2}+1} &= \frac{c_3\mathrm{e}^{c_2}}{x^2} \\
\sqrt{\frac{y^4+x^2y^2+x^4}{x^4}} &= \frac{c_3\mathrm{e}^{c_2}}{x^2}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\sqrt{\frac{y^4+x^2y^2+x^4}{x^4}} = \frac{c_3\mathrm{e}^{c_2}}{x^2} \tag{1}
$$

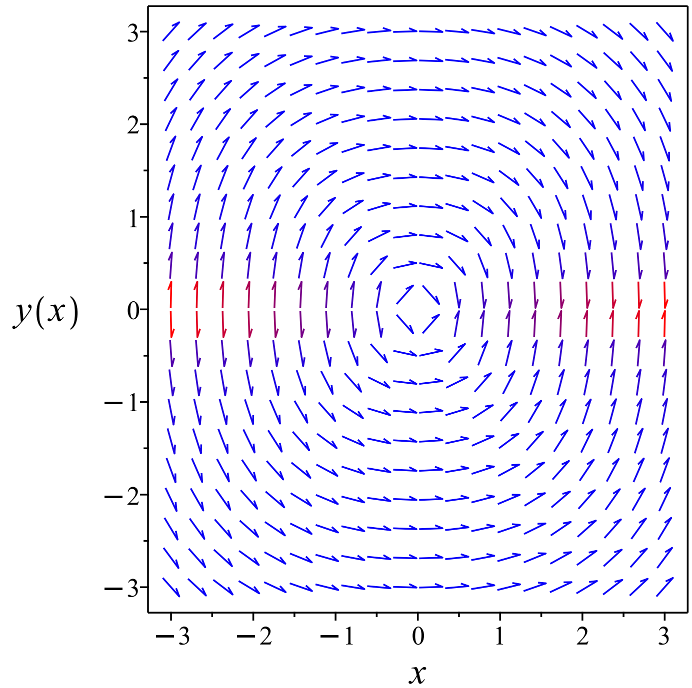

Figure 285: Slope field plot

Verification of solutions

$$\sqrt{\frac{y^4+x^2y^2+x^4}{x^4}}=\frac{c_3\mathrm{e}^{c_2}}{x^2}$$

Verified OK.

7.1.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{x(2x^2+y^2)}{y\,(x^2+2y^2)}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 - \frac{x(2x^2+y^2)(b_3-a_2)}{y(x^2+2y^2)} - \frac{x^2(2x^2+y^2)^2 a_3}{y^2(x^2+2y^2)^2} \\ & - \left(-\frac{2x^2+y^2}{y(x^2+2y^2)} - \frac{4x^2}{y(x^2+2y^2)} + \frac{2x^2(2x^2+y^2)}{y(x^2+2y^2)^2}\right)(xa_2+ya_3+a_1) \\ & - \left(-\frac{2x}{x^2+2y^2} + \frac{x(2x^2+y^2)}{y^2(x^2+2y^2)} + \frac{4x(2x^2+y^2)}{(x^2+2y^2)^2}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{4x^6a_3+2x^6b_2-4x^5ya_2+4x^5yb_3+2x^4y^2a_3+10x^4y^2b_2-16x^3y^3a_2+16x^3y^3b_3-10x^2y^4a_3-2x^2y^4b_2-}{y^2(x^2+2y}$$
$$=0$$

Setting the numerator to zero gives

$$\begin{aligned} & -4x^6a_3-2x^6b_2+4x^5ya_2-4x^5yb_3-2x^4y^2a_3-10x^4y^2b_2+16x^3y^3a_2 \\ & -16x^3y^3b_3+10x^2y^4a_3+2x^2y^4b_2+4x\,y^5a_2-4x\,y^5b_3+2y^6a_3+4y^6b_2 \\ & -2x^5b_1+2x^4ya_1-11x^3y^2b_1+11x^2y^3a_1-2x\,y^4b_1+2y^5a_1=0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & 4a_2v_1^5v_2+16a_2v_1^3v_2^3+4a_2v_1v_2^5-4a_3v_1^6-2a_3v_1^4v_2^2+10a_3v_1^2v_2^4+2a_3v_2^6 \\ & -2b_2v_1^6-10b_2v_1^4v_2^2+2b_2v_1^2v_2^4+4b_2v_2^6-4b_3v_1^5v_2-16b_3v_1^3v_2^3-4b_3v_1v_2^5 \\ & +2a_1v_1^4v_2+11a_1v_1^2v_2^3+2a_1v_2^5-2b_1v_1^5-11b_1v_1^3v_2^2-2b_1v_1v_2^4=0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(-4a_3 - 2b_2)\, v_1^6 + (4a_2 - 4b_3)\, v_1^5 v_2 - 2b_1 v_1^5 + (-2a_3 - 10b_2)\, v_1^4 v_2^2 \\
&+ 2a_1 v_1^4 v_2 + (16a_2 - 16b_3)\, v_1^3 v_2^3 - 11 b_1 v_1^3 v_2^2 + (10a_3 + 2b_2)\, v_1^2 v_2^4 \\
&+ 11 a_1 v_1^2 v_2^3 + (4a_2 - 4b_3)\, v_1 v_2^5 - 2b_1 v_1 v_2^4 + (2a_3 + 4b_2)\, v_2^6 + 2a_1 v_2^5 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
2a_1 &= 0 \\
11a_1 &= 0 \\
-11b_1 &= 0 \\
-2b_1 &= 0 \\
4a_2 - 4b_3 &= 0 \\
16a_2 - 16b_3 &= 0 \\
-4a_3 - 2b_2 &= 0 \\
-2a_3 - 10b_2 &= 0 \\
2a_3 + 4b_2 &= 0 \\
10a_3 + 2b_2 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{x(2x^2+y^2)}{y\,(x^2+2y^2)}\right)(x) \\
&= \frac{2x^4+2y^2x^2+2y^4}{x^2y+2y^3} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{2x^4+2y^2x^2+2y^4}{x^2y+2y^3}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(x^4+y^2x^2+y^4)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{x(2x^2+y^2)}{y\,(x^2+2y^2)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{x(2x^2+y^2)}{2\left(x^2+xy+y^2\right)\left(x^2-xy+y^2\right)} \\
S_y &= \frac{y(x^2+2y^2)}{2\left(x^2+xy+y^2\right)\left(x^2-xy+y^2\right)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\ln\left(yx+y^2+x^2\right)}{4} + \frac{\ln\left(y^2-yx+x^2\right)}{4} = c_1
$$

Which simplifies to

$$
\frac{\ln\left(yx+y^2+x^2\right)}{4} + \frac{\ln\left(y^2-yx+x^2\right)}{4} = c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x(2x^2+y^2)}{y(x^2+2y^2)}$ 	$R = x$ $S = \frac{\ln(x^2+xy+y^2)}{4} +$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\frac{\ln(yx + y^2 + x^2)}{4} + \frac{\ln(y^2 - yx + x^2)}{4} = c_1 \tag{1}$$

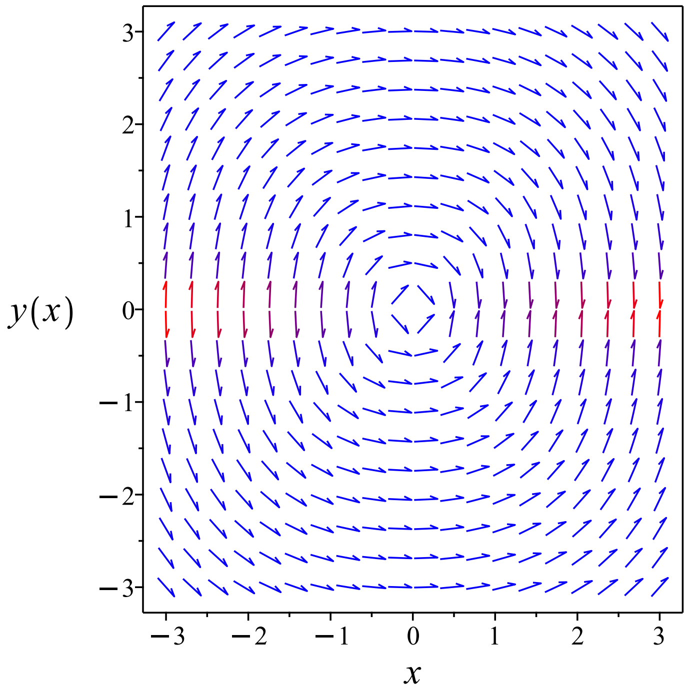

Figure 286: Slope field plot

Verification of solutions

$$\frac{\ln\left(yx+y^2+x^2\right)}{4}+\frac{\ln\left(y^2-yx+x^2\right)}{4}=c_1$$

Verified OK.

7.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(y\left(x^2 + 2y^2\right)\right) \mathrm{d}y = \left(-x\left(2x^2 + y^2\right)\right) \mathrm{d}x$$
$$\left(x\left(2x^2 + y^2\right)\right) \mathrm{d}x + \left(y\left(x^2 + 2y^2\right)\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = x\left(2x^2 + y^2\right)$$
$$N(x, y) = y\left(x^2 + 2y^2\right)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x\left(2x^2 + y^2\right)\right) \\ &= 2xy\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(y\left(x^2 + 2y^2\right)\right) \\ &= 2xy\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int x(2x^2 + y^2) \, \mathrm{d}x$$

$$\phi = \frac{(2x^2 + y^2)^2}{8} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{(2x^2 + y^2)\, y}{2} + f'(y) \tag{4}$$

$$= x^2 y + \frac{1}{2} y^3 + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y(x^2 + 2y^2)$. Therefore equation (4) becomes

$$y(x^2 + 2y^2) = x^2 y + \frac{1}{2} y^3 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{3y^3}{2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(\frac{3y^3}{2}\right) \mathrm{d}y$$

$$f(y) = \frac{3y^4}{8} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(2x^2+y^2)^2}{8} + \frac{3y^4}{8} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(2x^2+y^2)^2}{8} + \frac{3y^4}{8}$$

Summary
The solution(s) found are the following

$$\frac{(2x^2+y^2)^2}{8} + \frac{3y^4}{8} = c_1 \tag{1}$$

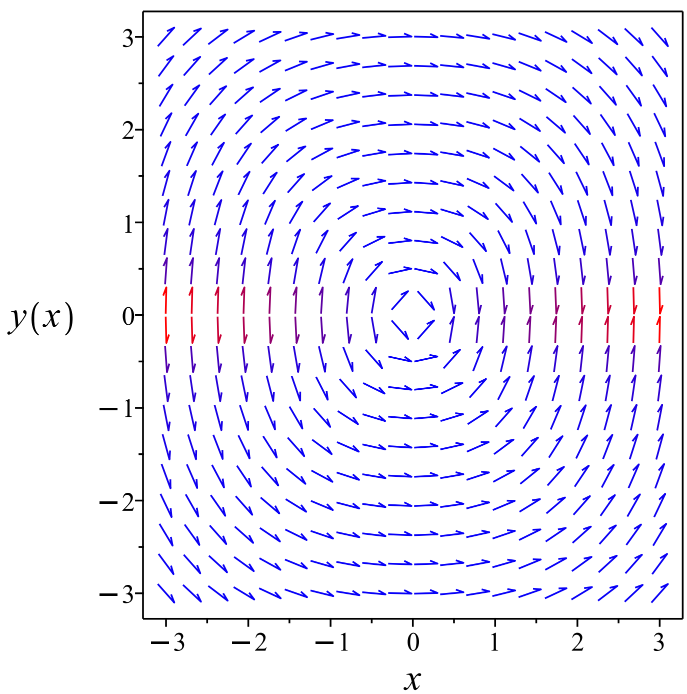

Figure 287: Slope field plot

Verification of solutions

$$\frac{(2x^2+y^2)^2}{8} + \frac{3y^4}{8} = c_1$$

Verified OK.

7.1.4 Maple step by step solution

Let's solve

$x(2x^2 + y^2) + y(x^2 + 2y^2)\, y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  - Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

  - Evaluate derivatives

    $2xy = 2xy$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\,, N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int x(2x^2 + y^2)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = \frac{(2x^2+y^2)^2}{8} + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

  $y(x^2 + 2y^2) = \frac{(2x^2+y^2)y}{2} + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = y(x^2 + 2y^2) - \frac{(2x^2+y^2)y}{2}$

- Solve for $f_1(y)$

  $f_1(y) = \frac{3y^4}{8}$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$$F(x,y) = \frac{(2x^2+y^2)^2}{8} + \frac{3y^4}{8}$$

- Substitute $F(x,y)$ into the solution of the ODE

$$\frac{(2x^2+y^2)^2}{8} + \frac{3y^4}{8} = c_1$$

- Solve for y

$$\left\{y = -\frac{\sqrt{-2x^2-2\sqrt{-3x^4+8c_1}}}{2}, y = \frac{\sqrt{-2x^2-2\sqrt{-3x^4+8c_1}}}{2}, y = -\frac{\sqrt{-2x^2+2\sqrt{-3x^4+8c_1}}}{2}, y = \frac{\sqrt{-2x^2+2\sqrt{-3x^4+8c_1}}}{2}\right.$$

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact, _rational]`

$$\boxed{6y^2x + (6x^2y + 4y^3)\, y' = -3x^2}$$

7.2.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(6x^2y+4y^3\right)\mathrm{d}y &= \left(-6y^2x-3x^2\right)\mathrm{d}x\\ \left(6y^2x+3x^2\right)\mathrm{d}x + \left(6x^2y+4y^3\right)\mathrm{d}y &= 0 \qquad (2\text{A})\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 6y^2x+3x^2\\ N(x,y) &= 6x^2y+4y^3\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(6y^2x+3x^2\right)\\ &= 12xy\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(6x^2y+4y^3\right)\\ &= 12xy\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 6y^2x + 3x^2 \, \mathrm{d}x$$
$$\phi = x^2(3y^2 + x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 6x^2y + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 6x^2y + 4y^3$. Therefore equation (4) becomes

$$6x^2y + 4y^3 = 6x^2y + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 4y^3$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (4y^3) \, \mathrm{d}y$$
$$f(y) = y^4 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x^2(3y^2 + x) + y^4 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x^2(3y^2 + x) + y^4$$

Summary

The solution(s) found are the following

$$x^2(3y^2+x)+y^4=c_1 \tag{1}$$

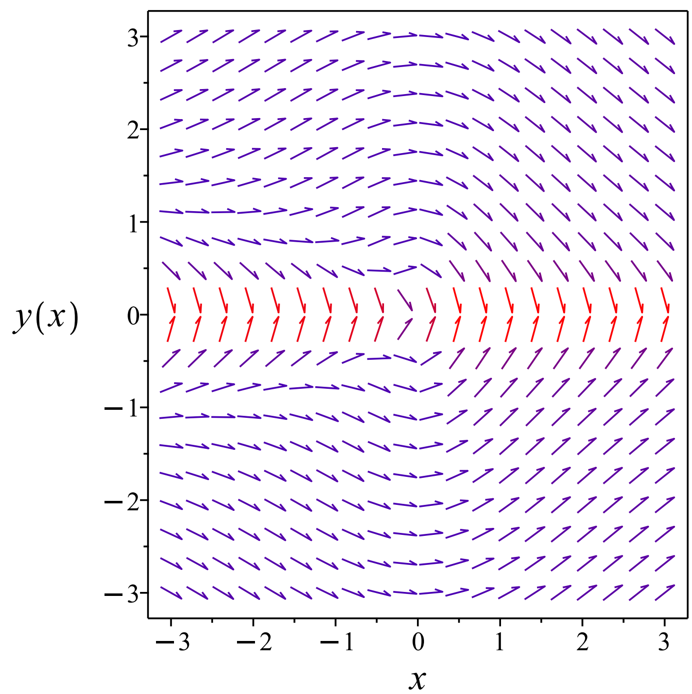

Figure 288: Slope field plot

Verification of solutions

$$x^2(3y^2+x)+y^4=c_1$$

Verified OK.

7.2.2 Maple step by step solution

Let's solve

$6y^2x+(6x^2y+4y^3)\,y'=-3x^2$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

$F'(x, y) = 0$

- Compute derivative of lhs

  $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

- Evaluate derivatives

  $12xy = 12xy$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (6y^2x + 3x^2)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = 3y^2x^2 + x^3 + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

  $6x^2y + 4y^3 = 6x^2y + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 4y^3$

- Solve for $f_1(y)$

  $f_1(y) = y^4$

- Substitute $f_1(y)$ into equation for $F(x, y)$

  $F(x, y) = 3y^2x^2 + y^4 + x^3$

- Substitute $F(x, y)$ into the solution of the ODE

  $3y^2x^2 + y^4 + x^3 = c_1$

- Solve for y

  $\left\{y = -\frac{\sqrt{-6x^2-2\sqrt{9x^4-4x^3+4c_1}}}{2}, y = \frac{\sqrt{-6x^2-2\sqrt{9x^4-4x^3+4c_1}}}{2}, y = -\frac{\sqrt{-6x^2+2\sqrt{9x^4-4x^3+4c_1}}}{2}, y = \frac{\sqrt{-6x^2+2\sqrt{}}}{}\right.$

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact]`

$$\boxed{\frac{x}{\sqrt{x^2+y^2}}+\frac{1}{y}+\left(\frac{y}{\sqrt{x^2+y^2}}+\frac{1}{y}-\frac{x}{y^2}\right)y'=-\frac{1}{x}}$$

7.3.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{y}{\sqrt{x^2+y^2}} + \frac{1}{y} - \frac{x}{y^2}\right)\mathrm{d}y = \left(-\frac{x}{\sqrt{x^2+y^2}} - \frac{1}{x} - \frac{1}{y}\right)\mathrm{d}x$$
$$\left(\frac{x}{\sqrt{x^2+y^2}} + \frac{1}{x} + \frac{1}{y}\right)\mathrm{d}x + \left(\frac{y}{\sqrt{x^2+y^2}} + \frac{1}{y} - \frac{x}{y^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{x}{\sqrt{x^2+y^2}} + \frac{1}{x} + \frac{1}{y}$$
$$N(x,y) = \frac{y}{\sqrt{x^2+y^2}} + \frac{1}{y} - \frac{x}{y^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{x}{\sqrt{x^2+y^2}} + \frac{1}{x} + \frac{1}{y}\right)\\ &= -\frac{xy}{(x^2+y^2)^{\frac{3}{2}}} - \frac{1}{y^2}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{y}{\sqrt{x^2+y^2}}+\frac{1}{y}-\frac{x}{y^2}\right)\\ &= -\frac{xy}{(x^2+y^2)^{\frac{3}{2}}}-\frac{1}{y^2}\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{x}{\sqrt{x^2+y^2}}+\frac{1}{x}+\frac{1}{y}\,\mathrm{d}x\end{aligned}$$

$$\phi = \frac{\sqrt{x^2+y^2}\,y+y\ln(x)+x}{y}+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{\frac{y^2}{\sqrt{x^2+y^2}}+\sqrt{x^2+y^2}+\ln(x)}{y}-\frac{\sqrt{x^2+y^2}\,y+y\ln(x)+x}{y^2}+f'(y) \tag{4}$$

$$= \frac{y^3-x\sqrt{x^2+y^2}}{y^2\sqrt{x^2+y^2}}+f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=\frac{y}{\sqrt{x^2+y^2}}+\frac{1}{y}-\frac{x}{y^2}$. Therefore equation (4) becomes

$$\frac{y}{\sqrt{x^2+y^2}}+\frac{1}{y}-\frac{x}{y^2} = \frac{y^3-x\sqrt{x^2+y^2}}{y^2\sqrt{x^2+y^2}}+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{y}\right) \mathrm{d}y$$
$$f(y) = \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\sqrt{x^2+y^2}\,y + y\ln(x) + x}{y} + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\sqrt{x^2+y^2}\,y + y\ln(x) + x}{y} + \ln(y)$$

Summary

The solution(s) found are the following

$$\frac{y\sqrt{x^2+y^2} + y\ln(x) + x}{y} + \ln(y) = c_1 \tag{1}$$

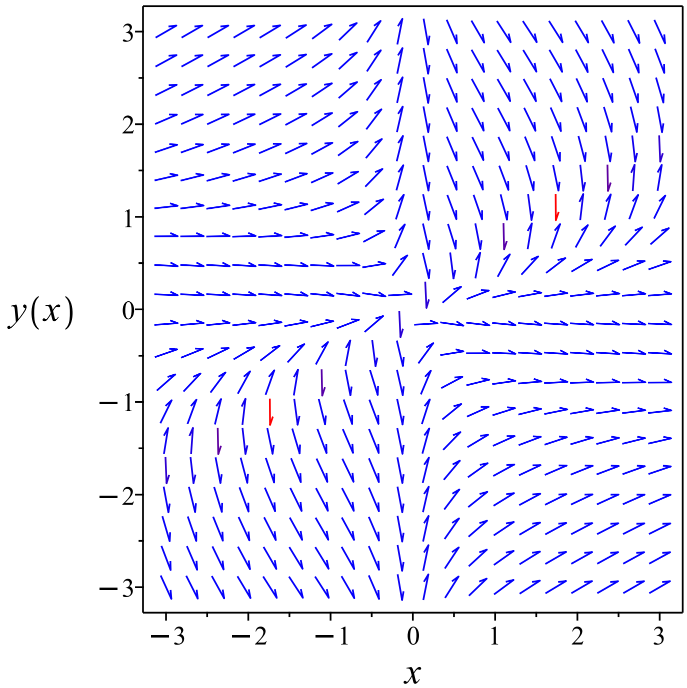

Figure 289: Slope field plot

Verification of solutions

$$\frac{y\sqrt{x^2+y^2}+y\ln(x)+x}{y}+\ln(y)=c_1$$

Verified OK.

7.3.2 Maple step by step solution

Let's solve

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact]`

$$\boxed{3x^2\tan(y) - \frac{2y^3}{x^3} + \left(x^3\sec(y)^2 + 4y^3 + \frac{3y^2}{x^2}\right)y' = 0}$$

7.4.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(x^3 \sec(y)^2 + 4y^3 + \frac{3y^2}{x^2}\right)\mathrm{d}y = \left(-3x^2 \tan(y) + \frac{2y^3}{x^3}\right)\mathrm{d}x$$
$$\left(3x^2 \tan(y) - \frac{2y^3}{x^3}\right)\mathrm{d}x + \left(x^3 \sec(y)^2 + 4y^3 + \frac{3y^2}{x^2}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = 3x^2 \tan(y) - \frac{2y^3}{x^3}$$
$$N(x,y) = x^3 \sec(y)^2 + 4y^3 + \frac{3y^2}{x^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(3x^2 \tan(y) - \frac{2y^3}{x^3}\right)\\ &= \frac{3x^5 \sec(y)^2 - 6y^2}{x^3}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x^3 \sec(y)^2 + 4y^3 + \frac{3y^2}{x^2}\right) \\ &= 3x^2 \sec(y)^2 - \frac{6y^2}{x^3}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\ \int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int 3x^2 \tan(y) - \frac{2y^3}{x^3} \,\mathrm{d}x\end{aligned}$$

$$\phi = \tan(y)\, x^3 + \frac{y^3}{x^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \left(\tan(y)^2 + 1\right) x^3 + \frac{3y^2}{x^2} + f'(y) \tag{4}$$

$$= \frac{x^5 \sec(y)^2 + 3y^2}{x^2} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^3 \sec(y)^2 + 4y^3 + \frac{3y^2}{x^2}$. Therefore equation (4) becomes

$$x^3 \sec(y)^2 + 4y^3 + \frac{3y^2}{x^2} = \frac{x^5 \sec(y)^2 + 3y^2}{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 4y^3$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (4y^3)\,\mathrm{d}y$$

$$f(y) = y^4 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \tan(y)\,x^3 + \frac{y^3}{x^2} + y^4 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \tan(y)\,x^3 + \frac{y^3}{x^2} + y^4$$

Summary

The solution(s) found are the following

$$\tan(y)\,x^3 + \frac{y^3}{x^2} + y^4 = c_1 \tag{1}$$

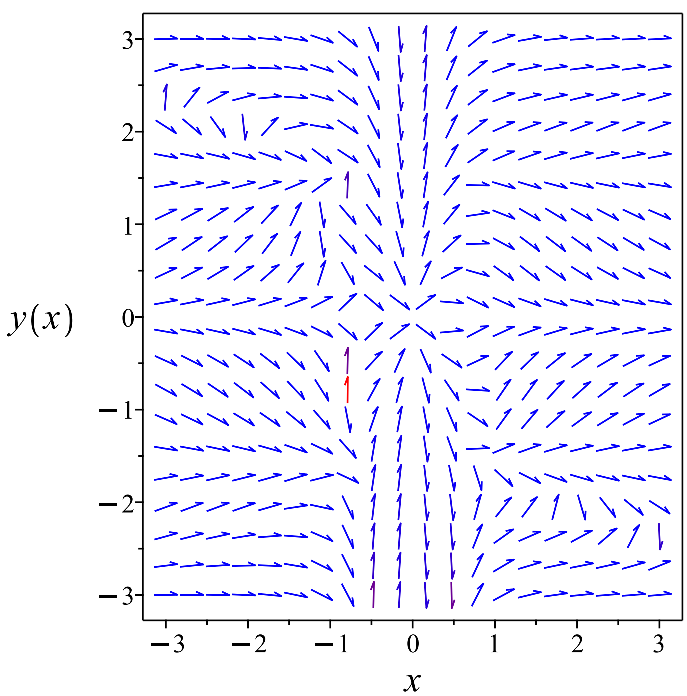

Figure 290: Slope field plot

Verification of solutions

$$\tan(y)\,x^3 + \frac{y^3}{x^2} + y^4 = c_1$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 7, Total differential equations. The integrating factor. Exercises page 61
Problem number: 179.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _exact, _rational]
```

$$\boxed{\frac{x^2+y^2}{x^2y}-\frac{(x^2+y^2)\,y'}{y^2x}=-2x}$$

7.5.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$\frac{x^2+u(x)^2\,x^2}{x^3u\,(x)}-\frac{\left(x^2+u(x)^2\,x^2\right)\left(u'(x)\,x+u(x)\right)}{u\,(x)^2\,x^3}=-2x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u)\\ &= f(x)g(u)\\ &= \frac{2u^2x}{u^2+1} \end{aligned}$$

Where $f(x) = 2x$ and $g(u) = \frac{u^2}{u^2+1}$. Integrating both sides gives

$$\frac{1}{\frac{u^2}{u^2+1}}\,du = 2x\,dx$$

$$\int \frac{1}{\frac{u^2}{u^2+1}}\,du = \int 2x\,dx$$

$$u - \frac{1}{u} = x^2 + c_2$$

The solution is

$$u(x) - \frac{1}{u(x)} - x^2 - c_2 = 0$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y}{x} - \frac{x}{y} - x^2 - c_2 = 0$$

$$\frac{y}{x} - \frac{x}{y} - x^2 - c_2 = 0$$

Summary

The solution(s) found are the following

$$\frac{y}{x} - \frac{x}{y} - x^2 - c_2 = 0 \tag{1}$$

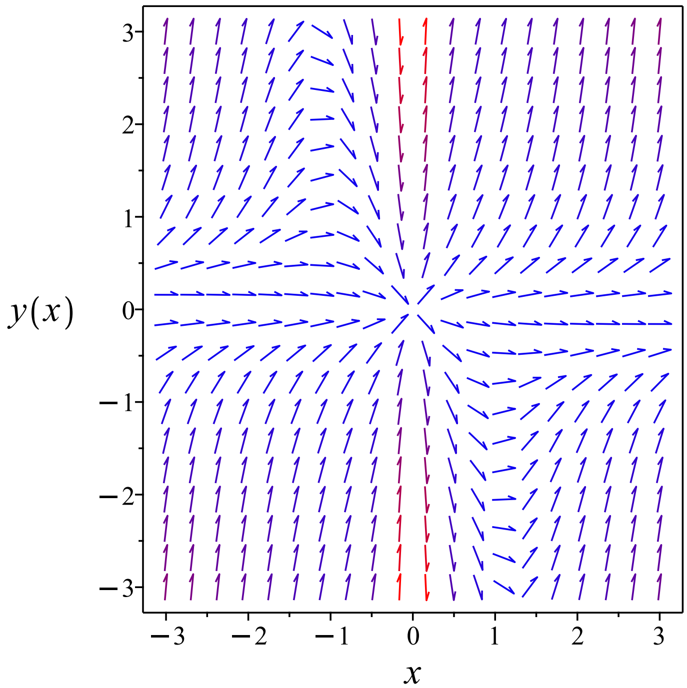

Figure 291: Slope field plot

Verification of solutions

$$\frac{y}{x}-\frac{x}{y}-x^2-c_2=0$$

Verified OK.

7.5.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{x^2+y^2}{y^2 x}\right) \mathrm{d}y &= \left(-2x - \frac{x^2+y^2}{x^2 y}\right) \mathrm{d}x \\
\left(2x + \frac{x^2+y^2}{x^2 y}\right) \mathrm{d}x + \left(-\frac{x^2+y^2}{y^2 x}\right) \mathrm{d}y &= 0 \qquad (2\mathrm{A})
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x,y) &= 2x + \frac{x^2+y^2}{x^2 y} \\
N(x,y) &= -\frac{x^2+y^2}{y^2 x}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2x + \frac{x^2+y^2}{x^2 y}\right) \\
&= \frac{-x^2+y^2}{y^2 x^2}
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{x^2+y^2}{y^2 x}\right) \\
&= \frac{-x^2+y^2}{y^2 x^2}
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1) \\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int 2x + \frac{x^2+y^2}{x^2 y} \, \mathrm{d}x \\
\phi &= \frac{x^2-y^2}{yx} + x^2 + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\begin{aligned}
\frac{\partial \phi}{\partial y} &= -\frac{2}{x} - \frac{x^2-y^2}{y^2 x} + f'(y) \qquad (4) \\
&= \frac{-x^2-y^2}{y^2 x} + f'(y)
\end{aligned}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{x^2+y^2}{y^2 x}$. Therefore equation (4) becomes

$$
-\frac{x^2+y^2}{y^2 x} = \frac{-x^2-y^2}{y^2 x} + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^2 - y^2}{yx} + x^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^2 - y^2}{yx} + x^2$$

Summary

The solution(s) found are the following

$$\frac{x^2 - y^2}{yx} + x^2 = c_1 \tag{1}$$

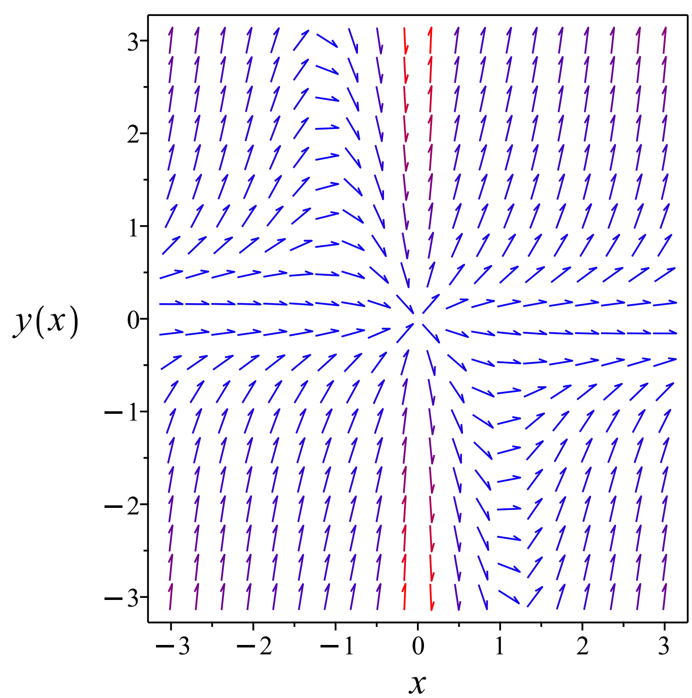

Figure 292: Slope field plot

Verification of solutions

$$\frac{x^2 - y^2}{yx} + x^2 = c_1$$

Verified OK.

7.5.3 Maple step by step solution

Let's solve

$\frac{x^2+y^2}{x^2 y} - \frac{(x^2+y^2)y'}{y^2 x} = -2x$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  - Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

  - Evaluate derivatives

    $\frac{2}{x^2} - \frac{x^2+y^2}{x^2 y^2} = -\frac{2}{y^2} + \frac{x^2+y^2}{x^2 y^2}$

  - Simplify

    $\frac{-x^2+y^2}{y^2 x^2} = \frac{-x^2+y^2}{y^2 x^2}$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int \left(2x + \frac{x^2+y^2}{x^2 y}\right) dx + f_1(y)$

- Evaluate integral

  $F(x, y) = \frac{x - \frac{y^2}{x}}{y} + x^2 + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $-\frac{x^2+y^2}{y^2x} = -\frac{x-\frac{y^2}{x}}{y^2} - \frac{2}{x} + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = -\frac{x^2+y^2}{y^2x} + \frac{x-\frac{y^2}{x}}{y^2} + \frac{2}{x}$

- Solve for $f_1(y)$

  $f_1(y) = 0$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = \frac{x-\frac{y^2}{x}}{y} + x^2$

- Substitute $F(x,y)$ into the solution of the ODE

  $\frac{x-\frac{y^2}{x}}{y} + x^2 = c_1$

- Solve for y

  $\left\{y = \left(\frac{x^2}{2} - \frac{c_1}{2} - \frac{\sqrt{x^4-2c_1x^2+c_1^2+4}}{2}\right)x, y = \left(\frac{x^2}{2} - \frac{c_1}{2} + \frac{\sqrt{x^4-2c_1x^2+c_1^2+4}}{2}\right)x\right\}$

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact]`

$$\boxed{\frac{\sin(2x)}{y}+\left(y-\frac{\sin(x)^2}{y^2}\right)y'=-x}$$

7.6.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(y - \frac{\sin(x)^2}{y^2}\right) \mathrm{d}y = \left(-\frac{\sin(2x)}{y} - x\right) \mathrm{d}x$$

$$\left(\frac{\sin(2x)}{y} + x\right) \mathrm{d}x + \left(y - \frac{\sin(x)^2}{y^2}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = \frac{\sin(2x)}{y} + x$$
$$N(x, y) = y - \frac{\sin(x)^2}{y^2}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{\sin(2x)}{y} + x\right) \\ &= -\frac{\sin(2x)}{y^2}\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(y - \frac{\sin(x)^2}{y^2}\right) \\
&= -\frac{\sin(2x)}{y^2}
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int \frac{\sin(2x)}{y} + x \,\mathrm{d}x
\end{aligned}$$

$$\phi = \frac{x^2}{2} - \frac{\cos(2x)}{2y} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{\cos(2x)}{2y^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y - \frac{\sin(x)^2}{y^2}$. Therefore equation (4) becomes

$$y - \frac{\sin(x)^2}{y^2} = \frac{\cos(2x)}{2y^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$\begin{aligned}
f'(y) &= -\frac{-2y^3 + 2\sin(x)^2 + \cos(2x)}{2y^2} \\
&= \frac{2y^3 - 1}{2y^2}
\end{aligned}$$

Integrating the above w.r.t y results in

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{2y^3-1}{2y^2}\right)\mathrm{d}y$$

$$f(y) = \frac{y^2}{2} + \frac{1}{2y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^2}{2} - \frac{\cos(2x)}{2y} + \frac{y^2}{2} + \frac{1}{2y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^2}{2} - \frac{\cos(2x)}{2y} + \frac{y^2}{2} + \frac{1}{2y}$$

Summary

The solution(s) found are the following

$$\frac{x^2}{2} - \frac{\cos(2x)}{2y} + \frac{y^2}{2} + \frac{1}{2y} = c_1 \tag{1}$$

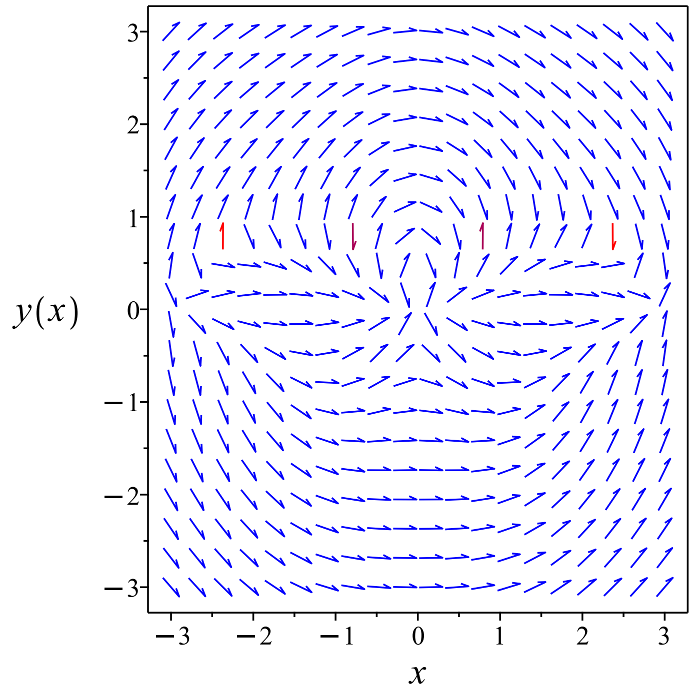

Figure 293: Slope field plot

Verification of solutions

$$\frac{x^2}{2} - \frac{\cos(2x)}{2y} + \frac{y^2}{2} + \frac{1}{2y} = c_1$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 7, Total differential equations. The integrating factor. Exercises page 61
Problem number: 181.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

