Comparing the above to (5) shows that

$$
\begin{align}
s &= -1 \\
t &= 1
\end{align}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 290: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x) (\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x) (\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x) c_1 + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\tan(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\tan(x)\,dx$$

Hence

$$u_1 = \sin(x) - \ln(\sec(x) + \tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)\cos(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sin(x)\,dx$$

Hence

$$u_2 = -\cos(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (\sin(x) - \ln(\sec(x) + \tan(x)))\cos(x) - \cos(x)\sin(x)$$

Which simplifies to

$$y_p(x) = -\cos(x)\ln(\sec(x) + \tan(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x)\,c_1 + c_2\sin(x)) + (-\cos(x)\ln(\sec(x) + \tan(x))) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \cos(x) c_1 + c_2 \sin(x) - \cos(x) \ln(\sec(x) + \tan(x)) \tag{1}$$

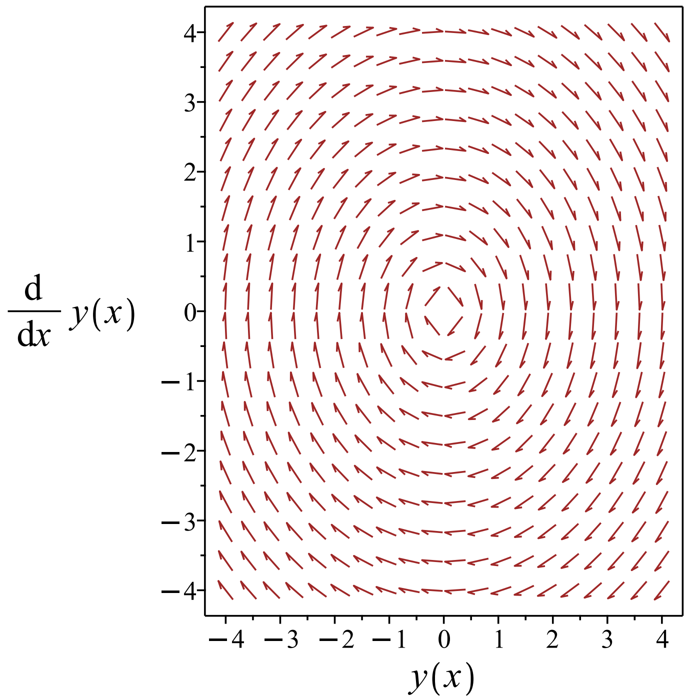

Figure 359: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) - \cos(x) \ln(\sec(x) + \tan(x))$$

Verified OK.

11.11.3 Maple step by step solution

Let's solve

$y'' + y = \tan(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = \cos(x) c_1 + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \tan(x)\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int \sin(x) \tan(x) dx\right) + \sin(x) \left(\int \sin(x) dx\right)$
  - Compute integrals

    $y_p(x) = -\cos(x) \ln(\sec(x) + \tan(x))$
- Substitute particular solution into general solution to ODE

  $y = \cos(x) c_1 + c_2 \sin(x) - \cos(x) \ln(\sec(x) + \tan(x))$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \sec(x)\tan(x)}$$

11.12.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \sec(x)\tan(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(\cos(x) c_1 + c_2 \sin(x))$$

Or

$$y = \cos(x) c_1 + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = \cos(x) c_1 + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sec(x)\sin(x)\tan(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)^2\,dx$$

Hence

$$u_1 = -\tan(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)\cos(x)\sec(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \tan(x)\,dx$$

Hence

$$u_2 = -\ln(\cos(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-\tan(x) + x)\cos(x) - \ln(\cos(x))\sin(x)$$

Which simplifies to

$$y_p(x) = -\sin(x) + \cos(x)\,x - \ln(\cos(x))\sin(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (\cos(x) c_1 + c_2 \sin(x)) + (-\sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = \cos(x) c_1 + c_2 \sin(x) - \sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x) \tag{1}$$