```
[_exact, _rational]
```

$$\boxed{-y+\left(2y-x+3y^{2}\right)y'=-3x^{2}+2x}$$

7.7.1 Solving as differentialType ode

Writing the ode as

$$y'=\frac{-3x^{2}+2x+y}{2y-x+3y^{2}} \tag{1}$$

Which becomes

$$\left(-3y^{2}-2y\right)dy=(-x)\,dy+\left(3x^{2}-2x-y\right)dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy+\left(3x^{2}-2x-y\right)dx=d\left(x^{3}-x^{2}-xy\right)$$

Hence (2) becomes

$$\left(-3y^{2}-2y\right)dy=d\left(x^{3}-x^{2}-xy\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81}\right.}{6}$$

$$y = -\frac{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 8}\right.}{12}$$

$$y = -\frac{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 8}\right.}{12}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81c_1^2}\right.}{6} - \frac{6\left(-\frac{x}{3}-\frac{1}{9}\right)}{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81}\right.} - \frac{1}{3} + c_1 \tag{1}$$

$$y = -\frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81}\right.}{12} + \frac{-x-\frac{1}{3}}{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81}\right.} - \frac{1}{3} + \frac{i\sqrt{3}\left(\frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81c_1^2+54c_1x-15x^2+12c_1}\right)^{\frac{1}{3}}}{6} + \frac{}{\left(-36x\right.}\right.}{2} + c_1 \tag{2}$$

$$y = -\frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81}\right.}{12} + \frac{-x-\frac{1}{3}}{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81}\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81c_1^2+54c_1x-15x^2+12c_1}\right)^{\frac{1}{3}}}{6} + \frac{}{\left(-36x\right.}\right.}{2} + c_1 \tag{3}$$

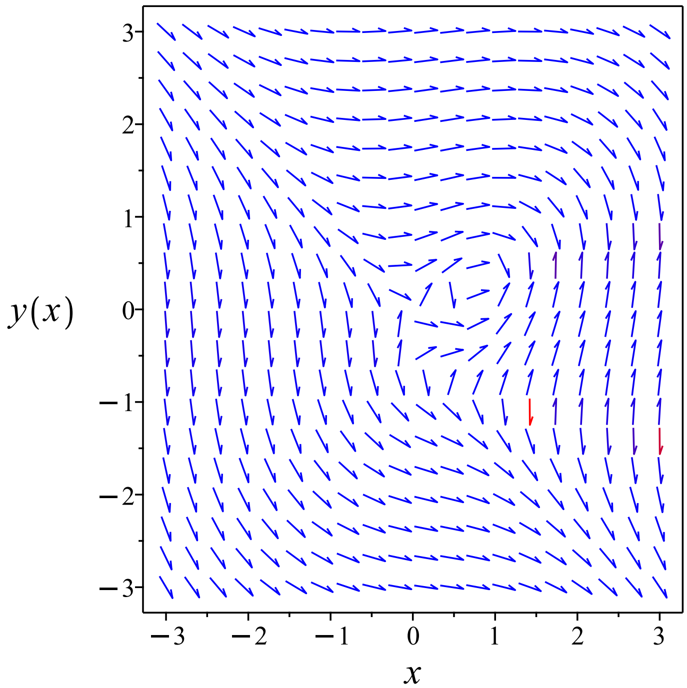

Figure 294: Slope field plot

Verification of solutions

$$y = \frac{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81c_1^2 \cdots}\right.}{6} - \frac{6\left(-\frac{x}{3} - \frac{1}{9}\right)}{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81 \cdots}\right.} - \frac{1}{3} + c_1$$

Verified OK.

$$y = -\frac{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81 \cdots}\right.}{12} + \frac{-x - \frac{1}{3}}{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81 \cdots}\right.} - \frac{1}{3} + \frac{i\sqrt{3}\left(\frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81c_1^2+54c_1x-15x^2+12c_1}\right)^{\frac{1}{3}}}{6} + \frac{\cdots}{\left(-36x \cdots\right.}\right.}{2 \cdots} + c_1$$

Verified OK.

$$y = -\frac{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81 \cdots}\right.}{12} + \frac{-x - \frac{1}{3}}{\left(-36x - 108x^3 + 108x^2 - 108c_1 - 8 + 12\sqrt{81x^6 - 162x^5 + 162c_1x^3 + 135x^4 - 162c_1x^2 - 54x^3 + 81 \cdots}\right.} - \frac{1}{3} - \frac{i\sqrt{3}\left(\frac{\left(-36x-108x^3+108x^2-108c_1-8+12\sqrt{81x^6-162x^5+162c_1x^3+135x^4-162c_1x^2-54x^3+81c_1^2+54c_1x-15x^2+12c_1}\right)^{\frac{1}{3}}}{6} + \frac{\cdots}{\left(-36x \cdots\right.}\right.}{2 \cdots} + c_1$$

Verified OK.

7.7.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(3y^2-x+2y\right)\mathrm{d}y&=\left(-3x^2+2x+y\right)\mathrm{d}x\\ \left(3x^2-2x-y\right)\mathrm{d}x+\left(3y^2-x+2y\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=3x^2-2x-y\\ N(x,y)&=3y^2-x+2y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3x^2 - 2x - y) \\ &= -1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(3y^2 - x + 2y) \\ &= -1\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 3x^2 - 2x - y \, \mathrm{d}x$$

$$\phi = x(x^2 - x - y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3y^2 - x + 2y$. Therefore equation (4) becomes

$$3y^2 - x + 2y = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3y^2 + 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (3y^2 + 2y) \,\mathrm{d}y$$
$$f(y) = y^3 + y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(x^2 - x - y) + y^3 + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(x^2 - x - y) + y^3 + y^2$$

Summary

The solution(s) found are the following

$$x(x^2 - x - y) + y^3 + y^2 = c_1 \tag{1}$$

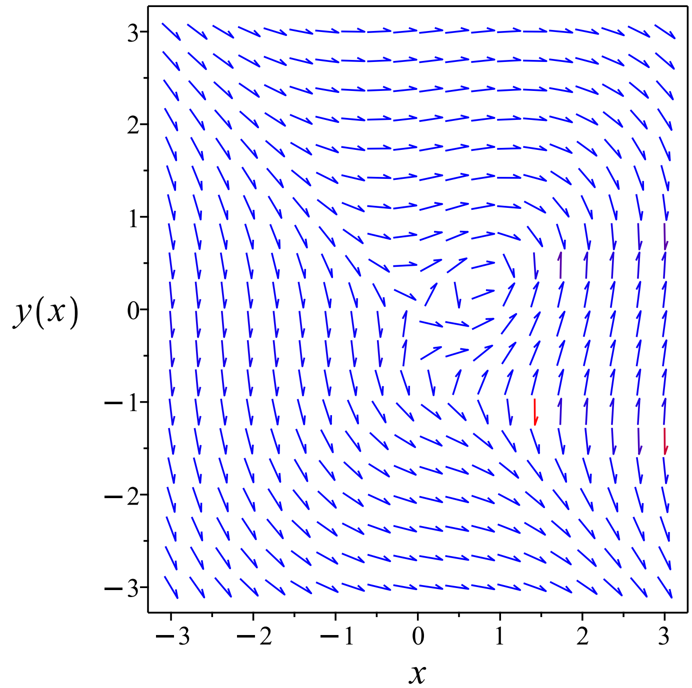

Figure 295: Slope field plot

Verification of solutions

$$x(x^2 - x - y) + y^3 + y^2 = c_1$$

Verified OK.

7.7.3 Maple step by step solution

Let's solve

$-y + (2y - x + 3y^2)\, y' = -3x^2 + 2x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y) = 0$

  ◦ Compute derivative of lhs

    $F'(x,y) + \left(\frac{\partial}{\partial y}F(x,y)\right) y' = 0$

- Evaluate derivatives

  $-1 = -1$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int (3x^2 - 2x - y)\, dx + f_1(y)$

- Evaluate integral

  $F(x,y) = x^3 - x^2 - xy + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $3y^2 - x + 2y = -x + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 3y^2 + 2y$

- Solve for $f_1(y)$

  $f_1(y) = y^3 + y^2$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = x^3 + y^3 - x^2 - xy + y^2$

- Substitute $F(x,y)$ into the solution of the ODE

  $x^3 + y^3 - x^2 - xy + y^2 = c_1$

- Solve for y

$$\left\{ y = \frac{\left(-36x-108x^3+108x^2+108c_1-8+12\sqrt{81x^6-162x^5-162c_1x^3+135x^4+162c_1x^2-54x^3+81c_1^2-54c_1x-15x^2-12c_1}\right)^{\frac{1}{3}}}{6} - \right.$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{\frac{xy}{\sqrt{x^2+1}}+2yx-\frac{y}{x}+\left(\sqrt{x^2+1}+x^2-\ln\left(x\right)\right)y'=0}$$

7.8.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y\left(2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}\right)}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)} \end{aligned}$$

Where $f(x) = \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}\,dx\\
\int \frac{1}{y}\,dy &= \int \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}\,dx\\
\ln\left(y\right) &= \int \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}dx + c_1\\
y &= \mathrm{e}^{\int \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx+c_1}\\
&= c_1\mathrm{e}^{\int \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{\int \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx} \tag{1}$$

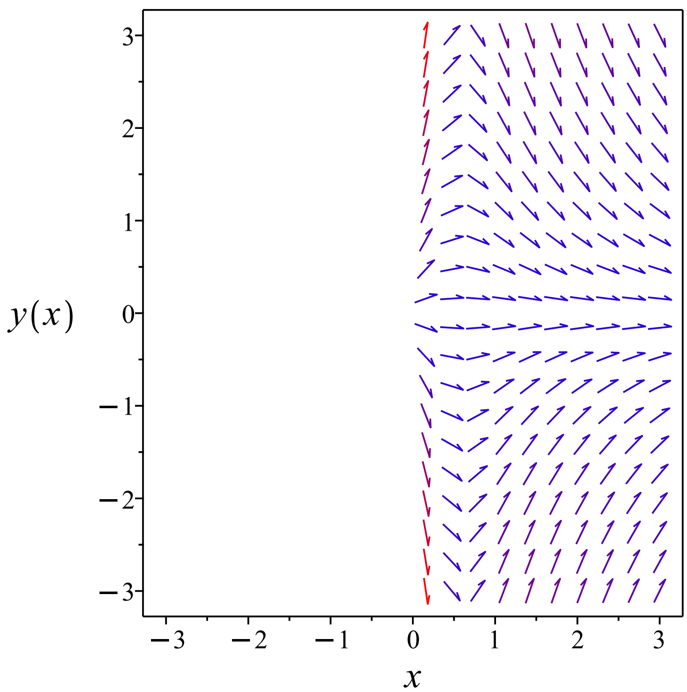

Figure 296: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{\int \frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx}$$

Verified OK.

7.8.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln\left(x\right)\right)\sqrt{x^2+1}+x^2+1\right)}$$
$$q(x) = 0$$

Hence the ode is

$$y' - \frac{\left(-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}\right)y}{x\left(\left(x^2-\ln\left(x\right)\right)\sqrt{x^2+1}+x^2+1\right)} = 0$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}\mu y = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\int -\frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx} y\right) = 0$$

Integrating gives

$$\mathrm{e}^{\int -\frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx} y = c_1$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx}$ results in

$$y = c_1 \mathrm{e}^{\int \frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{\int \frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx} \tag{1}$$

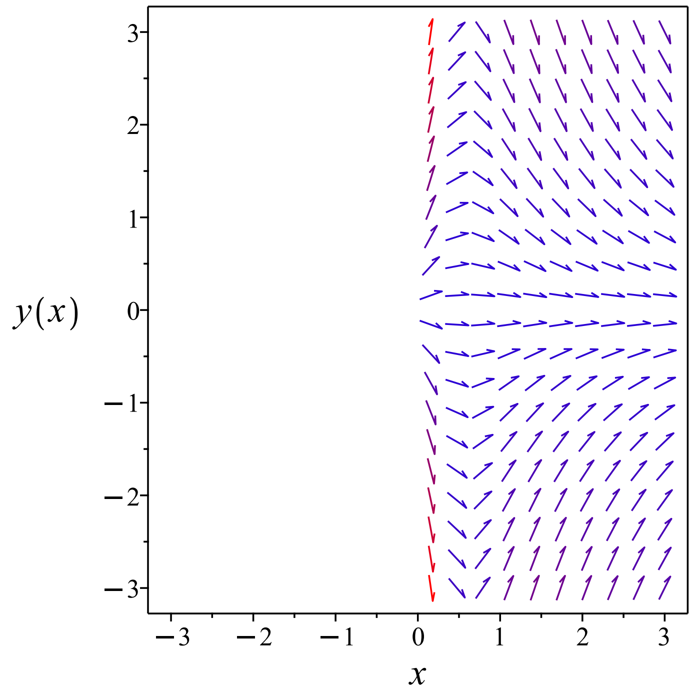

Figure 297: Slope field plot

Verification of solutions

$$y = c_1 e^{\int \frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx}$$

Verified OK.

7.8.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$\frac{x^2 u(x)}{\sqrt{x^2+1}} + 2u(x)\,x^2 - u(x) + \left(\sqrt{x^2+1} + x^2 - \ln(x)\right)\left(u'(x)\,x + u(x)\right) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= -\frac{u\left(-3x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1\right)}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}
\end{aligned}$$

Where $f(x) = -\frac{-3x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{-3x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}\,dx\\
\int\frac{1}{u}\,du &= \int -\frac{-3x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}\,dx\\
\ln\left(u\right) &= \int -\frac{-3x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}dx+c_2\\
u &= \mathrm{e}^{\int -\frac{-3x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx+c_2}\\
&= c_2\mathrm{e}^{\int -\frac{-3x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx}
\end{aligned}$$

Therefore the solution y is

$$\begin{aligned}
y &= ux\\
&= xc_2\mathrm{e}^{\int -\frac{-3x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = xc_2\mathrm{e}^{\int -\frac{-3x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx} \tag{1}$$

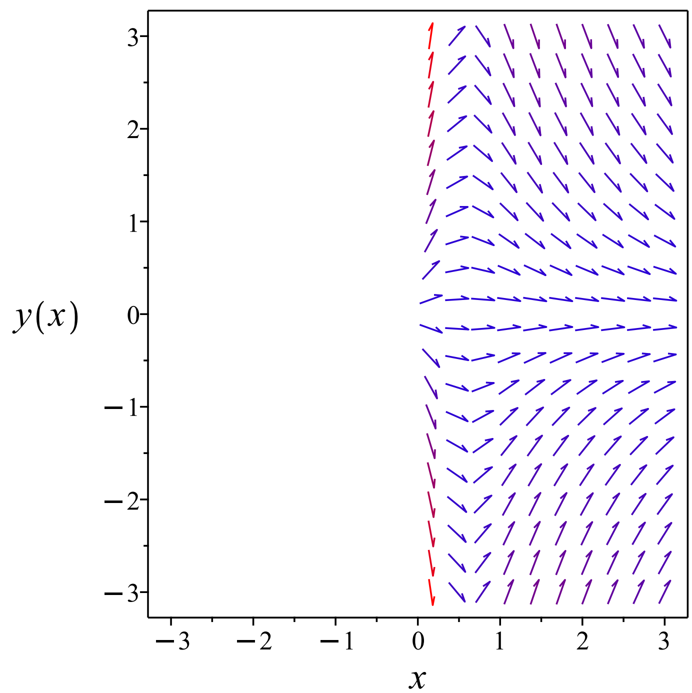

Figure 298: Slope field plot

Verification of solutions

$$
y = x c_2 \mathrm{e}^{\int -\frac{-3x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-2x^2+\sqrt{x^2+1}-1}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}dx}
$$

Verified OK.

7.8.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
y' = \frac{y\left(2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}\right)}{x\left(-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1\right)}
$$
$$
y' = \omega(x, y)
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 233: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{\int \frac{-2x^2\sqrt{x^2+1} - x^2 + \sqrt{x^2+1}}{x\left(\left(x^2 - \ln(x)\right)\sqrt{x^2+1} + x^2 + 1\right)} dx}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{\int \frac{-2x^2\sqrt{x^2+1}-x^2+\sqrt{x^2+1}}{x\left(\left(x^2-\ln(x)\right)\sqrt{x^2+1}+x^2+1\right)}dx}} dy \end{aligned}$$

7.8.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned} \frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N \end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might

or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y}\right) \mathrm{d}y = \left(\frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2\right.}\right.$$

$$\left(-\frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}\right)\mathrm{d}x + \left(\frac{1}{y}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= -\frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)} \\
N(x,y) &= \frac{1}{y}
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{2x^2\sqrt{x^2+1}+x^2-\sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1}+\ln\left(x\right)\sqrt{x^2+1}-x^2-1\right)}\right) \\
&= 0
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right) \\
&= 0
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\frac{2x^2\sqrt{x^2+1} + x^2 - \sqrt{x^2+1}}{x\left(-x^2\sqrt{x^2+1} + \ln(x)\sqrt{x^2+1} - x^2 - 1\right)} \mathrm{d}x$$

$$\phi = \int^x -\frac{2\_a^2\sqrt{\_a^2+1} + \_a^2 - \sqrt{\_a^2+1}}{\_a\left(-\_a^2\sqrt{\_a^2+1} + \ln(\_a)\sqrt{\_a^2+1} - \_a^2 - 1\right)} d\_a + f(y) \quad (3)$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(\frac{1}{y}\right) \mathrm{d}y$$

$$f(y) = \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \int^x -\frac{2\_a^2\sqrt{\_a^2+1} + \_a^2 - \sqrt{\_a^2+1}}{\_a\left(-\_a^2\sqrt{\_a^2+1} + \ln(\_a)\sqrt{\_a^2+1} - \_a^2 - 1\right)} d\_a + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \int^x -\frac{2\_a^2\sqrt{\_a^2+1}+\_a^2-\sqrt{\_a^2+1}}{\_a\left(-\_a^2\sqrt{\_a^2+1}+\ln\left(\_a\right)\sqrt{\_a^2+1}-\_a^2-1\right)}d\_a + \ln\left(y\right)$$

The solution becomes

$$y = \mathrm{e}^{-\left(\int^x -\frac{2\_a^2\sqrt{\_a^2+1}+\_a^2-\sqrt{\_a^2+1}}{\_a\left(-\_a^2\sqrt{\_a^2+1}+\ln(\_a)\sqrt{\_a^2+1}-\_a^2-1\right)}d\_a\right)+c_1}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\left(\int^x -\frac{2\_a^2\sqrt{\_a^2+1}+\_a^2-\sqrt{\_a^2+1}}{\_a\left(-\_a^2\sqrt{\_a^2+1}+\ln(\_a)\sqrt{\_a^2+1}-\_a^2-1\right)}d\_a\right)+c_1} \tag{1}$$

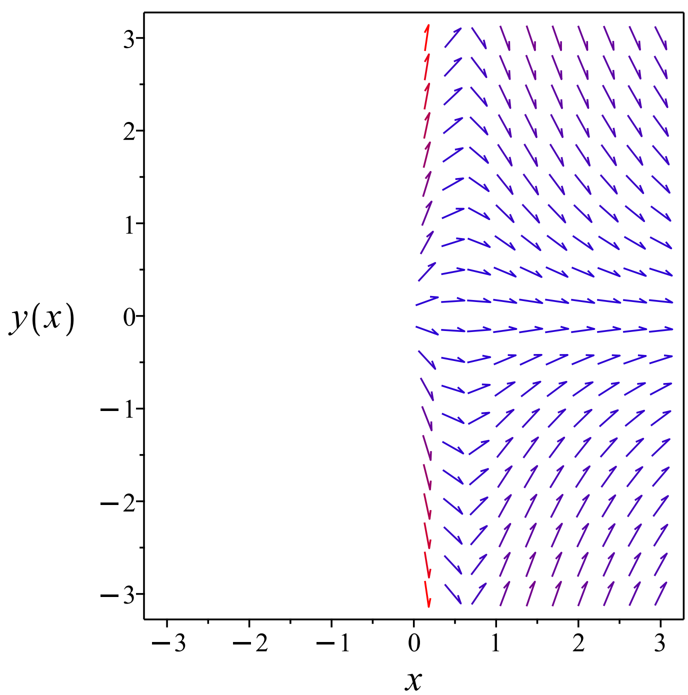

Figure 299: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-\left(\int^{x} -\frac{2\_a^{2}\sqrt{\_a^{2}+1}+\_a^{2}-\sqrt{\_a^{2}+1}}{\_a\left(-\_a^{2}\sqrt{\_a^{2}+1}+\ln(\_a)\sqrt{\_a^{2}+1}-\_a^{2}-1\right)}d\_a\right)+c_1}$$

Verified OK.

7.8.6 Maple step by step solution

Let's solve

$\frac{xy}{\sqrt{x^2+1}} + 2yx - \frac{y}{x} + \left(\sqrt{x^2+1} + x^2 - \ln(x)\right) y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int \left(\frac{xy}{\sqrt{x^2+1}} + 2yx - \frac{y}{x} + \left(\sqrt{x^2+1} + x^2 - \ln(x)\right) y'\right) dx = \int 0 dx + c_1$

- Evaluate integral

  $-\frac{\left(-\sqrt{x^2+1}\, x^3 + \sqrt{x^2+1}\, \ln(x) x - x^3 - x\right) y}{\sqrt{x^2+1}\, x} = c_1$

- Solve for y

  $y = -\frac{c_1\sqrt{x^2+1}}{-x^2\sqrt{x^2+1}+\ln(x)\sqrt{x^2+1}-x^2-1}$

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact]`

$$\boxed{\sin(y) + \sin(x)\, y + \left(\cos(y)\, x - \cos(x) + \frac{1}{y}\right) y' = -\frac{1}{x}}$$

7.9.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\cos(y)\, x - \cos(x) + \frac{1}{y}\right) \mathrm{d}y = \left(-\sin(y) - \sin(x)\, y - \frac{1}{x}\right) \mathrm{d}x$$
$$\left(\sin(y) + \sin(x)\, y + \frac{1}{x}\right) \mathrm{d}x + \left(\cos(y)\, x - \cos(x) + \frac{1}{y}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = \sin(y) + \sin(x)\, y + \frac{1}{x}$$
$$N(x, y) = \cos(y)\, x - \cos(x) + \frac{1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\sin(y) + \sin(x)\, y + \frac{1}{x}\right) \\ &= \cos(y) + \sin(x) \end{aligned}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\cos(y)\, x - \cos(x) + \frac{1}{y}\right)$$
$$= \cos(y) + \sin(x)$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\, dx = \int M\, dx$$
$$\int \frac{\partial \phi}{\partial x}\, dx = \int \sin(y) + \sin(x)\, y + \frac{1}{x}\, dx$$
$$\phi = \ln(x) - \cos(x)\, y + \sin(y)\, x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \cos(y)\, x - \cos(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \cos(y)\, x - \cos(x) + \frac{1}{y}$. Therefore equation (4) becomes

$$\cos(y)\, x - \cos(x) + \frac{1}{y} = \cos(y)\, x - \cos(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\, dy = \int \left(\frac{1}{y}\right) dy$$
$$f(y) = \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \ln(x) - \cos(x)\, y + \sin(y)\, x + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \ln(x) - \cos(x)\, y + \sin(y)\, x + \ln(y)$$

Summary

The solution(s) found are the following

$$\ln(x) - y\cos(x) + \sin(y)\, x + \ln(y) = c_1 \tag{1}$$

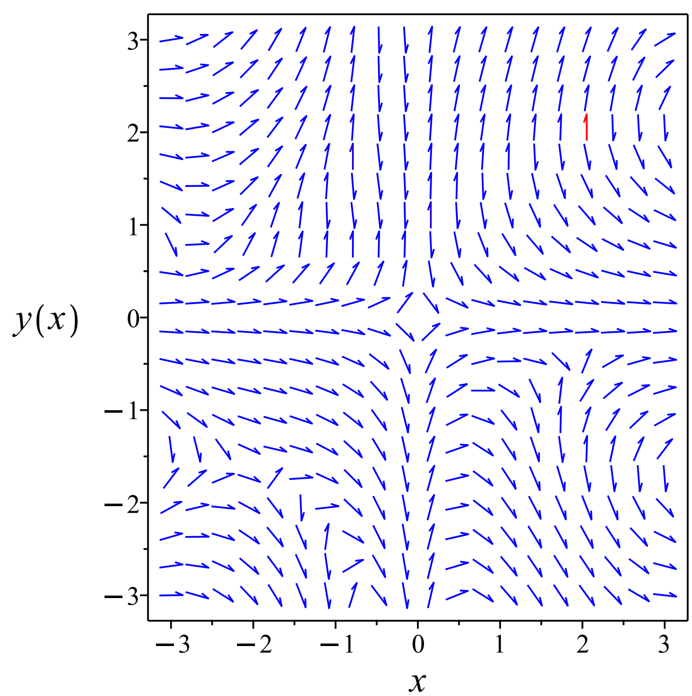

Figure 300: Slope field plot

Verification of solutions

$$\ln(x) - y\cos(x) + \sin(y)\, x + \ln(y) = c_1$$

Verified OK.

7.9.2 Maple step by step solution

Let's solve

$\sin(y)+\sin(x)\,y+\left(\cos(y)\,x-\cos(x)+\frac{1}{y}\right)y'=-\frac{1}{x}$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$

  - Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

  - Evaluate derivatives

    $\cos(y)+\sin(x)=\cos(y)+\sin(x)$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int\left(\sin(y)+\sin(x)\,y+\frac{1}{x}\right)dx+f_1(y)$

- Evaluate integral

  $F(x,y)=\ln(x)-\cos(x)\,y+\sin(y)\,x+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $\cos(y)\,x-\cos(x)+\frac{1}{y}=-\cos(x)+\cos(y)\,x+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=\frac{1}{y}$

- Solve for $f_1(y)$

  $f_1(y)=\ln(y)$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$$F(x,y) = \ln(x) - \cos(x)\, y + \sin(y)\, x + \ln(y)$$

- Substitute $F(x,y)$ into the solution of the ODE

$$\ln(x) - \cos(x)\, y + \sin(y)\, x + \ln(y) = c_1$$

- Solve for y

$$y = \mathit{RootOf}(-\sin(\_Z)\, x + \cos(x)\_Z - \ln(\_Zx) + c_1)$$

Problem number: 185.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact]`

$$\boxed{\frac{y+\sin(x)\cos(yx)^2}{\cos(yx)^2}+\left(\frac{x}{\cos(yx)^2}+\sin(y)\right)y'=0}$$

7.10.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{x}{\cos(xy)^2} + \sin(y)\right)\mathrm{d}y = \left(-\frac{y + \sin(x)\cos(xy)^2}{\cos(xy)^2}\right)\mathrm{d}x$$
$$\left(\frac{y + \sin(x)\cos(xy)^2}{\cos(xy)^2}\right)\mathrm{d}x + \left(\frac{x}{\cos(xy)^2} + \sin(y)\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{y + \sin(x)\cos(xy)^2}{\cos(xy)^2}$$
$$N(x,y) = \frac{x}{\cos(xy)^2} + \sin(y)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{y + \sin(x)\cos(xy)^2}{\cos(xy)^2}\right)\\ &= \sec(xy)^2\,(1 + 2\tan(xy)\,xy)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{x}{\cos(xy)^2} + \sin(y)\right)\\ &= \sec(xy)^2 (1 + 2\tan(xy)\, xy)\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{y + \sin(x)\cos(xy)^2}{\cos(xy)^2}\,\mathrm{d}x\end{aligned}$$

$$\phi = \tan(xy) - \cos(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x\left(1 + \tan(xy)^2\right) + f'(y) \tag{4}$$

$$= \sec(xy)^2\, x + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{x}{\cos(xy)^2} + \sin(y)$. Therefore equation (4) becomes

$$\frac{x}{\cos(xy)^2} + \sin(y) = \sec(xy)^2\, x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$\begin{aligned}f'(y) &= -\frac{\sec(xy)^2\, x\cos(xy)^2 - \sin(y)\cos(xy)^2 - x}{\cos(xy)^2}\\ &= \sin(y)\end{aligned}$$

Integrating the above w.r.t y results in

$$\int f'(y)\,\mathrm{d}y = \int (\sin(y))\,\mathrm{d}y$$
$$f(y) = -\cos(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \tan(xy) - \cos(x) - \cos(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \tan(xy) - \cos(x) - \cos(y)$$

Summary
The solution(s) found are the following

$$\tan(yx) - \cos(x) - \cos(y) = c_1 \tag{1}$$

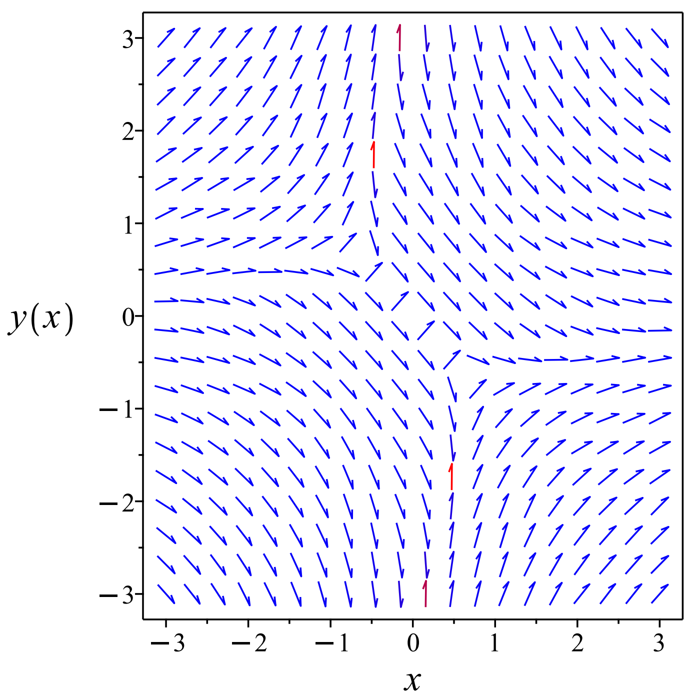

Figure 301: Slope field plot

Verification of solutions

$$\tan(yx) - \cos(x) - \cos(y) = c_1$$

Verified OK.

7.10.2 Maple step by step solution

Let's solve

$\frac{y+\sin(x)\cos(yx)^2}{\cos(yx)^2} + \left(\frac{x}{\cos(yx)^2} + \sin(y)\right) y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y) = 0$

  ◦ Compute derivative of lhs

    $F'(x,y) + \left(\frac{\partial}{\partial y}F(x,y)\right) y' = 0$

  ◦ Evaluate derivatives

    $\frac{1-2\sin(x)\cos(xy)x\sin(xy)}{\cos(xy)^2} + \frac{2\left(y+\sin(x)\cos(xy)^2\right)x\sin(xy)}{\cos(xy)^3} = \frac{1}{\cos(xy)^2} + \frac{2x\sin(xy)y}{\cos(xy)^3}$

  ◦ Simplify

    $\sec(xy)^2(1+2\tan(xy)xy) = \sec(xy)^2(1+2\tan(xy)xy)$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int \frac{y+\sin(x)\cos(xy)^2}{\cos(xy)^2}dx + f_1(y)$

- Evaluate integral

  $F(x,y) = \tan(xy) - \cos(x) + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

$$\frac{x}{\cos(xy)^2} + \sin(y) = x\left(1 + \tan(xy)^2\right) + \frac{d}{dy}f_1(y)$$

- Isolate for $\frac{d}{dy}f_1(y)$

$$\frac{d}{dy}f_1(y) = \frac{x}{\cos(xy)^2} + \sin(y) - x\left(1 + \tan(xy)^2\right)$$

- Solve for $f_1(y)$

$$f_1(y) = -\cos(y)$$

- Substitute $f_1(y)$ into equation for $F(x,y)$

$$F(x,y) = \tan(xy) - \cos(x) - \cos(y)$$

- Substitute $F(x,y)$ into the solution of the ODE

$$\tan(xy) - \cos(x) - \cos(y) = c_1$$

- Solve for y

$$y = \mathit{RootOf}(\_Zx - \arctan(\cos(\_Z) + c_1 + \cos(x)))$$

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, _dAlembert]
```

$$\boxed{\frac{2x}{y^{3}}+\frac{\left(y^{2}-3x^{2}\right) y'}{y^{4}}=0}$$

With initial conditions

$$[y(1)=1]$$

7.11.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y=u(x)\,x$ on the above ode results in new ode in $u(x)$

$$\frac{2}{x^{2}u\left(x\right)^{3}}+\frac{\left(u(x)^{2}\,x^{2}-3x^{2}\right)\left(u'(x)\,x+u(x)\right)}{u\left(x\right)^{4}x^{4}}=0$$

In canonical form the ODE is

$$\begin{aligned}u' &= F(x,u)\\ &= f(x)g(u)\\ &= -\frac{u^{3}-u}{x\left(u^{2}-3\right)}\end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{u^3-u}{u^2-3}$. Integrating both sides gives

$$\frac{1}{\frac{u^3-u}{u^2-3}} du = -\frac{1}{x} dx$$
$$\int \frac{1}{\frac{u^3-u}{u^2-3}} du = \int -\frac{1}{x} dx$$
$$-\ln(u-1) - \ln(u+1) + 3\ln(u) = -\ln(x) + c_2$$

Raising both side to exponential gives

$$e^{-\ln(u-1)-\ln(u+1)+3\ln(u)} = e^{-\ln(x)+c_2}$$

Which simplifies to

$$\frac{u^3}{u^2-1} = \frac{c_3}{x}$$

The solution is

$$\frac{u(x)^3}{u(x)^2-1} = \frac{c_3}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y^3}{x^3\left(\frac{y^2}{x^2}-1\right)} = \frac{c_3}{x}$$
$$\frac{y^3}{x(y^2-x^2)} = \frac{c_3}{x}$$

Which simplifies to

$$-\frac{y^3}{(-y+x)(y+x)} = c_3$$

Writing the solution as

$$-c_1 y^3 = (-y+x)(y+x)$$

Where $c_1 = \frac{1}{c_3}$ and solving for c_1 after applying initial conditions gives $c_1 = 0$. Hence the above solution becomes

$$0 = (-y+x)(y+x)$$

Summary
The solution(s) found are the following

$$0 = (-y + x)(y + x) \tag{1}$$

Verification of solutions

$$0 = (-y + x)(y + x)$$

Verified OK.

7.11.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{2xy}{-3x^2 + y^2} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 - \frac{2xy(b_3 - a_2)}{-3x^2 + y^2} - \frac{4x^2 y^2 a_3}{(-3x^2 + y^2)^2} \\ & - \left(-\frac{2y}{-3x^2 + y^2} - \frac{12x^2 y}{(-3x^2 + y^2)^2} \right) (x a_2 + y a_3 + a_1) \\ & - \left(-\frac{2x}{-3x^2 + y^2} + \frac{4x\, y^2}{(-3x^2 + y^2)^2} \right) (x b_2 + y b_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{3x^4b_2 + 2x^2y^2a_3 - 8x^2y^2b_2 + 4x\,y^3a_2 - 4x\,y^3b_3 + 2y^4a_3 + y^4b_2 - 6x^3b_1 + 6x^2ya_1 - 2x\,y^2b_1 + 2y^3a_1}{(3x^2 - y^2)^2} = 0$$

Setting the numerator to zero gives

$$3x^4b_2 + 2x^2y^2a_3 - 8x^2y^2b_2 + 4x\,y^3a_2 - 4x\,y^3b_3 + 2y^4a_3 + y^4b_2 - 6x^3b_1 + 6x^2ya_1 - 2x\,y^2b_1 + 2y^3a_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$4a_2v_1v_2^3 + 2a_3v_1^2v_2^2 + 2a_3v_2^4 + 3b_2v_1^4 - 8b_2v_1^2v_2^2 + b_2v_2^4 - 4b_3v_1v_2^3 + 6a_1v_1^2v_2 + 2a_1v_2^3 - 6b_1v_1^3 - 2b_1v_1v_2^2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$3b_2v_1^4 - 6b_1v_1^3 + (2a_3 - 8b_2)\,v_1^2v_2^2 + 6a_1v_1^2v_2 + (4a_2 - 4b_3)\,v_1v_2^3 - 2b_1v_1v_2^2 + (2a_3 + b_2)\,v_2^4 + 2a_1v_2^3 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
2a_1 &= 0 \\
6a_1 &= 0 \\
-6b_1 &= 0 \\
-2b_1 &= 0 \\
3b_2 &= 0 \\
4a_2 - 4b_3 &= 0 \\
2a_3 - 8b_2 &= 0 \\
2a_3 + b_2 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(-\frac{2xy}{-3x^2 + y^2}\right)(x) \\
&= \frac{x^2y - y^3}{3x^2 - y^2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2y-y^3}{3x^2-y^2}} dy \end{aligned}$$

Which results in

$$S = -\ln(y+x) - \ln(y-x) + 3\ln(y)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{2xy}{-3x^2 + y^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2x}{x^2 - y^2} \\ S_y &= -\frac{1}{y+x} + \frac{1}{-y+x} + \frac{3}{y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln(y+x) - \ln(y-x) + 3\ln(y) = c_1$$

Which simplifies to

$$-\ln(y+x) - \ln(y-x) + 3\ln(y) = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2xy}{-3x^2+y^2}$ 	$R = x$ $S = -\ln(y+x) - \ln(y -$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$\infty = c_1$$

Unable to solve for constant of integration. Warning: Unable to solve for constant of integration.

Verification of solutions N/A

7.11.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{-3x^2+y^2}{y^4}\right)\mathrm{d}y = \left(-\frac{2x}{y^3}\right)\mathrm{d}x$$

$$\left(\frac{2x}{y^3}\right)\mathrm{d}x + \left(\frac{-3x^2+y^2}{y^4}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = \frac{2x}{y^3}$$
$$N(x,y) = \frac{-3x^2+y^2}{y^4}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\frac{2x}{y^3}\right)\\ &= -\frac{6x}{y^4}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{-3x^2+y^2}{y^4}\right)\\ &= -\frac{6x}{y^4}\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\mathrm{d}x = \int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\mathrm{d}x = \int \frac{2x}{y^3}\mathrm{d}x$$
$$\phi = \frac{x^2}{y^3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{3x^2}{y^4} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-3x^2+y^2}{y^4}$. Therefore equation (4) becomes

$$\frac{-3x^2 + y^2}{y^4} = -\frac{3x^2}{y^4} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(\frac{1}{y^2}\right) \mathrm{d}y$$

$$f(y) = -\frac{1}{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^2}{y^3} - \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^2}{y^3} - \frac{1}{y}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$0 = c_1$$

$$c_1 = 0$$

Substituting c_1 found above in the general solution gives

$$\frac{x^2}{y^3} - \frac{1}{y} = 0$$

The above simplifies to

$$x^2 - y^2 = 0$$

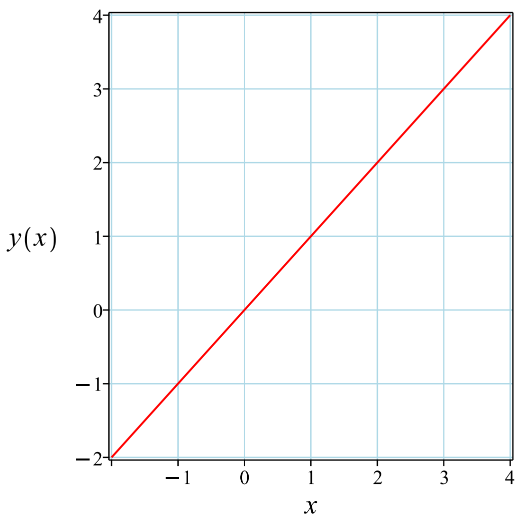
Solving for y from the above gives

$$y = x$$

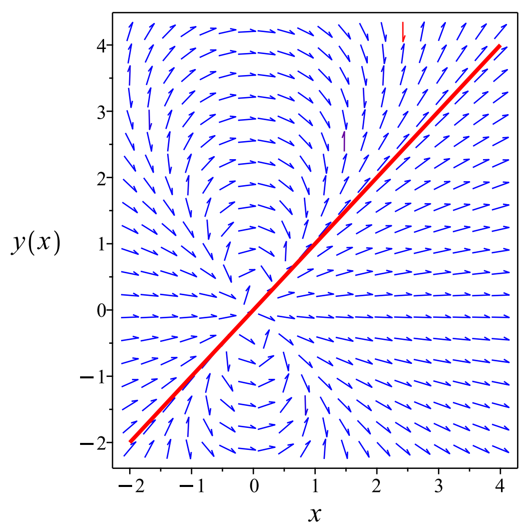
Summary

The solution(s) found are the following

$$y = x \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x$$

Verified OK.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

```
[_exact, _rational]
```

$$\boxed{y(x^2+y^2+a^2)\,y'+x(y^2-a^2+x^2)=0}$$

7.12.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(y\left(a^2+x^2+y^2\right)\right)\mathrm{d}y&=\left(-x\left(-a^2+x^2+y^2\right)\right)\mathrm{d}x\\ \left(x\left(-a^2+x^2+y^2\right)\right)\mathrm{d}x+\left(y\left(a^2+x^2+y^2\right)\right)\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=x\left(-a^2+x^2+y^2\right)\\ N(x,y)&=y\left(a^2+x^2+y^2\right)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(x\left(-a^2+x^2+y^2\right)\right)\\ &=2xy\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}\left(y\left(a^2+x^2+y^2\right)\right)\\ &=2xy\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x}=M \tag{1}$$

$$\frac{\partial\phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int x\left(-a^2 + x^2 + y^2\right) \mathrm{d}x$$

$$\phi = \frac{\left(a^2 - x^2 - y^2\right)^2}{4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\left(a^2 - x^2 - y^2\right) y + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y(a^2 + x^2 + y^2)$. Therefore equation (4) becomes

$$y\left(a^2 + x^2 + y^2\right) = -\left(a^2 - x^2 - y^2\right) y + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2a^2 y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(2a^2 y\right) \mathrm{d}y$$

$$f(y) = y^2 a^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\left(a^2 - x^2 - y^2\right)^2}{4} + y^2 a^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\left(a^2 - x^2 - y^2\right)^2}{4} + y^2 a^2$$

Summary

The solution(s) found are the following

$$\frac{\left(a^2-x^2-y^2\right)^2}{4}+y^2a^2=c_1 \tag{1}$$

Verification of solutions

$$\frac{\left(a^2-x^2-y^2\right)^2}{4}+y^2a^2=c_1$$

Verified OK.

7.12.2 Maple step by step solution

Let's solve

$y(x^2+y^2+a^2)\,y'+x(y^2-a^2+x^2)=0$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$
  - Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$
  - Evaluate derivatives

    $2xy=2xy$
  - Condition met, ODE is exact
- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$
- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int x(-a^2+x^2+y^2)\,dx+f_1(y)$
- Evaluate integral

  $F(x,y)=\frac{(-a^2+x^2+y^2)^2}{4}+f_1(y)$
- Take derivative of $F(x,y)$ with respect to y

$N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $y(a^2+x^2+y^2) = (-a^2+x^2+y^2)\,y + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = y(a^2+x^2+y^2) - (-a^2+x^2+y^2)\,y$

- Solve for $f_1(y)$

  $f_1(y) = y^2a^2$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = \frac{(-a^2+x^2+y^2)^2}{4} + y^2a^2$

- Substitute $F(x,y)$ into the solution of the ODE

  $\frac{(-a^2+x^2+y^2)^2}{4} + y^2a^2 = c_1$

- Solve for y

  $\left\{y = \sqrt{-a^2-x^2-2\sqrt{a^2x^2+c_1}}, y = \sqrt{-a^2-x^2+2\sqrt{a^2x^2+c_1}}, y = -\sqrt{-a^2-x^2-2\sqrt{a^2x^2-}}\right.$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, _dAlembert]
```

$$\boxed{3x^2y + y^3 + (x^3 + 3y^2x)\, y' = 0}$$

7.13.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$3x^3u(x) + u(x)^3\, x^3 + \left(x^3 + 3u(x)^2\, x^3\right) \left(u'(x)\, x + u(x)\right) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{4u(u^2+1)}{x\,(3u^2+1)} \end{aligned}$$

Where $f(x) = -\frac{4}{x}$ and $g(u) = \frac{(u^2+1)u}{3u^2+1}$. Integrating both sides gives

$$\frac{1}{\frac{(u^2+1)u}{3u^2+1}} \, du = -\frac{4}{x} \, dx$$

$$\int \frac{1}{\frac{(u^2+1)u}{3u^2+1}} \, du = \int -\frac{4}{x} \, dx$$

$$\ln\left(u(u^2+1)\right) = -4\ln(x) + c_2$$

Raising both side to exponential gives

$$u(u^2+1) = e^{-4\ln(x)+c_2}$$

Which simplifies to

$$u(u^2+1) = \frac{c_3}{x^4}$$

Which simplifies to

$$u(x)\left(u(x)^2+1\right) = \frac{c_3 e^{c_2}}{x^4}$$

The solution is

$$u(x)\left(u(x)^2+1\right) = \frac{c_3 e^{c_2}}{x^4}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y\left(\frac{y^2}{x^2}+1\right)}{x} = \frac{c_3 e^{c_2}}{x^4}$$

$$\frac{y(x^2+y^2)}{x^3} = \frac{c_3 e^{c_2}}{x^4}$$

Which simplifies to

$$y(x^2+y^2) = \frac{c_3 e^{c_2}}{x}$$

Summary

The solution(s) found are the following

$$y(x^2+y^2) = \frac{c_3 e^{c_2}}{x} \tag{1}$$

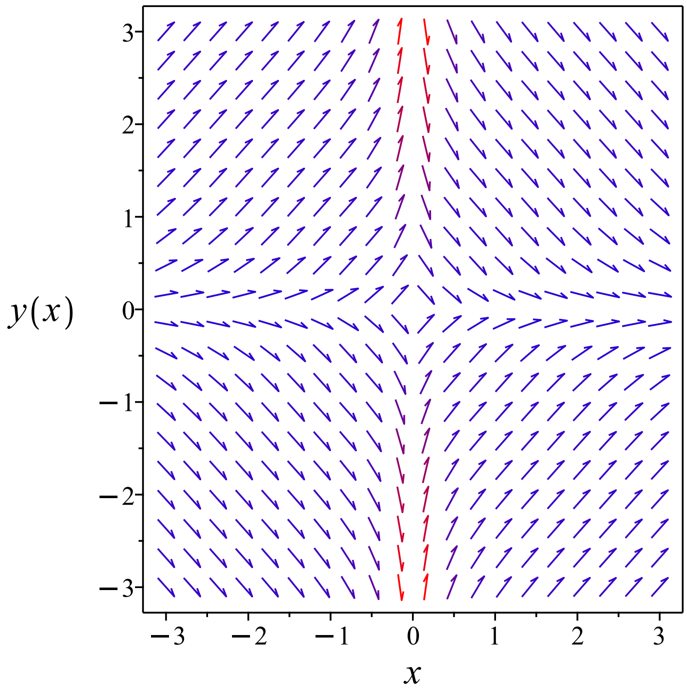

Figure 303: Slope field plot

Verification of solutions

$$y(x^2+y^2) = \frac{c_3 e^{c_2}}{x}$$

Verified OK.

7.13.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{y(3x^2+y^2)}{x(x^2+3y^2)}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 - \frac{y(3x^2+y^2)(b_3-a_2)}{x(x^2+3y^2)} - \frac{y^2(3x^2+y^2)^2 a_3}{x^2(x^2+3y^2)^2} \\ & - \left(-\frac{6y}{x^2+3y^2} + \frac{y(3x^2+y^2)}{x^2(x^2+3y^2)} + \frac{2y(3x^2+y^2)}{(x^2+3y^2)^2}\right)(xa_2+ya_3+a_1) \\ & - \left(-\frac{3x^2+y^2}{x(x^2+3y^2)} - \frac{2y^2}{x(x^2+3y^2)} + \frac{6y^2(3x^2+y^2)}{x(x^2+3y^2)^2}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{4x^6b_2 - 12x^4y^2a_3 + 16x^3y^3a_2 - 16x^3y^3b_3 + 12x^2y^4b_2 - 4y^6a_3 + 3x^5b_1 - 3x^4ya_1 - 6x^3y^2b_1 + 6x^2y^3a_1 + 3x}{(x^2+3y^2)^2 x^2}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} & 4x^6b_2 - 12x^4y^2a_3 + 16x^3y^3a_2 - 16x^3y^3b_3 + 12x^2y^4b_2 - 4y^6a_3 \\ & + 3x^5b_1 - 3x^4ya_1 - 6x^3y^2b_1 + 6x^2y^3a_1 + 3x\,y^4b_1 - 3y^5a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & 16a_2v_1^3v_2^3 - 12a_3v_1^4v_2^2 - 4a_3v_2^6 + 4b_2v_1^6 + 12b_2v_1^2v_2^4 - 16b_3v_1^3v_2^3 \\ & - 3a_1v_1^4v_2 + 6a_1v_1^2v_2^3 - 3a_1v_2^5 + 3b_1v_1^5 - 6b_1v_1^3v_2^2 + 3b_1v_1v_2^4 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$4b_2v_1^6 + 3b_1v_1^5 - 12a_3v_1^4v_2^2 - 3a_1v_1^4v_2 + (16a_2 - 16b_3)\,v_1^3v_2^3 \\ - 6b_1v_1^3v_2^2 + 12b_2v_1^2v_2^4 + 6a_1v_1^2v_2^3 + 3b_1v_1v_2^4 - 4a_3v_2^6 - 3a_1v_2^5 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -3a_1 &= 0 \\ 6a_1 &= 0 \\ -12a_3 &= 0 \\ -4a_3 &= 0 \\ -6b_1 &= 0 \\ 3b_1 &= 0 \\ 4b_2 &= 0 \\ 12b_2 &= 0 \\ 16a_2 - 16b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{y(3x^2+y^2)}{x\,(x^2+3y^2)}\right)(x) \\
&= \frac{4x^2y+4y^3}{x^2+3y^2} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{4x^2y+4y^3}{x^2+3y^2}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln\left(y(x^2+y^2)\right)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(3x^2+y^2)}{x\,(x^2+3y^2)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{x}{2x^2 + 2y^2} \\
S_y &= \frac{1}{4y} + \frac{y}{2x^2 + 2y^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{1}{4x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{1}{4R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\frac{\ln(R)}{4} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\ln(y)}{4} + \frac{\ln(x^2 + y^2)}{4} = -\frac{\ln(x)}{4} + c_1
$$

Which simplifies to

$$
\frac{\ln(y)}{4} + \frac{\ln(x^2 + y^2)}{4} = -\frac{\ln(x)}{4} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = -\frac{y(3x^2+y^2)}{x(x^2+3y^2)}$
</td><td>$R = x$
$S = \frac{\ln(y)}{4} + \frac{\ln(x^2+y^2)}{4}$</td><td>$\frac{dS}{dR} = -\frac{1}{4R}$
</td></tr>
</table>

Summary

The solution(s) found are the following

$$\frac{\ln(y)}{4} + \frac{\ln(x^2+y^2)}{4} = -\frac{\ln(x)}{4} + c_1 \tag{1}$$

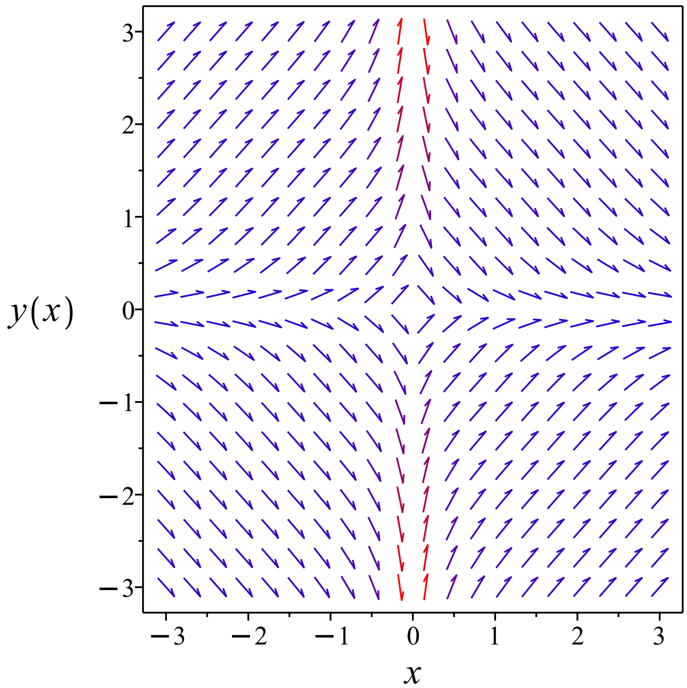

Figure 304: Slope field plot

Verification of solutions

$$\frac{\ln(y)}{4}+\frac{\ln(x^2+y^2)}{4}=-\frac{\ln(x)}{4}+c_1$$

Verified OK.

7.13.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(x^3 + 3y^2 x) \,\mathrm{d}y &= (-3x^2 y - y^3) \,\mathrm{d}x \\
(3x^2 y + y^3) \,\mathrm{d}x + (x^3 + 3y^2 x) \,\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= 3x^2 y + y^3 \\
N(x, y) &= x^3 + 3y^2 x
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3x^2 y + y^3) \\
&= 3x^2 + 3y^2
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^3 + 3y^2 x) \\
&= 3x^2 + 3y^2
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 3x^2y + y^3 \, \mathrm{d}x$$

$$\phi = xy(x^2 + y^2) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = (x^2 + y^2)\, x + 2y^2x + f'(y) \tag{4}$$

$$= x^3 + 3y^2x + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^3 + 3y^2x$. Therefore equation (4) becomes

$$x^3 + 3y^2x = x^3 + 3y^2x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = xy(x^2 + y^2) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = xy(x^2 + y^2)$$

Summary

The solution(s) found are the following

$$y(x^2 + y^2)\, x = c_1 \tag{1}$$

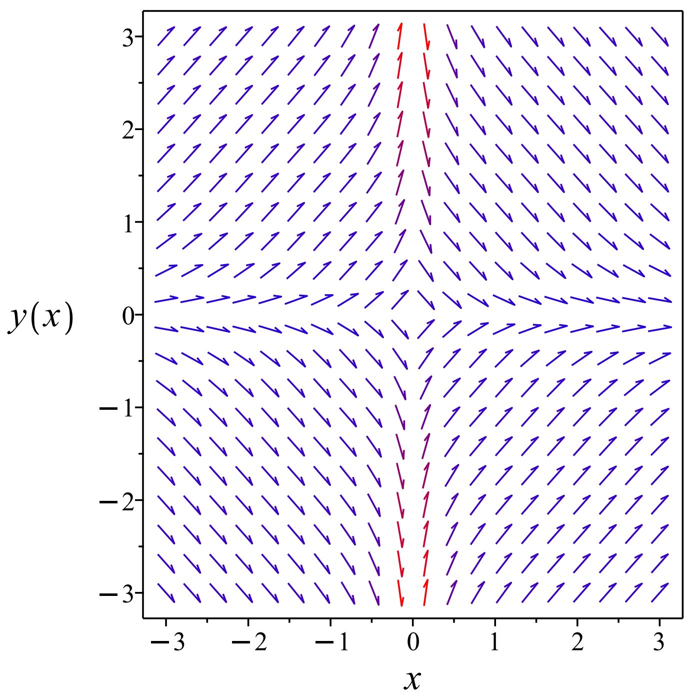

Figure 305: Slope field plot

Verification of solutions

$$y(x^2 + y^2)\, x = c_1$$

Verified OK.

7.13.4 Maple step by step solution

Let's solve

$3x^2y + y^3 + (x^3 + 3y^2x)\, y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

$F'(x, y) = 0$

- ◦ Compute derivative of lhs

  $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

- ◦ Evaluate derivatives

  $3x^2 + 3y^2 = 3x^2 + 3y^2$

- ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (3x^2 y + y^3)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = y(x^3 + y^2 x) + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $x^3 + 3y^2 x = x^3 + 3y^2 x + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = 0$

- Solve for $f_1(y)$

  $f_1(y) = 0$

- Substitute $f_1(y)$ into equation for $F(x, y)$

  $F(x, y) = y(x^3 + y^2 x)$

- Substitute $F(x, y)$ into the solution of the ODE

  $y(x^3 + y^2 x) = c_1$

- Solve for y

$$\left\{y = \frac{\left(\left(12\sqrt{3}\,\sqrt{4x^8+27c_1^2}+108c_1\right)x^2\right)^{\frac{1}{3}}}{6x} - \frac{2x^3}{\left(\left(12\sqrt{3}\,\sqrt{4x^8+27c_1^2}+108c_1\right)x^2\right)^{\frac{1}{3}}}, y = -\frac{\left(\left(12\sqrt{3}\,\sqrt{4x^8+27c_1^2}+108c_1\right)x^2\right)}{12x}\right.$$

$$\boxed{-x^2y + x^2(y - x)\, y' = -1}$$

7.14.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(x^2(y-x)\right)\mathrm{d}y &= \left(x^2y-1\right)\mathrm{d}x \\
\left(-x^2y+1\right)\mathrm{d}x + \left(x^2(y-x)\right)\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= -x^2y+1 \\
N(x,y) &= x^2(y-x)
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2y+1\right) \\
&= -x^2
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x^2(y-x)\right) \\
&= -3x^2+2xy
\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x^2\,(y-x)}\left(\left(-x^2\right) - \left(2x(y-x)-x^2\right)\right) \\
&= -\frac{2}{x}
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}x}\\ &= e^{\int -\frac{2}{x} \,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(x)}\\ &= \frac{1}{x^2}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^2}\left(-x^2 y + 1\right)\\ &= \frac{-x^2 y + 1}{x^2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{x^2}\left(x^2(y - x)\right)\\ &= y - x\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(\frac{-x^2 y + 1}{x^2}\right) + (y - x)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{-x^2y+1}{x^2} \mathrm{d}x$$
$$\phi = -xy - \frac{1}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y - x$. Therefore equation (4) becomes

$$y - x = -x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int (y) \mathrm{d}y$$
$$f(y) = \frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -xy - \frac{1}{x} + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -xy - \frac{1}{x} + \frac{y^2}{2}$$

Summary
The solution(s) found are the following

$$-yx - \frac{1}{x} + \frac{y^2}{2} = c_1 \tag{1}$$

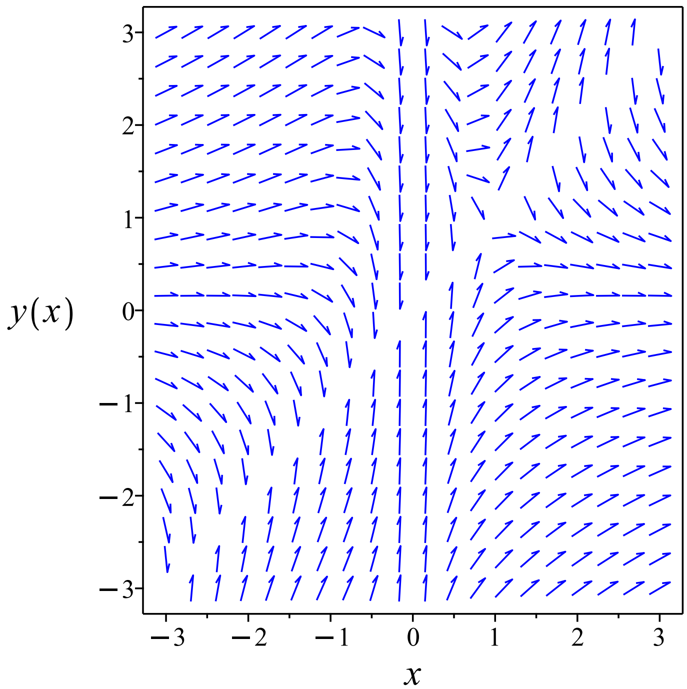

Figure 306: Slope field plot

Verification of solutions

$$-yx - \frac{1}{x} + \frac{y^2}{2} = c_1$$

Verified OK.

Section: Section 7, Total differential equations. The integrating factor. Exercises page 61
Problem number: 190.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y - y'x = -x^2}$$

7.15.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = x$$

Hence the ode is

$$y' - \frac{y}{x} = x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(x) \\ \frac{d}{dx}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)(x) \\ d\left(\frac{y}{x}\right) &= dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x} &= \int dx \\ \frac{y}{x} &= x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = c_1 x + x^2$$

which simplifies to

$$y = x(x + c_1)$$

Summary

The solution(s) found are the following

$$y = x(x + c_1) \tag{1}$$

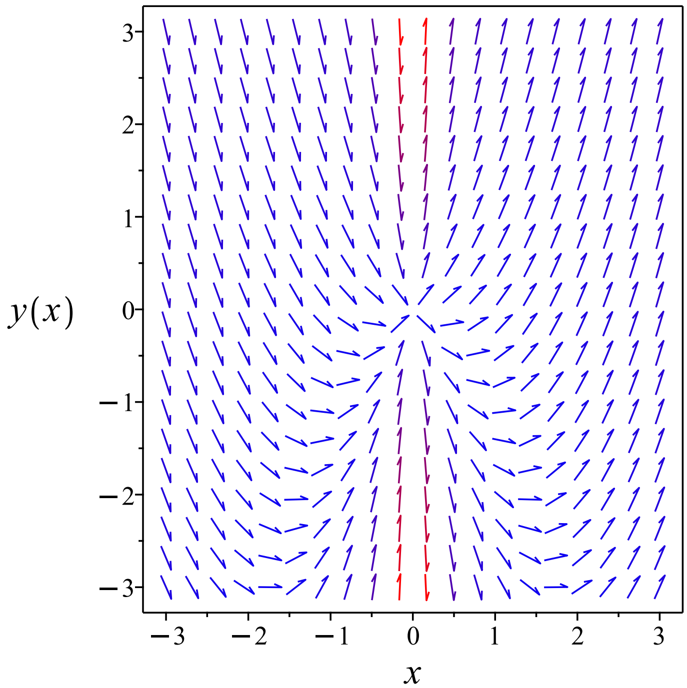

Figure 307: Slope field plot

Verification of solutions

$$y = x(x + c_1)$$

Verified OK.

7.15.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u(x)\,x - (u'(x)\,x + u(x))\,x = -x^2$$

Integrating both sides gives

$$\begin{aligned} u(x) &= \int 1\, \mathrm{d}x \\ &= x + c_2 \end{aligned}$$

Therefore the solution y is

$$\begin{aligned} y &= ux \\ &= x(x + c_2) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x(x + c_2) \tag{1}$$

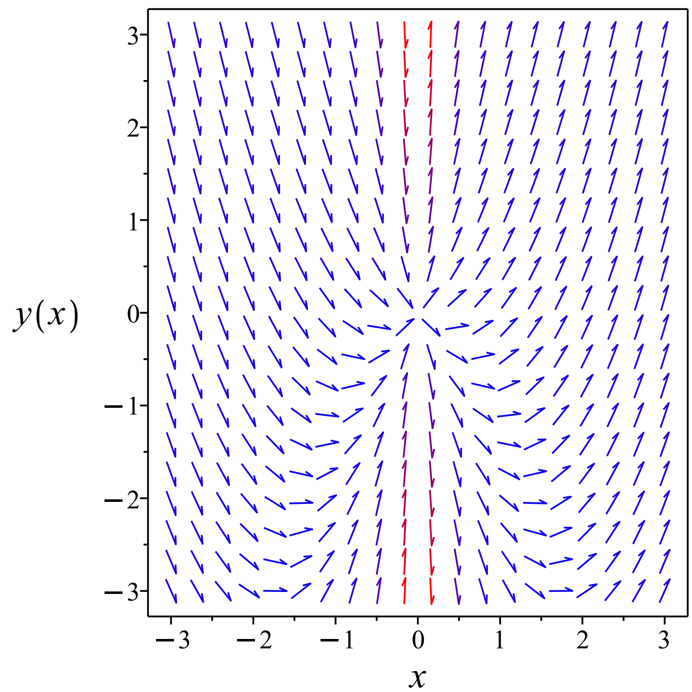

Figure 308: Slope field plot

Verification of solutions

$$y = x(x + c_2)$$

Verified OK.

7.15.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2 + y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 240: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= x
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2+y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{x^2} \\ S_y &= \frac{1}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x} = x + c_1$$

Which simplifies to

$$\frac{y}{x} = x + c_1$$

Which gives

$$y = x(x + c_1)$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2+y}{x}$ 	$R = x$ $S = \frac{y}{x}$	$\frac{dS}{dR} = 1$ 
Summary
The solution(s) found are the following

$$y = x(x + c_1) \tag{1}$$

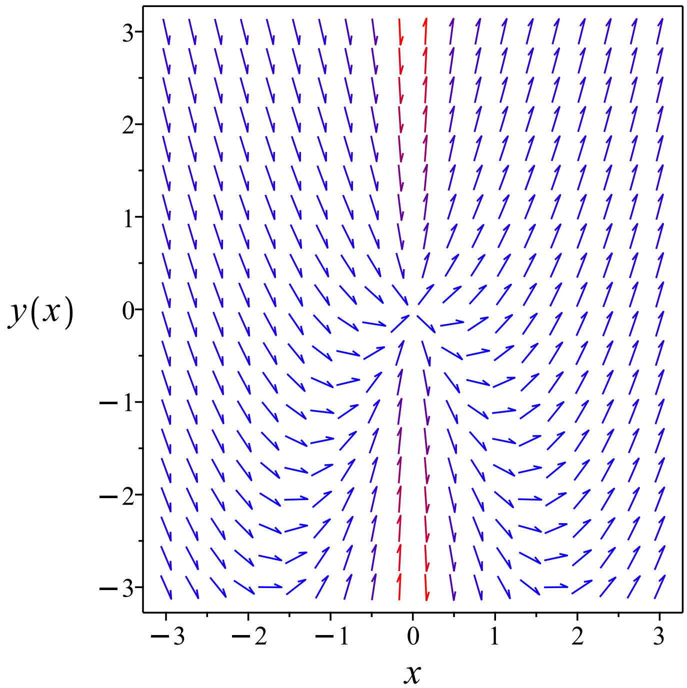

Figure 309: Slope field plot

Verification of solutions

$$y = x(x + c_1)$$

Verified OK.

7.15.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(-x) \,\mathrm{d}y = \left(-x^2 - y\right) \mathrm{d}x$$
$$\left(x^2 + y\right) \mathrm{d}x + (-x) \,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = x^2 + y$$
$$N(x, y) = -x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x^2 + y\right) \\ &= 1 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-x) \\ &= -1 \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= -\frac{1}{x}((1) - (-1)) \\ &= -\frac{2}{x} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\frac{2}{x} \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(x)} \\ &= \frac{1}{x^2} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{x^2}(x^2 + y) \\ &= \frac{x^2 + y}{x^2} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{x^2}(-x) \\ &= -\frac{1}{x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{x^2 + y}{x^2}\right) + \left(-\frac{1}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \frac{x^2+y}{x^2}\,\mathrm{d}x$$
$$\phi = x - \frac{y}{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = -\frac{1}{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = -\frac{1}{x}$. Therefore equation (4) becomes

$$-\frac{1}{x} = -\frac{1}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = x - \frac{y}{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x - \frac{y}{x}$$

The solution becomes

$$y = -(-x + c_1)\, x$$

Summary

The solution(s) found are the following

$$y = -(-x + c_1)\, x \tag{1}$$

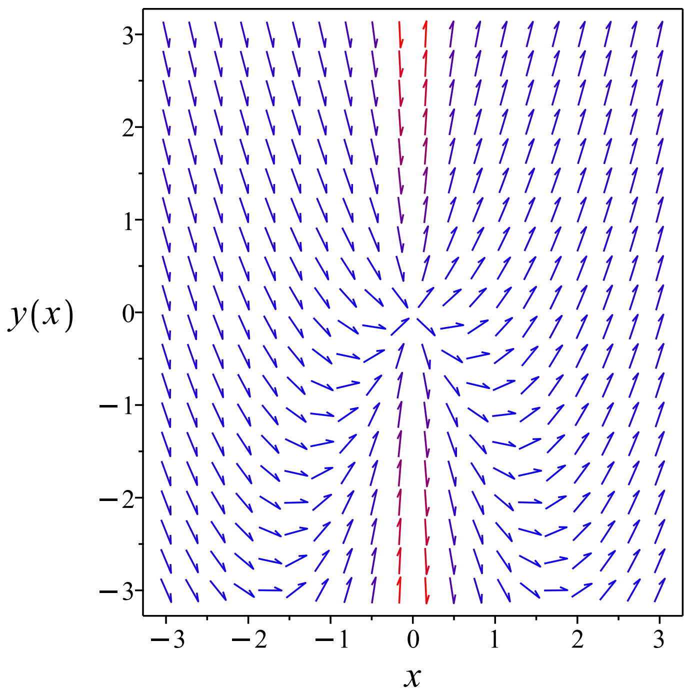

Figure 310: Slope field plot

Verification of solutions

$$y = -(-x + c_1)\, x$$

Verified OK.

7.15.5 Maple step by step solution

Let's solve

$y - y'x = -x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y}{x} + x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{x} = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = \mu(x)\, x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x)\, x dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \mu(x)\, x dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x) x dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{x}$

  $y = x\left(\int 1 dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = x(x + c_1)$

The type(s) of ODE detected by this program : **"bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Bernoulli]
```

$$\boxed{y^2 - 2xyy' = -x}$$

7.16.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y^2 + x}{2yx}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 243: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{x}{y}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2}{2x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y^2 + x}{2yx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y^2}{2x^2} \\ S_y &= \frac{y}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{2x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{2R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\ln(R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x} = \frac{\ln(x)}{2} + c_1$$

Which simplifies to

$$\frac{y^2}{2x} = \frac{\ln(x)}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y^2+x}{2yx}$ 	$R = x$ $S = \frac{y^2}{2x}$	$\frac{dS}{dR} = \frac{1}{2R}$ 
Summary
The solution(s) found are the following

$$\frac{y^2}{2x} = \frac{\ln(x)}{2} + c_1 \tag{1}$$

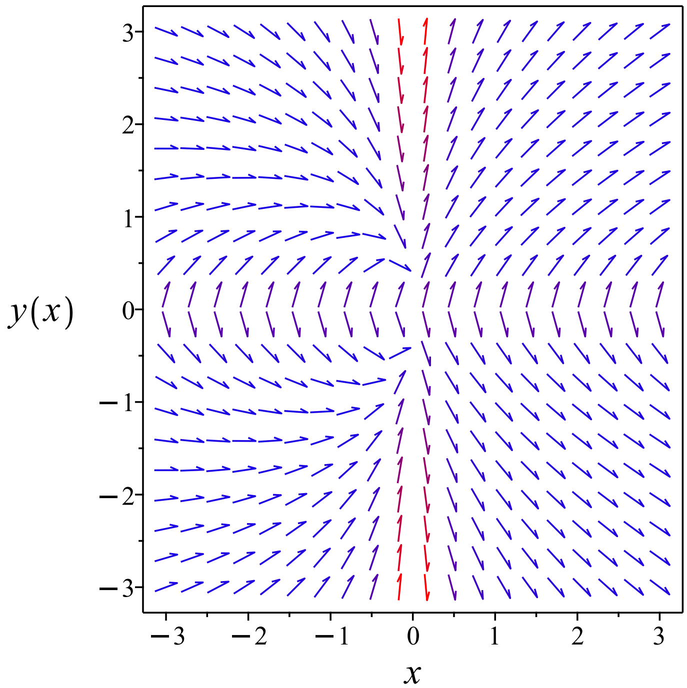

Figure 311: Slope field plot

Verification of solutions

$$\frac{y^2}{2x} = \frac{\ln(x)}{2} + c_1$$

Verified OK.

7.16.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{y^2 + x}{2yx} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{2x}y + \frac{1}{2}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{1}{2x} \\ f_1(x) &= \frac{1}{2} \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = \frac{y^2}{2x} + \frac{1}{2} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= \frac{w(x)}{2x} + \frac{1}{2} \\ w' &= \frac{w}{x} + 1 \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= 1 \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{w(x)}{x} = 1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= \mu \\ \frac{d}{dx}\left(\frac{w}{x}\right) &= \frac{1}{x} \\ d\left(\frac{w}{x}\right) &= \frac{1}{x}dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x} &= \int \frac{1}{x}\, dx \\ \frac{w}{x} &= \ln(x) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$w(x) = x\ln(x) + c_1 x$$

which simplifies to

$$w(x) = x(\ln(x) + c_1)$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = x(\ln(x) + c_1)$$

Solving for y gives

$$\begin{aligned}y(x) &= \sqrt{x(\ln(x) + c_1)} \\ y(x) &= -\sqrt{x(\ln(x) + c_1)}\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \sqrt{x (\ln (x) + c_1)} \tag{1}$$
$$y = -\sqrt{x (\ln (x) + c_1)} \tag{2}$$

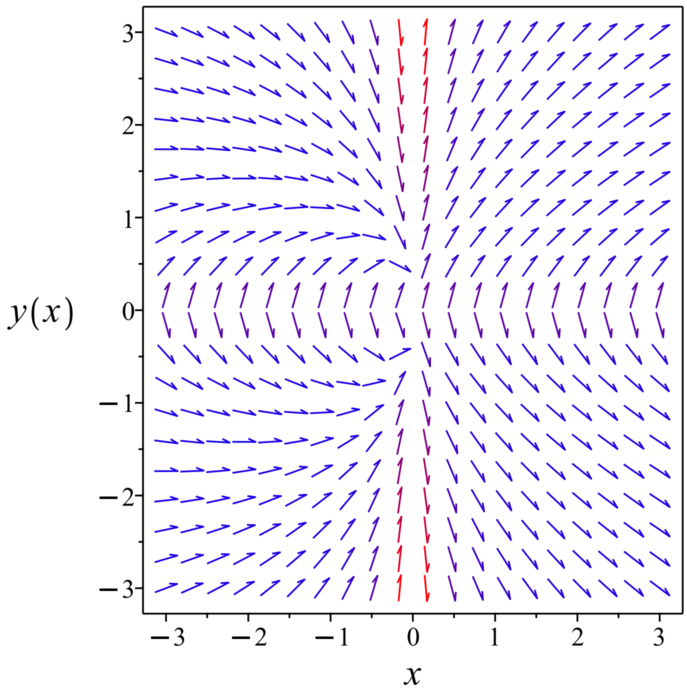

Figure 312: Slope field plot

Verification of solutions

$$y = \sqrt{x (\ln (x) + c_1)}$$

Verified OK.

$$y = -\sqrt{x (\ln (x) + c_1)}$$

Verified OK.

7.16.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(-2xy)\,\mathrm{d}y&=\left(-y^2-x\right)\mathrm{d}x\\ \left(y^2+x\right)\mathrm{d}x+(-2xy)\,\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=y^2+x\\ N(x,y)&=-2xy\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y^2 + x) \\ &= 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-2xy) \\ &= -2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= -\frac{1}{2xy}((2y) - (-2y)) \\ &= -\frac{2}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -\frac{2}{x} \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(x)} \\ &= \frac{1}{x^2}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \frac{1}{x^2}(y^2 + x) \\ &= \frac{y^2 + x}{x^2}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^2}(-2xy) \\
&= -\frac{2y}{x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{y^2+x}{x^2}\right) + \left(-\frac{2y}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \frac{y^2+x}{x^2}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{y^2}{x} + \ln(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -\frac{2y}{x} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{2y}{x}$. Therefore equation (4) becomes

$$
-\frac{2y}{x} = -\frac{2y}{x} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{y^2}{x} + \ln(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{y^2}{x} + \ln(x)$$

Summary

The solution(s) found are the following

$$-\frac{y^2}{x} + \ln(x) = c_1 \tag{1}$$

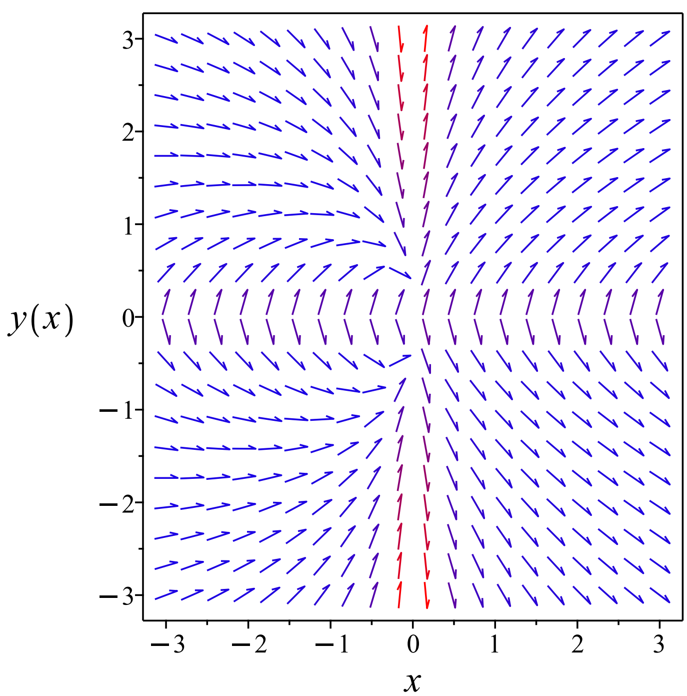

Figure 313: Slope field plot

Verification of solutions

$$-\frac{y^2}{x} + \ln(x) = c_1$$

Verified OK.

Problem number: 192.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{2x^2y + 2y + (2x^3 + 2x)\, y' = -5}$$

7.17.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = -\frac{5}{2x\,(x^2+1)}$$

Hence the ode is

$$y' + \frac{y}{x} = -\frac{5}{2x\,(x^2+1)}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{1}{x}dx} \\
&= x
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(-\frac{5}{2x\left(x^{2}+1\right)}\right) \\
\frac{d}{dx}(xy) &= (x)\left(-\frac{5}{2x\left(x^{2}+1\right)}\right) \\
d(xy) &= \left(-\frac{5}{2x^{2}+2}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
xy &= \int -\frac{5}{2x^{2}+2}\, dx \\
xy &= -\frac{5\arctan\left(x\right)}{2}+c_{1}
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$
y = -\frac{5\arctan\left(x\right)}{2x}+\frac{c_{1}}{x}
$$

Summary
The solution(s) found are the following

$$
y = -\frac{5\arctan\left(x\right)}{2x}+\frac{c_{1}}{x} \tag{1}
$$

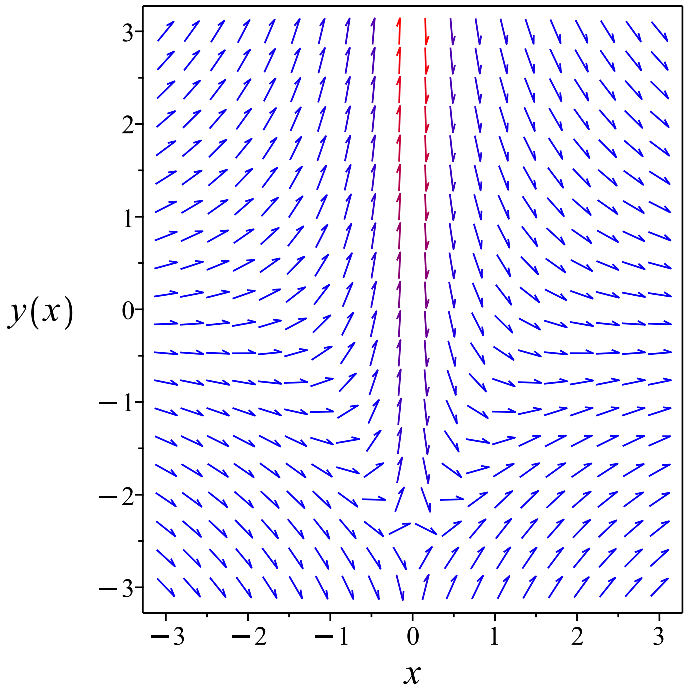

Figure 314: Slope field plot

Verification of solutions

$$y = -\frac{5 \arctan(x)}{2x} + \frac{c_1}{x}$$

Verified OK.

7.17.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{2x^2y + 2y + 5}{2x(x^2 + 1)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 245: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy\end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{2x^2 y + 2y + 5}{2x\,(x^2+1)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{5}{2x^2 + 2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{5}{2R^2 + 2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{5 \arctan (R)}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = -\frac{5 \arctan (x)}{2} + c_1$$

Which simplifies to

$$yx = -\frac{5 \arctan (x)}{2} + c_1$$

Which gives

$$y = -\frac{5 \arctan (x) - 2c_1}{2x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2x^2y+2y+5}{2x(x^2+1)}$ 	$R = x$ $S = xy$	$\frac{dS}{dR} = -\frac{5}{2R^2+2}$ 
Summary

The solution(s) found are the following

$$y = -\frac{5\arctan(x) - 2c_1}{2x} \tag{1}$$

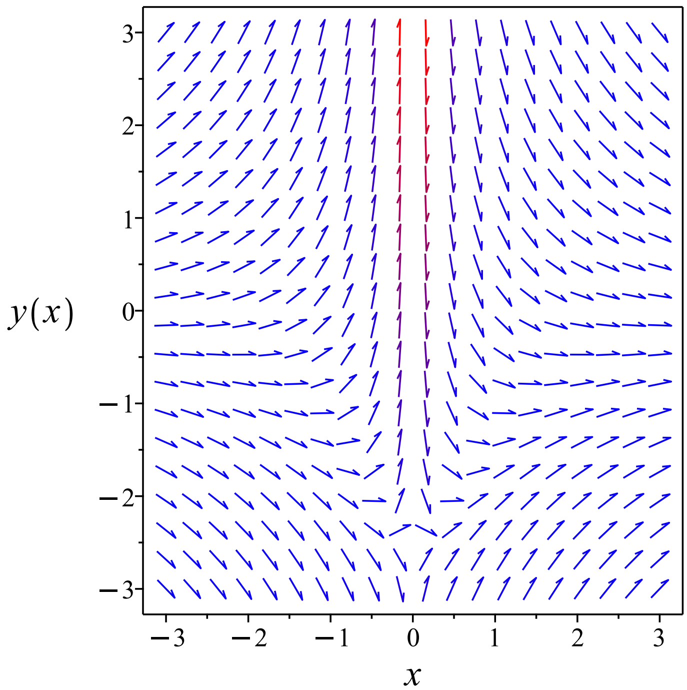

Figure 315: Slope field plot

Verification of solutions

$$y = -\frac{5\arctan(x) - 2c_1}{2x}$$

Verified OK.

7.17.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2x^3 + 2x)\,\mathrm{d}y &= (-2x^2y - 2y - 5)\,\mathrm{d}x \\ (2x^2y + 2y + 5)\,\mathrm{d}x + (2x^3 + 2x)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 2x^2y + 2y + 5 \\ N(x, y) &= 2x^3 + 2x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(2x^2y + 2y + 5) \\ &= 2x^2 + 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x^3+2x)\\ &= 6x^2+2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x^3+2x}\left(\left(2x^2+2\right)-\left(6x^2+2\right)\right)\\ &= -\frac{2x}{x^2+1}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \,\mathrm{d}x}\\ &= e^{\int -\frac{2x}{x^2+1} \,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-\ln\left(x^2+1\right)}\\ &= \frac{1}{x^2+1}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^2+1}\left(2x^2y+2y+5\right)\\ &= \frac{2x^2y+2y+5}{x^2+1}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{x^2+1}\left(2x^3+2x\right)\\ &= 2x\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\frac{2x^2y + 2y + 5}{x^2 + 1}\right) + (2x)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \frac{2x^2y + 2y + 5}{x^2 + 1}\,\mathrm{d}x$$
$$\phi = 2xy + 5\arctan(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = 2x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = 2x$. Therefore equation (4) becomes

$$2x = 2x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = 2xy + 5\arctan(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 2xy + 5\arctan(x)$$

Summary

The solution(s) found are the following

$$2yx + 5\arctan(x) = c_1 \tag{1}$$

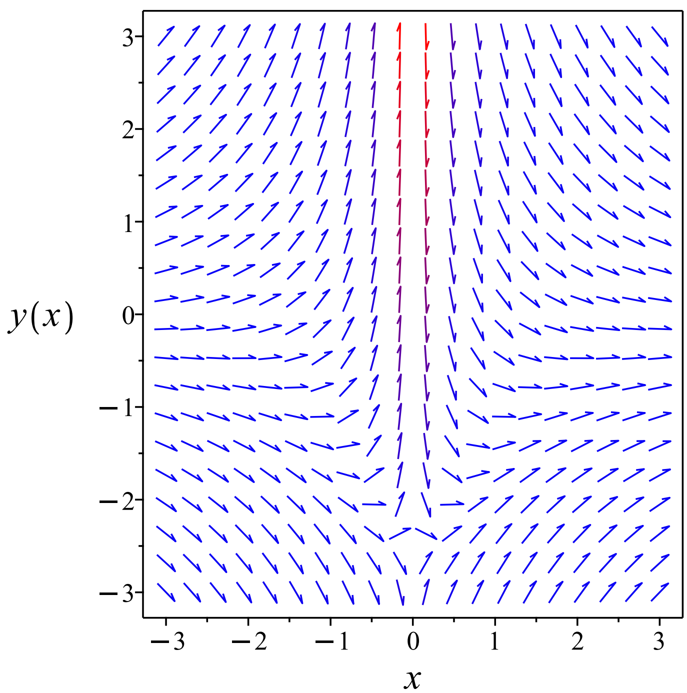

Figure 316: Slope field plot

Verification of solutions

$$2yx + 5\arctan(x) = c_1$$

Verified OK.

7.17.4 Maple step by step solution

Let's solve

$2x^2y + 2y + (2x^3 + 2x)\, y' = -5$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{x} - \frac{5}{2x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{x} = -\frac{5}{2x(x^2+1)}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = -\frac{5\mu(x)}{2x(x^2+1)}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = x$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int -\frac{5\mu(x)}{2x(x^2+1)} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int -\frac{5\mu(x)}{2x(x^2+1)} dx + c_1$

- Solve for y

  $y = \frac{\int -\frac{5\mu(x)}{2x\left(x^2+1\right)} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = x$

  $y = \frac{\int -\frac{5}{2\left(x^2+1\right)} dx + c_1}{x}$

- Evaluate the integrals on the rhs

  $y = \frac{-\frac{5\arctan(x)}{2} + c_1}{x}$

The type(s) of ODE detected by this program : **"bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_Bernoulli]`

$$\boxed{-2y^3x+3y'y^2x^2=-x^4\ln(x)}$$

7.18.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{-x^3\ln(x)+2y^3}{3y^2x}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 248: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\,g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\,F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\,e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\,y + g(x)\,y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\,y + f_2(x)\,y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0\\
\eta(x,y) &= \frac{x^2}{y^2}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2}{y^2}} dy \end{aligned}$$

Which results in

$$S = \frac{y^3}{3x^2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{-x^3 \ln(x) + 2y^3}{3y^2 x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2y^3}{3x^3} \\ S_y &= \frac{y^2}{x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{\ln(x)}{3} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{\ln(R)}{3}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{R \ln(R)}{3} + \frac{R}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^3}{3x^2} = -\frac{x \ln(x)}{3} + \frac{x}{3} + c_1$$

Which simplifies to

$$\frac{y^3}{3x^2} = -\frac{x \ln(x)}{3} + \frac{x}{3} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>

Summary

The solution(s) found are the following

$$\frac{y^3}{3x^2} = -\frac{x \ln(x)}{3} + \frac{x}{3} + c_1 \tag{1}$$

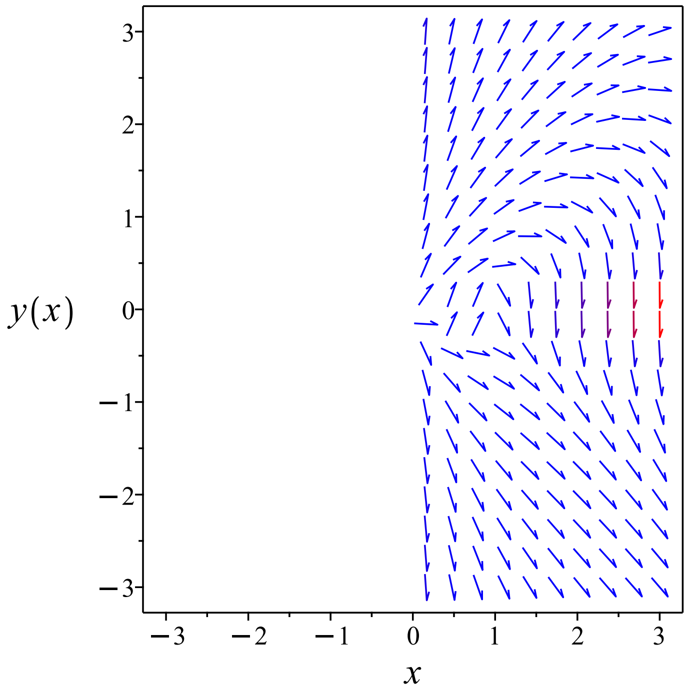

Figure 317: Slope field plot

Verification of solutions

$$\frac{y^3}{3x^2} = -\frac{x\ln(x)}{3} + \frac{x}{3} + c_1$$

Verified OK.

7.18.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{-x^3\ln(x) + 2y^3}{3y^2x} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{2}{3x}y - \frac{x^2\ln(x)}{3}\frac{1}{y^2} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= \frac{2}{3x} \\ f_1(x) &= -\frac{x^2 \ln(x)}{3} \\ n &= -2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y^2}$ gives

$$y'y^2 = \frac{2y^3}{3x} - \frac{x^2 \ln(x)}{3} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^3 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 3y^2y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{3} &= \frac{2w(x)}{3x} - \frac{x^2 \ln(x)}{3} \\ w' &= \frac{2w}{x} - x^2 \ln(x) \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= -x^2 \ln(x) \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{2w(x)}{x} = -x^2 \ln(x)$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{2}{x}dx} \\ &= \frac{1}{x^2}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)\left(-x^2 \ln(x)\right) \\ \frac{d}{dx}\left(\frac{w}{x^2}\right) &= \left(\frac{1}{x^2}\right)\left(-x^2 \ln(x)\right) \\ d\left(\frac{w}{x^2}\right) &= (-\ln(x))\ dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x^2} &= \int -\ln(x)\ dx \\ \frac{w}{x^2} &= -x\ln(x) + x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^2}$ results in

$$w(x) = x^2(-x\ln(x) + x) + c_1 x^2$$

which simplifies to

$$w(x) = -x^2(x\ln(x) - c_1 - x)$$

Replacing w in the above by y^3 using equation (5) gives the final solution.

$$y^3 = -x^2(x\ln(x) - c_1 - x)$$

Solving for y gives

$$\begin{aligned}y(x) &= \left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}} \\ y(x) &= -\frac{\left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}}\left(1 + i\sqrt{3}\right)}{2} \\ y(x) &= \frac{\left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}}\left(i\sqrt{3} - 1\right)}{2}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}} \tag{1}$$

$$y = -\frac{\left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}}\left(1 + i\sqrt{3}\right)}{2} \tag{2}$$

$$y = \frac{\left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}}\left(i\sqrt{3} - 1\right)}{2} \tag{3}$$

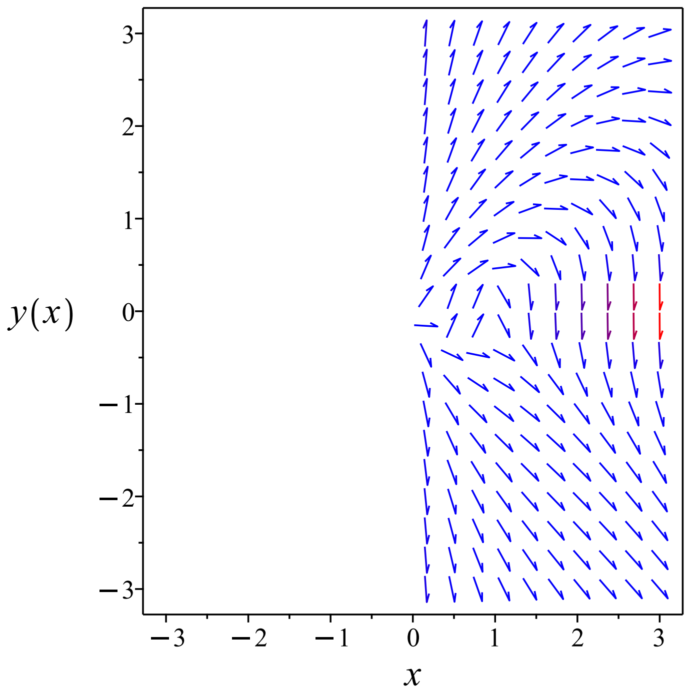

Figure 318: Slope field plot

Verification of solutions

$$y = \left(-x^2(x\ln(x) - c_1 - x)\right)^{\frac{1}{3}}$$

Verified OK.

7.18.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition

$\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(3y^2x^2)\,\mathrm{d}y &= \left(-x^4 \ln(x) + 2x\,y^3\right)\mathrm{d}x \\ \left(x^4 \ln(x) - 2x\,y^3\right)\mathrm{d}x + (3y^2x^2)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= x^4 \ln(x) - 2x\,y^3 \\ N(x,y) &= 3y^2x^2\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x^4 \ln(x) - 2x\,y^3\right) \\ &= -6y^2x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(3y^2x^2) \\ &= 6y^2x\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{3x^2y^2}\left((-6y^2x) - (6y^2x)\right) \\ &= -\frac{4}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x} \\ &= e^{\int -\frac{4}{x}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-4\ln(x)} \\ &= \frac{1}{x^4}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \frac{1}{x^4}\left(x^4 \ln(x) - 2x\,y^3\right) \\ &= \frac{x^3 \ln(x) - 2y^3}{x^3}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \frac{1}{x^4}\left(3y^2x^2\right) \\ &= \frac{3y^2}{x^2}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(\frac{x^3 \ln(x) - 2y^3}{x^3}\right) + \left(\frac{3y^2}{x^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{x^3 \ln(x) - 2y^3}{x^3} \mathrm{d}x$$

$$\phi = x \ln(x) - x + \frac{y^3}{x^2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{3y^2}{x^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{3y^2}{x^2}$. Therefore equation (4) becomes

$$\frac{3y^2}{x^2} = \frac{3y^2}{x^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = x \ln(x) - x + \frac{y^3}{x^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x \ln(x) - x + \frac{y^3}{x^2}$$

Summary

The solution(s) found are the following

$$x \ln(x) - x + \frac{y^3}{x^2} = c_1 \tag{1}$$

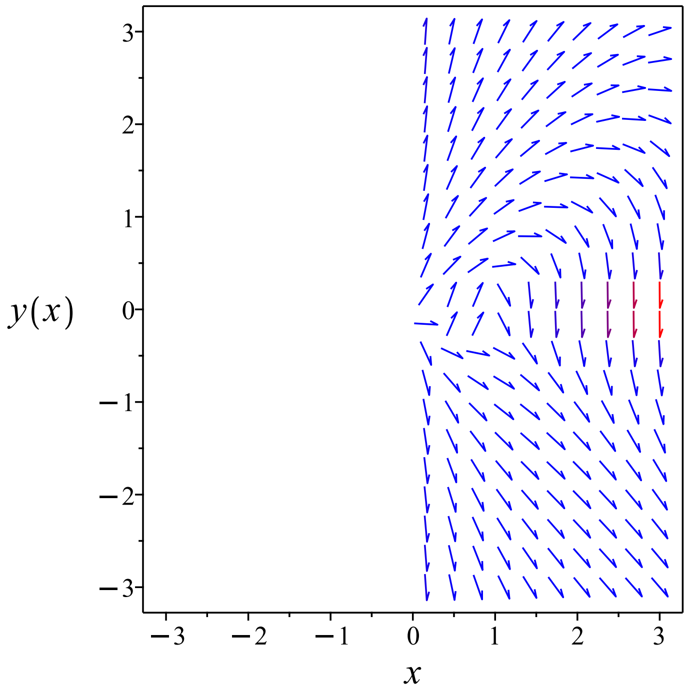

Figure 319: Slope field plot

Verification of solutions

$$x\ln(x) - x + \frac{y^3}{x^2} = c_1$$

Verified OK.

```
[`y=_G(x,y')`]
```

$$\boxed{\cos(y)\,y' + \sin(y) = -\sin(x) - x}$$

7.19.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\cos(y))\,\mathrm{d}y &= (-x - \sin(x) - \sin(y))\,\mathrm{d}x\\ (x + \sin(x) + \sin(y))\,\mathrm{d}x + (\cos(y))\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= x + \sin(x) + \sin(y)\\ N(x, y) &= \cos(y)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x + \sin(x) + \sin(y))\\ &= \cos(y)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(y))\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \sec(y)\,((\cos(y)) - (0))\\ &= 1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int 1 \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{x} \\ &= \mathrm{e}^{x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{x}(x + \sin(x) + \sin(y)) \\ &= (x + \sin(x) + \sin(y))\, \mathrm{e}^{x}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{x}(\cos(y)) \\ &= \mathrm{e}^{x} \cos(y)\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ ((x + \sin(x) + \sin(y))\, \mathrm{e}^{x}) + (\mathrm{e}^{x} \cos(y))\, \frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \, \mathrm{d}x \\ \int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int (x + \sin(x) + \sin(y))\, \mathrm{e}^{x} \, \mathrm{d}x\end{aligned}$$

$$\phi = \frac{\mathrm{e}^{x}(-2 + 2x - \cos(x) + \sin(x) + 2\sin(y))}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = e^{x} \cos(y) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = e^{x} \cos(y)$. Therefore equation (4) becomes

$$e^{x} \cos(y) = e^{x} \cos(y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{e^{x}(-2 + 2x - \cos(x) + \sin(x) + 2\sin(y))}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{e^{x}(-2 + 2x - \cos(x) + \sin(x) + 2\sin(y))}{2}$$

Summary

The solution(s) found are the following

$$\frac{e^{x}(-2 + 2x - \cos(x) + \sin(x) + 2\sin(y))}{2} = c_1 \tag{1}$$

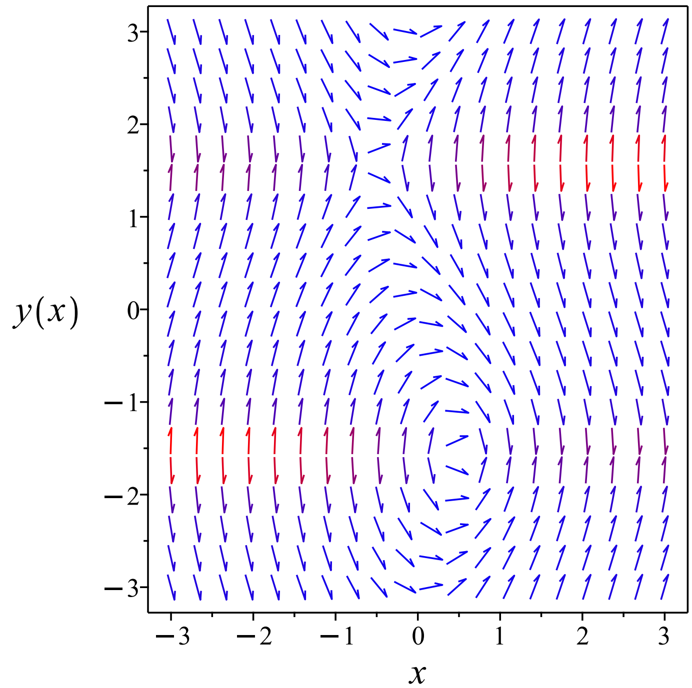

Figure 320: Slope field plot

Verification of solutions

$$\frac{e^x(-2 + 2x - \cos(x) + \sin(x) + 2\sin(y))}{2} = c_1$$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

`[_rational]`

$$\boxed{2y^2x - 3y^3 + (7 - 3y^2x)\, y' = 0}$$

7.20.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-3y^2x+7\right)\mathrm{d}y&=\left(-2y^2x+3y^3\right)\mathrm{d}x\\ \left(2y^2x-3y^3\right)\mathrm{d}x+\left(-3y^2x+7\right)\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=2y^2x-3y^3\\ N(x,y)&=-3y^2x+7\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(2y^2x-3y^3\right)\\ &=y(4x-9y)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}\left(-3y^2x+7\right)\\ &=-3y^2\end{aligned}$$

Since $\frac{\partial M}{\partial y}\neq\frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A&=\frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\ &=\frac{1}{-3y^2x+7}\left(\left(4xy-9y^2\right)-\left(-3y^2\right)\right)\\ &=\frac{-4xy+6y^2}{3y^2x-7}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= \frac{1}{y^2 (2x-3y)}\left(\left(-3y^2\right) - \left(4xy - 9y^2\right)\right) \\ &= -\frac{2}{y} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \, dy} \\ &= e^{\int -\frac{2}{y} \, dy} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(y)} \\ &= \frac{1}{y^2} \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{y^2}\left(2y^2x - 3y^3\right) \\ &= 2x - 3y \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{y^2}\left(-3y^2x + 7\right) \\ &= \frac{-3y^2x + 7}{y^2} \end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{dy}{dx} &= 0 \\ (2x-3y) + \left(\frac{-3y^2x + 7}{y^2}\right)\frac{dy}{dx} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int 2x - 3y\,\mathrm{d}x$$
$$\phi = x(x-3y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = -3x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \frac{-3y^2x+7}{y^2}$. Therefore equation (4) becomes

$$\frac{-3y^2x+7}{y^2} = -3x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{7}{y^2}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{7}{y^2}\right)\mathrm{d}y$$
$$f(y) = -\frac{7}{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(x-3y) - \frac{7}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(x - 3y) - \frac{7}{y}$$