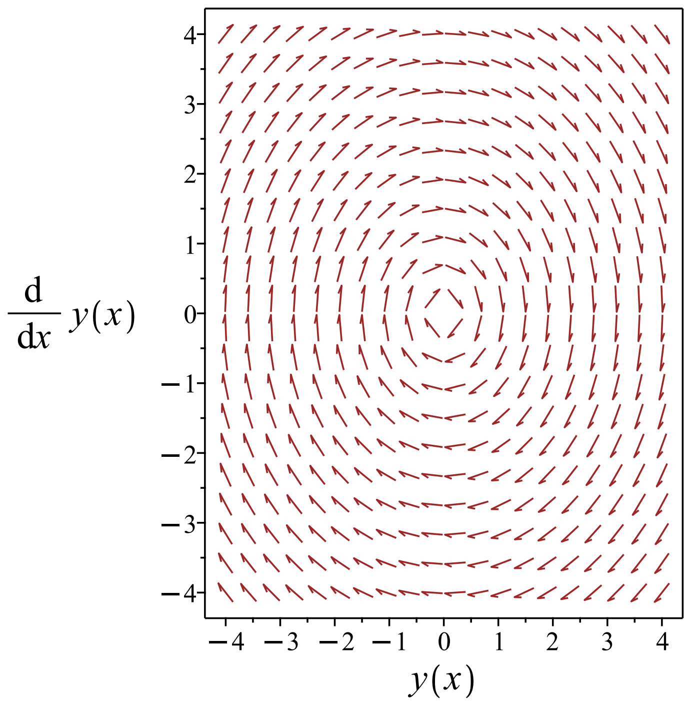

Figure 360: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) - \sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x)$$

Verified OK.

11.12.2 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{aligned}
y'' + y &= 0 \qquad (1)\\
Ay'' + By' + Cy &= 0 \qquad (2)
\end{aligned}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1\\
B &= 0 \qquad (3)\\
C &= 1
\end{aligned}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \qquad (4)
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \qquad (5)\\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-1}{1} \qquad (6)
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -1\\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -z(x) \qquad (7)
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 292: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x) (\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x) (\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x) c_1 + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sec(x)\sin(x)\tan(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int \tan(x)^2 dx$$

Hence

$$u_1 = -\tan(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)\cos(x)\sec(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \tan(x) dx$$

Hence

$$u_2 = -\ln(\cos(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-\tan(x) + x)\cos(x) - \ln(\cos(x))\sin(x)$$

Which simplifies to

$$y_p(x) = -\sin(x) + \cos(x)x - \ln(\cos(x))\sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x)c_1 + c_2\sin(x)) + (-\sin(x) + \cos(x)x - \ln(\cos(x))\sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(x) c_1 + c_2 \sin(x) - \sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x) \tag{1}$$

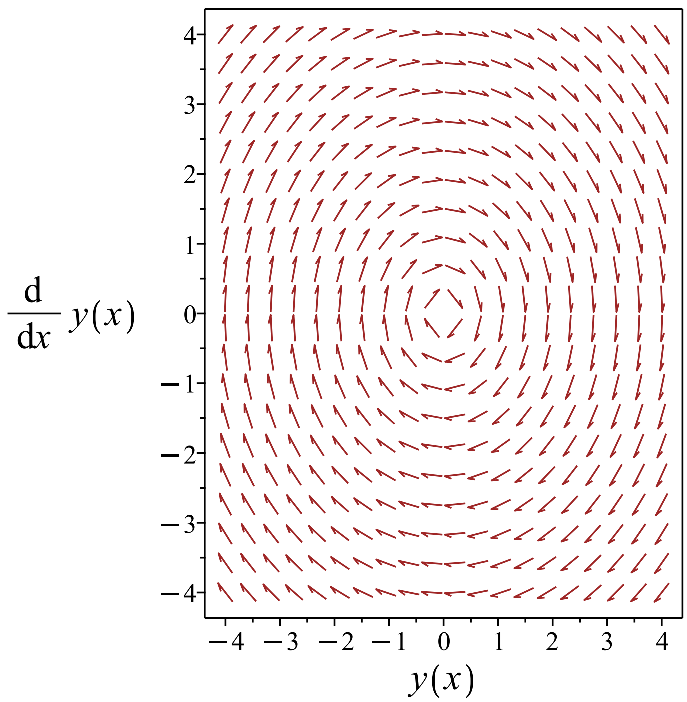

Figure 361: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) - \sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x)$$

Verified OK.