Summary

The solution(s) found are the following

$$x(x - 3y) - \frac{7}{y} = c_1 \tag{1}$$

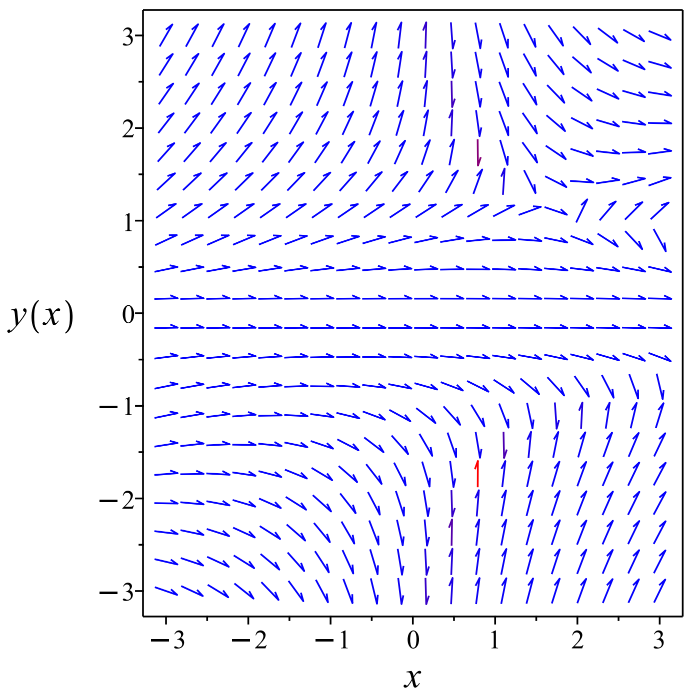

Figure 321: Slope field plot

Verification of solutions

$$x(x - 3y) - \frac{7}{y} = c_1$$

Verified OK.

$$\boxed{3y^2 + \left(2y^3 - 6yx\right) y' = x}$$

7.21.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{3y^2 - x}{2y\left(y^2 - 3x\right)} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2-\frac{(3y^2-x)(b_3-a_2)}{2y(y^2-3x)}-\frac{(3y^2-x)^2 a_3}{4y^2(y^2-3x)^2} \\ & -\left(\frac{1}{2y(y^2-3x)}-\frac{3(3y^2-x)}{2y(y^2-3x)^2}\right)(xa_2+ya_3+a_1) \\ & -\left(-\frac{3}{y^2-3x}+\frac{3y^2-x}{2y^2(y^2-3x)}+\frac{3y^2-x}{(y^2-3x)^2}\right)(xb_2+yb_3+b_1)=0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-4y^6b_2+30x\,y^4b_2-6y^5a_2+12y^5b_3-24x^2y^2b_2+4x\,y^3a_2-8x\,y^3b_3-7y^4a_3+6y^4b_1+6x^3b_2-6x^2ya_2}{4y^2(-y^2+3x)^2}=0$$

Setting the numerator to zero gives

$$\begin{aligned} & 4y^6b_2-30x\,y^4b_2+6y^5a_2-12y^5b_3+24x^2y^2b_2-4x\,y^3a_2+8x\,y^3b_3+7y^4a_3-6y^4b_1 \\ & -6x^3b_2+6x^2ya_2-12x^2yb_3+6x\,y^2a_3-12x\,y^2b_1+16y^3a_1-x^2a_3-6x^2b_1=0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & 4b_2v_2^6+6a_2v_2^5-30b_2v_1v_2^4-12b_3v_2^5-4a_2v_1v_2^3+7a_3v_2^4-6b_1v_2^4+24b_2v_1^2v_2^2 \\ & +8b_3v_1v_2^3+16a_1v_2^3+6a_2v_1^2v_2+6a_3v_1v_2^2-12b_1v_1v_2^2-6b_2v_1^3-12b_3v_1^2v_2-a_3v_1^2 \\ & -6b_1v_1^2=0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}&-6b_2v_1^3 + 24b_2v_1^2v_2^2 + (6a_2 - 12b_3)\, v_1^2v_2 + (-a_3 - 6b_1)\, v_1^2 \\ &- 30b_2v_1v_2^4 + (-4a_2 + 8b_3)\, v_1v_2^3 + (6a_3 - 12b_1)\, v_1v_2^2 \\ &+ 4b_2v_2^6 + (6a_2 - 12b_3)\, v_2^5 + (7a_3 - 6b_1)\, v_2^4 + 16a_1v_2^3 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} 16a_1 &= 0 \\ -30b_2 &= 0 \\ -6b_2 &= 0 \\ 4b_2 &= 0 \\ 24b_2 &= 0 \\ -4a_2 + 8b_3 &= 0 \\ 6a_2 - 12b_3 &= 0 \\ -a_3 - 6b_1 &= 0 \\ 6a_3 - 12b_1 &= 0 \\ 7a_3 - 6b_1 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 2b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 2x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{3y^2 - x}{2y\,(y^2 - 3x)}\right)(2x) \\
&= \frac{-y^4 + x^2}{-y^3 + 3xy} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-y^4+x^2}{-y^3+3xy}} dy
\end{aligned}$$

Which results in

$$S = \ln\left(y^2 + x\right) - \frac{\ln\left(y^2 - x\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{3y^2 - x}{2y\,(y^2 - 3x)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{-3y^2 + x}{-2y^4 + 2x^2} \\
S_y &= \frac{-y^3 + 3xy}{-y^4 + x^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\ln\left(x + y^2\right) - \frac{\ln\left(-x + y^2\right)}{2} = c_1
$$

Which simplifies to

$$
\ln\left(x + y^2\right) - \frac{\ln\left(-x + y^2\right)}{2} = c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{3y^2-x}{2y(y^2-3x)}$ 	$R = x$ $S = \ln(y^2 + x) - \frac{\ln(y^2 -}{2}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\ln(x + y^2) - \frac{\ln(-x + y^2)}{2} = c_1 \tag{1}$$

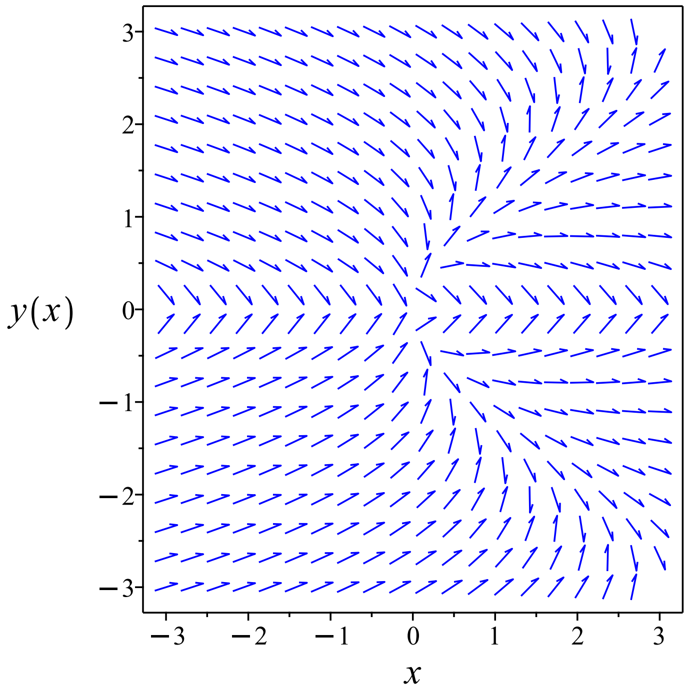

Figure 322: Slope field plot

Verification of solutions

$$\ln \left(x+y^{2}\right)-\frac{\ln \left(-x+y^{2}\right)}{2}=c_{1}$$

Verified OK.

The type(s) of ODE detected by this program : **"bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_rational, _Bernoulli]
```

$$\boxed{y^2 - 2xyy' = -x^2 - 1}$$

7.22.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^2 + y^2 + 1}{2xy}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 250: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{x}{y}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x}{y}} dy \end{aligned}$$

Which results in

$$S = \frac{y^2}{2x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2 + y^2 + 1}{2xy}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y^2}{2x^2} \\ S_y &= \frac{y}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{x^2 + 1}{2x^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R^2 + 1}{2R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R}{2} - \frac{1}{2R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y^2}{2x} = \frac{x}{2} - \frac{1}{2x} + c_1$$

Which simplifies to

$$\frac{y^2}{2x} = \frac{x}{2} - \frac{1}{2x} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2+y^2+1}{2xy}$ 	$R = x$ $S = \frac{y^2}{2x}$	$\frac{dS}{dR} = \frac{R^2+1}{2R^2}$ 
Summary

The solution(s) found are the following

$$\frac{y^2}{2x} = \frac{x}{2} - \frac{1}{2x} + c_1 \tag{1}$$

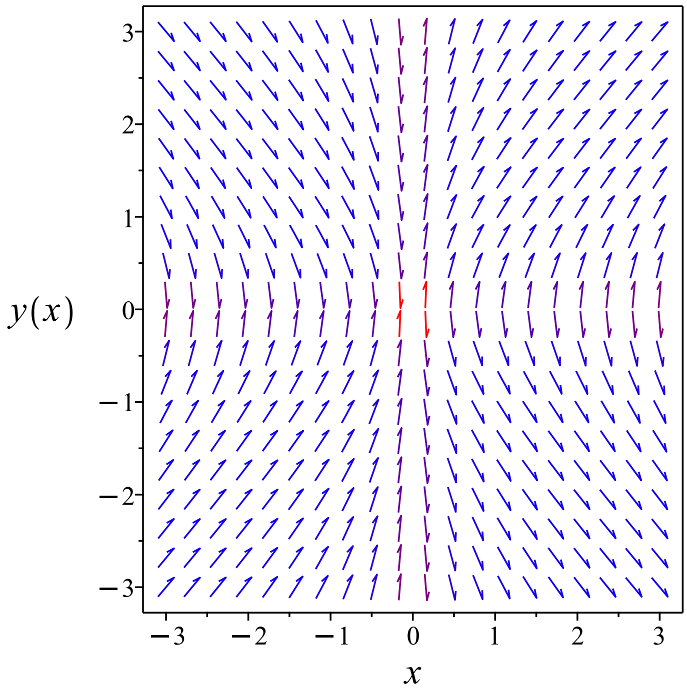

Figure 323: Slope field plot

Verification of solutions

$$\frac{y^2}{2x} = \frac{x}{2} - \frac{1}{2x} + c_1$$

Verified OK.

7.22.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 + y^2 + 1}{2xy} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = \frac{1}{2x}y + \frac{x^2 + 1}{2x}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= \frac{1}{2x} \\
f_1(x) &= \frac{x^2+1}{2x} \\
n &= -1
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$
y'y = \frac{y^2}{2x} + \frac{x^2+1}{2x} \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= y^2
\end{aligned} \tag{5}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = 2yy' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
\frac{w'(x)}{2} &= \frac{w(x)}{2x} + \frac{x^2+1}{2x} \\
w' &= \frac{w}{x} + \frac{x^2+1}{x}
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{x^2+1}{x}
\end{aligned}
$$

Hence the ode is

$$w'(x) - \frac{w(x)}{x} = \frac{x^2+1}{x}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{1}{x}dx}\\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)\left(\frac{x^2+1}{x}\right)\\ \frac{d}{dx}\left(\frac{w}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{x^2+1}{x}\right)\\ d\left(\frac{w}{x}\right) &= \left(\frac{x^2+1}{x^2}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{w}{x} &= \int \frac{x^2+1}{x^2}\, dx\\ \frac{w}{x} &= x - \frac{1}{x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$w(x) = x\left(x - \frac{1}{x}\right) + c_1 x$$

which simplifies to

$$w(x) = c_1 x + x^2 - 1$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = c_1 x + x^2 - 1$$

Solving for y gives

$$\begin{aligned}y(x) &= \sqrt{c_1 x + x^2 - 1}\\ y(x) &= -\sqrt{c_1 x + x^2 - 1}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{c_1 x + x^2 - 1} \tag{1}$$

$$y = -\sqrt{c_1 x + x^2 - 1} \tag{2}$$

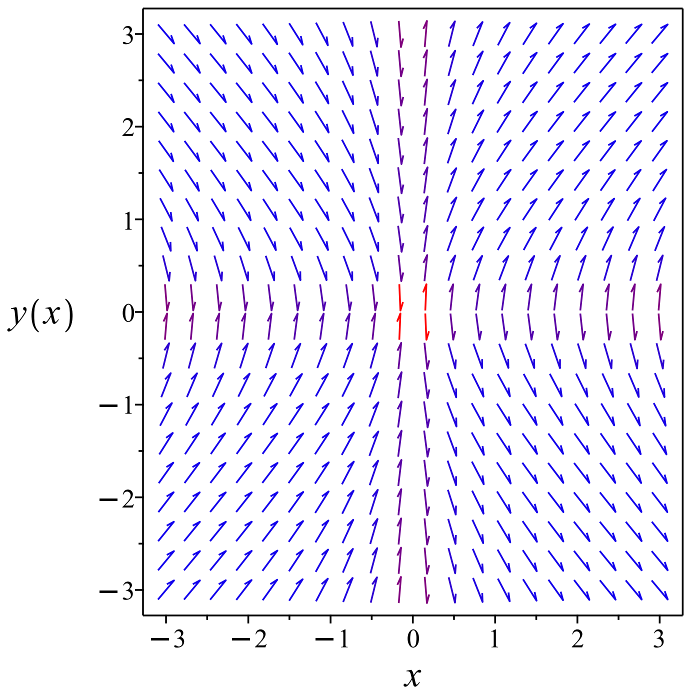

Figure 324: Slope field plot

Verification of solutions

$$y = \sqrt{c_1 x + x^2 - 1}$$

Verified OK.

$$y = -\sqrt{c_1 x + x^2 - 1}$$

Verified OK.

7.22.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(-2xy)\,\mathrm{d}y&=\left(-x^2-y^2-1\right)\mathrm{d}x\\ \left(x^2+y^2+1\right)\mathrm{d}x+(-2xy)\,\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=x^2+y^2+1\\ N(x,y)&=-2xy\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x^2 + y^2 + 1\right)\\ &= 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-2xy)\\ &= -2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= -\frac{1}{2xy}((2y) - (-2y))\\ &= -\frac{2}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x}\\ &= e^{\int -\frac{2}{x} \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-2\ln(x)}\\ &= \frac{1}{x^2}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{x^2}\left(x^2 + y^2 + 1\right)\\ &= \frac{x^2 + y^2 + 1}{x^2}\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^2}(-2xy) \\
&= -\frac{2y}{x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{x^2+y^2+1}{x^2}\right) + \left(-\frac{2y}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int \frac{x^2+y^2+1}{x^2}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{x^2-y^2-1}{x} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial\phi}{\partial y} = -\frac{2y}{x} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = -\frac{2y}{x}$. Therefore equation (4) becomes

$$
-\frac{2y}{x} = -\frac{2y}{x} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x^2 - y^2 - 1}{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x^2 - y^2 - 1}{x}$$

Summary

The solution(s) found are the following

$$\frac{-y^2 + x^2 - 1}{x} = c_1 \tag{1}$$

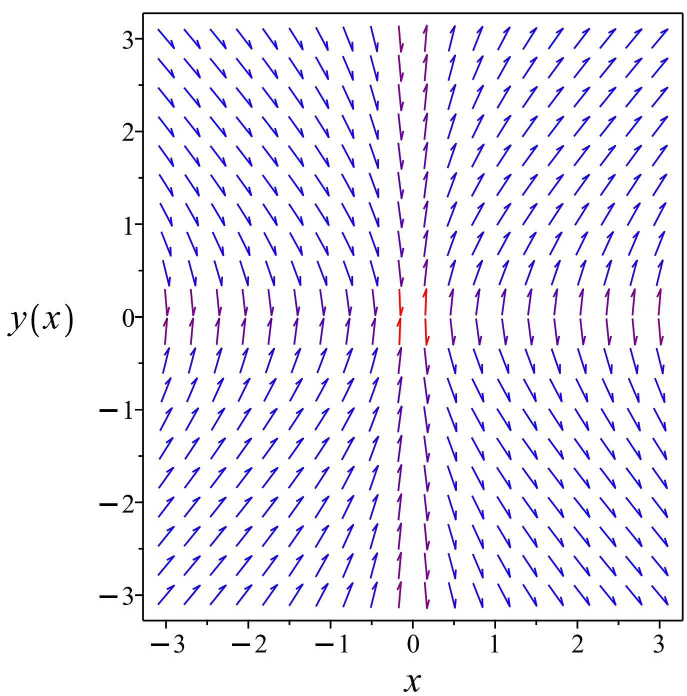

Figure 325: Slope field plot

Verification of solutions

$$\frac{-y^2+x^2-1}{x}=c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x)*G(y),0]`], [
   _Abel, `2nd type`, `class A`]]
```

$$\boxed{-yx + (x^2 + y)\, y' = -x}$$

7.23.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{(y-1)\, x}{x^2 + y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 2 to use as anstaz gives

$$\xi = x^2 a_4 + xya_5 + y^2 a_6 + xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = x^2 b_4 + xyb_5 + y^2 b_6 + xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, b_1, b_2, b_3, b_4, b_5, b_6\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&2xb_4 + yb_5 + b_2 + \frac{(y-1)\,x(-2xa_4 + xb_5 - ya_5 + 2yb_6 - a_2 + b_3)}{x^2+y} \\
&- \frac{(y-1)^2\,x^2(xa_5 + 2ya_6 + a_3)}{(x^2+y)^2} \\
&- \left(\frac{y-1}{x^2+y} - \frac{2(y-1)\,x^2}{(x^2+y)^2}\right)(x^2a_4 + xya_5 + y^2a_6 + xa_2 + ya_3 + a_1) \\
&- \left(\frac{x}{x^2+y} - \frac{(y-1)\,x}{(x^2+y)^2}\right)(x^2b_4 + xyb_5 + y^2b_6 + xb_2 + yb_3 + b_1) = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{x^5b_4 - x^4ya_4 + x^4yb_5 - x^3y^2a_5 + x^3y^2b_6 - x^2y^3a_6 + x^4a_4 - x^4b_5 + 2x^3ya_5 + 4x^3yb_4 - 2x^3yb_6 - 3x^2y^2a_4 +}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&x^5b_4 - x^4ya_4 + x^4yb_5 - x^3y^2a_5 + x^3y^2b_6 - x^2y^3a_6 + x^4a_4 - x^4b_5 + 2x^3ya_5 \\
&+4x^3yb_4 - 2x^3yb_6 - 3x^2y^2a_4 + 3x^2y^2a_6 + 3x^2y^2b_5 - 2x\,y^3a_5 + 2x\,y^3b_6 - y^4a_6 \\
&- x^3a_5 - x^3b_1 - x^3b_3 - x^3b_4 + x^2ya_1 + x^2ya_3 + 3x^2ya_4 - 2x^2ya_6 + 2x^2yb_2 \\
&- 2x^2yb_5 - 2x\,y^2a_2 + 2x\,y^2a_5 + x\,y^2b_3 + 2x\,y^2b_4 - 3x\,y^2b_6 - y^3a_3 + y^3a_6 \\
&+y^3b_5 - x^2a_1 - x^2a_3 - x^2b_2 + 2xya_2 - 2xyb_3 - y^2a_1 + y^2a_3 + y^2b_2 - xb_1 + ya_1 \\
&= 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-a_4 v_1^4 v_2 - a_5 v_1^3 v_2^2 - a_6 v_1^2 v_2^3 + b_4 v_1^5 + b_5 v_1^4 v_2 + b_6 v_1^3 v_2^2 + a_4 v_1^4 - 3a_4 v_1^2 v_2^2 \\
&+ 2a_5 v_1^3 v_2 - 2a_5 v_1 v_2^3 + 3a_6 v_1^2 v_2^2 - a_6 v_2^4 + 4b_4 v_1^3 v_2 - b_5 v_1^4 + 3b_5 v_1^2 v_2^2 \\
&- 2b_6 v_1^3 v_2 + 2b_6 v_1 v_2^3 + a_1 v_1^2 v_2 - 2a_2 v_1 v_2^2 + a_3 v_1^2 v_2 - a_3 v_2^3 + 3a_4 v_1^2 v_2 \\
&- a_5 v_1^3 + 2a_5 v_1 v_2^2 - 2a_6 v_1^2 v_2 + a_6 v_2^3 - b_1 v_1^3 + 2b_2 v_1^2 v_2 - b_3 v_1^3 \\
&+ b_3 v_1 v_2^2 - b_4 v_1^3 + 2b_4 v_1 v_2^2 - 2b_5 v_1^2 v_2 + b_5 v_2^3 - 3b_6 v_1 v_2^2 - a_1 v_1^2 - a_1 v_2^2 \\
&+ 2a_2 v_1 v_2 - a_3 v_1^2 + a_3 v_2^2 - b_2 v_1^2 + b_2 v_2^2 - 2b_3 v_1 v_2 + a_1 v_2 - b_1 v_1 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&b_4 v_1^5 + (-a_4 + b_5) v_1^4 v_2 + (a_4 - b_5) v_1^4 + (-a_5 + b_6) v_1^3 v_2^2 \\
&+ (2a_5 + 4b_4 - 2b_6) v_1^3 v_2 + (-a_5 - b_1 - b_3 - b_4) v_1^3 - a_6 v_1^2 v_2^3 \\
&+ (-3a_4 + 3a_6 + 3b_5) v_1^2 v_2^2 + (a_1 + a_3 + 3a_4 - 2a_6 + 2b_2 - 2b_5) v_1^2 v_2 \\
&+ (-a_1 - a_3 - b_2) v_1^2 + (-2a_5 + 2b_6) v_1 v_2^3 \\
&+ (-2a_2 + 2a_5 + b_3 + 2b_4 - 3b_6) v_1 v_2^2 + (2a_2 - 2b_3) v_1 v_2 - b_1 v_1 \\
&- a_6 v_2^4 + (-a_3 + a_6 + b_5) v_2^3 + (-a_1 + a_3 + b_2) v_2^2 + a_1 v_2 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
a_1 &= 0 \\
b_4 &= 0 \\
-a_6 &= 0 \\
-b_1 &= 0 \\
2a_2 - 2b_3 &= 0 \\
-a_4 + b_5 &= 0 \\
a_4 - b_5 &= 0 \\
-2a_5 + 2b_6 &= 0 \\
-a_5 + b_6 &= 0 \\
-a_1 - a_3 - b_2 &= 0 \\
-a_1 + a_3 + b_2 &= 0 \\
-a_3 + a_6 + b_5 &= 0 \\
-3a_4 + 3a_6 + 3b_5 &= 0 \\
2a_5 + 4b_4 - 2b_6 &= 0 \\
-a_5 - b_1 - b_3 - b_4 &= 0 \\
-2a_2 + 2a_5 + b_3 + 2b_4 - 3b_6 &= 0 \\
a_1 + a_3 + 3a_4 - 2a_6 + 2b_2 - 2b_5 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -b_6 \\
a_3 &= b_5 \\
a_4 &= b_5 \\
a_5 &= b_6 \\
a_6 &= 0 \\
b_1 &= 0 \\
b_2 &= -b_5 \\
b_3 &= -b_6 \\
b_4 &= 0 \\
b_5 &= b_5 \\
b_6 &= b_6
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = xy - x$$
$$\eta = y^2 - y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y^2 - y - \left(\frac{(y-1)\,x}{x^2+y}\right)(xy - x) \\
&= \frac{x^2y + y^3 - x^2 - y^2}{x^2+y} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{x^2y+y^3-x^2-y^2}{x^2+y}} dy
\end{aligned}$$

Which results in

$$S = -\frac{\ln(x^2+y^2)}{2} + \ln(y-1)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{(y-1)\,x}{x^2+y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{x}{x^2+y^2} \\
S_y &= -\frac{y}{x^2+y^2} + \frac{1}{y-1}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{\ln\left(x^2+y^2\right)}{2} + \ln\left(y-1\right) = c_1$$

Which simplifies to

$$-\frac{\ln\left(x^2+y^2\right)}{2} + \ln\left(y-1\right) = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{(y-1)x}{x^2+y}$ 	$R = x$ $S = -\frac{\ln(x^2+y^2)}{2} + \ln(y$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$-\frac{\ln(x^2+y^2)}{2} + \ln(y-1) = c_1 \tag{1}$$

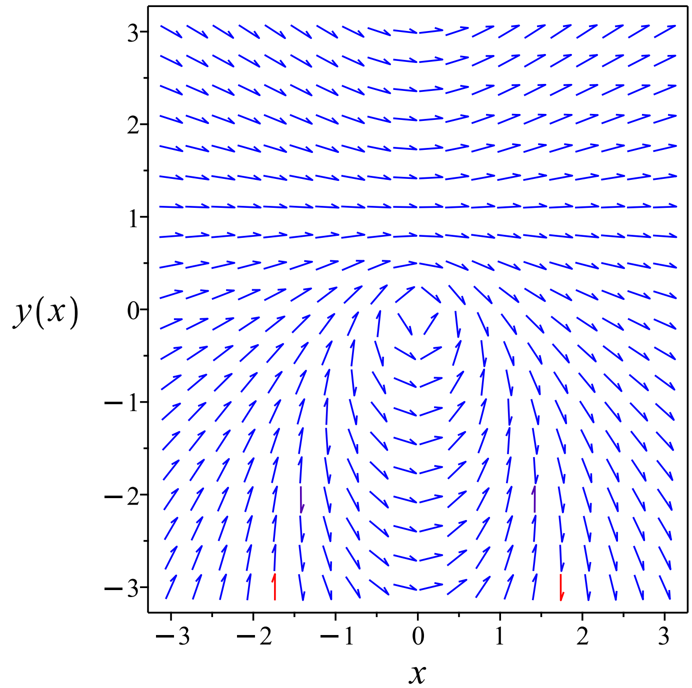

Figure 326: Slope field plot

Verification of solutions

$$-\frac{\ln(x^2+y^2)}{2}+\ln(y-1)=c_1$$

Verified OK.

7.23.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x^2 + y)\,\mathrm{d}y &= (xy - x)\,\mathrm{d}x \\ (-xy + x)\,\mathrm{d}x + (x^2 + y)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -xy + x \\ N(x, y) &= x^2 + y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-xy + x) \\ &= -x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^2 + y) \\ &= 2x\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{x^2+y}((-x) - (2x)) \\ &= -\frac{3x}{x^2+y} \end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned} B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\ &= -\frac{1}{(y-1)\,x}((2x) - (-x)) \\ &= -\frac{3}{y-1} \end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned} \mu &= e^{\int B \,\mathrm{d}y} \\ &= e^{\int -\frac{3}{y-1} \,\mathrm{d}y} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-3\ln(y-1)} \\ &= \frac{1}{(y-1)^3} \end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{(y-1)^3}(-xy + x) \\ &= -\frac{x}{(y-1)^2} \end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{(y-1)^3}\left(x^2+y\right) \\
&= \frac{x^2+y}{(y-1)^3}
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(-\frac{x}{(y-1)^2}\right) + \left(\frac{x^2+y}{(y-1)^3}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{x}{(y-1)^2}\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{x^2}{2\,(y-1)^2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = \frac{x^2}{(y-1)^3} + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{x^2+y}{(y-1)^3}$. Therefore equation (4) becomes

$$
\frac{x^2+y}{(y-1)^3} = \frac{x^2}{(y-1)^3} + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y}{(y-1)^3}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{y}{(y-1)^3}\right) \mathrm{d}y$$
$$f(y) = -\frac{1}{y-1} - \frac{1}{2(y-1)^2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2(y-1)^2} - \frac{1}{y-1} - \frac{1}{2(y-1)^2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2(y-1)^2} - \frac{1}{y-1} - \frac{1}{2(y-1)^2}$$

Summary

The solution(s) found are the following

$$-\frac{x^2}{2(y-1)^2} - \frac{1}{y-1} - \frac{1}{2(y-1)^2} = c_1 \tag{1}$$

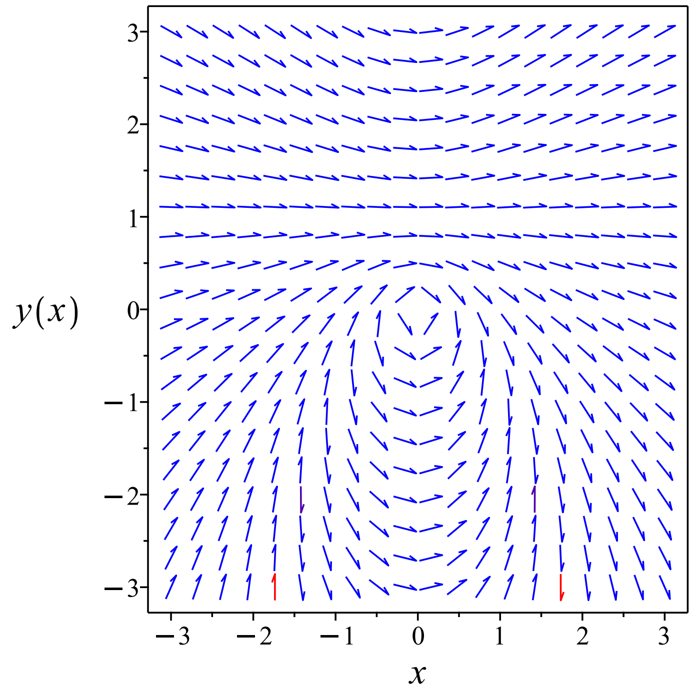

Figure 327: Slope field plot

Verification of solutions

$$-\frac{x^2}{2\left(y-1\right)^2}-\frac{1}{y-1}-\frac{1}{2\left(y-1\right)^2}=c_1$$

Verified OK.

ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{4y'^2 = 9x}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{3\sqrt{x}}{2} \tag{1}$$
$$y' = -\frac{3\sqrt{x}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{3\sqrt{x}}{2}\, \mathrm{d}x \\ &= x^{\frac{3}{2}} + c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x^{\frac{3}{2}} + c_1 \tag{1}$$

Verification of solutions

$$y = x^{\frac{3}{2}} + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{3\sqrt{x}}{2}\, \mathrm{d}x \\ &= -x^{\frac{3}{2}} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -x^{\frac{3}{2}} + c_2 \tag{1}$$

Verification of solutions

$$y = -x^{\frac{3}{2}} + c_2$$

Verified OK.

8.1.1 Maple step by step solution

Let's solve

$4y'^2 = 9x$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int 4y'^2 dx = \int 9x dx + c_1$

- Cannot compute integral

  $\int 4y'^2 dx = \frac{9x^2}{2} + c_1$

Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 200.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y'^2 - 2yy' - y^2(e^{2x} - 1) = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = (e^x + 1)\, y \tag{1}$$
$$y' = (1 - e^x)\, y \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)g(y) \\ &= (e^x + 1)\, y \end{aligned}$$

Where $f(x) = e^x + 1$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\, dy &= e^x + 1\, dx \\
\int \frac{1}{y}\, dy &= \int e^x + 1\, dx \\
\ln(y) &= x + e^x + c_1 \\
y &= e^{x + e^x + c_1} \\
&= c_1 e^{x + e^x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{x + e^x} \tag{1}$$

Verification of solutions

$$y = c_1 e^{x + e^x}$$

Verified OK.

Solving equation (2)

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x, y) \\
&= f(x) g(y) \\
&= (1 - e^x)\, y
\end{aligned}$$

Where $f(x) = 1 - e^x$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\, dy &= 1 - e^x\, dx \\
\int \frac{1}{y}\, dy &= \int 1 - e^x\, dx \\
\ln(y) &= x - e^x + c_2 \\
y &= e^{x - e^x + c_2} \\
&= c_2 e^{x - e^x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 e^{x - e^x} \tag{1}$$

Verification of solutions

$$y = c_2 \mathrm{e}^{x-\mathrm{e}^x}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 203.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"exact", "linear", "quadrature", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{{y'}^2 - (2x+y)\,y' + yx = -x^2}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = x \tag{1}$$
$$y' = y + x \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int x \, \mathrm{d}x \\ &= \frac{x^2}{2} + c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x^2}{2} + c_1 \tag{1}$$

Verification of solutions

$$y = \frac{x^2}{2} + c_1$$

Verified OK.

Solving equation (2)

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = x$$

Hence the ode is

$$y' - y = x$$

The integrating factor μ is

$$\mu = e^{\int(-1)dx}$$
$$= e^{-x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(x)$$
$$\frac{d}{dx}(e^{-x}y) = (e^{-x})(x)$$
$$d(e^{-x}y) = (x e^{-x})\, dx$$

Integrating gives

$$e^{-x}y = \int x e^{-x}\, dx$$
$$e^{-x}y = -(x+1)e^{-x} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = -e^{x}(x+1)e^{-x} + c_2 e^{x}$$

which simplifies to

$$y = -x - 1 + c_2 e^{x}$$

Summary

The solution(s) found are the following

$$y = -x - 1 + c_2 e^x \tag{1}$$

Verification of solutions

$$y = -x - 1 + c_2 e^x$$

Verified OK.

Internal problem ID [15092]
Internal file name [`OUTPUT/15092_Sunday_April_21_2024_01_29_35_PM_19635907/index.tex`]

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 204.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"first_order_nonlinear_p_but_separable"**

Maple gives the following as the ode type

```
[[_1st_order, _with_exponential_symmetries]]
```

$$\boxed{{y'}^{3}+(x+2)\,\mathrm{e}^{y}=0}$$

8.6.1 Solving as first order nonlinear p but separable ode

The ode has the form

$$(y')^{\frac{n}{m}}=f(x)g(y) \tag{1}$$

Where $n=3, m=1, f=-x-2, g=\mathrm{e}^{y}$. Hence the ode is

$$(y')^{3}=\mathrm{e}^{y}(-x-2)$$

Solving for y' from (1) gives

$$\begin{aligned}
y' &= (fg)^{\frac{1}{3}} \\
y' &= -\frac{(fg)^{\frac{1}{3}}}{2}+\frac{i\sqrt{3}\,(fg)^{\frac{1}{3}}}{2} \\
y' &= -\frac{(fg)^{\frac{1}{3}}}{2}-\frac{i\sqrt{3}\,(fg)^{\frac{1}{3}}}{2}
\end{aligned}$$

To be able to solve as separable ode, we have to now assume that $f > 0, g > 0$.

$$
\begin{aligned}
-x - 2 &> 0 \\
e^y &> 0
\end{aligned}
$$

Under the above assumption the differential equations become separable and can be written as

$$
\begin{aligned}
y' &= f^{\frac{1}{3}} g^{\frac{1}{3}} \\
y' &= \frac{f^{\frac{1}{3}} g^{\frac{1}{3}} \left(i\sqrt{3}-1\right)}{2} \\
y' &= -\frac{f^{\frac{1}{3}} g^{\frac{1}{3}} \left(1+i\sqrt{3}\right)}{2}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\frac{1}{g^{\frac{1}{3}}}\, dy &= \left(f^{\frac{1}{3}}\right)\, dx \\
\frac{2}{g^{\frac{1}{3}} \left(i\sqrt{3}-1\right)}\, dy &= \left(f^{\frac{1}{3}}\right)\, dx \\
-\frac{2}{g^{\frac{1}{3}} \left(1+i\sqrt{3}\right)}\, dy &= \left(f^{\frac{1}{3}}\right)\, dx
\end{aligned}
$$

Replacing $f(x), g(y)$ by their values gives

$$
\begin{aligned}
\frac{1}{\left(e^y\right)^{\frac{1}{3}}}\, dy &= \left((-x-2)^{\frac{1}{3}}\right)\, dx \\
\frac{2}{\left(e^y\right)^{\frac{1}{3}} \left(i\sqrt{3}-1\right)}\, dy &= \left((-x-2)^{\frac{1}{3}}\right)\, dx \\
-\frac{2}{\left(e^y\right)^{\frac{1}{3}} \left(1+i\sqrt{3}\right)}\, dy &= \left((-x-2)^{\frac{1}{3}}\right)\, dx
\end{aligned}
$$

Integrating now gives the solutions.

$$
\begin{aligned}
\int \frac{1}{\left(e^y\right)^{\frac{1}{3}}} dy &= \int (-x-2)^{\frac{1}{3}}\, dx + c_1 \\
\int \frac{2}{\left(e^y\right)^{\frac{1}{3}} \left(i\sqrt{3}-1\right)} dy &= \int (-x-2)^{\frac{1}{3}}\, dx + c_1 \\
\int -\frac{2}{\left(e^y\right)^{\frac{1}{3}} \left(1+i\sqrt{3}\right)} dy &= \int (-x-2)^{\frac{1}{3}}\, dx + c_1
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
-\frac{3}{\left(e^{y}\right)^{\frac{1}{3}}} &= -\frac{3(-x-2)^{\frac{4}{3}}}{4}+c_1 \\
-\frac{6}{\left(e^{y}\right)^{\frac{1}{3}}\left(i\sqrt{3}-1\right)} &= -\frac{3(-x-2)^{\frac{4}{3}}}{4}+c_1 \\
\frac{6}{\left(e^{y}\right)^{\frac{1}{3}}\left(1+i\sqrt{3}\right)} &= -\frac{3(-x-2)^{\frac{4}{3}}}{4}+c_1
\end{aligned}
$$

Therefore

$$
y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^{3}}\right)
$$

$$
y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^{3}}\right)
$$

$$
y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^{3}}\right)
$$

Summary

The solution(s) found are the following

$$
y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^{3}}\right) \tag{1}
$$

$$
y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^{3}}\right) \tag{2}
$$

$$
y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^{3}}\right) \tag{3}
$$

Verification of solutions

$$y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^3}\right)$$

Verified OK. `{0 < -x-2, 0 < exp(y)}`

$$y = \ln\left(\frac{1728}{\left(3\left(-x-2\right)^{\frac{4}{3}}-4c_1\right)^3}\right)$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISE-LYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 205.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y'^3 - yy'^2 + x^2y' - x^2y = 0}$$

Solving the given ode for y' results in 3 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = ix \tag{1}$$
$$y' = -ix \tag{2}$$
$$y' = y \tag{3}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int ix \, \mathrm{d}x \\ &= \frac{ix^2}{2} + c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{ix^2}{2} + c_1 \tag{1}$$

Verification of solutions

$$y = \frac{i x^2}{2} + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int -ix \, \mathrm{d}x \\ &= -\frac{i x^2}{2} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{i x^2}{2} + c_2 \tag{1}$$

Verification of solutions

$$y = -\frac{i x^2}{2} + c_2$$

Verified OK.

Solving equation (3)

Integrating both sides gives

$$\begin{aligned} \int \frac{1}{y} dy &= c_3 + x \\ \ln(y) &= c_3 + x \\ y &= \mathrm{e}^{c_3 + x} \\ y &= c_3 \mathrm{e}^{x} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_3 \mathrm{e}^{x} \tag{1}$$

Verification of solutions

$$y = c_3 \mathrm{e}^{x}$$

Verified OK.

8.7.1 Maple step by step solution

Let's solve

$y'^3 - yy'^2 + x^2y' - x^2y = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int 1dx + c_1$

- Evaluate integral

  $\ln(y) = x + c_1$

- Solve for y

  $y = e^{x+c_1}$

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries]]
```

$$\boxed{{y'}^2 - yy' = -\mathrm{e}^x}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2} \tag{1}$$

$$y' = \frac{y}{2} - \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$y' = \frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}$$

$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \left(\frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right)(b_3 - a_2) - \left(\frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right)^2 a_3 + \frac{\mathrm{e}^x (xa_2 + ya_3 + a_1)}{\sqrt{y^2 - 4\,\mathrm{e}^x}} - \left(\frac{1}{2} + \frac{y}{2\sqrt{y^2 - 4\,\mathrm{e}^x}}\right)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{-(y^2 - 4\,\mathrm{e}^x)^{\frac{3}{2}} a_3 - \sqrt{y^2 - 4\,\mathrm{e}^x}\, y^2 a_3 - 2y^3 a_3 + 4\,\mathrm{e}^x x a_2 + 12\,\mathrm{e}^x y a_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, x b_2 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, y a_2 - 2}{4\sqrt{y^2 - 4\,\mathrm{e}^x}}$$

$$= 0$$

Setting the numerator to zero gives

$$-(y^2 - 4\,\mathrm{e}^x)^{\frac{3}{2}} a_3 - \sqrt{y^2 - 4\,\mathrm{e}^x}\, y^2 a_3 - 2y^3 a_3 + 4\,\mathrm{e}^x x a_2 + 12\,\mathrm{e}^x y a_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, x b_2 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, y a_2 - 2xyb_2 - 2y^2 a_2 + 4\,\mathrm{e}^x a_1 + 8\,\mathrm{e}^x a_2 - 8\,\mathrm{e}^x b_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, b_1 + 4b_2\sqrt{y^2 - 4\,\mathrm{e}^x} - 2yb_1 = 0 \tag{6E}$$

Simplifying the above gives

$$-(y^2 - 4\,\mathrm{e}^x)^{\frac{3}{2}} a_3 - 2(y^2 - 4\,\mathrm{e}^x)\, y a_3 - \sqrt{y^2 - 4\,\mathrm{e}^x}\, y^2 a_3 + 4\,\mathrm{e}^x x a_2 + 4\,\mathrm{e}^x y a_3 - 2(y^2 - 4\,\mathrm{e}^x)\, a_2 + 2(y^2 - 4\,\mathrm{e}^x)\, b_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, x b_2 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, y a_2 - 2xyb_2 - 2y^2 b_3 + 4\,\mathrm{e}^x a_1 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, b_1 + 4b_2\sqrt{y^2 - 4\,\mathrm{e}^x} - 2yb_1 = 0 \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
-2\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3 - 2y^3a_3 + 4\,\mathrm{e}^x x a_2 + 4\,\mathrm{e}^x\sqrt{y^2-4\,\mathrm{e}^x}\,a_3 + 12\,\mathrm{e}^x y a_3 \\
- 2\sqrt{y^2-4\,\mathrm{e}^x}\,x b_2 - 2xyb_2 - 2\sqrt{y^2-4\,\mathrm{e}^x}\,y a_2 - 2y^2a_2 + 4\,\mathrm{e}^x a_1 \\
+ 8\,\mathrm{e}^x a_2 - 8\,\mathrm{e}^x b_3 - 2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1 + 4b_2\sqrt{y^2-4\,\mathrm{e}^x} - 2yb_1 = 0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \sqrt{y^2-4\,\mathrm{e}^x}, \mathrm{e}^x\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\left\{x = v_1, y = v_2, \sqrt{y^2-4\,\mathrm{e}^x} = v_3, \mathrm{e}^x = v_4\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
-2v_2^3a_3 - 2v_3v_2^2a_3 + 4v_4v_1a_2 - 2v_2^2a_2 - 2v_3v_2a_2 + 12v_4v_2a_3 + 4v_4v_3a_3 \\
- 2v_1v_2b_2 - 2v_3v_1b_2 + 4v_4a_1 + 8v_4a_2 - 2v_2b_1 - 2v_3b_1 + 4b_2v_3 - 8v_4b_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2, v_3, v_4\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
-2v_1v_2b_2 - 2v_3v_1b_2 + 4v_4v_1a_2 - 2v_2^3a_3 - 2v_3v_2^2a_3 - 2v_2^2a_2 - 2v_3v_2a_2 \\
+ 12v_4v_2a_3 - 2v_2b_1 + 4v_4v_3a_3 + (-2b_1 + 4b_2)\,v_3 + (4a_1 + 8a_2 - 8b_3)\,v_4 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-2a_2 &= 0 \\
4a_2 &= 0 \\
-2a_3 &= 0 \\
4a_3 &= 0 \\
12a_3 &= 0 \\
-2b_1 &= 0 \\
-2b_2 &= 0 \\
-2b_1 + 4b_2 &= 0 \\
4a_1 + 8a_2 - 8b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= 2b_3\\ a_2 &= 0\\ a_3 &= 0\\ b_1 &= 0\\ b_2 &= 0\\ b_3 &= b_3\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= 2\\ \eta &= y\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi\\ &= y - \left(\frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right)(2)\\ &= -\sqrt{y^2 - 4\,\mathrm{e}^x}\\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy\\ &= \int \frac{1}{-\sqrt{y^2 - 4\,\mathrm{e}^x}} dy\end{aligned}$$

Which results in

$$S = -\ln\left(y + \sqrt{y^2 - 4\,e^x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{2} + \frac{\sqrt{y^2 - 4\,e^x}}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{2\,e^x}{\sqrt{y^2 - 4\,e^x}\,\left(y + \sqrt{y^2 - 4\,e^x}\right)} \\
S_y &= -\frac{1}{\sqrt{y^2 - 4\,e^x}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{y\sqrt{y^2 - 4\,e^x} + y^2 - 4\,e^x}{\sqrt{y^2 - 4\,e^x}\,\left(y + \sqrt{y^2 - 4\,e^x}\right)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln\left(y + \sqrt{y^2 - 4\,e^x}\right) = c_1$$

Which simplifies to

$$-\ln\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right) = c_1$$

Which gives

$$y = \frac{\left(4\,\mathrm{e}^{x} \mathrm{e}^{2 c_1}+1\right) \mathrm{e}^{-c_1}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(4\,\mathrm{e}^{x} \mathrm{e}^{2 c_1}+1\right) \mathrm{e}^{-c_1}}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\left(4\,\mathrm{e}^{x} \mathrm{e}^{2 c_1}+1\right) \mathrm{e}^{-c_1}}{2}$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y' = \frac{y}{2}-\frac{\sqrt{y^{2}-4\,\mathrm{e}^{x}}}{2}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2+\left(\frac{y}{2}-\frac{\sqrt{y^2-4\,\mathrm{e}^x}}{2}\right)(b_3-a_2)-\left(\frac{y}{2}-\frac{\sqrt{y^2-4\,\mathrm{e}^x}}{2}\right)^2 a_3 \\
&-\frac{\mathrm{e}^x(xa_2+ya_3+a_1)}{\sqrt{y^2-4\,\mathrm{e}^x}}-\left(\frac{1}{2}-\frac{y}{2\sqrt{y^2-4\,\mathrm{e}^x}}\right)(xb_2+yb_3+b_1)=0
\end{aligned}
\tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{(y^2-4\,\mathrm{e}^x)^{\frac{3}{2}}\,a_3+\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3-2y^3a_3+4\,\mathrm{e}^x xa_2+12\,\mathrm{e}^x ya_3+2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2+2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2-2}{4\sqrt{y^2-4\,\mathrm{e}^x}}
$$

$$
=0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-(y^2-4\,\mathrm{e}^x)^{\frac{3}{2}}\,a_3-\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3+2y^3a_3-4\,\mathrm{e}^x xa_2-12\,\mathrm{e}^x ya_3 \\
&-2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2+2xyb_2+2y^2a_2-4\,\mathrm{e}^x a_1 \\
&-8\,\mathrm{e}^x a_2+8\,\mathrm{e}^x b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}+2yb_1=0
\end{aligned}
\tag{6E}
$$

Simplifying the above gives

$$
\begin{aligned}
&-(y^2-4\,\mathrm{e}^x)^{\frac{3}{2}}\,a_3+2(y^2-4\,\mathrm{e}^x)\,ya_3-\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3-4\,\mathrm{e}^x xa_2-4\,\mathrm{e}^x ya_3 \\
&+2(y^2-4\,\mathrm{e}^x)\,a_2-2(y^2-4\,\mathrm{e}^x)\,b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2 \\
&+2xyb_2+2y^2b_3-4\,\mathrm{e}^x a_1-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}+2yb_1=0
\end{aligned}
\tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&-2\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3+2y^3a_3-4\,\mathrm{e}^x xa_2+4\,\mathrm{e}^x\sqrt{y^2-4\,\mathrm{e}^x}\,a_3-12\,\mathrm{e}^x ya_3 \\
&-2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2+2xyb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2+2y^2a_2-4\,\mathrm{e}^x a_1 \\
&-8\,\mathrm{e}^x a_2+8\,\mathrm{e}^x b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}+2yb_1=0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$
\left\{x,y,\sqrt{y^2-4\,\mathrm{e}^x},\mathrm{e}^x\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{y^2 - 4\,\mathrm{e}^x} = v_3, \mathrm{e}^x = v_4\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &2v_2^3a_3 - 2v_3v_2^2a_3 - 4v_4v_1a_2 + 2v_2^2a_2 - 2v_3v_2a_2 - 12v_4v_2a_3 + 4v_4v_3a_3 \\ &+ 2v_1v_2b_2 - 2v_3v_1b_2 - 4v_4a_1 - 8v_4a_2 + 2v_2b_1 - 2v_3b_1 + 4b_2v_3 + 8v_4b_3 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$\begin{aligned} &2v_1v_2b_2 - 2v_3v_1b_2 - 4v_4v_1a_2 + 2v_2^3a_3 - 2v_3v_2^2a_3 + 2v_2^2a_2 - 2v_3v_2a_2 - 12v_4v_2a_3 \\ &+ 2v_2b_1 + 4v_4v_3a_3 + (-2b_1 + 4b_2)\,v_3 + (-4a_1 - 8a_2 + 8b_3)\,v_4 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -4a_2 &= 0 \\ -2a_2 &= 0 \\ 2a_2 &= 0 \\ -12a_3 &= 0 \\ -2a_3 &= 0 \\ 2a_3 &= 0 \\ 4a_3 &= 0 \\ 2b_1 &= 0 \\ -2b_2 &= 0 \\ 2b_2 &= 0 \\ -2b_1 + 4b_2 &= 0 \\ -4a_1 - 8a_2 + 8b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 2b_3 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 2 \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x,y)\,\xi \\ &= y - \left(\frac{y}{2} - \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right)(2) \\ &= \sqrt{y^2 - 4\,\mathrm{e}^x} \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\sqrt{y^2 - 4\,\mathrm{e}^x}} dy \end{aligned}$$

Which results in

$$S = \ln\left(y + \sqrt{y^2 - 4\,e^x}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{2} - \frac{\sqrt{y^2 - 4\,e^x}}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{2\,e^x}{\sqrt{y^2 - 4\,e^x}\,\left(y + \sqrt{y^2 - 4\,e^x}\right)} \\
S_y &= \frac{1}{\sqrt{y^2 - 4\,e^x}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln\left(y + \sqrt{y^2 - 4\,e^x}\right) = c_1$$

Which simplifies to

$$\ln\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right) = c_1$$

Which gives

$$y = \frac{\left(\mathrm{e}^{2c_1}+4\,\mathrm{e}^{x}\right)\mathrm{e}^{-c_1}}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\mathrm{e}^{2c_1}+4\,\mathrm{e}^{x}\right)\mathrm{e}^{-c_1}}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\left(\mathrm{e}^{2c_1}+4\,\mathrm{e}^{x}\right)\mathrm{e}^{-c_1}}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`]]
```

$$\boxed{y'^2 - 4y'x + 2y = -2x^2}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = 2x + \sqrt{2x^2 - 2y} \tag{1}$$
$$y' = 2x - \sqrt{2x^2 - 2y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$y' = 2x + \sqrt{2x^2 - 2y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \left(2x + \sqrt{2x^2 - 2y}\right)(b_3 - a_2) - \left(2x + \sqrt{2x^2 - 2y}\right)^2 a_3 - \left(2 + \frac{2x}{\sqrt{2x^2 - 2y}}\right)(xa_2 + ya_3 + a_1) + \frac{xb_2 + yb_3 + b_1}{\sqrt{2x^2 - 2y}} = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{(2x^2 - 2y)^{\frac{3}{2}} a_3 + 4\sqrt{2x^2 - 2y}\, x^2 a_3 + 8x^3 a_3 + 4\sqrt{2x^2 - 2y}\, xa_2 - 2\sqrt{2x^2 - 2y}\, xb_3 + 2\sqrt{2x^2 - 2y}\, ya_3 + 4}{\sqrt{2x^2 - 2y}} = 0$$

Setting the numerator to zero gives

$$-(2x^2 - 2y)^{\frac{3}{2}} a_3 - 4\sqrt{2x^2 - 2y}\, x^2 a_3 - 8x^3 a_3 - 4\sqrt{2x^2 - 2y}\, xa_2 + 2\sqrt{2x^2 - 2y}\, xb_3 - 2\sqrt{2x^2 - 2y}\, ya_3 - 4x^2 a_2 + 2x^2 b_3 + 6xya_3 - 2\sqrt{2x^2 - 2y}\, a_1 + b_2\sqrt{2x^2 - 2y} - 2xa_1 + xb_2 + 2ya_2 - yb_3 + b_1 = 0 \tag{6E}$$

Simplifying the above gives

$$-(2x^2 - 2y)^{\frac{3}{2}} a_3 - 4(2x^2 - 2y)\, xa_3 - 4\sqrt{2x^2 - 2y}\, x^2 a_3 - (2x^2 - 2y)\, a_2 + (2x^2 - 2y)\, b_3 - 4\sqrt{2x^2 - 2y}\, xa_2 + 2\sqrt{2x^2 - 2y}\, xb_3 - 2\sqrt{2x^2 - 2y}\, ya_3 - 2x^2 a_2 - 2xya_3 - 2\sqrt{2x^2 - 2y}\, a_1 + b_2\sqrt{2x^2 - 2y} - 2xa_1 + xb_2 + yb_3 + b_1 = 0 \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$-6\sqrt{2x^2-2y}\,x^2a_3-8x^3a_3-4\sqrt{2x^2-2y}\,xa_2+2\sqrt{2x^2-2y}\,xb_3-4x^2a_2+2x^2b_3+6xya_3-2\sqrt{2x^2-2y}\,a_1+b_2\sqrt{2x^2-2y}-2xa_1+xb_2+2ya_2-yb_3+b_1=0$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$\left\{x,y,\sqrt{2x^2-2y}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x,y\}$ in them

$$\left\{x=v_1,y=v_2,\sqrt{2x^2-2y}=v_3\right\}$$

The above PDE (6E) now becomes

$$-8v_1^3a_3-6v_3v_1^2a_3-4v_1^2a_2-4v_3v_1a_2+6v_1v_2a_3+2v_1^2b_3+2v_3v_1b_3-2v_1a_1-2v_3a_1+2v_2a_2+v_1b_2+b_2v_3-v_2b_3+b_1=0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1,v_2,v_3\}$$

Equation (7E) now becomes

$$-8v_1^3a_3-6v_3v_1^2a_3+(-4a_2+2b_3)\,v_1^2+6v_1v_2a_3+(-4a_2+2b_3)\,v_1v_3+(-2a_1+b_2)\,v_1+(2a_2-b_3)\,v_2+(-2a_1+b_2)\,v_3+b_1=0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}b_1&=0\\-8a_3&=0\\-6a_3&=0\\6a_3&=0\\-2a_1+b_2&=0\\-4a_2+2b_3&=0\\2a_2-b_3&=0\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= a_1 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 2a_1 \\
b_3 &= 2a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 1 \\
\eta &= 2x
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= 2x - \left(2x + \sqrt{2x^2 - 2y}\right)(1) \\
&= -\sqrt{2x^2 - 2y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{-\sqrt{2x^2 - 2y}} dy
\end{aligned}
$$

Which results in

$$S = \sqrt{2x^2 - 2y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y)S_y}{R_x + \omega(x, y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = 2x + \sqrt{2x^2 - 2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{2x}{\sqrt{2x^2 - 2y}} \\ S_y &= -\frac{1}{\sqrt{2x^2 - 2y}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\sqrt{2x^2 - 2y} = -x + c_1$$

Which simplifies to

$$\sqrt{2x^2-2y} = -x+c_1$$

Which gives

$$y = -\frac{1}{2}c_1^2 + c_1 x + \frac{1}{2}x^2$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{2}c_1^2 + c_1 x + \frac{1}{2}x^2 \tag{1}$$

Verification of solutions

$$y = -\frac{1}{2}c_1^2 + c_1 x + \frac{1}{2}x^2$$

Verified OK.

Solving equation (2)

Writing the ode as

$$\begin{aligned} y' &= 2x - \sqrt{2x^2-2y} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 + \left(2x - \sqrt{2x^2-2y}\right)(b_3 - a_2) - \left(2x - \sqrt{2x^2-2y}\right)^2 a_3 \\ - \left(2 - \frac{2x}{\sqrt{2x^2-2y}}\right)(xa_2 + ya_3 + a_1) - \frac{xb_2 + yb_3 + b_1}{\sqrt{2x^2-2y}} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{\left(2x^2-2y\right)^{\frac{3}{2}} a_3+4\sqrt{2x^2-2y}\, x^2 a_3-8x^3 a_3+4\sqrt{2x^2-2y}\, x a_2-2\sqrt{2x^2-2y}\, x b_3+2\sqrt{2x^2-2y}\, y a_3-4\cdots}{\sqrt{2x^2-2y}}$$
$$=0$$

Setting the numerator to zero gives

$$\begin{aligned} &-\left(2x^2-2y\right)^{\frac{3}{2}} a_3-4\sqrt{2x^2-2y}\, x^2 a_3+8x^3 a_3-4\sqrt{2x^2-2y}\, x a_2 \\ &+2\sqrt{2x^2-2y}\, x b_3-2\sqrt{2x^2-2y}\, y a_3+4x^2 a_2-2x^2 b_3-6xy a_3 \\ &-2\sqrt{2x^2-2y}\, a_1+b_2\sqrt{2x^2-2y}+2x a_1-x b_2-2y a_2+y b_3-b_1=0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned} &-\left(2x^2-2y\right)^{\frac{3}{2}} a_3+4\left(2x^2-2y\right) x a_3-4\sqrt{2x^2-2y}\, x^2 a_3+\left(2x^2-2y\right) a_2 \\ &-\left(2x^2-2y\right) b_3-4\sqrt{2x^2-2y}\, x a_2+2\sqrt{2x^2-2y}\, x b_3-2\sqrt{2x^2-2y}\, y a_3 \\ &+2x^2 a_2+2xy a_3-2\sqrt{2x^2-2y}\, a_1+b_2\sqrt{2x^2-2y}+2x a_1-x b_2-y b_3-b_1=0 \end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned} &8x^3 a_3-6\sqrt{2x^2-2y}\, x^2 a_3+4x^2 a_2-2x^2 b_3-4\sqrt{2x^2-2y}\, x a_2+2\sqrt{2x^2-2y}\, x b_3 \\ &-6xy a_3+2x a_1-x b_2-2\sqrt{2x^2-2y}\, a_1+b_2\sqrt{2x^2-2y}-2y a_2+y b_3-b_1=0 \end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{2x^2-2y}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x=v_1, y=v_2, \sqrt{2x^2-2y}=v_3\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned} &8v_1^3 a_3-6v_3 v_1^2 a_3+4v_1^2 a_2-4v_3 v_1 a_2-6v_1 v_2 a_3-2v_1^2 b_3+2v_3 v_1 b_3 \\ &+2v_1 a_1-2v_3 a_1-2v_2 a_2-v_1 b_2+b_2 v_3+v_2 b_3-b_1=0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$8v_1^3a_3 - 6v_3v_1^2a_3 + (4a_2 - 2b_3)v_1^2 - 6v_1v_2a_3 + (-4a_2 + 2b_3)v_1v_3 \\ + (2a_1 - b_2)v_1 + (-2a_2 + b_3)v_2 + (-2a_1 + b_2)v_3 - b_1 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -6a_3 &= 0 \\ 8a_3 &= 0 \\ -b_1 &= 0 \\ -2a_1 + b_2 &= 0 \\ 2a_1 - b_2 &= 0 \\ -4a_2 + 2b_3 &= 0 \\ -2a_2 + b_3 &= 0 \\ 4a_2 - 2b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= a_1 \\ a_2 &= a_2 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 2a_1 \\ b_3 &= 2a_2 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 1 \\ \eta &= 2x \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x, y)\,\xi \\ &= 2x - \left(2x - \sqrt{2x^2 - 2y}\right)(1) \\ &= \sqrt{2x^2 - 2y} \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\sqrt{2x^2 - 2y}} dy \end{aligned}$$

Which results in

$$S = -\sqrt{2x^2 - 2y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = 2x - \sqrt{2x^2 - 2y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{2x}{\sqrt{2x^2 - 2y}} \\ S_y &= \frac{1}{\sqrt{2x^2 - 2y}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\sqrt{2x^2 - 2y} = -x + c_1$$

Which simplifies to

$$-\sqrt{2x^2 - 2y} = -x + c_1$$

Which gives

$$y = -\frac{1}{2}c_1^2 + c_1 x + \frac{1}{2}x^2$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{2}c_1^2 + c_1 x + \frac{1}{2}x^2 \tag{1}$$

Verification of solutions

$$y = -\frac{1}{2}c_1^2 + c_1 x + \frac{1}{2}x^2$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISE-LYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 208.
ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{y - {y'}^{2} \mathrm{e}^{y'} = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = 2\,\mathrm{LambertW}\left(\frac{\sqrt{y}}{2}\right) \tag{1}$$

$$y' = 2\,\mathrm{LambertW}\left(-\frac{\sqrt{y}}{2}\right) \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{2\,\mathrm{LambertW}\left(\frac{\sqrt{y}}{2}\right)} dy = \int dx$$

$$\frac{y}{4\,\mathrm{LambertW}\left(\frac{\sqrt{y}}{2}\right)^{2}} + \frac{y}{2\,\mathrm{LambertW}\left(\frac{\sqrt{y}}{2}\right)} = x + c_1$$

Summary
The solution(s) found are the following

$$\frac{y}{4 \operatorname{LambertW}\left(\frac{\sqrt{y}}{2}\right)^{2}}+\frac{y}{2 \operatorname{LambertW}\left(\frac{\sqrt{y}}{2}\right)}=x+c_{1} \tag{1}$$

Verification of solutions

$$\frac{y}{4 \operatorname{LambertW}\left(\frac{\sqrt{y}}{2}\right)^{2}}+\frac{y}{2 \operatorname{LambertW}\left(\frac{\sqrt{y}}{2}\right)}=x+c_{1}$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\int \frac{1}{2 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)} d y=\int d x$$

$$\frac{y}{4 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)^{2}}+\frac{y}{2 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)}=x+c_{2}$$

Summary
The solution(s) found are the following

$$\frac{y}{4 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)^{2}}+\frac{y}{2 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)}=x+c_{2} \tag{1}$$

Verification of solutions

$$\frac{y}{4 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)^{2}}+\frac{y}{2 \operatorname{LambertW}\left(-\frac{\sqrt{y}}{2}\right)}=x+c_{2}$$

Verified OK.

8.10.1 Maple step by step solution

Let's solve

$y - {y'}^2 e^{y'} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\mathit{LambertW}\left(\frac{\sqrt{y}}{2}\right)} = 2$

- Integrate both sides with respect to x

  $\int \frac{y'}{\mathit{LambertW}\left(\frac{\sqrt{y}}{2}\right)}dx = \int 2dx + c_1$

- Evaluate integral

  $\frac{y}{2\mathit{LambertW}\left(\frac{\sqrt{y}}{2}\right)^2} + \frac{y}{\mathit{LambertW}\left(\frac{\sqrt{y}}{2}\right)} = 2x + c_1$

- Solve for y

  $y = \left(\mathit{LambertW}\left(\frac{(2x+c_1)\mathrm{e}}{2}\right) - 1\right)^2 \left(\mathrm{e}^{\frac{\mathit{LambertW}\left(\frac{(2x+c_1)\mathrm{e}}{2}\right)}{2} - \frac{1}{2}}\right)^2$

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{-{y'}^{2}+2y' = -x+2}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = 1+\sqrt{x-1} \tag{1}$$
$$y' = 1-\sqrt{x-1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned} y &= \int 1+\sqrt{x-1}\,\mathrm{d}x \\ &= x+\frac{2(x-1)^{\frac{3}{2}}}{3}+c_1 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x+\frac{2(x-1)^{\frac{3}{2}}}{3}+c_1 \tag{1}$$

Verification of solutions

$$y = x + \frac{2(x-1)^{\frac{3}{2}}}{3} + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int 1 - \sqrt{x-1}\, \mathrm{d}x \\ &= x - \frac{2(x-1)^{\frac{3}{2}}}{3} + c_2 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x - \frac{2(x-1)^{\frac{3}{2}}}{3} + c_2 \tag{1}$$

Verification of solutions

$$y = x - \frac{2(x-1)^{\frac{3}{2}}}{3} + c_2$$

Verified OK.

Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 214.
ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{x{y'}^{2}-{\mathrm e}^{\frac{1}{y'}}=0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{1}{2\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)} \tag{1}$$

$$y' = \frac{1}{2\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\begin{aligned}
y &= \int \frac{1}{2\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)}\,\mathrm{d}x \\
&= \frac{x}{4\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)^{2}} + \frac{x}{2\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)} + c_1
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x}{4\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)^2} + \frac{x}{2\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)} + c_1 \tag{1}$$

Verification of solutions

$$y = \frac{x}{4\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)^2} + \frac{x}{2\,\mathrm{LambertW}\left(\frac{\sqrt{x}}{2}\right)} + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{1}{2\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)}\,\mathrm{d}x \\ &= \frac{x}{4\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)^2} + \frac{x}{2\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)} + c_2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x}{4\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)^2} + \frac{x}{2\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{x}{4\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)^2} + \frac{x}{2\,\mathrm{LambertW}\left(-\frac{\sqrt{x}}{2}\right)} + c_2$$

Verified OK.

8.16.1 Maple step by step solution

Let's solve

$x{y'}^2 - \mathrm{e}^{\frac{1}{y'}} = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

$$\int \left(x{y'}^{2}-e^{\frac{1}{y'}}\right)dx = \int 0 dx + c_1$$

- Cannot compute integral

$$\int \left(x{y'}^{2}-e^{\frac{1}{y'}}\right)dx = c_1$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8. First order not solved for the derivative. Exercises page 67
Problem number: 215.
ODE order: 1.
ODE degree: 6.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{x\left(y'^2+1\right)^{\frac{3}{2}} = a}$$

Solving the given ode for y' results in 6 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{\left(a\,x^2\right)^{\frac{2}{3}}-x^2}}{x} \tag{1}$$

$$y' = -\frac{\sqrt{\left(a\,x^2\right)^{\frac{2}{3}}-x^2}}{x} \tag{2}$$

$$y' = \frac{\sqrt{-2i\left(a\,x^2\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^2\right)^{\frac{2}{3}}-4x^2}}{2x} \tag{3}$$

$$y' = -\frac{\sqrt{-2i\left(a\,x^2\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^2\right)^{\frac{2}{3}}-4x^2}}{2x} \tag{4}$$

$$y' = \frac{\sqrt{2}\,\sqrt{i\left(a\,x^2\right)^{\frac{2}{3}}\sqrt{3}-\left(a\,x^2\right)^{\frac{2}{3}}-2x^2}}{2x} \tag{5}$$

$$y' = -\frac{\sqrt{2}\,\sqrt{i\left(a\,x^2\right)^{\frac{2}{3}}\sqrt{3}-\left(a\,x^2\right)^{\frac{2}{3}}-2x^2}}{2x} \tag{6}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$y = \int \frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}\,\mathrm{d}x$$
$$= \int \frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}dx + c_1$$

Summary
The solution(s) found are the following

$$y = \int \frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}dx + c_1 \tag{1}$$

Verification of solutions

$$y = \int \frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}dx + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$y = \int -\frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}\,\mathrm{d}x$$
$$= \int -\frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}dx + c_2$$

Summary
The solution(s) found are the following

$$y = \int -\frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}dx + c_2 \tag{1}$$

Verification of solutions

$$y = \int -\frac{\sqrt{(a\,x^2)^{\frac{2}{3}} - x^2}}{x}dx + c_2$$

Verified OK.

Solving equation (3)

Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}\,\mathrm{d}x \\
&= \int \frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}dx + c_3
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \int \frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}dx + c_3 \tag{1}
$$

Verification of solutions

$$
y = \int \frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}dx + c_3
$$

Verified OK.

Solving equation (4)

Integrating both sides gives

$$
\begin{aligned}
y &= \int -\frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}\,\mathrm{d}x \\
&= \int -\frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}dx + c_4
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \int -\frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}dx + c_4 \tag{1}
$$

Verification of solutions

$$
y = \int -\frac{\sqrt{-2i\left(a\,x^{2}\right)^{\frac{2}{3}}\sqrt{3}-2\left(a\,x^{2}\right)^{\frac{2}{3}}-4x^{2}}}{2x}dx + c_4
$$

Verified OK.

Solving equation (5)

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}\,\mathrm{d}x \\ &= \int \frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}dx + c_5 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \int \frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}dx + c_5 \tag{1}$$

Verification of solutions

$$y = \int \frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}dx + c_5$$

Verified OK.

Solving equation (6)

Integrating both sides gives

$$\begin{aligned} y &= \int -\frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}\,\mathrm{d}x \\ &= \int -\frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}dx + c_6 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \int -\frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}dx + c_6 \tag{1}$$

Verification of solutions

$$y = \int -\frac{\sqrt{2}\,\sqrt{i\,(a\,x^2)^{\frac{2}{3}}\,\sqrt{3}-(a\,x^2)^{\frac{2}{3}}-2x^2}}{2x}dx + c_6$$

Verified OK.

8.21.2 Maple step by step solution

Let's solve

$y - \arcsin(y') - \ln(y'^2 + 1) = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\sin\left(\mathit{RootOf}\left(-y + \_Z + \ln\left(\sin(\_Z)^2 + 1\right)\right)\right)} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{\sin\left(\mathit{RootOf}\left(-y + \_Z + \ln\left(\sin(\_Z)^2 + 1\right)\right)\right)} dx = \int 1 dx + c_1$

- Cannot compute integral

  $\int \frac{y'}{\sin\left(\mathit{RootOf}\left(-y + \_Z + \ln\left(\sin(\_Z)^2 + 1\right)\right)\right)} dx = x + c_1$

Problem number: 220.
ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{y-2y'x-\ln(y')=0}$$

9.1.1 Solving as dAlembert ode

Let $p=y'$ the ode becomes

$$y-2px-\ln(p)=0$$

Solving for y from the above results in

$$y=2px+\ln(p) \tag{1A}$$

This has the form

$$y=xf(p)+g(p) \tag{*}$$

Where f,g are functions of $p=y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$\begin{aligned} p &= f+(xf'+g')\frac{dp}{dx} \\ p-f &= (xf'+g')\frac{dp}{dx} \end{aligned} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = 2p$$
$$g = \ln(p)$$

Hence (2) becomes

$$-p = \left(2x + \frac{1}{p}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p = 0$$

Solving for p from the above gives

$$p = 0$$

Substituting these in (1A) gives

$$y = -\infty$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = -\frac{p(x)}{2x + \frac{1}{p(x)}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = -\frac{2x(p) + \frac{1}{p}}{p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p}$$
$$q(p) = -\frac{1}{p^2}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2x(p)}{p} = -\frac{1}{p^2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{p}dp}\\ &= p^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dp}(\mu x) &= (\mu)\left(-\frac{1}{p^2}\right)\\ \frac{d}{dp}(p^2 x) &= (p^2)\left(-\frac{1}{p^2}\right)\\ d(p^2 x) &= -1\, dp\end{aligned}$$

Integrating gives

$$\begin{aligned}p^2 x &= \int -1\, dp\\ p^2 x &= -p + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = p^2$ results in

$$x(p) = -\frac{1}{p} + \frac{c_1}{p^2}$$

which simplifies to

$$x(p) = \frac{-p + c_1}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = e^{-\operatorname{LambertW}(2x\, e^{y}) + y}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{2(-2c_1 x + \operatorname{LambertW}(2x\, e^{y}))\, x}{\operatorname{LambertW}(2x\, e^{y})^2}$$

Summary

The solution(s) found are the following

$$y = -\infty \tag{1}$$

$$x = -\frac{2(-2c_1 x + \text{LambertW}(2x\,e^y))\,x}{\text{LambertW}(2x\,e^y)^2} \tag{2}$$

Verification of solutions

$$y = -\infty$$

Warning, solution could not be verified

$$x = -\frac{2(-2c_1 x + \text{LambertW}(2x\,e^y))\,x}{\text{LambertW}(2x\,e^y)^2}$$

Verified OK.

Problem number: 221.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{y - x(1 + y') - {y'}^2 = 0}$$

9.2.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - x(1 + p) - p^2 = 0$$

Solving for y from the above results in

$$y = x(1 + p) + p^2 \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$

$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= 1 + p \\
g &= p^2
\end{aligned}
$$

Hence (2) becomes

$$
-1 = (x + 2p)\, p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
-1 = 0
$$

No singular solution are found

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = -\frac{1}{x + 2p\,(x)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = -x(p) - 2p \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p) + p(p)x(p) = q(p)
$$

Where here

$$
\begin{aligned}
p(p) &= 1 \\
q(p) &= -2p
\end{aligned}
$$

Hence the ode is

$$
\frac{d}{dp}x(p) + x(p) = -2p
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int 1 dp} \\
&= \mathrm{e}^{p}
\end{aligned}
$$

The ode becomes

$$\frac{d}{dp}(\mu x) = (\mu)(-2p)$$
$$\frac{d}{dp}(e^p x) = (e^p)(-2p)$$
$$d(e^p x) = (-2p\,e^p)\,dp$$

Integrating gives

$$e^p x = \int -2p\,e^p\,dp$$
$$e^p x = -2(p-1)\,e^p + c_1$$

Dividing both sides by the integrating factor $\mu = e^p$ results in

$$x(p) = -2\,e^{-p}(p-1)\,e^p + c_1 e^{-p}$$

which simplifies to

$$x(p) = -2p + 2 + c_1 e^{-p}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = -\frac{x}{2} + \frac{\sqrt{x^2+4y-4x}}{2}$$
$$p = -\frac{x}{2} - \frac{\sqrt{x^2+4y-4x}}{2}$$

Substituting the above in the solution for x found above gives

$$x = x - \sqrt{x^2+4y-4x} + 2 + c_1 e^{\frac{x}{2} - \frac{\sqrt{x^2+4y-4x}}{2}}$$
$$x = x + \sqrt{x^2+4y-4x} + 2 + c_1 e^{\frac{x}{2} + \frac{\sqrt{x^2+4y-4x}}{2}}$$

Summary

The solution(s) found are the following

$$x = x - \sqrt{x^2+4y-4x} + 2 + c_1 e^{\frac{x}{2} - \frac{\sqrt{x^2+4y-4x}}{2}} \tag{1}$$
$$x = x + \sqrt{x^2+4y-4x} + 2 + c_1 e^{\frac{x}{2} + \frac{\sqrt{x^2+4y-4x}}{2}} \tag{2}$$

Verification of solutions

$$x = x - \sqrt{x^2 + 4y - 4x} + 2 + c_1 \mathrm{e}^{\frac{x}{2} - \frac{\sqrt{x^2+4y-4x}}{2}}$$

Verified OK.

$$x = x + \sqrt{x^2 + 4y - 4x} + 2 + c_1 \mathrm{e}^{\frac{x}{2} + \frac{\sqrt{x^2+4y-4x}}{2}}$$

Verified OK.

Problem number: 222.
ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[_dAlembert]`

$$\boxed{y - 2y'x - \sin(y') = 0}$$

9.3.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - 2px - \sin(p) = 0$$

Solving for y from the above results in

$$y = 2px + \sin(p) \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = 2p$$
$$g = \sin(p)$$

Hence (2) becomes

$$-p = (2x + \cos(p))\, p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p = 0$$

Solving for p from the above gives

$$p = 0$$

Substituting these in (1A) gives

$$y = 0$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = -\frac{p(x)}{2x + \cos(p(x))} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = -\frac{2x(p) + \cos(p)}{p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p}$$
$$q(p) = -\frac{\cos(p)}{p}$$

Hence the ode is

$$\frac{d}{dp}x(p)+\frac{2x(p)}{p}=-\frac{\cos\left(p\right)}{p}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2}{p}dp}\\ &= p^2\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(-\frac{\cos\left(p\right)}{p}\right)\\ \frac{\mathrm{d}}{\mathrm{d}p}\left(p^2 x\right) &= \left(p^2\right)\left(-\frac{\cos\left(p\right)}{p}\right)\\ \mathrm{d}\left(p^2 x\right) &= \left(-p\cos\left(p\right)\right)\,\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}p^2 x &= \int -p\cos\left(p\right)\,\mathrm{d}p\\ p^2 x &= -\cos\left(p\right)-p\sin\left(p\right)+c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu=p^2$ results in

$$x(p)=\frac{-\cos\left(p\right)-p\sin\left(p\right)}{p^2}+\frac{c_1}{p^2}$$

which simplifies to

$$x(p)=\frac{-\cos\left(p\right)-p\sin\left(p\right)+c_1}{p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p=\mathrm{RootOf}\left(2\_Zx+\sin\left(\_Z\right)-y\right)$$

Substituting the above in the solution for x found above gives

$$x = \frac{-\cos\left(\mathrm{RootOf}\left(2\_Zx+\sin\left(\_Z\right)-y\right)\right)-\mathrm{RootOf}\left(2\_Zx+\sin\left(\_Z\right)-y\right)\sin\left(\mathrm{RootOf}\left(2\_Zx+\sin\left(\_Z\right)\right.\right.}{\mathrm{RootOf}\left(2\_Zx+\sin\left(\_Z\right)-y\right)^2}$$

Summary
The solution(s) found are the following

$$y = 0 \tag{1}$$

$$x = \frac{-\cos(\mathrm{RootOf}(2\_Zx + \sin(\_Z) - y)) - \mathrm{RootOf}(2\_Zx + \sin(\_Z) - y)\sin(\mathrm{RootOf}(2\_Zx + \sin(\_Z)}{\mathrm{RootOf}(2\_Zx + \sin(\_Z) - y)^2} \tag{2}$$

Verification of solutions

$$y = 0$$

Verified OK.

$$x = \frac{-\cos(\mathrm{RootOf}(2\_Zx + \sin(\_Z) - y)) - \mathrm{RootOf}(2\_Zx + \sin(\_Z) - y)\sin(\mathrm{RootOf}(2\_Zx + \sin(\_Z)}{\mathrm{RootOf}(2\_Zx + \sin(\_Z) - y)^2}$$

Verified OK.

Problem number: 223.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[_dAlembert]`

$$\boxed{y - x{y'}^2 + \frac{1}{y'} = 0}$$

9.4.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - x\,p^2 + \frac{1}{p} = 0$$

Solving for y from the above results in

$$y = x\,p^2 - \frac{1}{p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = p^2$$
$$g = -\frac{1}{p}$$

Hence (2) becomes

$$-p^2 + p = \left(2xp + \frac{1}{p^2}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-p^2 + p = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 1$$

Removing solutions for p which leads to undefined results and substituting these in (1A) gives

$$y = x - 1$$

The general solution is found when $\frac{dp}{dx} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{-p(x)^2 + p(x)}{2p(x)\,x + \frac{1}{p(x)^2}} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{2x(p)\,p + \frac{1}{p^2}}{-p^2 + p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{2}{p-1}$$
$$q(p) = -\frac{1}{p^3 (p-1)}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{2x(p)}{p-1} = -\frac{1}{p^3 (p-1)}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2}{p-1}dp}$$
$$= (p-1)^2$$

The ode becomes

$$\frac{d}{dp}(\mu x) = (\mu)\left(-\frac{1}{p^3 (p-1)}\right)$$
$$\frac{d}{dp}\left((p-1)^2 x\right) = \left((p-1)^2\right)\left(-\frac{1}{p^3 (p-1)}\right)$$
$$d\left((p-1)^2 x\right) = \left(\frac{-p+1}{p^3}\right) dp$$

Integrating gives

$$(p-1)^2 x = \int \frac{-p+1}{p^3} dp$$
$$(p-1)^2 x = -\frac{1}{2p^2} + \frac{1}{p} + c_1$$

Dividing both sides by the integrating factor $\mu = (p-1)^2$ results in

$$x(p) = \frac{-\frac{1}{2p^2} + \frac{1}{p}}{(p-1)^2} + \frac{c_1}{(p-1)^2}$$

which simplifies to

$$x(p) = \frac{2c_1 p^2 + 2p - 1}{2(p-1)^2 p^2}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = \frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{6x} + \frac{2y}{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}$$

$$p = -\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{12x} - \frac{y}{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+}{x}}\right.\right.}{6x}\right.}{}$$

$$p = -\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{12x} - \frac{y}{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(\frac{\left(\left(108+12\sqrt{3}\,\sqrt{\frac{-4y^3+}{x}}\right.\right.}{6x}\right.}{}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{54\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}} 3^{\frac{1}{3}} 2^{\frac{2}{3}} x^3 \left(-\frac{2^{\frac{1}{3}}\left(\sqrt{\frac{-4y^3+27x}{x}}\, c_1 3^{\frac{1}{6}} + 2\left(y+\frac{3c_1}{2}\right)3^{\frac{2}{3}}\right)x\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{3} - \frac{2^{\frac{2}{3}}}{}\right.}{\left(2^{\frac{2}{3}}3^{\frac{1}{3}}xy + \left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}}\right)^2 \left(2\,2^{\frac{1}{3}}3^{\frac{2}{3}}yx + 2^{\frac{2}{3}}3^{\frac{1}{3}}\left(\left(9+\sqrt{3}\right.\right.\right.}$$

$$x = -\frac{36\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}}\left(\left(\frac{8yc_1}{9}-\frac{2x}{3}\right)\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}} + x\left(-\frac{2^{\frac{1}{3}}\left(\left(i3^{\frac{2}{3}}+3^{\frac{1}{6}}\right)c_1\sqrt{\frac{-4}{}}\right.}{}\right.\right.}{\left(-\frac{\left(i3^{\frac{5}{6}}-3^{\frac{1}{3}}\right)2^{\frac{2}{3}}\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}}}{6} + x\left(2\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}\right.\right.}$$

$$x = \frac{36\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}} 3^{\frac{1}{3}} 2^{\frac{2}{3}} \left(\left(-\frac{8yc_{1}}{9}+\frac{2x}{3}\right)\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}} + x\left(-\frac{2^{\frac{1}{3}}\left(\left(i3^{\frac{2}{3}}-3^{\frac{1}{6}}\right)c_{1}\cdots\right.}{\cdots}\right.\right.}{\left(-\frac{\left(3^{\frac{1}{3}}+i3^{\frac{5}{6}}\right)2^{\frac{2}{3}}\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}}}{6} + x\left(-2\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{1}{3}}\cdots\right.\right.}$$

<u>Summary</u>

The solution(s) found are the following

$$y = x-1 \tag{1}$$

$$x = -\frac{54\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}} 3^{\frac{1}{3}} 2^{\frac{2}{3}} x^{3}\left(-\frac{2^{\frac{1}{3}}\left(\sqrt{\frac{-4y^{3}+27x}{x}}\,c_{1}3^{\frac{1}{6}}+2\left(y+\frac{3c_{1}}{2}\right)3^{\frac{2}{3}}\right)x\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{1}{3}}}{3} - \frac{2^{\frac{2}{3}}\cdots}{\cdots}\right.}{\left(2^{\frac{2}{3}}3^{\frac{1}{3}}xy+\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}}\right)^{2}\left(2\,2^{\frac{1}{3}}3^{\frac{2}{3}}yx+2^{\frac{2}{3}}3^{\frac{1}{3}}\left(\left(9+\sqrt{3}\cdots\right.\right.\right.} \tag{2}$$

$$x = -\frac{36\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}}\left(\left(\frac{8yc_{1}}{9}-\frac{2x}{3}\right)\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}} + x\left(-\frac{2^{\frac{1}{3}}\left(\left(i3^{\frac{2}{3}}+3^{\frac{1}{6}}\right)c_{1}\sqrt{\frac{-4\cdots}{\cdots}}\right.}{\cdots}\right.\right.}{\left(-\frac{\left(i3^{\frac{5}{6}}-3^{\frac{1}{3}}\right)2^{\frac{2}{3}}\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}}}{6} + x\left(2\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{1}{3}}\cdots\right.\right.} \tag{3}$$

$$x = \frac{36\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}} 3^{\frac{1}{3}} 2^{\frac{2}{3}} \left(\left(-\frac{8yc_{1}}{9}+\frac{2x}{3}\right)\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}} + x\left(-\frac{2^{\frac{1}{3}}\left(\left(i3^{\frac{2}{3}}-3^{\frac{1}{6}}\right)c_{1}\cdots\right.}{\cdots}\right.\right.}{\left(-\frac{\left(3^{\frac{1}{3}}+i3^{\frac{5}{6}}\right)2^{\frac{2}{3}}\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{2}{3}}}{6} + x\left(-2\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^{3}+27x}{x}}\right)x^{2}\right)^{\frac{1}{3}}\cdots\right.\right.} \tag{4}$$

Verification of solutions

$$y = x - 1$$

Verified OK.

$$x = -\frac{54\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}} 3^{\frac{1}{3}} 2^{\frac{2}{3}} x^3 \left(-\frac{2^{\frac{1}{3}}\left(\sqrt{\frac{-4y^3+27x}{x}}\,c_1 3^{\frac{1}{6}}+2\left(y+\frac{3c_1}{2}\right)3^{\frac{2}{3}}\right)x\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{1}{3}}}{3} - 2^{\frac{2}{3}}\right.}{\left(2^{\frac{2}{3}}3^{\frac{1}{3}}xy+\left(\left(9+\sqrt{3}\,\sqrt{\frac{-4y^3+27x}{x}}\right)x^2\right)^{\frac{2}{3}}\right)^2\left(2\,2^{\frac{1}{3}}3^{\frac{2}{3}}yx+2^{\frac{2}{3}}3^{\frac{1}{3}}\left(\left(9+\sqrt{3}\right.\right.\right.}$$

ODE order: 1.
ODE degree: 0.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[_dAlembert]`

$$\boxed{y - \frac{3xy'}{2} - e^{y'} = 0}$$

9.5.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$y - \frac{3xp}{2} - e^{p} = 0$$

Solving for y from the above results in

$$y = \frac{3xp}{2} + e^{p} \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$

$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = \frac{3p}{2}$$
$$g = e^{p}$$

Hence (2) becomes

$$-\frac{p}{2} = \left(\frac{3x}{2} + e^{p}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$-\frac{p}{2} = 0$$

Solving for p from the above gives

$$p = 0$$

Substituting these in (1A) gives

$$y = 1$$

The general solution is found when $\frac{dp}{dx} \neq 0$. From eq. (2A). This results in

$$p'(x) = -\frac{p(x)}{2\left(\frac{3x}{2} + e^{p(x)}\right)} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = -\frac{2\left(\frac{3x(p)}{2} + e^{p}\right)}{p} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{3}{p}$$
$$q(p) = -\frac{2\,e^{p}}{p}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{3x(p)}{p} = -\frac{2\,e^{p}}{p}$$

The integrating factor μ is

$$\mu = e^{\int \frac{3}{p}dp}$$
$$= p^3$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) = (\mu)\left(-\frac{2\,e^{p}}{p}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}p}(p^3 x) = (p^3)\left(-\frac{2\,e^{p}}{p}\right)$$
$$\mathrm{d}(p^3 x) = \left(-2p^2 e^{p}\right)\,\mathrm{d}p$$

Integrating gives

$$p^3 x = \int -2p^2 e^{p}\,\mathrm{d}p$$
$$p^3 x = -2\left(p^2 - 2p + 2\right)e^{p} + c_1$$

Dividing both sides by the integrating factor $\mu = p^3$ results in

$$x(p) = -\frac{2(p^2 - 2p + 2)\,e^{p}}{p^3} + \frac{c_1}{p^3}$$

which simplifies to

$$x(p) = \frac{(-2p^2 + 4p - 4)\,e^{p} + c_1}{p^3}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$p = -\operatorname{LambertW}\left(\frac{2\,e^{\frac{2y}{3x}}}{3x}\right) + \frac{2y}{3x}$$

Substituting the above in the solution for x found above gives

$$x = -\frac{27\left(\left(-2\operatorname{LambertW}\left(\frac{2\,e^{\frac{2y}{3x}}}{3x}\right)^2 x^2 - 4x\left(x - \frac{2y}{3}\right)\operatorname{LambertW}\left(\frac{2\,e^{\frac{2y}{3x}}}{3x}\right) - 4x^2 + \frac{8yx}{3} - \frac{8y^2}{9}\right)e^{-\frac{3x\operatorname{LambertW}(}{3x}}}{\left(3x\operatorname{LambertW}\left(\frac{2\,e^{\frac{2y}{3x}}}{3x}\right) - 2y\right)^3}$$

Summary

The solution(s) found are the following

$$y = 1 \tag{1}$$

$$x = -\frac{27\left(\left(-2\,\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{2y}{3x}}}{3x}\right)^{2} x^{2} - 4x\left(x - \frac{2y}{3}\right)\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{2y}{3x}}}{3x}\right) - 4x^{2} + \frac{8yx}{3} - \frac{8y^{2}}{9}\right)\mathrm{e}^{-\frac{3x\,\mathrm{LambertW}\left(\right.}{3x}}}{\left(3x\,\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{2y}{3x}}}{3x}\right) - 2y\right)^{3}} \tag{2}$$

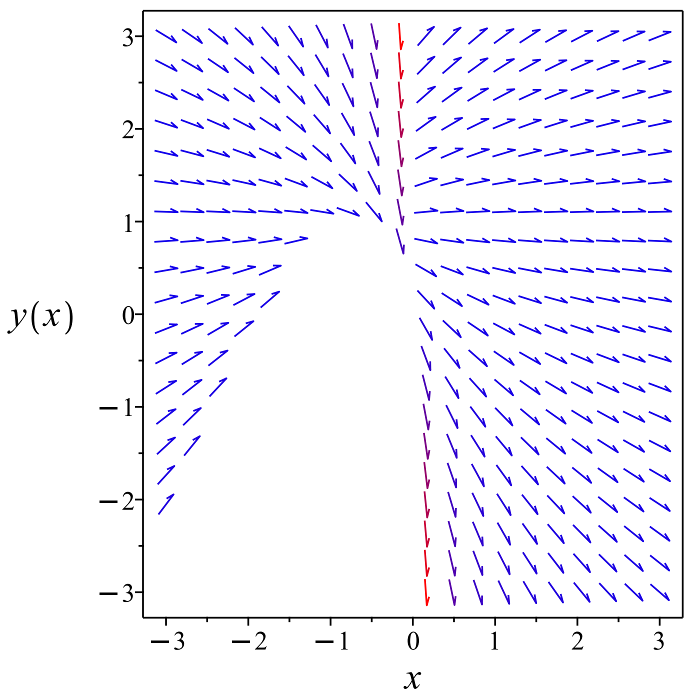

Figure 331: Slope field plot

Verification of solutions

$$y = 1$$

Verified OK.

$x =$

$$-\frac{27\left(\left(-2\,\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{2y}{3x}}}{3x}\right)^{2} x^{2}-4x\left(x-\frac{2y}{3}\right)\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{2y}{3x}}}{3x}\right)-4x^{2}+\frac{8yx}{3}-\frac{8y^{2}}{9}\right)\mathrm{e}^{-\frac{3x\,\mathrm{LambertW}\left(\right.}{3x}}}{\left(3x\,\mathrm{LambertW}\left(\frac{2\,\mathrm{e}^{\frac{2y}{3x}}}{3x}\right)-2y\right)^{3}}$$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8.3. The Lagrange and Clairaut equations. Exercises page 72
Problem number: 225.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _Clairaut]`

$$\boxed{y - xy' - \frac{a}{y'^2} = 0}$$

9.6.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - \frac{a}{p^2} = 0$$

Solving for y from the above results in

$$y = \frac{x\,p^3 + a}{p^2} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= xp + \frac{a}{p^2} \\ &= xp + \frac{a}{p^2} \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = \frac{a}{p^2}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + \frac{a}{c_1^2}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = \frac{a}{p^2}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x - \frac{2a}{p^3} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$
\begin{aligned}
p_1 &= \frac{2^{\frac{1}{3}} \left(a\, x^{2}\right)^{\frac{1}{3}}}{x} \\
p_2 &= -\frac{2^{\frac{1}{3}} \left(a\, x^{2}\right)^{\frac{1}{3}}}{2 x}+\frac{i \sqrt{3}\, 2^{\frac{1}{3}} \left(a\, x^{2}\right)^{\frac{1}{3}}}{2 x} \\
p_3 &= -\frac{2^{\frac{1}{3}} \left(a\, x^{2}\right)^{\frac{1}{3}}}{2 x}-\frac{i \sqrt{3}\, 2^{\frac{1}{3}} \left(a\, x^{2}\right)^{\frac{1}{3}}}{2 x}
\end{aligned}
$$

Substituting the above back in (1) results in

$$
\begin{aligned}
y_1 &= \frac{3 a\, x^{2} 2^{\frac{1}{3}}}{2 \left(a\, x^{2}\right)^{\frac{2}{3}}} \\
y_2 &= -\frac{3 a\, x^{2} 2^{\frac{1}{3}}}{\left(a\, x^{2}\right)^{\frac{2}{3}} \left(1+i \sqrt{3}\right)} \\
y_3 &= \frac{3 a\, x^{2} 2^{\frac{1}{3}}}{\left(a\, x^{2}\right)^{\frac{2}{3}} \left(i \sqrt{3}-1\right)}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x +\frac{a}{c_1^{2}} \tag{1}
$$

$$
y = \frac{3 a\, x^{2} 2^{\frac{1}{3}}}{2 \left(a\, x^{2}\right)^{\frac{2}{3}}} \tag{2}
$$

$$
y = -\frac{3 a\, x^{2} 2^{\frac{1}{3}}}{\left(a\, x^{2}\right)^{\frac{2}{3}} \left(1+i \sqrt{3}\right)} \tag{3}
$$

$$
y = \frac{3 a\, x^{2} 2^{\frac{1}{3}}}{\left(a\, x^{2}\right)^{\frac{2}{3}} \left(i \sqrt{3}-1\right)} \tag{4}
$$

Verification of solutions

$$y = c_1 x + \frac{a}{c_1^2}$$

Verified OK.

$$y = \frac{3a\,x^2 2^{\frac{1}{3}}}{2\left(a\,x^2\right)^{\frac{2}{3}}}$$

Verified OK.

$$y = -\frac{3a\,x^2 2^{\frac{1}{3}}}{\left(a\,x^2\right)^{\frac{2}{3}}\left(1 + i\sqrt{3}\right)}$$

Verified OK.

$$y = \frac{3a\,x^2 2^{\frac{1}{3}}}{\left(a\,x^2\right)^{\frac{2}{3}}\left(i\sqrt{3} - 1\right)}$$

Verified OK.