11.12.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x) \tan(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$
- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$
- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = \cos(x) c_1 + c_2 \sin(x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x) \tan(x)\right]$
  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$
  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$
  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\cos(x) \left(\int \tan(x)^2 dx\right) + \sin(x) \left(\int \tan(x) dx\right)$
  - Compute integrals

    $y_p(x) = -\sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x)$

- Substitute particular solution into general solution to ODE

  $y = \cos(x) c_1 + c_2 \sin(x) - \sin(x) + \cos(x) x - \ln(\cos(x)) \sin(x)$

Problem number: 2(g).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = \sec(x)\csc(x)}$$

11.13.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = \sec(x)\csc(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = \mathrm{e}^0(\cos(x) c_1 + c_2 \sin(x))$$

Or

$$y = \cos(x) c_1 + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = \cos(x) c_1 + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)\csc(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int \sec(x)\, dx$$

Hence

$$u_1 = -\ln(\sec(x) + \tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)\csc(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \csc(x)\, dx$$

Hence

$$u_2 = -\ln(\csc(x) + \cot(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\cos(x)\ln(\sec(x) + \tan(x)) - \sin(x)\ln(\csc(x) + \cot(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x) c_1 + c_2 \sin(x)) + (-\cos(x)\ln(\sec(x) + \tan(x)) - \sin(x)\ln(\csc(x) + \cot(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(x) c_1 + c_2 \sin(x) - \cos(x) \ln(\sec(x) + \tan(x)) - \sin(x) \ln(\csc(x) + \cot(x)) \tag{1}$$

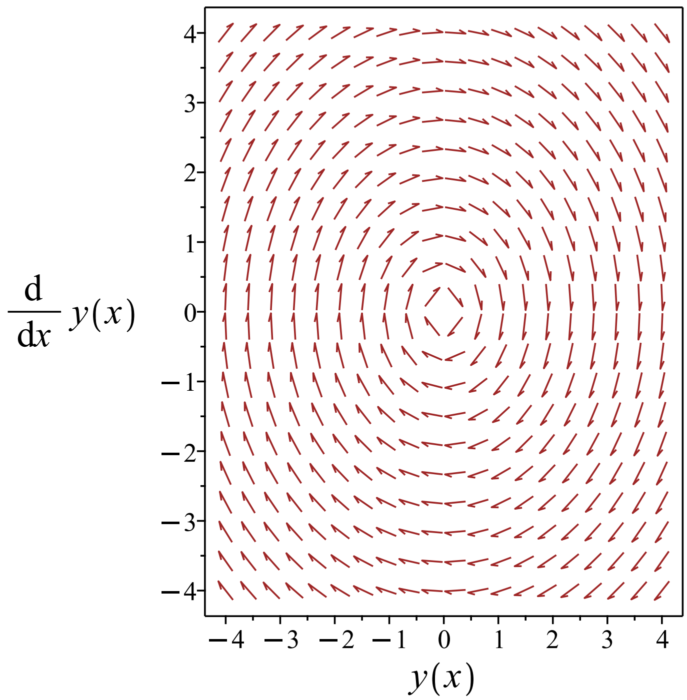

Figure 362: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) - \cos(x) \ln(\sec(x) + \tan(x)) - \sin(x) \ln(\csc(x) + \cot(x))$$

Verified OK.

11.13.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 294: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x)(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x)(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\, c_1 + c_2 \sin(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)$$
$$y_2 = \sin(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ \frac{d}{dx}(\cos(x)) & \frac{d}{dx}(\sin(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{vmatrix}$$

Therefore

$$W = (\cos(x))(\cos(x)) - (\sin(x))(-\sin(x))$$

Which simplifies to

$$W = \cos(x)^2 + \sin(x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\sec(x)\csc(x)}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \sec(x)\,dx$$

Hence

$$u_1 = -\ln(\sec(x)+\tan(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\sec(x)\csc(x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \csc(x)\,dx$$

Hence

$$u_2 = -\ln(\csc(x)+\cot(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\cos(x)\ln(\sec(x)+\tan(x)) - \sin(x)\ln(\csc(x)+\cot(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x)\,c_1 + c_2\sin(x)) + (-\cos(x)\ln(\sec(x)+\tan(x)) - \sin(x)\ln(\csc(x)+\cot(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(x)\,c_1 + c_2\sin(x) - \cos(x)\ln(\sec(x)+\tan(x)) - \sin(x)\ln(\csc(x)+\cot(x)) \tag{1}$$

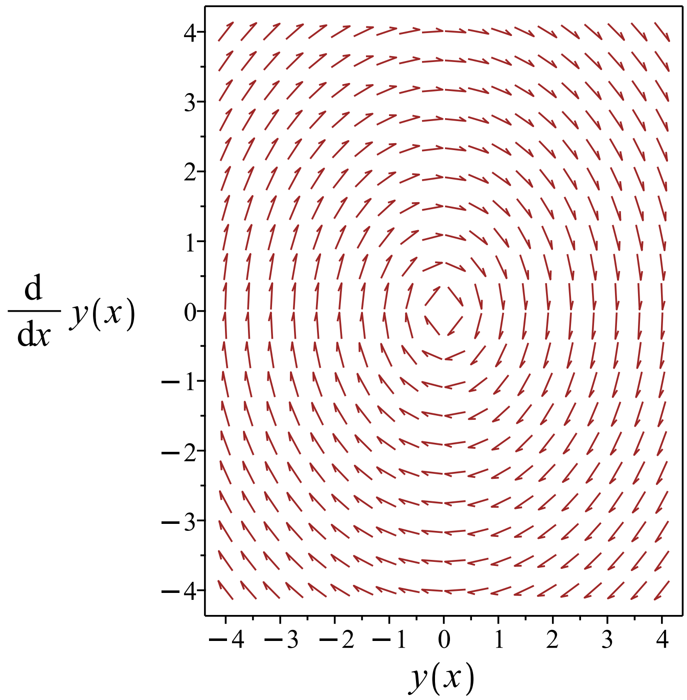

Figure 363: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) - \cos(x) \ln(\sec(x) + \tan(x)) - \sin(x) \ln(\csc(x) + \cot(x))$$

Verified OK.

11.13.3 Maple step by step solution

Let's solve

$y'' + y = \sec(x) \csc(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x) c_1 + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sec(x)\csc(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \left[\begin{array}{cc} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{array}\right]$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\cos(x)\left(\int \sec(x)\, dx\right) + \sin(x)\left(\int \csc(x)\, dx\right)$

  ◦ Compute integrals

  $y_p(x) = -\cos(x)\ln(\sec(x) + \tan(x)) - \sin(x)\ln(\csc(x) + \cot(x))$

- Substitute particular solution into general solution to ODE

  $y = \cos(x) c_1 + c_2 \sin(x) - \cos(x)\ln(\sec(x) + \tan(x)) - \sin(x)\ln(\csc(x) + \cot(x))$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 2y' + y = 2x}$$

11.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = 2x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(-2)^2 - (4)\,(1)\,(1)}\\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 \mathrm{e}^{x} + c_2 x\,\mathrm{e}^{x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{x} + c_2 x\,\mathrm{e}^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{x\,\mathrm{e}^{x}, \mathrm{e}^{x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_2x + A_1 - 2A_2 = 2x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 4, A_2 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x + 4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^x + c_2 x\, e^x) + (2x + 4) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + 2x + 4$$

Summary

The solution(s) found are the following

$$y = e^x (c_2 x + c_1) + 2x + 4 \tag{1}$$

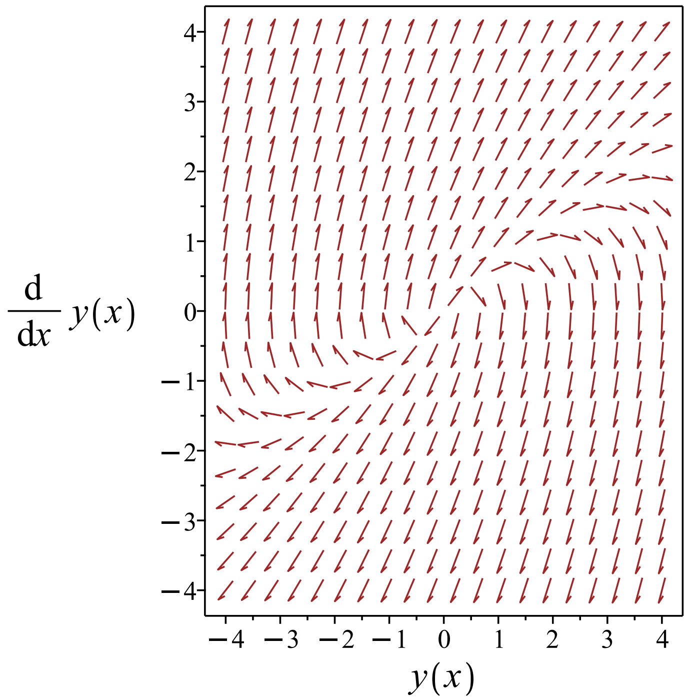

Figure 364: Slope field plot

Verification of solutions

$$y = e^{x}(c_2x + c_1) + 2x + 4$$

Verified OK.