Problem number: 226.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _Clairaut]`

$$\boxed{y - xy' - y'^2 = 0}$$

9.7.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$-p^2 - xp + y = 0$$

Solving for y from the above results in

$$y = p^2 + xp \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= p^2 + xp \\ &= p^2 + xp \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = p^2$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned} p &= \frac{d}{dx}(xp + g) \\ p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\ p &= p + (x + g')\frac{dp}{dx} \\ 0 &= (x + g')\frac{dp}{dx} \end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned} \frac{dp}{dx} &= 0 \\ p &= c_1 \end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1^2 + c_1 x$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = p^2$, then the above equation becomes

$$\begin{aligned} x + g'(p) &= x + 2p \\ &= 0 \end{aligned}$$

Solving the above for p results in

$$p_1 = -\frac{x}{2}$$

Substituting the above back in (1) results in

$$y_1 = -\frac{x^2}{4}$$

Summary

The solution(s) found are the following

$$y = c_1^2 + c_1 x \tag{1}$$

$$y = -\frac{x^2}{4} \tag{2}$$

Verification of solutions

$$y = c_1^2 + c_1 x$$

Verified OK.

$$y = -\frac{x^2}{4}$$

Verified OK.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _rational, _Clairaut]`

$$\boxed{xy'^2 - yy' - y' = -1}$$

9.8.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$x\,p^2 - yp - p = -1$$

Solving for y from the above results in

$$y = \frac{x\,p^2 - p + 1}{p} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= px - \frac{p-1}{p} \\ &= px - \frac{p-1}{p} \end{aligned}$$

Writing the ode as

$$y = px + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = px + g \tag{1}$$

Then we see that

$$g = -\frac{p-1}{p}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned} p &= \frac{d}{dx}(xp+g) \\ p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\ p &= p + (x+g')\frac{dp}{dx} \\ 0 &= (x+g')\frac{dp}{dx} \end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned} \frac{dp}{dx} &= 0 \\ p &= c_1 \end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x - \frac{c_1 - 1}{c_1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = -\frac{p-1}{p}$, then the above equation becomes

$$\begin{aligned} x + g'(p) &= x - \frac{1}{p} + \frac{p-1}{p^2} \\ &= 0 \end{aligned}$$

Solving the above for p results in

$$
\begin{aligned}
p_1 &= \frac{1}{\sqrt{x}} \\
p_2 &= -\frac{1}{\sqrt{x}}
\end{aligned}
$$

Substituting the above back in (1) results in

$$
\begin{aligned}
y_1 &= 2\sqrt{x} - 1 \\
y_2 &= -1 - 2\sqrt{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x - \frac{c_1 - 1}{c_1} \tag{1}
$$

$$
y = 2\sqrt{x} - 1 \tag{2}
$$

Problem number: 228.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], _Clairaut]
```

$$\boxed{y - xy' - a\sqrt{1 + y'^2} = 0}$$

9.9.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$y - xp - a\sqrt{p^2 + 1} = 0$$

Solving for y from the above results in

$$y = a\sqrt{p^2 + 1} + xp \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= a\sqrt{p^2 + 1} + xp \\ &= a\sqrt{p^2 + 1} + xp \end{aligned}$$

Writing the ode as

$$y = xp + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = xp + g \tag{1}$$

Then we see that

$$g = a\sqrt{p^2 + 1}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x + a\sqrt{c_1^2 + 1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = a\sqrt{p^2 + 1}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + \frac{ap}{\sqrt{p^2 + 1}} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = \frac{x}{\sqrt{a^2 - x^2}}$$
$$p_2 = -\frac{x}{\sqrt{a^2 - x^2}}$$

Substituting the above back in (1) results in

$$y_1 = \frac{a\sqrt{\frac{a^2}{a^2-x^2}}\,\sqrt{a^2 - x^2} + x^2}{\sqrt{a^2 - x^2}}$$
$$y_2 = \frac{a\sqrt{\frac{a^2}{a^2-x^2}}\,\sqrt{a^2 - x^2} - x^2}{\sqrt{a^2 - x^2}}$$

Summary

The solution(s) found are the following

$$y = c_1 x + a\sqrt{c_1^2 + 1} \tag{1}$$
$$y = \frac{a\sqrt{\frac{a^2}{a^2-x^2}}\,\sqrt{a^2 - x^2} + x^2}{\sqrt{a^2 - x^2}} \tag{2}$$
$$y = \frac{a\sqrt{\frac{a^2}{a^2-x^2}}\,\sqrt{a^2 - x^2} - x^2}{\sqrt{a^2 - x^2}} \tag{3}$$

Verification of solutions

$$y = c_1 x + a\sqrt{c_1^2 + 1}$$

Verified OK.

$$y = \frac{a\sqrt{\frac{a^2}{a^2-x^2}}\,\sqrt{a^2 - x^2} + x^2}{\sqrt{a^2 - x^2}}$$

Verified OK.

$$y = \frac{a\sqrt{\frac{a^2}{a^2-x^2}}\,\sqrt{a^2 - x^2} - x^2}{\sqrt{a^2 - x^2}}$$

Verified OK.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 8.3. The Lagrange and Clairaut equations. Exercises page 72
Problem number: 229.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"clairaut"**

Maple gives the following as the ode type

`[[_homogeneous, `class G`], _rational, _Clairaut]`

$$\boxed{-\frac{1}{y'^2} = -x + \frac{y}{y'}}$$

9.10.1 Solving as clairaut ode

This is Clairaut ODE. It has the form

$$y = xy' + g(y')$$

Where g is function of $y'(x)$. Let $p = y'$ the ode becomes

$$-\frac{1}{p^2} = -x + \frac{y}{p}$$

Solving for y from the above results in

$$y = \frac{x\,p^2 - 1}{p} \tag{1A}$$

The above ode is a Clairaut ode which is now solved. We start by replacing y' by p which gives

$$\begin{aligned} y &= px - \frac{1}{p} \\ &= px - \frac{1}{p} \end{aligned}$$

Writing the ode as

$$y = px + g(p)$$

We now write $g \equiv g(p)$ to make notation simpler but we should always remember that g is function of p which in turn is function of x. Hence the above becomes

$$y = px + g \tag{1}$$

Then we see that

$$g = -\frac{1}{p}$$

Taking derivative of (1) w.r.t. x gives

$$\begin{aligned}
p &= \frac{d}{dx}(xp + g) \\
p &= \left(p + x\frac{dp}{dx}\right) + \left(g'\frac{dp}{dx}\right) \\
p &= p + (x + g')\frac{dp}{dx} \\
0 &= (x + g')\frac{dp}{dx}
\end{aligned}$$

Where g' is derivative of $g(p)$ w.r.t. p. The general solution is given by

$$\begin{aligned}
\frac{dp}{dx} &= 0 \\
p &= c_1
\end{aligned}$$

Substituting this in (1) gives the general solution as

$$y = c_1 x - \frac{1}{c_1}$$

The singular solution is found from solving for p from

$$x + g'(p) = 0$$

And substituting the result back in (1). Since we found above that $g = -\frac{1}{p}$, then the above equation becomes

$$\begin{aligned}
x + g'(p) &= x + \frac{1}{p^2} \\
&= 0
\end{aligned}$$

Solving the above for p results in

$$p_1 = -\frac{1}{\sqrt{-x}}$$
$$p_2 = \frac{1}{\sqrt{-x}}$$

Substituting the above back in (1) results in

$$y_1 = 2\sqrt{-x}$$
$$y_2 = -2\sqrt{-x}$$

Summary

The solution(s) found are the following

$$y = c_1 x - \frac{1}{c_1} \tag{1}$$
$$y = 2\sqrt{-x} \tag{2}$$
$$y = -2\sqrt{-x} \tag{3}$$

Verification of solutions

$$y = c_1 x - \frac{1}{c_1}$$

Verified OK.

$$y = 2\sqrt{-x}$$

Verified OK.

$$y = -2\sqrt{-x}$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[[_1st_order, `_with_symmetry_[F(x),G(x)]`], _Riccati]
```

$$\boxed{y' \mathrm{e}^{-x} + y^2 - 2y\,\mathrm{e}^{x} = 1 - \mathrm{e}^{2x}}$$

10.1.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\left(y^2 - 2y\,\mathrm{e}^{x} - 1 + \mathrm{e}^{2x}\right)\mathrm{e}^{x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = 2y\,\mathrm{e}^{2x} - \mathrm{e}^{x} y^2 - \mathrm{e}^{3x} + \mathrm{e}^{x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -(-1 + \mathrm{e}^{2x})\,\mathrm{e}^{x}$, $f_1(x) = 2(\mathrm{e}^{x})^2$ and $f_2(x) = -\mathrm{e}^{x}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-\mathrm{e}^{x} u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -e^{x} \\ f_1 f_2 &= -2\, e^{x} e^{2x} \\ f_2^2 f_0 &= -e^{3x} \left(-1 + e^{2x}\right) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-e^{x} u''(x) - \left(-e^{x} - 2\, e^{x} e^{2x}\right) u'(x) - e^{3x} \left(-1 + e^{2x}\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = e^{\frac{x}{2} + \frac{e^{2x}}{2}} \left(c_1 \sinh\left(\frac{x}{2}\right) + c_2 \cosh\left(\frac{x}{2}\right)\right)$$

The above shows that

$$u'(x) = \left(\left(e^{2x} c_2 + \frac{c_1}{2} + \frac{c_2}{2}\right) \cosh\left(\frac{x}{2}\right) + \sinh\left(\frac{x}{2}\right) \left(c_1 e^{2x} + \frac{c_1}{2} + \frac{c_2}{2}\right)\right) e^{\frac{x}{2} + \frac{e^{2x}}{2}}$$

Using the above in (1) gives the solution

$$y = \frac{\left(\left(e^{2x} c_2 + \frac{c_1}{2} + \frac{c_2}{2}\right) \cosh\left(\frac{x}{2}\right) + \sinh\left(\frac{x}{2}\right) \left(c_1 e^{2x} + \frac{c_1}{2} + \frac{c_2}{2}\right)\right) e^{-x}}{c_1 \sinh\left(\frac{x}{2}\right) + c_2 \cosh\left(\frac{x}{2}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\left((c_3 + 1)\, e^{-x} + 2\, e^{x}\right) \cosh\left(\frac{x}{2}\right) + 2 \sinh\left(\frac{x}{2}\right) \left(\left(\frac{c_3}{2} + \frac{1}{2}\right) e^{-x} + e^{x} c_3\right)}{2 c_3 \sinh\left(\frac{x}{2}\right) + 2 \cosh\left(\frac{x}{2}\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{\left((c_3 + 1)\, e^{-x} + 2\, e^{x}\right) \cosh\left(\frac{x}{2}\right) + 2 \sinh\left(\frac{x}{2}\right) \left(\left(\frac{c_3}{2} + \frac{1}{2}\right) e^{-x} + e^{x} c_3\right)}{2 c_3 \sinh\left(\frac{x}{2}\right) + 2 \cosh\left(\frac{x}{2}\right)} \tag{1}$$

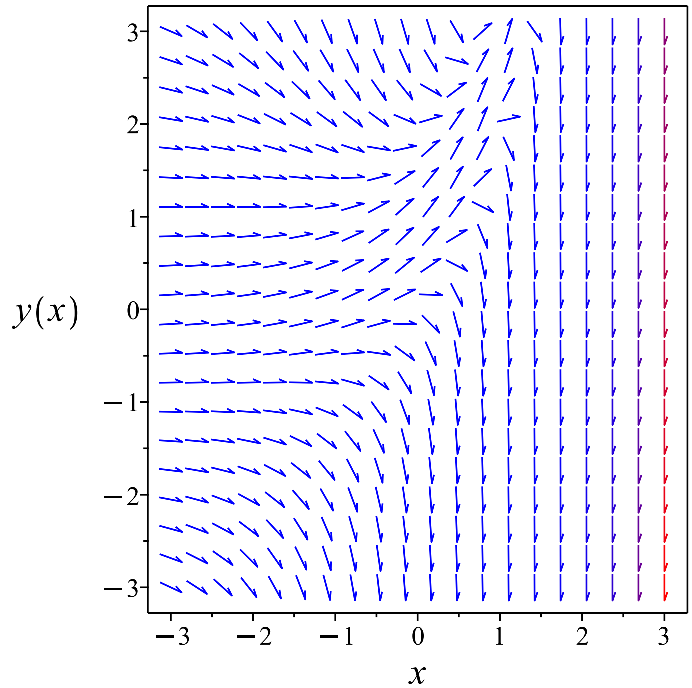

Figure 332: Slope field plot

Verification of solutions

$$y = \frac{\left(\left(c_3+1\right)\mathrm{e}^{-x}+2\,\mathrm{e}^{x}\right)\cosh\left(\frac{x}{2}\right)+2\sinh\left(\frac{x}{2}\right)\left(\left(\frac{c_3}{2}+\frac{1}{2}\right)\mathrm{e}^{-x}+\mathrm{e}^{x}c_3\right)}{2c_3\sinh\left(\frac{x}{2}\right)+2\cosh\left(\frac{x}{2}\right)}$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[[_1st_order, `_with_symmetry_[F(x),G(x)]`], _Riccati]`

$$\boxed{y'+y^2-2y\sin(x)=-\sin(x)^2+\cos(x)}$$

10.2.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -y^2+2y\sin(x)-\sin(x)^2+\cos(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -y^2+2y\sin(x)-\sin(x)^2+\cos(x)$$

With Riccati ODE standard form

$$y' = f_0(x)+f_1(x)y+f_2(x)y^2$$

Shows that $f_0(x)=-\sin(x)^2+\cos(x)$, $f_1(x)=2\sin(x)$ and $f_2(x)=-1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= -2\sin(x) \\ f_2^2f_0 &= -\sin(x)^2 + \cos(x) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x) + 2\sin(x)\,u'(x) + \left(-\sin(x)^2 + \cos(x)\right)u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{e}^{-\cos(x)}(c_2x + c_1)$$

The above shows that

$$u'(x) = \mathrm{e}^{-\cos(x)}(\sin(x)\,(c_2x + c_1) + c_2)$$

Using the above in (1) gives the solution

$$y = \frac{\sin(x)\,(c_2x + c_1) + c_2}{c_2x + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\sin(x)\,(c_3 + x) + 1}{c_3 + x}$$

Summary

The solution(s) found are the following

$$y = \frac{\sin(x)\,(c_3 + x) + 1}{c_3 + x} \tag{1}$$

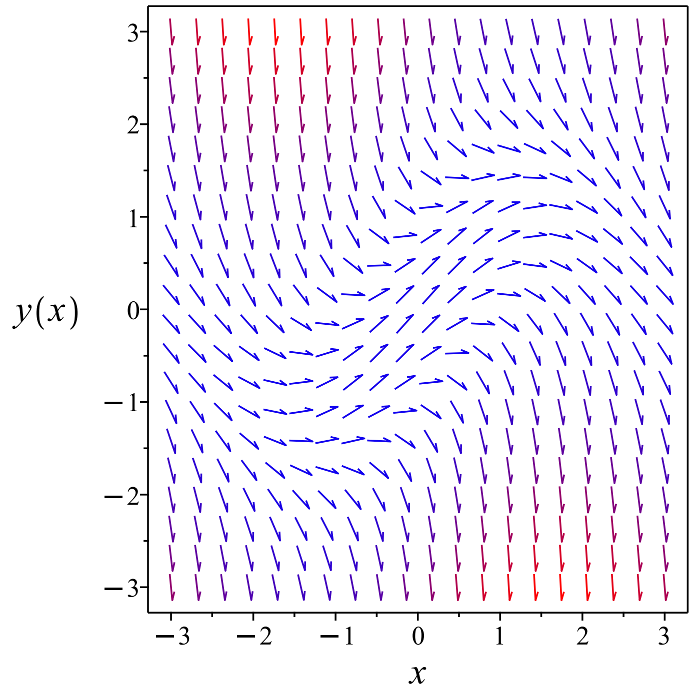

Figure 333: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{\sin(x)(c_3 + x) + 1}{c_3 + x}$$

The type(s) of ODE detected by this program : **"riccati", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], _rational, _Riccati]
```

$$\boxed{xy' - y^2 + (2x+1)\,y = x^2 + 2x}$$

10.3.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{x^2 - 2xy + y^2 + 2x - y}{x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&b_2 + \frac{(x^2-2xy+y^2+2x-y)(b_3-a_2)}{x} - \frac{(x^2-2xy+y^2+2x-y)^2 a_3}{x^2} \\
&- \left(\frac{2x-2y+2}{x} - \frac{x^2-2xy+y^2+2x-y}{x^2}\right)(xa_2+ya_3+a_1) \\
&- \frac{(2y-2x-1)(xb_2+yb_3+b_1)}{x} = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{x^4a_3 - 4x^3ya_3 + 6x^2y^2a_3 - 4x\,y^3a_3 + y^4a_3 + 2x^3a_2 + 4x^3a_3 - 2x^3b_2 - x^3b_3 - 2x^2ya_2 - 9x^2ya_3 + 2x^2yb}{}$$
$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&-x^4a_3 + 4x^3ya_3 - 6x^2y^2a_3 + 4x\,y^3a_3 - y^4a_3 - 2x^3a_2 - 4x^3a_3 + 2x^3b_2 + x^3b_3 \\
&+ 2x^2ya_2 + 9x^2ya_3 - 2x^2yb_2 - 8x\,y^2a_3 - x\,y^2b_3 + 3y^3a_3 - x^2a_1 - 2x^2a_2 - 4x^2a_3 \\
&+ 2x^2b_1 + 2b_2x^2 + 2x^2b_3 + 4xya_3 - 2xyb_1 + y^2a_1 - 2y^2a_3 + xb_1 - ya_1 = 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&-a_3v_1^4 + 4a_3v_1^3v_2 - 6a_3v_1^2v_2^2 + 4a_3v_1v_2^3 - a_3v_2^4 - 2a_2v_1^3 + 2a_2v_1^2v_2 \\
&- 4a_3v_1^3 + 9a_3v_1^2v_2 - 8a_3v_1v_2^2 + 3a_3v_2^3 + 2b_2v_1^3 - 2b_2v_1^2v_2 \\
&+ b_3v_1^3 - b_3v_1v_2^2 - a_1v_1^2 + a_1v_2^2 - 2a_2v_1^2 - 4a_3v_1^2 + 4a_3v_1v_2 \\
&- 2a_3v_2^2 + 2b_1v_1^2 - 2b_1v_1v_2 + 2b_2v_1^2 + 2b_3v_1^2 - a_1v_2 + b_1v_1 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&-a_3v_1^4+4a_3v_1^3v_2+(-2a_2-4a_3+2b_2+b_3)\,v_1^3-6a_3v_1^2v_2^2+(2a_2+9a_3-2b_2)\,v_1^2v_2 \\
&+(-a_1-2a_2-4a_3+2b_1+2b_2+2b_3)\,v_1^2+4a_3v_1v_2^3+(-8a_3-b_3)\,v_1v_2^2 \\
&+(4a_3-2b_1)\,v_1v_2+b_1v_1-a_3v_2^4+3a_3v_2^3+(a_1-2a_3)\,v_2^2-a_1v_2=0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
b_1 &= 0 \\
-a_1 &= 0 \\
-6a_3 &= 0 \\
-a_3 &= 0 \\
3a_3 &= 0 \\
4a_3 &= 0 \\
a_1-2a_3 &= 0 \\
-8a_3-b_3 &= 0 \\
4a_3-2b_1 &= 0 \\
2a_2+9a_3-2b_2 &= 0 \\
-2a_2-4a_3+2b_2+b_3 &= 0 \\
-a_1-2a_2-4a_3+2b_1+2b_2+2b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= b_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= b_2 \\
b_3 &= 0
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= x \\
\eta &= x
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}\eta &= \eta - \omega(x,y)\,\xi \\ &= x - \left(\frac{x^2 - 2xy + y^2 + 2x - y}{x}\right)(x) \\ &= -x^2 + 2xy - y^2 - x + y \\ \xi &= 0\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{-x^2 + 2xy - y^2 - x + y} dy\end{aligned}$$

Which results in

$$S = -\ln(-1 - x + y) + \ln(-x + y)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2 - 2xy + y^2 + 2x - y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{1}{(x-y+1)(x-y)} \\
S_y &= -\frac{1}{(x-y+1)(x-y)}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln(-1-x+y) + \ln(-x+y) = -\ln(x) + c_1$$

Which simplifies to

$$-\ln(-1-x+y) + \ln(-x+y) = -\ln(x) + c_1$$

Which gives

$$y = \frac{e^{c_1}x - x^2 + e^{c_1}}{e^{c_1} - x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2-2xy+y^2+2x-y}{x}$ 	$R = x$ $S = -\ln(-1-x+y) +$	$\frac{dS}{dR} = -\frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = \frac{e^{c_1} x - x^2 + e^{c_1}}{e^{c_1} - x} \tag{1}$$

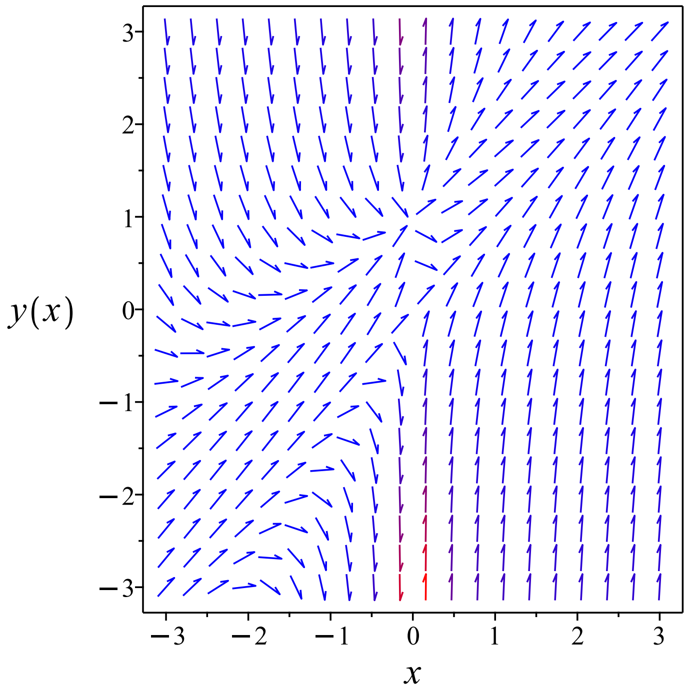

Figure 334: Slope field plot

Verification of solutions

$$y = \frac{e^{c_1} x - x^2 + e^{c_1}}{e^{c_1} - x}$$

Verified OK.

10.3.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2 - 2xy + y^2 + 2x - y}{x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x - 2y + \frac{y^2}{x} + 2 - \frac{y}{x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{x^2+2x}{x}$, $f_1(x) = \frac{-2x-1}{x}$ and $f_2(x) = \frac{1}{x}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\frac{u}{x}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{1}{x^2} \\ f_1 f_2 &= \frac{-2x-1}{x^2} \\ f_2^2 f_0 &= \frac{x^2+2x}{x^3} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\frac{u''(x)}{x} - \left(-\frac{1}{x^2} + \frac{-2x-1}{x^2}\right) u'(x) + \frac{(x^2+2x)\, u(x)}{x^3} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \frac{\mathrm{e}^{-x}(c_1 x + c_2)}{x}$$

The above shows that

$$u'(x) = -\frac{\mathrm{e}^{-x}(c_1 x^2 + c_2 x + c_2)}{x^2}$$

Using the above in (1) gives the solution

$$y = \frac{c_1 x^2 + c_2 x + c_2}{c_1 x + c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{c_3 x^2 + x + 1}{c_3 x + 1}$$

Summary
The solution(s) found are the following

$$y = \frac{c_3 x^2 + x + 1}{c_3 x + 1} \tag{1}$$

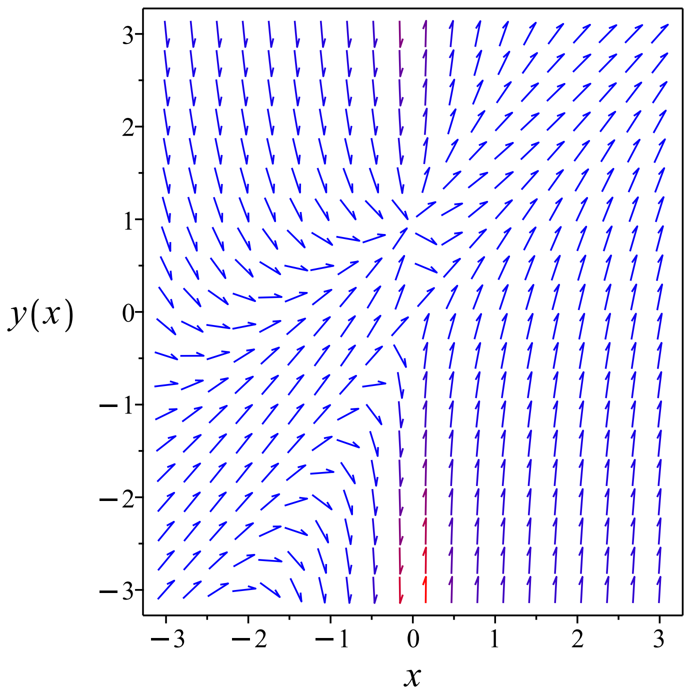

Figure 335: Slope field plot

Verification of solutions

$$y = \frac{c_3 x^2 + x + 1}{c_3 x + 1}$$

Verified OK.

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Riccati]
```

$$\boxed{x^2y' - y^2x^2 - yx = 1}$$

10.4.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{x^2y^2 + xy + 1}{x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2 + \frac{(x^2y^2 + xy + 1)(b_3 - a_2)}{x^2} - \frac{(x^2y^2 + xy + 1)^2 a_3}{x^4} \\
&- \left(\frac{2x\, y^2 + y}{x^2} - \frac{2(x^2y^2 + xy + 1)}{x^3}\right)(xa_2 + ya_3 + a_1) \\
&- \frac{(2x^2y + x)(xb_2 + yb_3 + b_1)}{x^2} = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{x^4y^4a_3 + 2x^5yb_2 + x^4y^2a_2 + x^4y^2b_3 + 2x^3y^3a_3 + 2x^4yb_1 + 2x^2y^2a_3 + x^3b_1 - x^2ya_1 - x^2a_2 - x^2b_3 - 2xa_1}{x^4}
= 0
$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-x^4y^4a_3 - 2x^5yb_2 - x^4y^2a_2 - x^4y^2b_3 - 2x^3y^3a_3 - 2x^4yb_1 \\
&- 2x^2y^2a_3 - x^3b_1 + x^2ya_1 + x^2a_2 + x^2b_3 + 2xa_1 - a_3 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\{x, y\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\{x = v_1, y = v_2\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-a_3v_1^4v_2^4 - a_2v_1^4v_2^2 - 2a_3v_1^3v_2^3 - 2b_2v_1^5v_2 - b_3v_1^4v_2^2 - 2b_1v_1^4v_2 \\
&- 2a_3v_1^2v_2^2 + a_1v_1^2v_2 - b_1v_1^3 + a_2v_1^2 + b_3v_1^2 + 2a_1v_1 - a_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} -2b_2v_1^5v_2 - a_3v_1^4v_2^4 + (-a_2 - b_3)\, v_1^4v_2^2 - 2b_1v_1^4v_2 - 2a_3v_1^3v_2^3 \\ - b_1v_1^3 - 2a_3v_1^2v_2^2 + a_1v_1^2v_2 + (a_2 + b_3)\, v_1^2 + 2a_1v_1 - a_3 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_1 &= 0 \\ 2a_1 &= 0 \\ -2a_3 &= 0 \\ -a_3 &= 0 \\ -2b_1 &= 0 \\ -b_1 &= 0 \\ -2b_2 &= 0 \\ -a_2 - b_3 &= 0 \\ a_2 + b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= -b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= -x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{x^2y^2 + xy + 1}{x^2}\right)(-x) \\
&= \frac{x^2y^2 + 2xy + 1}{x} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{x^2y^2 + 2xy + 1}{x}} dy
\end{aligned}$$

Which results in

$$S = -\frac{1}{xy + 1}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{x^2y^2 + xy + 1}{x^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{y}{(xy+1)^2} \\
S_y &= \frac{x}{(xy+1)^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \ln(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\frac{1}{yx+1} = \ln(x) + c_1
$$

Which simplifies to

$$
-\frac{1}{yx+1} = \ln(x) + c_1
$$

Which gives

$$
y = -\frac{\ln(x) + c_1 + 1}{x(\ln(x) + c_1)}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^2y^2+xy+1}{x^2}$ 	$R = x$ $S = -\frac{1}{xy+1}$	$\frac{dS}{dR} = \frac{1}{R}$ 
Summary

The solution(s) found are the following

$$y = -\frac{\ln(x) + c_1 + 1}{x(\ln(x) + c_1)} \tag{1}$$

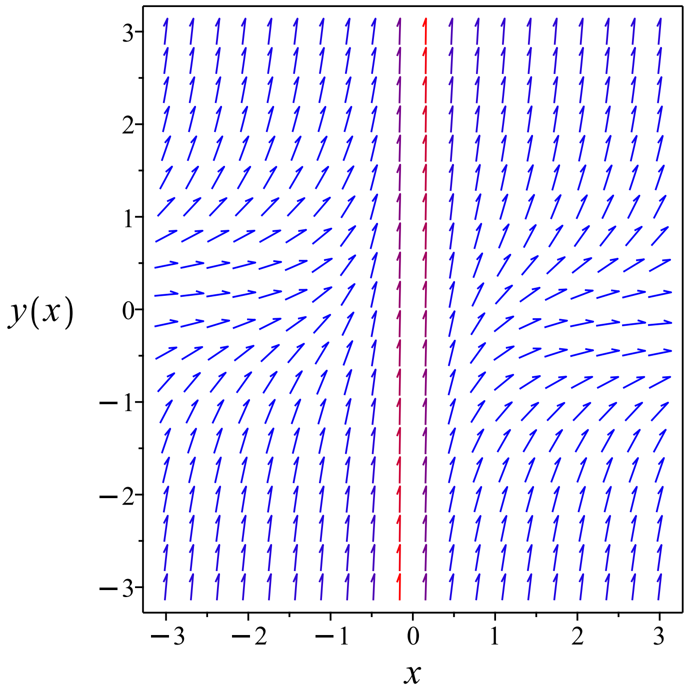

Figure 336: Slope field plot

Verification of solutions

$$y = -\frac{\ln(x) + c_1 + 1}{x(\ln(x) + c_1)}$$

Verified OK.

10.4.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(x^2) \, \mathrm{d}y &= (x^2 y^2 + xy + 1) \, \mathrm{d}x \\
(-x^2 y^2 - xy - 1) \, \mathrm{d}x + (x^2) \, \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -x^2 y^2 - xy - 1 \\
N(x, y) &= x^2
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y} (-x^2 y^2 - xy - 1) \\
&= -2x^2 y - x
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x} (x^2) \\
&= 2x
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x^2}\left((-2x^2y - x) - (2x)\right) \\
&= \frac{-2xy - 3}{x}
\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= -\frac{1}{x^2y^2 + xy + 1}\left((2x) - (-2x^2y - x)\right) \\
&= \frac{-2x^2y - 3x}{x^2y^2 + xy + 1}
\end{aligned}$$

Since B depends on x, it can not be used to obtain an integrating factor.We will now try a third method to find an integrating factor. Let

$$R = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN}$$

R is now checked to see if it is a function of only $t = xy$. Therefore

$$\begin{aligned}
R &= \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN} \\
&= \frac{(2x) - (-2x^2y - x)}{x\left(-x^2y^2 - xy - 1\right) - y\left(x^2\right)} \\
&= \frac{-2xy - 3}{\left(xy + 1\right)^2}
\end{aligned}$$

Replacing all powers of terms xy by t gives

$$R = \frac{-2t - 3}{\left(t + 1\right)^2}$$

Since R depends on t only, then it can be used to find an integrating factor. Let the integrating factor be μ then

$$\begin{aligned}
\mu &= e^{\int R \,\mathrm{d}t} \\
&= e^{\int \left(\frac{-2t-3}{(t+1)^2}\right) \mathrm{d}t}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\frac{1}{t+1}-2\ln(t+1)}\\ &= \frac{\mathrm{e}^{\frac{1}{t+1}}}{(t+1)^2}\end{aligned}$$

Now t is replaced back with xy giving

$$\mu = \frac{\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}$$

Multiplying M and N by this integrating factor gives new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\left(-x^2y^2-xy-1\right)\\ &= -\frac{\left(x^2y^2+xy+1\right)\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\left(x^2\right)\\ &= \frac{x^2\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\end{aligned}$$

A modified ODE is now obtained from the original ODE, which is exact and can solved. The modified ODE is

$$\begin{aligned}\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(-\frac{\left(x^2y^2+xy+1\right)\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\right)+\left(\frac{x^2\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$

$$\int \frac{\partial\phi}{\partial x}\,\mathrm{d}x = \int -\frac{(x^2y^2+xy+1)\,\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}\,\mathrm{d}x$$

$$\phi = -x\,\mathrm{e}^{\frac{1}{xy+1}} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = \frac{x^2\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = \frac{x^2\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2}$. Therefore equation (4) becomes

$$\frac{x^2\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2} = \frac{x^2\mathrm{e}^{\frac{1}{xy+1}}}{(xy+1)^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -x\,\mathrm{e}^{\frac{1}{xy+1}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x\,\mathrm{e}^{\frac{1}{xy+1}}$$

The solution becomes

$$y = -\frac{\ln\left(-\frac{c_1}{x}\right) - 1}{x\ln\left(-\frac{c_1}{x}\right)}$$

Summary
The solution(s) found are the following

$$y = -\frac{\ln\left(-\frac{c_1}{x}\right) - 1}{x \ln\left(-\frac{c_1}{x}\right)} \tag{1}$$

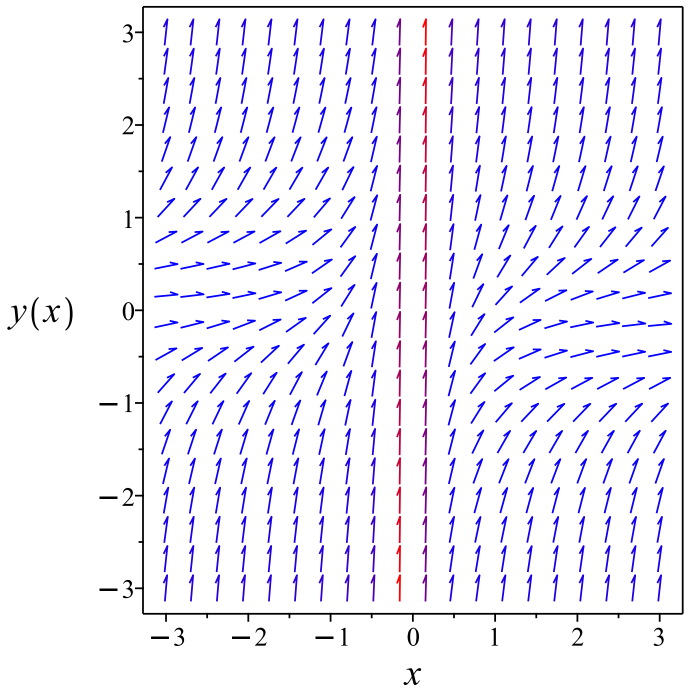

Figure 337: Slope field plot

Verification of solutions

$$y = -\frac{\ln\left(-\frac{c_1}{x}\right) - 1}{x \ln\left(-\frac{c_1}{x}\right)}$$

Verified OK.

10.4.3 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{x^2y^2 + xy + 1}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + \frac{y}{x} + \frac{1}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{1}{x^2}$, $f_1(x) = \frac{1}{x}$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= \frac{1}{x} \\ f_2^2 f_0 &= \frac{1}{x^2} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) - \frac{u'(x)}{x} + \frac{u(x)}{x^2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = x(\ln(x)\, c_2 + c_1)$$

The above shows that

$$u'(x) = \ln(x)\, c_2 + c_1 + c_2$$

Using the above in (1) gives the solution

$$y = -\frac{\ln(x)\, c_2 + c_1 + c_2}{x(\ln(x)\, c_2 + c_1)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-\ln(x) - c_3 - 1}{x(\ln(x) + c_3)}$$

Summary

The solution(s) found are the following

$$y = \frac{-\ln(x) - c_3 - 1}{x(\ln(x) + c_3)} \tag{1}$$

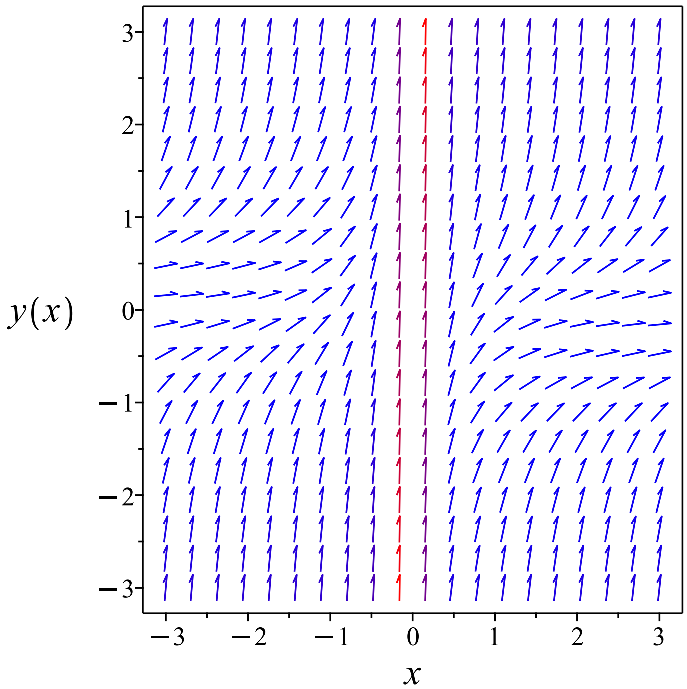

Figure 338: Slope field plot

Verification of solutions

$$y = \frac{-\ln(x) - c_3 - 1}{x(\ln(x) + c_3)}$$

Verified OK.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y'^2 - 4y = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = 2\sqrt{y} \tag{1}$$
$$y' = -2\sqrt{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{2\sqrt{y}} dy = \int dx$$
$$\sqrt{y} = c_1 + x$$

Summary
The solution(s) found are the following

$$\sqrt{y} = c_1 + x \tag{1}$$

Verification of solutions

$$\sqrt{y} = c_1 + x$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{2\sqrt{y}}dy = \int dx$$
$$-\sqrt{y} = x + c_2$$

Summary

The solution(s) found are the following

$$-\sqrt{y} = x + c_2 \tag{1}$$

Verification of solutions

$$-\sqrt{y} = x + c_2$$

Verified OK.