11.14.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2\, dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 2x\,\mathrm{e}^{-x}$$
$$\left(\mathrm{e}^{-x}y\right)'' = 2x\,\mathrm{e}^{-x}$$

Integrating once gives

$$\left(\mathrm{e}^{-x}y\right)' = -2(1+x)\,\mathrm{e}^{-x} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-x}y\right) = (2x+4)\,\mathrm{e}^{-x} + c_1x + c_2$$

Hence the solution is

$$y = \frac{(2x+4)\,\mathrm{e}^{-x} + c_1x + c_2}{\mathrm{e}^{-x}}$$

Or

$$y = c_1x\,\mathrm{e}^{x} + c_2\mathrm{e}^{x} + 2x + 4$$

Summary

The solution(s) found are the following

$$y = c_1x\,\mathrm{e}^{x} + c_2\mathrm{e}^{x} + 2x + 4 \tag{1}$$

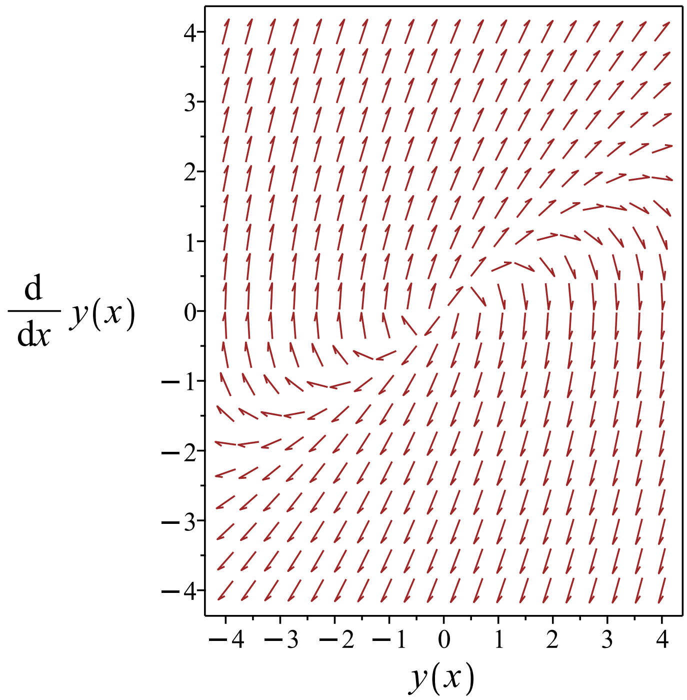

Figure 365: Slope field plot

Verification of solutions

$$y = c_1 x\,e^x + c_2 e^x + 2x + 4$$

Verified OK.

11.14.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 296: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1 (\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^x + c_2 x\,\mathrm{e}^x
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{x\,\mathrm{e}^x, \mathrm{e}^x\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_2 x + A_1
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
A_2 x + A_1 - 2A_2 = 2x
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 4, A_2 = 2]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 2x + 4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^x + c_2 x\, e^x) + (2x + 4) \end{aligned}$$