11.2.1 Maple step by step solution

Let's solve

$y'^2 - 4y = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{\sqrt{y}} = 2$

- Integrate both sides with respect to x

  $\int \frac{y'}{\sqrt{y}}dx = \int 2dx + c_1$

- Evaluate integral

  $2\sqrt{y} = 2x + c_1$

- Solve for y

  $y = x^2 + c_1x + \frac{1}{4}c_1^2$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 11. Singular solutions of differential equations. Exercises page 92
Problem number: 262.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries]]
```

$$\boxed{{y'}^3 - 4xyy' + 8y^2 = 0}$$

Solving the given ode for y' results in 3 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}{3} + \frac{4yx}{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} \tag{1}$$

$$y' = -\frac{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}{6} - \frac{2yx}{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} + i\sqrt{3}\left(\frac{\left(-108y^2 + 12\sqrt{\cdot}\right.}{}\right. \tag{2}$$

$$y' = -\frac{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}{6} - \frac{2yx}{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} - i\sqrt{3}\left(\frac{\left(-108y^2 + 12\sqrt{\cdot}\right.}{}\right. \tag{3}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$
\begin{align*}
y' &= \frac{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{2}{3}} + 12xy}{3\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}} \\
y' &= \omega(x, y)
\end{align*}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = xa_2 + ya_3 + a_1 \tag{1E}
$$

$$
\eta = xb_2 + yb_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, b_1, b_2, b_3\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{\left(\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)(b_3-a_2)}{3\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}} - \frac{\left(\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)^2 a_3}{9\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}} - \left(\frac{-\frac{144x^2y^3}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}\sqrt{-12y^3x^3+81y^4}}+12y}{3\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}} + \frac{24\left(\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)x^2y^3}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}\sqrt{-12y^3x^3+81y^4}}\right)(xa_2+ya_3+a_1) - \left(\frac{\frac{-144y+\frac{2\left(-216x^3y^2+1944y^3\right)}{3\sqrt{-12y^3x^3+81y^4}}}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}+12x}{3\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}} - \frac{\left(\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)\left(-216y+\frac{-216x^3y^2+1944y^3}{\sqrt{-12y^3x^3+81y^4}}\right)}{9\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}}\right)(xb_2 + yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-72\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}\sqrt{-12y^3x^3+81y^4}\,xyb_2+8\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}\sqrt{-}}{} = 0$$

Setting the numerator to zero gives

$$
\begin{aligned}
&72\bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{2}{3}} \sqrt{-12y^3x^3+81y^4}\, x y b_2 \\
&- 8\bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{4}{3}} \sqrt{-12y^3x^3+81y^4}\, x y a_3 \\
&- 48\bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{2}{3}} \sqrt{-12y^3x^3+81y^4}\, x^2 y^2 a_3 \\
&- 48\left(-12y^3x^3+81y^4\right)^{\frac{3}{2}} a_3 + 58320 y^6 a_3 \\
&- 11664 y^5 a_1 + 2592\sqrt{-12y^3x^3+81y^4}\, x\, y^3 a_2 \\
&+ 72\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x^4 y^2 b_2 \\
&+ 72\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x^3 y^3 a_2 \\
&+ 72\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x^3 y^3 b_3 \\
&+ 72\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x^2 y^4 a_3 \\
&+ 72\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x^3 y^2 b_1 \\
&+ 72\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x^2 y^3 a_1 \\
&- 648\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} x\, y^3 b_2 \\
&+ 72\bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{2}{3}} \sqrt{-12y^3x^3+81y^4}\, y^2 b_3 \\
&+ 432\sqrt{-12y^3x^3+81y^4}\, x^2 y^2 b_2 \\
&- 864\sqrt{-12y^3x^3+81y^4}\, x\, y^3 b_3 + 72\bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{2}{3}} \sqrt{-12y^3x^3+81y^4}\, y b_1 \\
&+ 432\sqrt{-12y^3x^3+81y^4}\, x\, y^2 b_1 - \bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{5}{3}} \sqrt{-12y^3x^3+81y^4}\, a_2 \\
&+ \bigg(-108y^2 \\
&+ 12\sqrt{-12y^3x^3+81y^4}\bigg)^{\frac{5}{3}} \sqrt{-12y^3x^3+81y^4}\, b_3 \\
&- 648\left(-108y^2 + 12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} y^4 b_3 \\
&+ 3b_2\bigg(-108y^2
\end{aligned}
\tag{6E}
$$

Simplifying the above gives

$$\text{Expression too large to display} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\text{Expression too large to display}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{-y^3 (4x^3-27y)}, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3-27y)}\right)^{\frac{1}{3}}, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3-27y)}\right)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{-y^3 (4x^3-27y)} = v_3, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3-27y)}\right)^{\frac{1}{3}} = v_4, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3-27y)}\right)^{\frac{2}{3}} = v_5\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
-36v_2\Big(&-48v_3\sqrt{3}\,v_1^3v_2^2a_3 - 6v_3v_5\sqrt{3}\,v_1b_2 - 9v_3v_5\sqrt{3}\,v_2a_2 \\
&+ 3v_3v_5\sqrt{3}\,v_2b_3 - 36v_3\sqrt{3}\,v_1^2v_2b_2 - 216v_3\sqrt{3}\,v_1v_2^2a_2 + 72v_3\sqrt{3}\,v_1v_2^2b_3 \\
&+ 27v_3v_4\sqrt{3}\,v_2b_2 - 36v_3\sqrt{3}\,v_1v_2b_1 - 4860v_2^5a_3 + 972v_2^4a_1 + 324v_2^3v_1b_1 \\
&- 72v_1^5v_2^2b_2 + 324v_2^3v_1^2b_2 + 1944v_2^4v_1a_2 - 216v_1^4v_2^3a_2 + 72v_1^4v_2^3b_3 \\
&+ 792v_1^3v_2^4a_3 - 72v_1^4v_2^2b_1 - 72v_1^3v_2^3a_1 - 648v_1v_2^4b_3 + 81v_5v_2^3a_2 - 27v_5v_2^3b_3 \\
&+ 54v_5v_2^2b_1 - 243v_4v_2^3b_2 + 4v_3v_5\sqrt{3}\,v_1^2v_2a_3 - 72v_3v_4\sqrt{3}\,v_1v_2^2a_3 \\
&- 96v_4v_1^4v_2^3a_3 - 6v_5v_1^4v_2b_2 - 18v_5v_1^3v_2^2a_2 + 6v_5v_1^3v_2^2b_3 - 6v_5v_1^2v_2^3a_3 \\
&- 6v_5v_1^3v_2b_1 - 6v_5v_1^2v_2^2a_1 + 36v_4v_1^3v_2^2b_2 + 648v_4v_1v_2^4a_3 \\
&+ 540v_3\sqrt{3}\,v_2^3a_3 + 54v_5v_1v_2^2b_2 - 6v_3v_5\sqrt{3}\,b_1 - 108v_3\sqrt{3}\,v_2^2a_1\Big) = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&-972\sqrt{3}\,b_2v_3v_4v_2^2+216v_3v_5\sqrt{3}\,b_1v_2+1728\sqrt{3}\,a_3v_3v_1^3v_2^3\\
&+1296\sqrt{3}\,b_2v_3v_1^2v_2^2+1296\sqrt{3}\,b_1v_3v_1v_2^2+8748b_2v_4v_2^4\\
&+\left(-2916a_2+972b_3\right)v_5v_2^4-1944b_1v_5v_2^3-34992a_1v_2^5\\
&+174960a_3v_2^6-28512a_3v_1^3v_2^5+2592a_1v_1^3v_2^4-11664b_2v_1^2v_2^4\\
&-11664b_1v_1v_2^4+2592v_2^3b_2v_1^5+2592b_1v_1^4v_2^3-144\sqrt{3}\,a_3v_3v_5v_1^2v_2^2\\
&+2592\sqrt{3}\,a_3v_3v_4v_1v_2^3+216\sqrt{3}\,b_2v_3v_5v_1v_2+3456a_3v_4v_1^4v_2^4\\
&+\left(7776a_2-2592b_3\right)v_1^4v_2^4+216b_2v_5v_1^4v_2^2-1296b_2v_4v_1^3v_2^3\\
&+\left(648a_2-216b_3\right)v_5v_1^3v_2^3+216b_1v_5v_1^3v_2^2+216a_3v_5v_1^2v_2^4\\
&+216a_1v_5v_1^2v_2^3-23328a_3v_4v_1v_2^5+\left(-69984a_2+23328b_3\right)v_1v_2^5\\
&+\left(7776\sqrt{3}\,a_2-2592\sqrt{3}\,b_3\right)v_3v_1v_2^3-1944b_2v_5v_1v_2^3-19440\sqrt{3}\,a_3v_3v_2^4\\
&+3888\sqrt{3}\,a_1v_3v_2^3+\left(324\sqrt{3}\,a_2-108\sqrt{3}\,b_3\right)v_3v_5v_2^2=0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-34992a_1 &= 0\\
216a_1 &= 0\\
2592a_1 &= 0\\
-28512a_3 &= 0\\
-23328a_3 &= 0\\
216a_3 &= 0\\
3456a_3 &= 0\\
174960a_3 &= 0\\
-11664b_1 &= 0\\
-1944b_1 &= 0\\
216b_1 &= 0\\
2592b_1 &= 0\\
-11664b_2 &= 0\\
-1944b_2 &= 0\\
-1296b_2 &= 0\\
216b_2 &= 0\\
2592b_2 &= 0\\
8748b_2 &= 0\\
3888\sqrt{3}\, a_1 &= 0\\
-19440\sqrt{3}\, a_3 &= 0\\
-144\sqrt{3}\, a_3 &= 0\\
1728\sqrt{3}\, a_3 &= 0\\
2592\sqrt{3}\, a_3 &= 0\\
216\sqrt{3}\, b_1 &= 0\\
1296\sqrt{3}\, b_1 &= 0\\
-972\sqrt{3}\, b_2 &= 0\\
216\sqrt{3}\, b_2 &= 0\\
1296\sqrt{3}\, b_2 &= 0\\
-69984a_2 + 23328b_3 &= 0\\
-2916a_2 + 972b_3 &= 0\\
648a_2 - 216b_3 &= 0\\
7776a_2 - 2592b_3 &= 0\\
324\sqrt{3}\, a_2 - 108\sqrt{3}\, b_3 &= 0\\
7776\sqrt{3}\, a_2 - 2592\sqrt{3}\, b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= \frac{b_3}{3} \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{x}{3} \\
\eta &= y
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Therefore

$$
\begin{aligned}
\frac{dy}{dx} &= \frac{\eta}{\xi} \\
&= \frac{y}{\frac{x}{3}} \\
&= \frac{3y}{x}
\end{aligned}
$$

This is easily solved to give

$$
y = c_1 x^3
$$

Where now the coordinate R is taken as the constant of integration. Hence

$$
R = \frac{y}{x^3}
$$

And S is found from

$$\begin{aligned}dS &= \frac{dx}{\xi}\\ &= \frac{dx}{\frac{x}{3}}\end{aligned}$$

Integrating gives

$$\begin{aligned}S &= \int \frac{dx}{T}\\ &= 3\ln(x)\end{aligned}$$

Where the constant of integration is set to zero as we just need one solution. Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{2}{3}} + 12xy}{3\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= -\frac{3y}{x^4}\\ R_y &= \frac{1}{x^3}\\ S_x &= \frac{3}{x}\\ S_y &= 0\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{9x^3\left(-108y^2 + 12\sqrt{3}\,\sqrt{-4y^3x^3 + 27y^4}\right)^{\frac{1}{3}}}{\left(-108y^2 + 12\sqrt{3}\,\sqrt{-4y^3x^3 + 27y^4}\right)^{\frac{2}{3}} x + 12x^2y - 9y\left(-108y^2 + 12\sqrt{3}\,\sqrt{-4y^3x^3 + 27y^4}\right)^{\frac{1}{3}}} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{9\,12^{\frac{1}{3}}\left(\sqrt{3}\,\sqrt{27R-4} - 9\sqrt{R}\right)^{\frac{1}{3}}}{\sqrt{R}\left(12^{\frac{2}{3}}\left(\sqrt{3}\,\sqrt{27R-4} - 9\sqrt{R}\right)^{\frac{2}{3}} - 9\sqrt{R}\,12^{\frac{1}{3}}\left(\sqrt{3}\,\sqrt{27R-4} - 9\sqrt{R}\right)^{\frac{1}{3}} + 12\right)}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int \frac{9\left(12\sqrt{81R-12}-108\sqrt{R}\right)^{\frac{1}{3}}}{\left(2\,18^{\frac{1}{3}}\left(\left(\sqrt{81R-12}-9\sqrt{R}\right)^{2}\right)^{\frac{1}{3}}-9\sqrt{R}\,\left(12\sqrt{81R-12}-108\sqrt{R}\right)^{\frac{1}{3}}+12\right)\sqrt{R}}dR + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}}{\left(2\,18^{\frac{1}{3}}\left(\left(\sqrt{81\_a-12}-9\sqrt{\_a}\right)^{2}\right)^{\frac{1}{3}}-9\sqrt{\_a}\,\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}+12\right)\sqrt{\_a}}d\_a$$

Which simplifies to

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}}{\left(2\,18^{\frac{1}{3}}\left(\left(\sqrt{81\_a-12}-9\sqrt{\_a}\right)^{2}\right)^{\frac{1}{3}}-9\sqrt{\_a}\,\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}+12\right)\sqrt{\_a}}d\_a$$

Summary

The solution(s) found are the following

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}}{\left(2\,18^{\frac{1}{3}}\left(\left(\sqrt{81\_a-12}-9\sqrt{\_a}\right)^{2}\right)^{\frac{1}{3}}-9\sqrt{\_a}\,\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}+12\right)\sqrt{\_a}}d\_a + c_1 \tag{1}$$

Verification of solutions

$$3\ln(x) = \int^{\frac{y}{x^3}} \frac{9\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}}{\left(2\,18^{\frac{1}{3}}\left(\left(\sqrt{81\_a-12}-9\sqrt{\_a}\right)^{2}\right)^{\frac{1}{3}}-9\sqrt{\_a}\,\left(12\sqrt{81\_a-12}-108\sqrt{\_a}\right)^{\frac{1}{3}}+12\right)\sqrt{\_a}}d\_a + c_1$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y' = \frac{i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} - 12i\sqrt{3}\,yx - \left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}} - 12xy}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}$$

$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 \\
& + \frac{\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx-\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12xy\right)(b_3 -}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}} \\
& - \frac{\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx-\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12xy\right)^2 a_3}{36\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}} \\
& - \left(\frac{-\frac{144i\sqrt{3}\,x^2y^3}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}\sqrt{-12y^3x^3+81y^4}}-12i\sqrt{3}\,y+\frac{144x^2y^3}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}\sqrt{-12y^3x^3+81y^4}}-12y}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}\right. \\
& + \frac{12\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx-\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12xy\right)x^2}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}\sqrt{-12y^3x^3+81y^4}} \\
& + ya_3 + a_1) \\
& - \left(\frac{\frac{2i\sqrt{3}\left(-216y+\frac{-216x^3y^2+1944y^3}{\sqrt{-12y^3x^3+81y^4}}\right)}{3\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}-12i\sqrt{3}\,x-\frac{2\left(-216y+\frac{-216x^3y^2+1944y^3}{\sqrt{-12y^3x^3+81y^4}}\right)}{3\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}-12x}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}\right. \\
& - \frac{\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx-\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12xy\right)\left(-\right.}{18\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}} \\
& + yb_3 + b_1) = 0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

$$\text{Expression too large to display} \tag{6E}$$

Simplifying the above gives

$$\text{Expression too large to display} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\text{Expression too large to display}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{-y^3 (4x^3 - 27y)}, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{1}{3}}, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{-y^3 (4x^3 - 27y)} = v_3, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{1}{3}} = v_4, \left(-108y^2 + 12\sqrt{3}\,\sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{2}{3}} = v_5\right\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
72v_2\Big(&72i\sqrt{3}\,v_1^4v_2^3b_3 + 792i\sqrt{3}\,v_1^3v_2^4a_3 - 72i\sqrt{3}\,v_1^4v_2^2b_1\\
&- 72i\sqrt{3}\,v_1^3v_2^3a_1 - 81i\sqrt{3}\,v_5v_2^3a_2 + 27i\sqrt{3}\,v_5v_2^3b_3\\
&+ 324i\sqrt{3}\,v_2^3v_1^2b_2 + 1944i\sqrt{3}\,v_2^4v_1a_2 - 648i\sqrt{3}\,v_1v_2^4b_3\\
&- 144iv_3v_1^3v_2^2a_3 - 54i\sqrt{3}\,v_5v_2^2b_1 + 324i\sqrt{3}\,v_2^3v_1b_1\\
&+ 18iv_5v_3v_1b_2 + 27iv_5v_3v_2a_2 - 9iv_5v_3v_2b_3 - 108iv_3v_1^2v_2b_2\\
&- 648iv_3v_1v_2^2a_2 + 216iv_3v_1v_2^2b_3 - 108iv_3v_1v_2b_1\\
&- 6v_5v_1^4v_2b_2 - 18v_5v_1^3v_2^2a_2 + 6v_5v_1^3v_2^2b_3 - 6v_5v_1^2v_2^3a_3\\
&- 6v_5v_1^3v_2b_1 - 6v_5v_1^2v_2^2a_1 - 72v_4v_1^3v_2^2b_2 - 1296v_4v_1v_2^4a_3\\
&+ 540\sqrt{3}\,v_3v_2^3a_3 + 54v_5v_1v_2^2b_2 - 6\sqrt{3}\,v_5v_3b_1 - 108\sqrt{3}\,v_3v_2^2a_1\\
&- 36\sqrt{3}\,v_3v_1^2v_2b_2 - 216\sqrt{3}\,v_3v_1v_2^2a_2 + 72\sqrt{3}\,v_3v_1v_2^2b_3\\
&- 54\sqrt{3}\,v_4v_3v_2b_2 - 36\sqrt{3}\,v_3v_1v_2b_1 - 72i\sqrt{3}\,v_1^5v_2^2b_2\\
&- 216i\sqrt{3}\,v_1^4v_2^3a_2 + 192v_4v_1^4v_2^3a_3 - 4860i\sqrt{3}\,v_2^5a_3\\
&+ 972i\sqrt{3}\,v_2^4a_1 + 1620iv_3v_2^3a_3 + 18iv_5v_3b_1 - 324iv_3v_2^2a_1\\
&- 48\sqrt{3}\,v_3v_1^3v_2^2a_3 - 6\sqrt{3}\,v_5v_3v_1b_2 - 9\sqrt{3}\,v_5v_3v_2a_2\\
&+ 3\sqrt{3}\,v_5v_3v_2b_3 + 324v_2^3v_1b_1 - 72v_1^5v_2^2b_2 + 1944v_2^4v_1a_2\\
&+ 324v_2^3v_1^2b_2 - 216v_1^4v_2^3a_2 + 72v_1^4v_2^3b_3 + 792v_1^3v_2^4a_3 - 72v_1^4v_2^2b_1\\
&- 72v_1^3v_2^3a_1 - 648v_1v_2^4b_3 + 81v_5v_2^3a_2 - 27v_5v_2^3b_3 + 54v_5v_2^2b_1\\
&+ 486v_4v_2^3b_2 - 4860v_2^5a_3 + 972v_2^4a_1 + 6i\sqrt{3}\,v_5v_1^3v_2b_1\\
&+ 6i\sqrt{3}\,v_5v_1^2v_2^2a_1 - 54i\sqrt{3}\,v_5v_1v_2^2b_2 - 12iv_5v_3v_1^2v_2a_3\\
&+ 144\sqrt{3}\,v_4v_3v_1v_2^2a_3 + 6i\sqrt{3}\,v_5v_1^4v_2b_2 + 18i\sqrt{3}\,v_5v_1^3v_2^2a_2\\
&- 6i\sqrt{3}\,v_5v_1^3v_2^2b_3 + 6i\sqrt{3}\,v_5v_1^2v_2^3a_3 + 4\sqrt{3}\,v_5v_3v_1^2v_2a_3\Big) = 0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2, v_3, v_4, v_5\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&34992b_2v_4v_2^4 + \left(23328i\sqrt{3}\,b_1 + 23328b_1\right) v_1v_2^4 \\
&+ \left(23328i\sqrt{3}\,b_2 + 23328b_2\right) v_1^2v_2^4 - 5184b_2v_4v_1^3v_2^3 \\

&+ \left(-432\sqrt{3}\,b_1 + 1296ib_1\right) v_3v_5v_2 - 93312a_3v_4v_1v_2^5 \\
&+ \left(-349920i\sqrt{3}\,a_3 - 349920a_3\right) v_2^6 \\
&+ \left(69984i\sqrt{3}\,a_1 + 69984a_1\right) v_2^5 - 3888\sqrt{3}\,b_2v_3v_4v_2^2 \\
&+ \left(288\sqrt{3}\,a_3 - 864ia_3\right) v_3v_5v_1^2v_2^2 \\
&+ \left(-432\sqrt{3}\,b_2 + 1296ib_2\right)
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-93312a_3 &= 0\\
13824a_3 &= 0\\
-5184b_2 &= 0\\
34992b_2 &= 0\\
10368\sqrt{3}\, a_3 &= 0\\
-3888\sqrt{3}\, b_2 &= 0\\
-7776\sqrt{3}\, a_1 - 23328ia_1 &= 0\\
-3456\sqrt{3}\, a_3 - 10368ia_3 &= 0\\
288\sqrt{3}\, a_3 - 864ia_3 &= 0\\
38880\sqrt{3}\, a_3 + 116640ia_3 &= 0\\
-2592\sqrt{3}\, b_1 - 7776ib_1 &= 0\\
-432\sqrt{3}\, b_1 + 1296ib_1 &= 0\\
-2592\sqrt{3}\, b_2 - 7776ib_2 &= 0\\
-432\sqrt{3}\, b_2 + 1296ib_2 &= 0\\
-349920i\sqrt{3}\, a_3 - 349920a_3 &= 0\\
-5184i\sqrt{3}\, a_1 - 5184a_1 &= 0\\
-5184i\sqrt{3}\, b_1 - 5184b_1 &= 0\\
-5184i\sqrt{3}\, b_2 - 5184b_2 &= 0\\
-3888i\sqrt{3}\, b_1 + 3888b_1 &= 0\\
-3888i\sqrt{3}\, b_2 + 3888b_2 &= 0\\
432i\sqrt{3}\, a_1 - 432a_1 &= 0\\
432i\sqrt{3}\, a_3 - 432a_3 &= 0\\
432i\sqrt{3}\, b_1 - 432b_1 &= 0\\
432i\sqrt{3}\, b_2 - 432b_2 &= 0\\
23328i\sqrt{3}\, b_1 + 23328b_1 &= 0\\
23328i\sqrt{3}\, b_2 + 23328b_2 &= 0\\
57024i\sqrt{3}\, a_3 + 57024a_3 &= 0\\
69984i\sqrt{3}\, a_1 + 69984a_1 &= 0\\
-15552\sqrt{3}\, a_2 + 5184\sqrt{3}\, b_3 - 46656ia_2 + 15552ib_3 &= 0\\
-648\sqrt{3}\, a_2 + 216\sqrt{3}\, b_3 + 1944ia_2 - 648ib_3 &= 0\\
-15552i\sqrt{3}\, a_2 + 5184i\sqrt{3}\, b_3 - 15552a_2 + 5184b_3 &= 0\\
-5832i\sqrt{3}\, a_2 + 1944i\sqrt{3}\, b_3 + 5832a_2 - 1944b_3 &= 0\\
1296i\sqrt{3}\, a_2 - 432i\sqrt{3}\, b_3 - 1296a_2 + 432b_3 &= 0\\
139968i\sqrt{3}\, a_2 - 46656i\sqrt{3}\, b_3 + 139968a_2 - 46656b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 3a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= 3y
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Unable to determine R. Terminating

Unable to determine ODE type.

Solving equation (3)

Writing the ode as

$$
y' = -\frac{i\sqrt{3}\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{2}{3}} - 12i\sqrt{3}\, yx + \left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{2}{3}} + 12xy}{6\left(-108y^2 + 12\sqrt{-12y^3x^3 + 81y^4}\right)^{\frac{1}{3}}}
$$

$$
y' = \omega(x, y)
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 \tag{5E}$$

$$-\frac{\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx+\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)(b_3}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}$$

$$-\frac{\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx+\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)^2 a_3}{36\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}}$$

$$-\left(-\frac{-\frac{144i\sqrt{3}\,x^2y^3}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}\sqrt{-12y^3x^3+81y^4}}-12i\sqrt{3}\,y-\frac{144x^2y^3}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}\sqrt{-12y^3x^3+81y^4}}+12y}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}\right.$$

$$-\frac{12\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx+\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)x}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}\sqrt{-12y^3x^3+81y^4}}$$

$$+ya_3+a_1)$$

$$-\left(-\frac{\frac{2i\sqrt{3}\left(-216y+\frac{-216x^3y^2+1944y^3}{\sqrt{-12y^3x^3+81y^4}}\right)}{3\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}-12i\sqrt{3}\,x+\frac{-144y+\frac{2\left(-216x^3y^2+1944y^3\right)}{3\sqrt{-12y^3x^3+81y^4}}}{\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}+12x}{6\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{1}{3}}}\right.$$

$$+\frac{\left(i\sqrt{3}\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}-12i\sqrt{3}\,yx+\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{2}{3}}+12xy\right)(-2}{18\left(-108y^2+12\sqrt{-12y^3x^3+81y^4}\right)^{\frac{4}{3}}}$$

$$+yb_3+b_1)=0$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

Expression too large to display (6E)

Simplifying the above gives

Expression too large to display (6E)

Since the PDE has radicals, simplifying gives

Expression too large to display

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{-y^3 (4x^3 - 27y)}, \left(-108y^2 + 12\sqrt{3}\, \sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{1}{3}}, \left(-108y^2 + 12\sqrt{3}\, \sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{2}{3}}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{-y^3 (4x^3 - 27y)} = v_3, \left(-108y^2 + 12\sqrt{3}\, \sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{1}{3}} = v_4, \left(-108y^2 + 12\sqrt{3}\, \sqrt{-y^3 (4x^3 - 27y)}\right)^{\frac{2}{3}} = v_5\right\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&-72v_2\Big(-4\sqrt{3}\,v_3v_5v_1^2v_2a_3 - 144\sqrt{3}\,v_3v_4v_1v_2^2a_3 \\
&+ 6i\sqrt{3}\,v_5v_1^4v_2b_2 + 18i\sqrt{3}\,v_5v_1^3v_2^2a_2 - 6i\sqrt{3}\,v_5v_1^3v_2^2b_3 \\
&+ 6i\sqrt{3}\,v_5v_1^2v_2^3a_3 + 6i\sqrt{3}\,v_5v_1^3v_2b_1 + 6i\sqrt{3}\,v_5v_1^2v_2^2a_1 \\
&- 54i\sqrt{3}\,v_5v_1v_2^2b_2 + 648v_1v_2^4b_3 - 81v_5v_2^3a_2 + 27v_5v_2^3b_3 \\
&- 54v_5v_2^2b_1 - 486v_4v_2^3b_2 - 324v_2^3v_1^2b_2 - 1944v_2^4v_1a_2 \\
&- 324v_2^3v_1b_1 + 4860v_2^5a_3 - 972v_2^4a_1 + 72v_1^5v_2^2b_2 \\

&+ 72v_1^3v_2^3a_1 - 4860i\sqrt{3}\,v_2^5a_3 + 972i\sqrt{3}\,v_2^4a_1 + 1620iv_3v_2^3a_3 \\
&+ 18iv_3v_5b_1 - 324iv_3v_2^2a_1 + 48\sqrt{3}\,v_3v_1^3v_2^2a_3 + 6\sqrt{3}\,v_3v_5v_1b_2 \\
&+ 9\sqrt{3}\,v_3v_5v_2a_2 - 3\sqrt{3}\,v_3v_5v_2b_3 + 36\sqrt{3}\,v_3v_1^2v_2b_2 \\
&+ 216\sqrt{3}\,v_3v_1v_2^2a_2 - 72\sqrt{3}\,v_3v_1v_2^2b_3 + 54\sqrt{3}\,v_3v_4v_2b_2 \\
&+ 36\sqrt{3}\,v_3v_1v_2b_1 - 192v_4v_1^4v_2^3a_3 + 6v_5v_1^4v_2b_2 + 18v_5v_1^3v_2^2a_2 \\
&- 6v_5v_1^3v_2^2b_3 + 6v_5v_1^2v_2^3a_3 + 6v_5v_1^3v_2b_1 + 6v_5v_1^2v_2^2a_1 \\
&+ 72v_4v_1^3v_2^2b_2 + 1296v_4v_1v_2^4a_3 - 540\sqrt{3}\,v_3v_2^3a_3 \\
&- 54v_5v_1v_2^2b_2 + 6\sqrt{3}\,v_3v_5b_1 + 108\sqrt{3}\,v_3v_2^2a_1 \\
&- 72i\sqrt{3}\,v_1^3v_2^3a_1 - 81i\sqrt{3}\,v_5v_2^3a_2 + 27i\sqrt{3}\,v_5v_2^3b_3 \\
&+ 324i\sqrt{3}\,v_2^3v_1^2b_2 + 1944i\sqrt{3}\,v_2^4v_1a_2 - 648i\sqrt{3}\,v_1v_2^4b_3 \\
&- 144iv_3v_1^3v_2^2a_3 - 54i\sqrt{3}\,v_5v_2^2b_1 + 324i\sqrt{3}\,v_2^3v_1b_1 \\
&+ 18iv_3v_5v_1b_2 + 27iv_3v_5v_2a_2 - 9iv_3v_5v_2b_3 - 108iv_3v_1^2v_2b_2 \\
&- 648iv_3v_1v_2^2a_2 + 216iv_3v_1v_2^2b_3 - 108iv_3v_1v_2b_1 \\
&- 72i\sqrt{3}\,v_1^5v_2^2b_2 - 216i\sqrt{3}\,v_1^4v_2^3a_2 + 72i\sqrt{3}\,v_1^4v_2^3b_3 \\
&+ 792i\sqrt{3}\,v_1^3v_2^4a_3 - 72i\sqrt{3}\,v_1^4v_2^2b_1 - 12iv_3v_5v_1^2v_2a_3\Big) = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&-93312a_3v_4v_1v_2^5 - 5184b_2v_4v_1^3v_2^3 + 13824a_3v_4v_1^4v_2^4 + \left(864ia_3 + 288\sqrt{3}\,a_3\right)v_3v_5v_1^2v_2^2 \\
&+ \left(-1296ib_2 - 432\sqrt{3}\,b_2\right)v_3v_5v_1v_2 - 3888\sqrt{3}\,b_2v_3v_4v_2^2 + \left(349920i\sqrt{3}\,a_3 - 349920a_3\right)v_2^6 \\
&+ \left(-69984i\sqrt{3}\,a_1 + 69984a_1\right)v_2^5 + 34992b_2v_4v_2^4 + 10368\sqrt{3}\,a_3v_3v_4v_1v_2^3 \\

\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-93312a_{3} &= 0 \\
13824a_{3} &= 0 \\
-5184b_{2} &= 0 \\
34992b_{2} &= 0 \\
10368\sqrt{3}\, a_{3} &= 0 \\
-3888\sqrt{3}\, b_{2} &= 0 \\
-116640i a_{3}+38880\sqrt{3}\, a_{3} &= 0 \\
-1296i b_{1}-432\sqrt{3}\, b_{1} &= 0 \\
-1296i b_{2}-432\sqrt{3}\, b_{2} &= 0 \\
864i a_{3}+288\sqrt{3}\, a_{3} &= 0 \\
7776i b_{1}-2592\sqrt{3}\, b_{1} &= 0 \\
7776i b_{2}-2592\sqrt{3}\, b_{2} &= 0 \\
10368i a_{3}-3456\sqrt{3}\, a_{3} &= 0 \\
23328i a_{1}-7776\sqrt{3}\, a_{1} &= 0 \\
-69984i\sqrt{3}\, a_{1}+69984a_{1} &= 0 \\
-57024i\sqrt{3}\, a_{3}+57024a_{3} &= 0 \\
-23328i\sqrt{3}\, b_{1}+23328b_{1} &= 0 \\
-23328i\sqrt{3}\, b_{2}+23328b_{2} &= 0 \\
-432i\sqrt{3}\, a_{1}-432a_{1} &= 0 \\
-432i\sqrt{3}\, a_{3}-432a_{3} &= 0 \\
-432i\sqrt{3}\, b_{1}-432b_{1} &= 0 \\
-432i\sqrt{3}\, b_{2}-432b_{2} &= 0 \\
3888i\sqrt{3}\, b_{1}+3888b_{1} &= 0 \\
3888i\sqrt{3}\, b_{2}+3888b_{2} &= 0 \\
5184i\sqrt{3}\, a_{1}-5184a_{1} &= 0 \\
5184i\sqrt{3}\, b_{1}-5184b_{1} &= 0 \\
5184i\sqrt{3}\, b_{2}-5184b_{2} &= 0 \\
349920i\sqrt{3}\, a_{3}-349920a_{3} &= 0 \\
-1944i a_{2}+648i b_{3}-648\sqrt{3}\, a_{2}+216\sqrt{3}\, b_{3} &= 0 \\
46656i a_{2}-15552i b_{3}-15552\sqrt{3}\, a_{2}+5184\sqrt{3}\, b_{3} &= 0 \\
-139968i\sqrt{3}\, a_{2}+46656i\sqrt{3}\, b_{3}+139968a_{2}-46656b_{3} &= 0 \\
-1296i\sqrt{3}\, a_{2}+432i\sqrt{3}\, b_{3}-1296a_{2}+432b_{3} &= 0 \\
5832i\sqrt{3}\, a_{2}-1944i\sqrt{3}\, b_{3}+5832a_{2}-1944b_{3} &= 0 \\
15552i\sqrt{3}\, a_{2}-5184i\sqrt{3}\, b_{3}-15552a_{2}+5184b_{3} &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 3a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= 3y
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Unable to determine R. Terminating

Unable to determine ODE type.

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 11. Singular solutions of differential equations. Exercises page 92
Problem number: 263.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y'^2 - y^2 = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = -y \tag{1}$$
$$y' = y \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int -\frac{1}{y}dy = \int dx$$
$$-\ln(y) = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{y} = e^{x+c_1}$$

Which simplifies to

$$\frac{1}{y} = c_2 e^x$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-x}}{c_2} \tag{1}$$

Verification of solutions

$$y = \frac{e^{-x}}{c_2}$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\begin{aligned}\int \frac{1}{y} dy &= c_3 + x \\ \ln(y) &= c_3 + x \\ y &= e^{c_3 + x} \\ y &= e^x c_3\end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^x c_3 \tag{1}$$

Verification of solutions

$$y = e^x c_3$$

Verified OK.

11.4.1 Maple step by step solution

Let's solve

$y'^2 - y^2 = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int 1 dx + c_1$

- Evaluate integral

  $\ln(y) = x + c_1$

- Solve for y

  $y = e^{x+c_1}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 11. Singular solutions of differential equations. Exercises page 92
Problem number: 265.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`]]
```

$$\boxed{(xy'+y)^2+3x^5(xy'-2y)=0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y'=\frac{-\frac{3x^5}{2}-y+\frac{3\sqrt{x^{10}+4yx^5}}{2}}{x} \tag{1}$$

$$y'=\frac{-\frac{3x^5}{2}-y-\frac{3\sqrt{x^{10}+4yx^5}}{2}}{x} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$\begin{aligned} y' &= -\frac{3x^5+2y-3\sqrt{x^{10}+4y\,x^5}}{2x} \\ y' &= \omega(x,y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &b_2 - \frac{\left(3x^5 + 2y - 3\sqrt{x^{10} + 4y\,x^5}\right)(b_3 - a_2)}{2x} \\ &- \frac{\left(3x^5 + 2y - 3\sqrt{x^{10} + 4y\,x^5}\right)^2 a_3}{4x^2} \\ &- \left(-\frac{15x^4 - \frac{3(10x^9+20x^4y)}{2\sqrt{x^{10}+4y\,x^5}}}{2x} + \frac{3x^5 + 2y - 3\sqrt{x^{10} + 4y\,x^5}}{2x^2}\right)(xa_2 + ya_3 + a_1) \\ &+ \frac{\left(2 - \frac{6x^5}{\sqrt{x^{10}+4y\,x^5}}\right)(xb_2 + yb_3 + b_1)}{2x} = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-18x^{15}a_3 + 9\sqrt{x^{10} + 4y\,x^5}\,x^{10}a_3 + 30x^{11}a_2 - 6x^{11}b_3 - 60x^{10}ya_3 + 24x^{10}a_1 - 30\sqrt{x^{10} + 4y\,x^5}\,x^6a_2 + 6\sqrt{}}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &18x^{15}a_3 - 9\sqrt{x^{10} + 4y\,x^5}\,x^{10}a_3 - 30x^{11}a_2 + 6x^{11}b_3 + 60x^{10}ya_3 - 24x^{10}a_1 \\ &+ 30\sqrt{x^{10} + 4y\,x^5}\,x^6a_2 - 6\sqrt{x^{10} + 4y\,x^5}\,x^6b_3 + 12\sqrt{x^{10} + 4y\,x^5}\,x^5ya_3 \\ &- 12x^7b_2 - 60x^6ya_2 + 12x^6yb_3 + 12x^5y^2a_3 + 24\sqrt{x^{10} + 4y\,x^5}\,x^5a_1 \\ &- 12x^6b_1 - 36x^5ya_1 - 9\left(x^{10} + 4y\,x^5\right)^{\frac{3}{2}} a_3 + 8b_2\sqrt{x^{10} + 4y\,x^5}\,x^2 \\ &- 8\sqrt{x^{10} + 4y\,x^5}\,y^2a_3 + 4\sqrt{x^{10} + 4y\,x^5}\,xb_1 - 4\sqrt{x^{10} + 4y\,x^5}\,ya_1 = 0 \end{aligned} \tag{6E}$$

Simplifying the above gives

$$
\begin{aligned}
&-9\sqrt{x^5\left(x^5+4y\right)}\,x^{10}a_3-30x^{11}a_2-30x^{10}ya_3-30x^{10}a_1\\
&+18\left(x^{10}+4y\,x^5\right)x^5a_3+30\sqrt{x^5\left(x^5+4y\right)}\,x^6a_2-6\sqrt{x^5\left(x^5+4y\right)}\,x^6b_3\\
&+12\sqrt{x^5\left(x^5+4y\right)}\,x^5ya_3-12x^7b_2-60x^6ya_2-12x^6yb_3\\
&-60x^5y^2a_3+24\sqrt{x^5\left(x^5+4y\right)}\,x^5a_1-12x^6b_1-60x^5ya_1\\
&-9\left(x^5\left(x^5+4y\right)\right)^{\frac{3}{2}}a_3+6\left(x^{10}+4y\,x^5\right)xb_3+18\left(x^{10}+4y\,x^5\right)ya_3\\
&+8b_2\sqrt{x^5\left(x^5+4y\right)}\,x^2-8\sqrt{x^5\left(x^5+4y\right)}\,y^2a_3+6\left(x^{10}+4y\,x^5\right)a_1\\
&+4\sqrt{x^5\left(x^5+4y\right)}\,xb_1-4\sqrt{x^5\left(x^5+4y\right)}\,ya_1=0
\end{aligned}
\tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&18x^{15}a_3-30x^{11}a_2+6x^{11}b_3-18\sqrt{x^5\left(x^5+4y\right)}\,x^{10}a_3+60x^{10}ya_3\\
&-24x^{10}a_1-12x^7b_2+30\sqrt{x^5\left(x^5+4y\right)}\,x^6a_2-6\sqrt{x^5\left(x^5+4y\right)}\,x^6b_3\\
&-60x^6ya_2+12x^6yb_3-24\sqrt{x^5\left(x^5+4y\right)}\,x^5ya_3+12x^5y^2a_3\\
&-12x^6b_1+24\sqrt{x^5\left(x^5+4y\right)}\,x^5a_1-36x^5ya_1+8b_2\sqrt{x^5\left(x^5+4y\right)}\,x^2\\
&-8\sqrt{x^5\left(x^5+4y\right)}\,y^2a_3+4\sqrt{x^5\left(x^5+4y\right)}\,xb_1-4\sqrt{x^5\left(x^5+4y\right)}\,ya_1=0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$
\left\{x,y,\sqrt{x^5\left(x^5+4y\right)}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x,y\}$ in them

$$
\left\{x=v_1,y=v_2,\sqrt{x^5\left(x^5+4y\right)}=v_3\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&18v_1^{15}a_3-30v_1^{11}a_2+60v_1^{10}v_2a_3-18v_3v_1^{10}a_3+6v_1^{11}b_3-24v_1^{10}a_1-60v_1^6v_2a_2\\
&+30v_3v_1^6a_2+12v_1^5v_2^2a_3-24v_3v_1^5v_2a_3-12v_1^7b_2+12v_1^6v_2b_3-6v_3v_1^6b_3\\
&-36v_1^5v_2a_1+24v_3v_1^5a_1-12v_1^6b_1-8v_3v_2^2a_3+8b_2v_3v_1^2-4v_3v_2a_1+4v_3v_1b_1=0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1,v_2,v_3\}
$$

Equation (7E) now becomes

$$18v_1^{15}a_3 + (-30a_2 + 6b_3)\, v_1^{11} + 60v_1^{10}v_2a_3 - 18v_3v_1^{10}a_3 - 24v_1^{10}a_1 - 12v_1^7b_2 + (-60a_2 + 12b_3)\, v_1^6v_2 + (30a_2 - 6b_3)\, v_1^6v_3 - 12v_1^6b_1 + 12v_1^5v_2^2a_3 - 24v_3v_1^5v_2a_3 - 36v_1^5v_2a_1 + 24v_3v_1^5a_1 + 8b_2v_3v_1^2 + 4v_3v_1b_1 - 8v_3v_2^2a_3 - 4v_3v_2a_1 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-36a_1 &= 0\\
-24a_1 &= 0\\
-4a_1 &= 0\\
24a_1 &= 0\\
-24a_3 &= 0\\
-18a_3 &= 0\\
-8a_3 &= 0\\
12a_3 &= 0\\
18a_3 &= 0\\
60a_3 &= 0\\
-12b_1 &= 0\\
4b_1 &= 0\\
-12b_2 &= 0\\
8b_2 &= 0\\
-60a_2 + 12b_3 &= 0\\
-30a_2 + 6b_3 &= 0\\
30a_2 - 6b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0\\
a_2 &= a_2\\
a_3 &= 0\\
b_1 &= 0\\
b_2 &= 0\\
b_3 &= 5a_2
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = x$$
$$\eta = 5y$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 5y - \left(-\frac{3x^5 + 2y - 3\sqrt{x^{10} + 4y\,x^5}}{2x}\right)(x) \\
&= 6y + \frac{3x^5}{2} - \frac{3\sqrt{x^{10} + 4y\,x^5}}{2} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{6y + \frac{3x^5}{2} - \frac{3\sqrt{x^{10} + 4y\,x^5}}{2}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(y)}{6} + \frac{\ln\left(-x^5 + \sqrt{x^{10} + 4y\,x^5}\right)}{6} - \frac{\ln\left(x^5 + \sqrt{x^{10} + 4y\,x^5}\right)}{6}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{3x^5 + 2y - 3\sqrt{x^{10} + 4y\,x^5}}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{5x^{\frac{3}{2}}}{6\sqrt{x^5 + 4y}} \\
S_y &= \frac{x^{\frac{5}{2}} + \sqrt{x^5 + 4y}}{6y\sqrt{x^5 + 4y}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\left(-x^5 + \sqrt{x^5\,(x^5 + 4y)} - \frac{2y}{3}\right)\sqrt{x^5 + 4y} + \left(\sqrt{x^5\,(x^5 + 4y)} - 4y\right)x^{\frac{5}{2}} - x^{\frac{15}{2}}}{4\sqrt{x^5 + 4y}\,xy} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{6R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{6} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y)}{6} + \frac{\ln\left(-x^5 + x^{\frac{5}{2}}\sqrt{x^5 + 4y}\right)}{6} - \frac{\ln\left(x^5 + x^{\frac{5}{2}}\sqrt{x^5 + 4y}\right)}{6} = -\frac{\ln(x)}{6} + c_1$$

Which simplifies to

$$\frac{\ln(y)}{6} + \frac{\ln\left(-x^5 + x^{\frac{5}{2}}\sqrt{x^5 + 4y}\right)}{6} - \frac{\ln\left(x^5 + x^{\frac{5}{2}}\sqrt{x^5 + 4y}\right)}{6} = -\frac{\ln(x)}{6} + c_1$$

Summary

The solution(s) found are the following

$$\frac{\ln(y)}{6}+\frac{\ln\left(-x^5+x^{\frac{5}{2}}\sqrt{x^5+4y}\right)}{6}-\frac{\ln\left(x^5+x^{\frac{5}{2}}\sqrt{x^5+4y}\right)}{6}=-\frac{\ln(x)}{6}+c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln(y)}{6}+\frac{\ln\left(-x^5+x^{\frac{5}{2}}\sqrt{x^5+4y}\right)}{6}-\frac{\ln\left(x^5+x^{\frac{5}{2}}\sqrt{x^5+4y}\right)}{6}=-\frac{\ln(x)}{6}+c_1$$

Verified OK.

Solving equation (2)

Writing the ode as

$$\begin{aligned}y' &= -\frac{3x^5+3\sqrt{x^{10}+4y\,x^5}+2y}{2x}\\ y' &= \omega(x,y)\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$

$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1,a_2,a_3,b_1,b_2,b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}&b_2-\frac{\left(3x^5+3\sqrt{x^{10}+4y\,x^5}+2y\right)(b_3-a_2)}{2x}\\ &-\frac{\left(3x^5+3\sqrt{x^{10}+4y\,x^5}+2y\right)^2 a_3}{4x^2}\\ &-\left(-\frac{15x^4+\frac{15x^9+30x^4y}{\sqrt{x^{10}+4y\,x^5}}}{2x}+\frac{3x^5+3\sqrt{x^{10}+4y\,x^5}+2y}{2x^2}\right)(xa_2+ya_3+a_1)\\ &+\frac{\left(\frac{6x^5}{\sqrt{x^{10}+4y\,x^5}}+2\right)(xb_2+yb_3+b_1)}{2x}=0\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{18x^{15}a_3 + 9\sqrt{x^{10}+4y\,x^5}\,x^{10}a_3 - 30x^{11}a_2 + 6x^{11}b_3 + 60x^{10}ya_3 - 24x^{10}a_1 - 30\sqrt{x^{10}+4y\,x^5}\,x^6a_2 + 6\sqrt{x}}{}$$

$= 0$

Setting the numerator to zero gives

$$\begin{aligned}&-18x^{15}a_3 - 9\sqrt{x^{10}+4y\,x^5}\,x^{10}a_3 + 30x^{11}a_2 - 6x^{11}b_3 - 60x^{10}ya_3 + 24x^{10}a_1\\&+ 30\sqrt{x^{10}+4y\,x^5}\,x^6a_2 - 6\sqrt{x^{10}+4y\,x^5}\,x^6b_3 + 12\sqrt{x^{10}+4y\,x^5}\,x^5ya_3\\&+ 12x^7b_2 + 60x^6ya_2 - 12x^6yb_3 - 12x^5y^2a_3 + 24\sqrt{x^{10}+4y\,x^5}\,x^5a_1\\&+ 12x^6b_1 + 36x^5ya_1 - 9\left(x^{10}+4y\,x^5\right)^{\frac{3}{2}}a_3 + 8b_2\sqrt{x^{10}+4y\,x^5}\,x^2\\&- 8\sqrt{x^{10}+4y\,x^5}\,y^2a_3 + 4\sqrt{x^{10}+4y\,x^5}\,xb_1 - 4\sqrt{x^{10}+4y\,x^5}\,ya_1 = 0\end{aligned} \tag{6E}$$

Simplifying the above gives

$$\begin{aligned}&-9\sqrt{x^5\left(x^5+4y\right)}\,x^{10}a_3 + 30x^{11}a_2 + 30x^{10}ya_3 + 30x^{10}a_1\\&- 18\left(x^{10}+4y\,x^5\right)x^5a_3 + 30\sqrt{x^5\left(x^5+4y\right)}\,x^6a_2\\&- 6\sqrt{x^5\left(x^5+4y\right)}\,x^6b_3 + 12\sqrt{x^5\left(x^5+4y\right)}\,x^5ya_3 + 12x^7b_2\\&+ 60x^6ya_2 + 12x^6yb_3 + 60x^5y^2a_3 + 24\sqrt{x^5\left(x^5+4y\right)}\,x^5a_1\\&+ 12x^6b_1 + 60x^5ya_1 - 9\left(x^5\left(x^5+4y\right)\right)^{\frac{3}{2}}a_3 - 6\left(x^{10}+4y\,x^5\right)xb_3\\&- 18\left(x^{10}+4y\,x^5\right)ya_3 + 8b_2\sqrt{x^5\left(x^5+4y\right)}\,x^2 - 8\sqrt{x^5\left(x^5+4y\right)}\,y^2a_3\\&- 6\left(x^{10}+4y\,x^5\right)a_1 + 4\sqrt{x^5\left(x^5+4y\right)}\,xb_1 - 4\sqrt{x^5\left(x^5+4y\right)}\,ya_1 = 0\end{aligned} \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$\begin{aligned}&-18x^{15}a_3 + 30x^{11}a_2 - 6x^{11}b_3 - 18\sqrt{x^5\left(x^5+4y\right)}\,x^{10}a_3 - 60x^{10}ya_3\\&+ 24x^{10}a_1 + 12x^7b_2 + 30\sqrt{x^5\left(x^5+4y\right)}\,x^6a_2 - 6\sqrt{x^5\left(x^5+4y\right)}\,x^6b_3\\&+ 60x^6ya_2 - 12x^6yb_3 - 24\sqrt{x^5\left(x^5+4y\right)}\,x^5ya_3 - 12x^5y^2a_3\\&+ 12x^6b_1 + 24\sqrt{x^5\left(x^5+4y\right)}\,x^5a_1 + 36x^5ya_1 + 8b_2\sqrt{x^5\left(x^5+4y\right)}\,x^2\\&- 8\sqrt{x^5\left(x^5+4y\right)}\,y^2a_3 + 4\sqrt{x^5\left(x^5+4y\right)}\,xb_1 - 4\sqrt{x^5\left(x^5+4y\right)}\,ya_1 = 0\end{aligned}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{x^5\left(x^5+4y\right)}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x = v_1, y = v_2, \sqrt{x^5 \left(x^5 + 4y\right)} = v_3\right\}$$

The above PDE (6E) now becomes

$$-18v_1^{15}a_3 + 30v_1^{11}a_2 - 60v_1^{10}v_2a_3 - 18v_3v_1^{10}a_3 - 6v_1^{11}b_3 + 24v_1^{10}a_1 + 60v_1^6v_2a_2 + 30v_3v_1^6a_2 - 12v_1^5v_2^2a_3 - 24v_3v_1^5v_2a_3 + 12v_1^7b_2 - 12v_1^6v_2b_3 - 6v_3v_1^6b_3 + 36v_1^5v_2a_1 + 24v_3v_1^5a_1 + 12v_1^6b_1 - 8v_3v_2^2a_3 + 8b_2v_3v_1^2 - 4v_3v_2a_1 + 4v_3v_1b_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$-18v_1^{15}a_3 + (30a_2 - 6b_3)v_1^{11} - 60v_1^{10}v_2a_3 - 18v_3v_1^{10}a_3 + 24v_1^{10}a_1 + 12v_1^7b_2 + (60a_2 - 12b_3)v_1^6v_2 + (30a_2 - 6b_3)v_1^6v_3 + 12v_1^6b_1 - 12v_1^5v_2^2a_3 - 24v_3v_1^5v_2a_3 + 36v_1^5v_2a_1 + 24v_3v_1^5a_1 + 8b_2v_3v_1^2 + 4v_3v_1b_1 - 8v_3v_2^2a_3 - 4v_3v_2a_1 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-4a_1 &= 0 \\
24a_1 &= 0 \\
36a_1 &= 0 \\
-60a_3 &= 0 \\
-24a_3 &= 0 \\
-18a_3 &= 0 \\
-12a_3 &= 0 \\
-8a_3 &= 0 \\
4b_1 &= 0 \\
12b_1 &= 0 \\
8b_2 &= 0 \\
12b_2 &= 0 \\
30a_2 - 6b_3 &= 0 \\
60a_2 - 12b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= a_2 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= 5a_2
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= 5y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= 5y - \left(-\frac{3x^5 + 3\sqrt{x^{10} + 4y\,x^5} + 2y}{2x}\right)(x) \\
&= 6y + \frac{3x^5}{2} + \frac{3\sqrt{x^{10} + 4y\,x^5}}{2} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{6y + \frac{3x^5}{2} + \frac{3\sqrt{x^{10}+4y\,x^5}}{2}} dy
\end{aligned}
$$