Which simplifies to

$$y = e^x (c_2 x + c_1) + 2x + 4$$

Summary

The solution(s) found are the following

$$y = e^x (c_2 x + c_1) + 2x + 4 \tag{1}$$

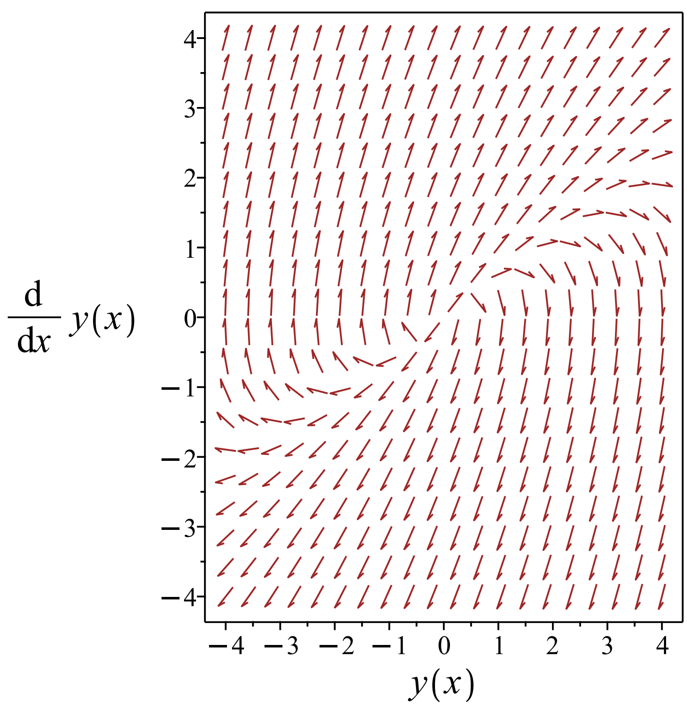

Figure 366: Slope field plot

Verification of solutions

$$y = e^{x}(c_2x + c_1) + 2x + 4$$

Verified OK.

11.14.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = 2x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

  $r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{x}$

- General solution of the ODE

  $y = c_1y_1(x) + c_2y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1e^{x} + c_2x\,e^{x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 2x\right]$

  ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{x} & x\,e^{x} \\ e^{x} & x\,e^{x} + e^{x} \end{bmatrix}$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$
- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -2\,\mathrm{e}^x \left(\int x^2 \mathrm{e}^{-x} dx - \left(\int x\,\mathrm{e}^{-x} dx\right) x\right)$
- Compute integrals

  $y_p(x) = 2x + 4$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,\mathrm{e}^x + c_1 \mathrm{e}^x + 2x + 4$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y' - 6y = e^{-x}}$$

11.15.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -6, f(x) = e^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 6y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \lambda\, e^{\lambda x} - 6\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(-6)}\\ &= \frac{1}{2} \pm \frac{5}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{1}{2} + \frac{5}{2}\\ \lambda_2 &= \frac{1}{2} - \frac{5}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ y &= c_1 e^{(3)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$y = e^{3x} c_1 + c_2 e^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = e^{3x} c_1 + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{3x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^{-x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{3x} c_1 + c_2 e^{-2x}\right) + \left(-\frac{e^{-x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{3x} c_1 + c_2 e^{-2x} - \frac{e^{-x}}{4} \tag{1}$$

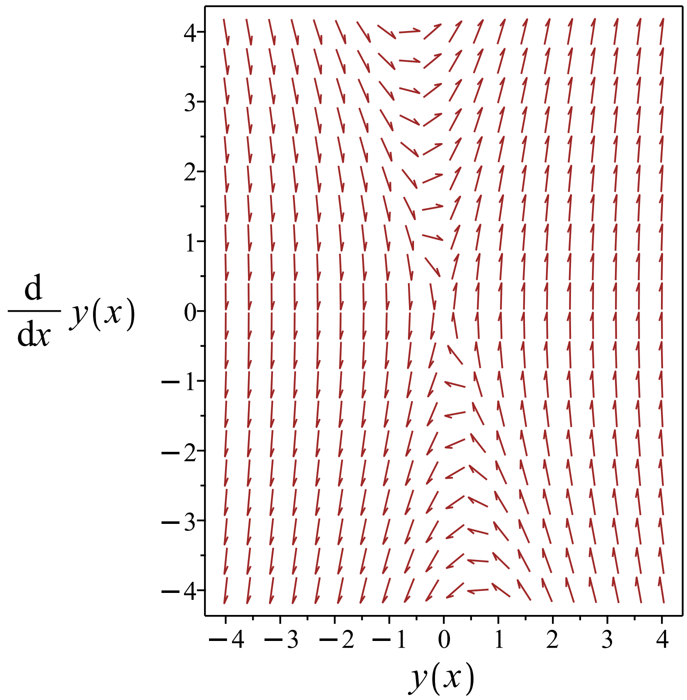

Figure 367: Slope field plot

Verification of solutions

$$y = e^{3x}c_1 + c_2e^{-2x} - \frac{e^{-x}}{4}$$

Verified OK.

11.15.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$A = 1$$
$$B = -1 \tag{3}$$
$$C = -6$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{25}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 25 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{25z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 298: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{25}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{5x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1\left(\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{5x}}{5}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x} \left(\frac{\mathrm{e}^{5x}}{5}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y' - 6y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + \frac{c_2 \mathrm{e}^{3x}}{5}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{-x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{3x}}{5}, \mathrm{e}^{-2x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{-x}
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{e^{-x}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + \frac{c_2 e^{3x}}{5}\right) + \left(-\frac{e^{-x}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + \frac{c_2 e^{3x}}{5} - \frac{e^{-x}}{4} \tag{1}$$

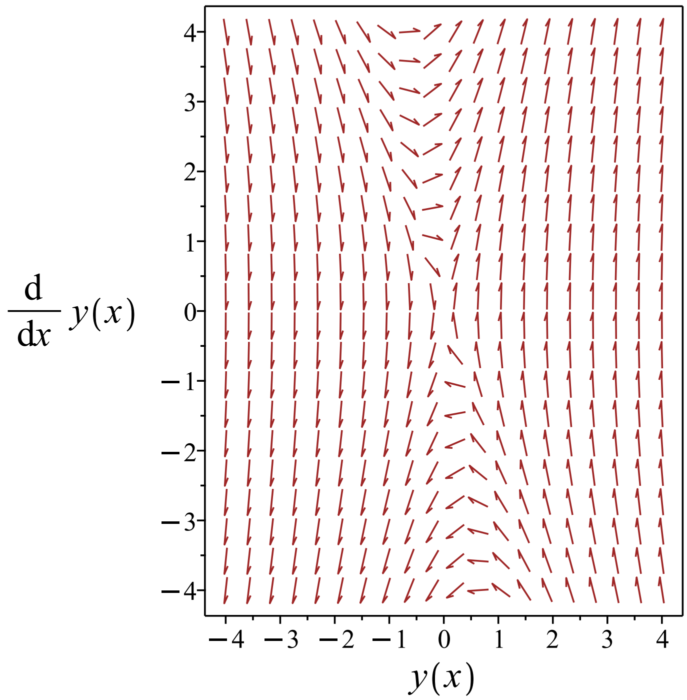

Figure 368: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 e^{-2x} + \frac{c_2 e^{3x}}{5} - \frac{e^{-x}}{4}$$

Verified OK.

11.15.3 Maple step by step solution

Let's solve

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2-1)\,y''-2xy'+2y=(x^2-1)^2}$$

11.16.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x^2-1, B=-2x, C=2, f(x)=x^4-2x^2+1$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$(x^2-1)\,y''-2xy'+2y=0$$

In normal form the ode

$$\left(x^2-1\right) y''-2xy'+2y = 0 \tag{1}$$

Becomes

$$y''+p(x)\, y'+q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2x}{x^2-1} \\ q(x) &= \frac{2}{x^2-1} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right) v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}-\frac{2n}{x^2-1}+\frac{2}{x^2-1} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{2}{x}-\frac{2x}{x^2-1}\right) v'(x) &= 0 \\ v''(x)-\frac{2v'(x)}{x^3-x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) - \frac{2u(x)}{x^3 - x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= \frac{2u}{x(x^2 - 1)} \end{aligned}$$

Where $f(x) = \frac{2}{x(x^2-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= \frac{2}{x(x^2 - 1)}\, dx \\ \int \frac{1}{u}\, du &= \int \frac{2}{x(x^2 - 1)}\, dx \\ \ln(u) &= \ln(1 + x) + \ln(x - 1) - 2\ln(x) + c_1 \\ u &= e^{\ln(1+x)+\ln(x-1)-2\ln(x)+c_1} \\ &= c_1 e^{\ln(1+x)+\ln(x-1)-2\ln(x)} \end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(1 - \frac{1}{x^2}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= c_1\left(x + \frac{1}{x}\right) + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(c_1\left(x + \frac{1}{x}\right) + c_2\right) x \\ &= c_1 x^2 + c_2 x + c_1 \end{aligned}$$

Now the particular solution to this ODE is found

$$\left(x^2-1\right) y''-2xy'+2y=x^4-2x^2+1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=x$$
$$y_2=x^2+1$$

In the Variation of parameters u_1, u_2 are found using

$$u_1=-\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2=\int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W=\begin{vmatrix} x & x^2+1 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2+1) \end{vmatrix}$$