Which results in

$$S = \frac{\ln(y)}{6} - \frac{\ln\left(-x^5 + \sqrt{x^{10} + 4y\,x^5}\right)}{6} + \frac{\ln\left(x^5 + \sqrt{x^{10} + 4y\,x^5}\right)}{6}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{3x^5 + 3\sqrt{x^{10} + 4y\,x^5} + 2y}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{5x^{\frac{3}{2}}}{6\sqrt{x^5 + 4y}} \\ S_y &= \frac{-x^{\frac{5}{2}} + \sqrt{x^5 + 4y}}{6\sqrt{x^5 + 4y}\,y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{\left(-x^5 - \sqrt{x^5\left(x^5 + 4y\right)} - \frac{2y}{3}\right)\sqrt{x^5 + 4y} + \left(\sqrt{x^5\left(x^5 + 4y\right)} + 4y\right)x^{\frac{5}{2}} + x^{\frac{15}{2}}}{4\sqrt{x^5 + 4y}\,xy} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{6R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln(R)}{6} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln \left(y\right)}{6}-\frac{\ln \left(-x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6}+\frac{\ln \left(x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6} = -\frac{\ln \left(x\right)}{6}+c_{1}$$

Which simplifies to

$$\frac{\ln \left(y\right)}{6}-\frac{\ln \left(-x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6}+\frac{\ln \left(x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6} = -\frac{\ln \left(x\right)}{6}+c_{1}$$

Summary

The solution(s) found are the following

$$\frac{\ln \left(y\right)}{6}-\frac{\ln \left(-x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6}+\frac{\ln \left(x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6} = -\frac{\ln \left(x\right)}{6}+c_{1} \tag{1}$$

Verification of solutions

$$\frac{\ln \left(y\right)}{6}-\frac{\ln \left(-x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6}+\frac{\ln \left(x^{5}+x^{\frac{5}{2}} \sqrt{x^{5}+4 y}\right)}{6} = -\frac{\ln \left(x\right)}{6}+c_{1}$$

Verified OK.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{y(y - 2xy')^2 - 2y' = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{2y^2x + \sqrt{4y^2x + 1} + 1}{4yx^2} \tag{1}$$

$$y' = \frac{2y^2x - \sqrt{4y^2x + 1} + 1}{4yx^2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$y' = \frac{2x\,y^2 + \sqrt{4x\,y^2 + 1} + 1}{4y\,x^2}$$

$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{\left(2x\,y^2 + \sqrt{4x\,y^2+1}+1\right)(b_3 - a_2)}{4y\,x^2} - \frac{\left(2x\,y^2 + \sqrt{4x\,y^2+1}+1\right)^2 a_3}{16y^2x^4} - \left(\frac{2y^2 + \frac{2y^2}{\sqrt{4x\,y^2+1}}}{4y\,x^2} - \frac{2x\,y^2+\sqrt{4x\,y^2+1}+1}{2y\,x^3}\right)(xa_2 + ya_3 + a_1) - \left(\frac{4xy + \frac{4xy}{\sqrt{4x\,y^2+1}}}{4y\,x^2} - \frac{2x\,y^2+\sqrt{4x\,y^2+1}+1}{4y^2x^2}\right)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-8b_2\sqrt{4x\,y^2+1}\,x^4y^2 - 4\sqrt{4x\,y^2+1}\,x^2y^4a_3 + 8\sqrt{4x\,y^2+1}\,x^3y^2b_1 - 8\sqrt{4x\,y^2+1}\,x^2y^3a_1 - 8x^3y^3a_2 - 16}{} = 0$$

Setting the numerator to zero gives

$$8b_2\sqrt{4x\,y^2+1}\,x^4y^2 + 4\sqrt{4x\,y^2+1}\,x^2y^4a_3 - 8\sqrt{4x\,y^2+1}\,x^3y^2b_1 + 8\sqrt{4x\,y^2+1}\,x^2y^3a_1 + 8x^3y^3a_2 + 16x^3y^3b_3 + 8x^2y^4a_3 + 24x^2y^3a_1 + 4\sqrt{4x\,y^2+1}\,x^3b_2 + 4\sqrt{4x\,y^2+1}\,x^2ya_2 + 8\sqrt{4x\,y^2+1}\,x^2yb_3 + 4\sqrt{4x\,y^2+1}\,x\,y^2a_3 - \left(4x\,y^2+1\right)^{\frac{3}{2}} a_3 + 4\sqrt{4x\,y^2+1}\,x^2b_1 + 8\sqrt{4x\,y^2+1}\,xya_1 + 4x^3b_2 + 4x^2ya_2 + 8x^2yb_3 - 4x\,y^2a_3 + 4x^2b_1 + 8xya_1 - a_3\sqrt{4x\,y^2+1} - 2a_3 = 0 \tag{6E}$$

Simplifying the above gives

$$
\begin{aligned}
&-8x^{3}y^{3}a_{2}-8x^{2}y^{4}a_{3}-8x^{2}y^{3}a_{1}-16x^{4}y^{2}b_{2}-16x^{3}y^{3}b_{3} \\
&-16x^{3}y^{2}b_{1}+4\left(4x\,y^{2}+1\right)x^{3}b_{2}+4\left(4x\,y^{2}+1\right)x^{2}b_{1} \\
&+4\sqrt{4x\,y^{2}+1}\,x^{3}b_{2}+4\sqrt{4x\,y^{2}+1}\,x^{2}b_{1}+8b_{2}\sqrt{4x\,y^{2}+1}\,x^{4}y^{2} \\
&+4\sqrt{4x\,y^{2}+1}\,x^{2}y^{4}a_{3}-8\sqrt{4x\,y^{2}+1}\,x^{3}y^{2}b_{1} \\
&+8\sqrt{4x\,y^{2}+1}\,x^{2}y^{3}a_{1}+4\left(4x\,y^{2}+1\right)x^{2}ya_{2}+8\left(4x\,y^{2}+1\right)x^{2}yb_{3} \\
&+4\left(4x\,y^{2}+1\right)x\,y^{2}a_{3}+8\left(4x\,y^{2}+1\right)xya_{1}+4\sqrt{4x\,y^{2}+1}\,x^{2}ya_{2} \\
&+8\sqrt{4x\,y^{2}+1}\,x^{2}yb_{3}+4\sqrt{4x\,y^{2}+1}\,x\,y^{2}a_{3}+8\sqrt{4x\,y^{2}+1}\,xya_{1} \\
&-\left(4x\,y^{2}+1\right)^{\frac{3}{2}}a_{3}-2\left(4x\,y^{2}+1\right)a_{3}-a_{3}\sqrt{4x\,y^{2}+1}=0
\end{aligned} \tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&8b_{2}\sqrt{4x\,y^{2}+1}\,x^{4}y^{2}+4\sqrt{4x\,y^{2}+1}\,x^{2}y^{4}a_{3}-8\sqrt{4x\,y^{2}+1}\,x^{3}y^{2}b_{1}+8x^{3}y^{3}a_{2} \\
&+16x^{3}y^{3}b_{3}+8\sqrt{4x\,y^{2}+1}\,x^{2}y^{3}a_{1}+8x^{2}y^{4}a_{3}+24x^{2}y^{3}a_{1}+4\sqrt{4x\,y^{2}+1}\,x^{3}b_{2} \\
&+4\sqrt{4x\,y^{2}+1}\,x^{2}ya_{2}+8\sqrt{4x\,y^{2}+1}\,x^{2}yb_{3}+4x^{3}b_{2}+4\sqrt{4x\,y^{2}+1}\,x^{2}b_{1}+4x^{2}ya_{2} \\
&+8x^{2}yb_{3}+8\sqrt{4x\,y^{2}+1}\,xya_{1}-4x\,y^{2}a_{3}+4x^{2}b_{1}+8xya_{1}-2a_{3}\sqrt{4x\,y^{2}+1}-2a_{3}=0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \sqrt{4x\,y^{2}+1}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\left\{x=v_{1}, y=v_{2}, \sqrt{4x\,y^{2}+1}=v_{3}\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&4v_{3}v_{1}^{2}v_{2}^{4}a_{3}+8b_{2}v_{3}v_{1}^{4}v_{2}^{2}+8v_{3}v_{1}^{2}v_{2}^{3}a_{1}+8v_{1}^{3}v_{2}^{3}a_{2}+8v_{1}^{2}v_{2}^{4}a_{3} \\
&-8v_{3}v_{1}^{3}v_{2}^{2}b_{1}+16v_{1}^{3}v_{2}^{3}b_{3}+24v_{1}^{2}v_{2}^{3}a_{1}+4v_{3}v_{1}^{2}v_{2}a_{2}+4v_{3}v_{1}^{3}b_{2} \\
&+8v_{3}v_{1}^{2}v_{2}b_{3}+8v_{3}v_{1}v_{2}a_{1}+4v_{1}^{2}v_{2}a_{2}-4v_{1}v_{2}^{2}a_{3}+4v_{3}v_{1}^{2}b_{1} \\
&+4v_{1}^{3}b_{2}+8v_{1}^{2}v_{2}b_{3}+8v_{1}v_{2}a_{1}+4v_{1}^{2}b_{1}-2a_{3}v_{3}-2a_{3}=0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_{1}, v_{2}, v_{3}\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&8b_2v_3v_1^4v_2^2 + (8a_2 + 16b_3)\, v_1^3v_2^3 - 8v_3v_1^3v_2^2b_1 + 4v_3v_1^3b_2 + 4v_1^3b_2 + 4v_3v_1^2v_2^4a_3 \\
&+ 8v_1^2v_2^4a_3 + 8v_3v_1^2v_2^3a_1 + 24v_1^2v_2^3a_1 + (4a_2 + 8b_3)\, v_1^2v_2v_3 + (4a_2 + 8b_3)\, v_1^2v_2 \\
&+ 4v_3v_1^2b_1 + 4v_1^2b_1 - 4v_1v_2^2a_3 + 8v_3v_1v_2a_1 + 8v_1v_2a_1 - 2a_3v_3 - 2a_3 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
8a_1 &= 0 \\
24a_1 &= 0 \\
-4a_3 &= 0 \\
-2a_3 &= 0 \\
4a_3 &= 0 \\
8a_3 &= 0 \\
-8b_1 &= 0 \\
4b_1 &= 0 \\
4b_2 &= 0 \\
8b_2 &= 0 \\
4a_2 + 8b_3 &= 0 \\
8a_2 + 16b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -2b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -2x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(\frac{2x\,y^2+\sqrt{4x\,y^2+1}+1}{4y\,x^2}\right)(-2x) \\
&= \frac{4x\,y^2+\sqrt{4x\,y^2+1}+1}{2xy} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{4x\,y^2+\sqrt{4x\,y^2+1}+1}{2xy}} dy
\end{aligned}$$

Which results in

$$S = \frac{\ln(y)}{2} + \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4x\,y^2+1}}\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2x\,y^2+\sqrt{4x\,y^2+1}+1}{4y\,x^2}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1\\
R_y &= 0\\
S_x &= -\frac{1}{4x\sqrt{4x\,y^2+1}}\\
S_y &= \frac{1-\frac{1}{\sqrt{4x\,y^2+1}}}{2y}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{4x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{4R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{\ln(R)}{4} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\ln(y)}{2} + \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2} = \frac{\ln(x)}{4} + c_1
$$

Which simplifies to

$$
\frac{\ln(y)}{2} + \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2} = \frac{\ln(x)}{4} + c_1
$$

Summary

The solution(s) found are the following

$$
\frac{\ln(y)}{2} + \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2} = \frac{\ln(x)}{4} + c_1 \tag{1}
$$

Verification of solutions

$$\frac{\ln(y)}{2}+\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2}=\frac{\ln(x)}{4}+c_1$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y'=\frac{2x\,y^2-\sqrt{4x\,y^2+1}+1}{4y\,x^2}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1,a_2,a_3,b_1,b_2,b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}&b_2+\frac{\left(2x\,y^2-\sqrt{4x\,y^2+1}+1\right)(b_3-a_2)}{4y\,x^2}-\frac{\left(2x\,y^2-\sqrt{4x\,y^2+1}+1\right)^2a_3}{16y^2x^4}\\&-\left(\frac{2y^2-\frac{2y^2}{\sqrt{4x\,y^2+1}}}{4y\,x^2}-\frac{2x\,y^2-\sqrt{4x\,y^2+1}+1}{2y\,x^3}\right)(xa_2+ya_3+a_1)\\&-\left(\frac{4xy-\frac{4xy}{\sqrt{4x\,y^2+1}}}{4y\,x^2}-\frac{2x\,y^2-\sqrt{4x\,y^2+1}+1}{4y^2x^2}\right)(xb_2+yb_3+b_1)=0\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$-\frac{-8b_2\sqrt{4x\,y^2+1}\,x^4y^2-4\sqrt{4x\,y^2+1}\,x^2y^4a_3+8\sqrt{4x\,y^2+1}\,x^3y^2b_1-8\sqrt{4x\,y^2+1}\,x^2y^3a_1+8x^3y^3a_2+16}{}$$
$$=0$$

Setting the numerator to zero gives

$$8b_2\sqrt{4x\,y^2+1}\,x^4y^2+4\sqrt{4x\,y^2+1}\,x^2y^4a_3-8\sqrt{4x\,y^2+1}\,x^3y^2b_1+8\sqrt{4x\,y^2+1}\,x^2y^3a_1-8x^3y^3a_2-16x^3y^3b_3-8x^2y^4a_3-24x^2y^3a_1+4\sqrt{4x\,y^2+1}\,x^3b_2+4\sqrt{4x\,y^2+1}\,x^2ya_2+8\sqrt{4x\,y^2+1}\,x^2yb_3+4\sqrt{4x\,y^2+1}\,x\,y^2a_3-\left(4x\,y^2+1\right)^{\frac{3}{2}}a_3+4\sqrt{4x\,y^2+1}\,x^2b_1+8\sqrt{4x\,y^2+1}\,xya_1-4x^3b_2-4x^2ya_2-8x^2yb_3+4x\,y^2a_3-4x^2b_1-8xya_1-a_3\sqrt{4x\,y^2+1}+2a_3=0 \tag{6E}$$

Simplifying the above gives

$$-\left(4x\,y^2+1\right)^{\frac{3}{2}}a_3+2\left(4x\,y^2+1\right)a_3-a_3\sqrt{4x\,y^2+1}+8b_2\sqrt{4x\,y^2+1}\,x^4y^2+4\sqrt{4x\,y^2+1}\,x^2y^4a_3-8\sqrt{4x\,y^2+1}\,x^3y^2b_1+8\sqrt{4x\,y^2+1}\,x^2y^3a_1-4\left(4x\,y^2+1\right)x^2ya_2-8\left(4x\,y^2+1\right)x^2yb_3-4\left(4x\,y^2+1\right)x\,y^2a_3-8\left(4x\,y^2+1\right)xya_1+4\sqrt{4x\,y^2+1}\,x^2ya_2+8\sqrt{4x\,y^2+1}\,x^2yb_3+4\sqrt{4x\,y^2+1}\,x\,y^2a_3+8\sqrt{4x\,y^2+1}\,xya_1+8x^3y^3a_2+8x^2y^4a_3+8x^2y^3a_1+16x^4y^2b_2+16x^3y^3b_3+16x^3y^2b_1-4\left(4x\,y^2+1\right)x^3b_2-4\left(4x\,y^2+1\right)x^2b_1+4\sqrt{4x\,y^2+1}\,x^3b_2+4\sqrt{4x\,y^2+1}\,x^2b_1=0 \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$8b_2\sqrt{4x\,y^2+1}\,x^4y^2+4\sqrt{4x\,y^2+1}\,x^2y^4a_3-8\sqrt{4x\,y^2+1}\,x^3y^2b_1-8x^3y^3a_2-16x^3y^3b_3+8\sqrt{4x\,y^2+1}\,x^2y^3a_1-8x^2y^4a_3-24x^2y^3a_1+4\sqrt{4x\,y^2+1}\,x^3b_2+4\sqrt{4x\,y^2+1}\,x^2ya_2+8\sqrt{4x\,y^2+1}\,x^2yb_3-4x^3b_2+4\sqrt{4x\,y^2+1}\,x^2b_1-4x^2ya_2-8x^2yb_3+8\sqrt{4x\,y^2+1}\,xya_1+4x\,y^2a_3-4x^2b_1-8xya_1-2a_3\sqrt{4x\,y^2+1}+2a_3=0$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\left\{x, y, \sqrt{4x\,y^2+1}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\left\{x=v_1, y=v_2, \sqrt{4x\,y^2+1}=v_3\right\}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&4v_3v_1^2v_2^4a_3 + 8b_2v_3v_1^4v_2^2 + 8v_3v_1^2v_2^3a_1 - 8v_1^3v_2^3a_2 - 8v_1^2v_2^4a_3 \\
&- 8v_3v_1^3v_2^2b_1 - 16v_1^3v_2^3b_3 - 24v_1^2v_2^3a_1 + 4v_3v_1^2v_2a_2 + 4v_3v_1^3b_2 \\
&+ 8v_3v_1^2v_2b_3 + 8v_3v_1v_2a_1 - 4v_1^2v_2a_2 + 4v_1v_2^2a_3 + 4v_3v_1^2b_1 \\
&- 4v_1^3b_2 - 8v_1^2v_2b_3 - 8v_1v_2a_1 - 4v_1^2b_1 - 2a_3v_3 + 2a_3 = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$\begin{aligned}
&8b_2v_3v_1^4v_2^2 + (-8a_2 - 16b_3)\, v_1^3v_2^3 - 8v_3v_1^3v_2^2b_1 + 4v_3v_1^3b_2 - 4v_1^3b_2 + 4v_3v_1^2v_2^4a_3 \\
&- 8v_1^2v_2^4a_3 + 8v_3v_1^2v_2^3a_1 - 24v_1^2v_2^3a_1 + (4a_2 + 8b_3)\, v_1^2v_2v_3 + (-4a_2 - 8b_3)\, v_1^2v_2 \\
&+ 4v_3v_1^2b_1 - 4v_1^2b_1 + 4v_1v_2^2a_3 + 8v_3v_1v_2a_1 - 8v_1v_2a_1 - 2a_3v_3 + 2a_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-24a_1 &= 0 \\
-8a_1 &= 0 \\
8a_1 &= 0 \\
-8a_3 &= 0 \\
-2a_3 &= 0 \\
2a_3 &= 0 \\
4a_3 &= 0 \\
-8b_1 &= 0 \\
-4b_1 &= 0 \\
4b_1 &= 0 \\
-4b_2 &= 0 \\
4b_2 &= 0 \\
8b_2 &= 0 \\
-8a_2 - 16b_3 &= 0 \\
-4a_2 - 8b_3 &= 0 \\
4a_2 + 8b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -2b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -2x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\, \xi \\
&= y - \left(\frac{2x\, y^2 - \sqrt{4x\, y^2 + 1} + 1}{4y\, x^2}\right) (-2x) \\
&= \frac{4x\, y^2 - \sqrt{4x\, y^2 + 1} + 1}{2xy} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{4x\, y^2 - \sqrt{4x\, y^2 + 1} + 1}{2xy}} dy
\end{aligned}
$$

Which results in

$$S = \frac{\ln(y)}{2} - \frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4x\,y^2+1}}\right)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{2x\,y^2 - \sqrt{4x\,y^2+1}+1}{4y\,x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{4x\sqrt{4x\,y^2+1}} \\ S_y &= \frac{1+\frac{1}{\sqrt{4x\,y^2+1}}}{2y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{4x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{4R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{\ln(R)}{4} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(y)}{2}-\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2}=\frac{\ln(x)}{4}+c_1$$

Which simplifies to

$$\frac{\ln(y)}{2}-\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2}=\frac{\ln(x)}{4}+c_1$$

Summary

The solution(s) found are the following

$$\frac{\ln(y)}{2}-\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2}=\frac{\ln(x)}{4}+c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln(y)}{2}-\frac{\operatorname{arctanh}\left(\frac{1}{\sqrt{4y^2x+1}}\right)}{2}=\frac{\ln(x)}{4}+c_1$$

Verified OK.

Problem number: 267.
ODE order: 1.
ODE degree: 3.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _dAlembert]
```

$$\boxed{8y'^3 - 12y'^2 - 27y = -27x}$$

11.8.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$8p^3 - 12p^2 - 27y = -27x$$

Solving for y from the above results in

$$y = \frac{8}{27}p^3 - \frac{4}{9}p^2 + x \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= 1 \\
g &= \frac{8}{27}p^3 - \frac{4}{9}p^2
\end{aligned}
$$

Hence (2) becomes

$$
p - 1 = \left(\frac{8}{9}p^2 - \frac{8}{9}p\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$
p - 1 = 0
$$

Solving for p from the above gives

$$
p = 1
$$

Substituting these in (1A) gives

$$
y = -\frac{4}{27} + x
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x) - 1}{\frac{8p(x)^2}{9} - \frac{8p(x)}{9}} \tag{3}
$$

This ODE is now solved for $p(x)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{8p}{9}dp &= x + c_1 \\
\frac{4p^2}{9} &= x + c_1
\end{aligned}
$$

Solving for p gives these solutions

$$
\begin{aligned}
p_1 &= -\frac{3\sqrt{x + c_1}}{2} \\
p_2 &= \frac{3\sqrt{x + c_1}}{2}
\end{aligned}
$$

Substituing the above solution for p in (2A) gives

$$
\begin{aligned}
y &= -(x + c_1)^{\frac{3}{2}} - c_1 \\
y &= (x + c_1)^{\frac{3}{2}} - c_1
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = -\frac{4}{27} + x \tag{1}$$

$$y = -(x + c_1)^{\frac{3}{2}} - c_1 \tag{2}$$

$$y = (x + c_1)^{\frac{3}{2}} - c_1 \tag{3}$$

Verification of solutions

$$y = -\frac{4}{27} + x$$

Verified OK.

$$y = -(x + c_1)^{\frac{3}{2}} - c_1$$

Verified OK.

$$y = (x + c_1)^{\frac{3}{2}} - c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{(y'-1)^2 - y^2 = 0}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = -y + 1 \tag{1}$$
$$y' = y + 1 \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{-y+1} dy = \int dx$$
$$-\ln(-y+1) = x + c_1$$

Raising both side to exponential gives

$$\frac{1}{-y+1} = e^{x+c_1}$$

Which simplifies to

$$\frac{1}{-y+1} = c_2 e^{x}$$

Summary

The solution(s) found are the following

$$y = -\frac{e^{-x}}{c_2} + 1 \tag{1}$$

Verification of solutions

$$y = -\frac{e^{-x}}{c_2} + 1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\int \frac{1}{y+1} dy = \int dx$$
$$\ln (y+1) = c_3 + x$$

Raising both side to exponential gives

$$y + 1 = e^{c_3 + x}$$

Which simplifies to

$$y + 1 = c_4 e^{x}$$

Summary

The solution(s) found are the following

$$y = c_4 e^{x} - 1 \tag{1}$$

Verification of solutions

$$y = c_4 e^{x} - 1$$

Verified OK.

11.9.1 Maple step by step solution

Let's solve

$(y'-1)^2 - y^2 = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y+1} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y+1} dx = \int 1 dx + c_1$

- Evaluate integral

  $\ln(y+1) = x + c_1$

- Solve for y

  $y = e^{x+c_1} - 1$

Problem number: 269.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_1st_order, _with_linear_symmetries], _dAlembert]`

$$\boxed{y - {y'}^2 + xy' = x}$$

11.10.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$-p^2 + xp + y = x$$

Solving for y from the above results in

$$y = (-p+1)\,x + p^2 \tag{1A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. The above ode is dAlembert ode which is now solved. Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$

$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = -p + 1$$
$$g = p^2$$

Hence (2) becomes

$$2p - 1 = (-x + 2p)\, p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$2p - 1 = 0$$

Solving for p from the above gives

$$p = \frac{1}{2}$$

Substituting these in (1A) gives

$$y = \frac{x}{2} + \frac{1}{4}$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{2p(x) - 1}{-x + 2p\,(x)} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{-x(p) + 2p}{2p - 1} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = \frac{1}{2p - 1}$$
$$q(p) = \frac{2p}{2p - 1}$$

Hence the ode is

$$\frac{d}{dp}x(p) + \frac{x(p)}{2p-1} = \frac{2p}{2p-1}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{1}{2p-1}dp} \\ &= \sqrt{2p-1}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}p}(\mu x) &= (\mu)\left(\frac{2p}{2p-1}\right) \\ \frac{\mathrm{d}}{\mathrm{d}p}\left(\sqrt{2p-1}\,x\right) &= \left(\sqrt{2p-1}\right)\left(\frac{2p}{2p-1}\right) \\ \mathrm{d}\left(\sqrt{2p-1}\,x\right) &= \left(\frac{2p}{\sqrt{2p-1}}\right)\mathrm{d}p\end{aligned}$$

Integrating gives

$$\begin{aligned}\sqrt{2p-1}\,x &= \int \frac{2p}{\sqrt{2p-1}}\,\mathrm{d}p \\ \sqrt{2p-1}\,x &= \frac{2\sqrt{2p-1}\,(p+1)}{3} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \sqrt{2p-1}$ results in

$$x(p) = \frac{2p}{3} + \frac{2}{3} + \frac{c_1}{\sqrt{2p-1}}$$

Now we need to eliminate p between the above and (1A). One way to do this is by solving (1) for p. This results in

$$\begin{aligned}p &= \frac{x}{2} + \frac{\sqrt{x^2+4y-4x}}{2} \\ p &= \frac{x}{2} - \frac{\sqrt{x^2+4y-4x}}{2}\end{aligned}$$

Substituting the above in the solution for x found above gives

$$\begin{aligned}x &= \frac{x}{3} + \frac{\sqrt{x^2+4y-4x}}{3} + \frac{2}{3} + \frac{c_1}{\sqrt{x+\sqrt{x^2+4y-4x}-1}} \\ x &= \frac{x}{3} - \frac{\sqrt{x^2+4y-4x}}{3} + \frac{2}{3} + \frac{c_1}{\sqrt{x-\sqrt{x^2+4y-4x}-1}}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x}{2}+\frac{1}{4} \tag{1}$$

$$x = \frac{x}{3}+\frac{\sqrt{x^{2}+4y-4x}}{3}+\frac{2}{3}+\frac{c_{1}}{\sqrt{x+\sqrt{x^{2}+4y-4x}-1}} \tag{2}$$

$$x = \frac{x}{3}-\frac{\sqrt{x^{2}+4y-4x}}{3}+\frac{2}{3}+\frac{c_{1}}{\sqrt{x-\sqrt{x^{2}+4y-4x}-1}} \tag{3}$$

Verification of solutions

$$y = \frac{x}{2}+\frac{1}{4}$$

Verified OK.

$$x = \frac{x}{3}+\frac{\sqrt{x^{2}+4y-4x}}{3}+\frac{2}{3}+\frac{c_{1}}{\sqrt{x+\sqrt{x^{2}+4y-4x}-1}}$$

Verified OK.

$$x = \frac{x}{3}-\frac{\sqrt{x^{2}+4y-4x}}{3}+\frac{2}{3}+\frac{c_{1}}{\sqrt{x-\sqrt{x^{2}+4y-4x}-1}}$$

Verified OK.

Problem number: 270.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"dAlembert"**

Maple gives the following as the ode type

`[[_homogeneous, `class A`], _dAlembert]`

$$\boxed{(xy' + y)^2 - y^2y' = 0}$$

11.11.1 Solving as dAlembert ode

Let $p = y'$ the ode becomes

$$(xp + y)^2 - y^2p = 0$$

Solving for y from the above results in

$$y = \frac{(1 + \sqrt{p})\, px}{p - 1} \tag{1A}$$

$$y = -\frac{(-1 + \sqrt{p})\, px}{p - 1} \tag{2A}$$

This has the form

$$y = xf(p) + g(p) \tag{*}$$

Where f, g are functions of $p = y'(x)$. Each of the above ode's is dAlembert ode which is now solved. Solving ode 1A Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$

$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$f = \frac{(1+\sqrt{p})\, p}{p-1}$$
$$g = 0$$

Hence (2) becomes

$$p - \frac{(1+\sqrt{p})\, p}{p-1} = x\left(\frac{\sqrt{p}}{2p-2} - \frac{(1+\sqrt{p})\, p}{(p-1)^2} + \frac{1+\sqrt{p}}{p-1}\right) p'(x) \tag{2A}$$

The singular solution is found by setting $\frac{dp}{dx} = 0$ in the above which gives

$$p - \frac{(1+\sqrt{p})\, p}{p-1} = 0$$

Solving for p from the above gives

$$p = 0$$
$$p = 4$$

Substituting these in (1A) gives

$$y = 0$$
$$y = 4x$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x} \neq 0$. From eq. (2A). This results in

$$p'(x) = \frac{p(x) - \frac{(1+\sqrt{p(x)})p(x)}{p(x)-1}}{x\left(\frac{\sqrt{p(x)}}{2p(x)-2} - \frac{(1+\sqrt{p(x)})p(x)}{(p(x)-1)^2} + \frac{1+\sqrt{p(x)}}{p(x)-1}\right)} \tag{3}$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$\frac{d}{dp}x(p) = \frac{x(p)\left(\frac{\sqrt{p}}{2p-2} - \frac{(1+\sqrt{p})p}{(p-1)^2} + \frac{1+\sqrt{p}}{p-1}\right)}{p - \frac{(1+\sqrt{p})p}{p-1}} \tag{4}$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$\frac{d}{dp}x(p) + p(p)x(p) = q(p)$$

Where here

$$p(p) = -\frac{p^{\frac{3}{2}} - 3\sqrt{p} - 2}{2p\left(p - 2 - \sqrt{p}\right)(p - 1)}$$
$$q(p) = 0$$

Hence the ode is

$$\frac{d}{dp}x(p) - \frac{\left(p^{\frac{3}{2}} - 3\sqrt{p} - 2\right)x(p)}{2p\left(p - 2 - \sqrt{p}\right)(p - 1)} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{p^{\frac{3}{2}} - 3\sqrt{p} - 2}{2p(p - 2 - \sqrt{p})(p - 1)}dp}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0$$
$$\frac{\mathrm{d}}{\mathrm{d}p}\left(e^{\int -\frac{p^{\frac{3}{2}} - 3\sqrt{p} - 2}{2p(p - 2 - \sqrt{p})(p - 1)}dp}x\right) = 0$$

Integrating gives

$$e^{\int -\frac{p^{\frac{3}{2}} - 3\sqrt{p} - 2}{2p(p - 2 - \sqrt{p})(p - 1)}dp}x = c_3$$

Dividing both sides by the integrating factor $\mu = e^{\int -\frac{p^{\frac{3}{2}} - 3\sqrt{p} - 2}{2p(p - 2 - \sqrt{p})(p - 1)}dp}$ results in

$$x(p) = c_3 e^{-\frac{\left(\int \frac{p^{\frac{3}{2}} - 3\sqrt{p} - 2}{p(-p + 2 + \sqrt{p})(p - 1)}dp\right)}{2}}$$

Since the solution $x(p)$ has unresolved integral, unable to continue.

Solving ode 2A Taking derivative of (*) w.r.t. x gives

$$p = f + (xf' + g')\frac{dp}{dx}$$
$$p - f = (xf' + g')\frac{dp}{dx} \tag{2}$$

Comparing the form $y = xf + g$ to (1A) shows that

$$
\begin{aligned}
f &= -\frac{\left(-1+\sqrt{p}\right) p}{p-1} \\
g &= 0
\end{aligned}
$$

Hence (2) becomes

$$
p+\frac{\left(-1+\sqrt{p}\right) p}{p-1} = x\left(-\frac{\sqrt{p}}{2\left(p-1\right)}+\frac{\left(-1+\sqrt{p}\right) p}{\left(p-1\right)^{2}}-\frac{-1+\sqrt{p}}{p-1}\right) p'(x) \tag{2A}
$$

The singular solution is found by setting $\frac{dp}{dx}=0$ in the above which gives

$$
p+\frac{\left(-1+\sqrt{p}\right) p}{p-1} = 0
$$

Solving for p from the above gives

$$
p = 0
$$

Substituting these in (1A) gives

$$
y = 0
$$

The general solution is found when $\frac{\mathrm{d}p}{\mathrm{d}x}\neq 0$. From eq. (2A). This results in

$$
p'(x) = \frac{p(x)+\frac{\left(-1+\sqrt{p(x)}\right)p(x)}{p(x)-1}}{x\left(-\frac{\sqrt{p(x)}}{2(p(x)-1)}+\frac{\left(-1+\sqrt{p(x)}\right)p(x)}{(p(x)-1)^{2}}-\frac{-1+\sqrt{p(x)}}{p(x)-1}\right)} \tag{3}
$$

This ODE is now solved for $p(x)$.

Inverting the above ode gives

$$
\frac{d}{dp}x(p) = \frac{x(p)\left(-\frac{\sqrt{p}}{2(p-1)}+\frac{(-1+\sqrt{p})p}{(p-1)^{2}}-\frac{-1+\sqrt{p}}{p-1}\right)}{p+\frac{(-1+\sqrt{p})p}{p-1}} \tag{4}
$$

This ODE is now solved for $x(p)$.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
\frac{d}{dp}x(p)+p(p)x(p) = q(p)
$$

Where here

$$
\begin{aligned}
p(p) &= -\frac{-p^{\frac{3}{2}} + 3\sqrt{p} - 2}{2p\left(p - 2 + \sqrt{p}\right)(p - 1)} \\
q(p) &= 0
\end{aligned}
$$

Hence the ode is

$$
\frac{d}{dp}x(p) - \frac{\left(-p^{\frac{3}{2}} + 3\sqrt{p} - 2\right)x(p)}{2p\left(p - 2 + \sqrt{p}\right)(p - 1)} = 0
$$

The integrating factor μ is

$$
\mu = \mathrm{e}^{\int -\frac{-p^{\frac{3}{2}} + 3\sqrt{p} - 2}{2p(p-2+\sqrt{p})(p-1)}dp}
$$

The ode becomes

$$
\frac{\mathrm{d}}{\mathrm{d}p}\mu x = 0
$$

$$
\frac{\mathrm{d}}{\mathrm{d}p}\left(\mathrm{e}^{\int -\frac{-p^{\frac{3}{2}} + 3\sqrt{p} - 2}{2p(p-2+\sqrt{p})(p-1)}dp} x\right) = 0
$$

Integrating gives

$$
\mathrm{e}^{\int -\frac{-p^{\frac{3}{2}} + 3\sqrt{p} - 2}{2p(p-2+\sqrt{p})(p-1)}dp} x = c_6
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-p^{\frac{3}{2}} + 3\sqrt{p} - 2}{2p(p-2+\sqrt{p})(p-1)}dp}$ results in

$$
x(p) = c_6 \mathrm{e}^{-\frac{\left(\int \frac{p^{\frac{3}{2}} - 3\sqrt{p} + 2}{p(p-2+\sqrt{p})(p-1)}dp\right)}{2}}
$$

Since the solution $x(p)$ has unresolved integral, unable to continue.

Summary

The solution(s) found are the following

$$
\begin{align*}
y &= 0 \tag{1} \\
y &= 4x \tag{2} \\
y &= 0 \tag{3}
\end{align*}
$$

Verification of solutions

$$y = 0$$

Verified OK.

$$y = 4x$$

Verified OK.

$$y = 0$$

Verified OK.

Problem number: 271.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y^2 {y'}^2 + y^2 = 1}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{\sqrt{1-y^2}}{y} \tag{1}$$

$$y' = -\frac{\sqrt{1-y^2}}{y} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{y}{\sqrt{-y^2+1}} dy = \int dx$$

$$\frac{(y-1)(y+1)}{\sqrt{1-y^2}} = x + c_1$$

Summary
The solution(s) found are the following

$$\frac{(y-1)(y+1)}{\sqrt{1-y^2}} = x + c_1 \tag{1}$$

Verification of solutions

$$\frac{(y-1)(y+1)}{\sqrt{1-y^2}} = x + c_1$$

Verified OK.

Solving equation (2)

Integrating both sides gives

$$\int -\frac{y}{\sqrt{-y^2+1}}dy = \int dx$$
$$-\frac{(y-1)(y+1)}{\sqrt{1-y^2}} = x + c_2$$

Summary
The solution(s) found are the following

$$-\frac{(y-1)(y+1)}{\sqrt{1-y^2}} = x + c_2 \tag{1}$$

Verification of solutions

$$-\frac{(y-1)(y+1)}{\sqrt{1-y^2}} = x + c_2$$

Verified OK.

11.12.1 Maple step by step solution

Let's solve

$y^2{y'}^2 + y^2 = 1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'y}{\sqrt{1-y^2}} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'y}{\sqrt{1-y^2}}dx = \int 1dx + c_1$

- Evaluate integral

  $-\sqrt{1-y^2} = x + c_1$

- Solve for y

  $\left\{y = \sqrt{-c_1^2 - 2c_1x - x^2 + 1}, y = -\sqrt{-c_1^2 - 2c_1x - x^2 + 1}\right\}$

Book: A book of problems in ordinary differential equations. M.L. KRASNOV, A.L. KISELYOV, G.I. MARKARENKO. MIR, MOSCOW. 1983
Section: Section 11. Singular solutions of differential equations. Exercises page 92
Problem number: 272.
ODE order: 1.
ODE degree: 2.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries]]
```

$$\boxed{y'^2 - yy' = -e^x}$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \frac{y}{2} + \frac{\sqrt{y^2 - 4\,e^x}}{2} \tag{1}$$
$$y' = \frac{y}{2} - \frac{\sqrt{y^2 - 4\,e^x}}{2} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Writing the ode as

$$y' = \frac{y}{2} + \frac{\sqrt{y^2 - 4\,e^x}}{2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \left(\frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right)(b_3 - a_2) - \left(\frac{y}{2} + \frac{\sqrt{y^2 - 4\,\mathrm{e}^x}}{2}\right)^2 a_3 + \frac{\mathrm{e}^x (xa_2 + ya_3 + a_1)}{\sqrt{y^2 - 4\,\mathrm{e}^x}} - \left(\frac{1}{2} + \frac{y}{2\sqrt{y^2 - 4\,\mathrm{e}^x}}\right)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{-(y^2 - 4\,\mathrm{e}^x)^{\frac{3}{2}} a_3 - \sqrt{y^2 - 4\,\mathrm{e}^x}\, y^2 a_3 - 2y^3 a_3 + 4\,\mathrm{e}^x x a_2 + 12\,\mathrm{e}^x y a_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, x b_2 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, y a_2 - \cdots}{4\sqrt{y^2 - 4\,\mathrm{e}^x}} = 0$$

Setting the numerator to zero gives

$$-(y^2 - 4\,\mathrm{e}^x)^{\frac{3}{2}} a_3 - \sqrt{y^2 - 4\,\mathrm{e}^x}\, y^2 a_3 - 2y^3 a_3 + 4\,\mathrm{e}^x x a_2 + 12\,\mathrm{e}^x y a_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, x b_2 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, y a_2 - 2xyb_2 - 2y^2 a_2 + 4\,\mathrm{e}^x a_1 + 8\,\mathrm{e}^x a_2 - 8\,\mathrm{e}^x b_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, b_1 + 4b_2\sqrt{y^2 - 4\,\mathrm{e}^x} - 2yb_1 = 0 \tag{6E}$$

Simplifying the above gives

$$-(y^2 - 4\,\mathrm{e}^x)^{\frac{3}{2}} a_3 - 2(y^2 - 4\,\mathrm{e}^x)\, y a_3 - \sqrt{y^2 - 4\,\mathrm{e}^x}\, y^2 a_3 + 4\,\mathrm{e}^x x a_2 + 4\,\mathrm{e}^x y a_3 - 2(y^2 - 4\,\mathrm{e}^x)\, a_2 + 2(y^2 - 4\,\mathrm{e}^x)\, b_3 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, x b_2 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, y a_2 - 2xyb_2 - 2y^2 b_3 + 4\,\mathrm{e}^x a_1 - 2\sqrt{y^2 - 4\,\mathrm{e}^x}\, b_1 + 4b_2\sqrt{y^2 - 4\,\mathrm{e}^x} - 2yb_1 = 0 \tag{6E}$$

Since the PDE has radicals, simplifying gives

$$-2\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3-2y^3a_3+4\,\mathrm{e}^x x a_2+4\,\mathrm{e}^x\sqrt{y^2-4\,\mathrm{e}^x}\,a_3+12\,\mathrm{e}^x y a_3 \\ -2\sqrt{y^2-4\,\mathrm{e}^x}\,x b_2-2xyb_2-2\sqrt{y^2-4\,\mathrm{e}^x}\,y a_2-2y^2a_2+4\,\mathrm{e}^x a_1 \\ +8\,\mathrm{e}^x a_2-8\,\mathrm{e}^x b_3-2\sqrt{y^2-4\,\mathrm{e}^x}\,b_1+4b_2\sqrt{y^2-4\,\mathrm{e}^x}-2yb_1=0$$

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$\left\{x,y,\sqrt{y^2-4\,\mathrm{e}^x},\mathrm{e}^x\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x,y\}$ in them

$$\left\{x=v_1,y=v_2,\sqrt{y^2-4\,\mathrm{e}^x}=v_3,\mathrm{e}^x=v_4\right\}$$

The above PDE (6E) now becomes

$$-2v_2^3a_3-2v_3v_2^2a_3+4v_4v_1a_2-2v_2^2a_2-2v_3v_2a_2+12v_4v_2a_3+4v_4v_3a_3 \\ -2v_1v_2b_2-2v_3v_1b_2+4v_4a_1+8v_4a_2-2v_2b_1-2v_3b_1+4b_2v_3-8v_4b_3=0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1,v_2,v_3,v_4\}$$

Equation (7E) now becomes

$$-2v_1v_2b_2-2v_3v_1b_2+4v_4v_1a_2-2v_2^3a_3-2v_3v_2^2a_3-2v_2^2a_2-2v_3v_2a_2 \\ +12v_4v_2a_3-2v_2b_1+4v_4v_3a_3+(-2b_1+4b_2)\,v_3+(4a_1+8a_2-8b_3)\,v_4=0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -2a_2&=0\\ 4a_2&=0\\ -2a_3&=0\\ 4a_3&=0\\ 12a_3&=0\\ -2b_1&=0\\ -2b_2&=0\\ -2b_1+4b_2&=0\\ 4a_1+8a_2-8b_3&=0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 2b_3 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 2 \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned} \eta &= \eta - \omega(x,y)\,\xi \\ &= y - \left(\frac{y}{2} + \frac{\sqrt{y^2-4\,\mathrm{e}^x}}{2}\right)(2) \\ &= -\sqrt{y^2-4\,\mathrm{e}^x} \\ \xi &= 0 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{-\sqrt{y^2-4\,\mathrm{e}^x}} dy \end{aligned}$$

Which results in

$$S = -\ln \left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{2}+\frac{\sqrt{y^{2}-4\,\mathrm{e}^{x}}}{2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1\\
R_y &= 0\\
S_x &= \frac{2\,\mathrm{e}^{x}}{\sqrt{y^{2}-4\,\mathrm{e}^{x}}\,\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right)}\\
S_y &= -\frac{1}{\sqrt{y^{2}-4\,\mathrm{e}^{x}}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{y\sqrt{y^{2}-4\,\mathrm{e}^{x}}+y^{2}-4\,\mathrm{e}^{x}}{\sqrt{y^{2}-4\,\mathrm{e}^{x}}\,\left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right)} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln \left(y+\sqrt{y^{2}-4\,\mathrm{e}^{x}}\right) = c_1$$

Which simplifies to

$$-\ln\left(y+\sqrt{y^2-4\,\mathrm{e}^x}\right)=c_1$$

Which gives

$$y=\frac{\left(4\,\mathrm{e}^x\mathrm{e}^{2c_1}+1\right)\mathrm{e}^{-c_1}}{2}$$

Summary

The solution(s) found are the following

$$y=\frac{\left(4\,\mathrm{e}^x\mathrm{e}^{2c_1}+1\right)\mathrm{e}^{-c_1}}{2} \tag{1}$$

Verification of solutions

$$y=\frac{\left(4\,\mathrm{e}^x\mathrm{e}^{2c_1}+1\right)\mathrm{e}^{-c_1}}{2}$$

Verified OK.

Solving equation (2)

Writing the ode as

$$y'=\frac{y}{2}-\frac{\sqrt{y^2-4\,\mathrm{e}^x}}{2}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1,a_2,a_3,b_1,b_2,b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_2+\left(\frac{y}{2}-\frac{\sqrt{y^2-4\,\mathrm{e}^x}}{2}\right)(b_3-a_2)-\left(\frac{y}{2}-\frac{\sqrt{y^2-4\,\mathrm{e}^x}}{2}\right)^2 a_3 \\
&\quad-\frac{\mathrm{e}^x(xa_2+ya_3+a_1)}{\sqrt{y^2-4\,\mathrm{e}^x}}-\left(\frac{1}{2}-\frac{y}{2\sqrt{y^2-4\,\mathrm{e}^x}}\right)(xb_2+yb_3+b_1)=0
\end{aligned}
\tag{5E}
$$

Putting the above in normal form gives

$$
-\frac{(y^2-4\,\mathrm{e}^x)^{\frac{3}{2}}\,a_3+\sqrt{y^2-4\,\mathrm{e}^x}\,y^2a_3-2y^3a_3+4\,\mathrm{e}^x xa_2+12\,\mathrm{e}^x ya_3+2\sqrt{y^2-4\,\mathrm{e}^x}\,xb_2+2\sqrt{y^2-4\,\mathrm{e}^x}\,ya_2-2}{4\sqrt{y^2-4\,\mathrm{e}^x}}
$$

$$=0$$

Setting the numerator to zero gives

$$
\begin{aligned}