Which gives

$$W=\begin{vmatrix} x & x^2+1 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W=(x)(2x)-\left(x^2+1\right)(1)$$

Which simplifies to

$$W = x^2 - 1$$

Which simplifies to

$$W = x^2 - 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^2+1)(x^4-2x^2+1)}{(x^2-1)^2} \, dx$$

Which simplifies to

$$u_1 = -\int (x^2+1) \, dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(x^4-2x^2+1)}{(x^2-1)^2} \, dx$$

Which simplifies to

$$u_2 = \int x dx$$

Hence

$$u_2 = \frac{x^2}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{1}{3}x^3 - x\right)x + \frac{(x^2+1)\,x^2}{2}$$

Which simplifies to

$$y_p(x) = \frac{1}{6}x^4 - \frac{1}{2}x^2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(c_1\left(x+\frac{1}{x}\right)+c_2\right)x\right) + \left(\frac{1}{6}x^4 - \frac{1}{2}x^2\right) \\
&= \frac{x^4}{6} - \frac{x^2}{2} + \left(c_1\left(x+\frac{1}{x}\right)+c_2\right)x
\end{aligned}
$$

Which simplifies to

$$
y = \frac{1}{6}x^4 - \frac{1}{2}x^2 + c_1x^2 + c_2x + c_1
$$

Summary

The solution(s) found are the following

$$
y = \frac{1}{6}x^4 - \frac{1}{2}x^2 + c_1x^2 + c_2x + c_1 \tag{1}
$$

Verification of solutions

$$
y = \frac{1}{6}x^4 - \frac{1}{2}x^2 + c_1x^2 + c_2x + c_1
$$

Verified OK.

11.16.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x^2 - 1 \\
B &= -2x \\
C &= 2 \\
F &= x^4 - 2x^2 + 1
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(x^2 - 1\right)(0) + (-2x)(-2) + (2)(-2x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-2x^3 + 2xv'' + (4)\, v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
\left(-2x^3 + 2x\right) u'(x) + 4u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= \frac{2u}{x\left(x^2 - 1\right)}
\end{aligned}
$$

Where $f(x) = \frac{2}{x(x^2-1)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= \frac{2}{x\left(x^2-1\right)}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{2}{x\left(x^2-1\right)}\, dx \\
\ln\left(u\right) &= \ln\left(1+x\right) + \ln\left(x-1\right) - 2\ln\left(x\right) + c_1 \\
u &= \mathrm{e}^{\ln(1+x)+\ln(x-1)-2\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{\ln(1+x)+\ln(x-1)-2\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = c_1\left(1 - \frac{1}{x^2}\right)
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1\left(1 - \frac{1}{x^2}\right)
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1(x^2-1)}{x^2}\, \mathrm{d}x \\
&= c_1\left(x + \frac{1}{x}\right) + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-2x)\left(c_1\left(x + \frac{1}{x}\right) + c_2\right) \\
&= -2c_1x^2 - 2c_2x - 2c_1
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = -2x^2 - 2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & -2x^2 - 2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(-2x^2 - 2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & -2x^2 - 2 \\ 1 & -4x \end{vmatrix}$$

Therefore

$$W = (x)(-4x) - (-2x^2 - 2)(1)$$

Which simplifies to

$$W = -2x^2 + 2$$

Which simplifies to

$$W = -2x^2 + 2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(-2x^2 - 2)(x^4 - 2x^2 + 1)}{(x^2 - 1)(-2x^2 + 2)} \, dx$$

Which simplifies to

$$u_1 = -\int (x^2 + 1)\, dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(x^4 - 2x^2 + 1)}{(x^2 - 1)(-2x^2 + 2)}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{x}{2} dx$$

Hence

$$u_2 = -\frac{x^2}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{1}{3}x^3 - x\right) x - \frac{x^2(-2x^2 - 2)}{4}$$

Which simplifies to

$$y_p(x) = \frac{1}{6}x^4 - \frac{1}{2}x^2$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (-2c_1x^2 - 2c_2x - 2c_1) + \left(\frac{1}{6}x^4 - \frac{1}{2}x^2\right) \\ &= \frac{x^4}{6} + \frac{(-1 - 4c_1)\, x^2}{2} - 2c_2x - 2c_1 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{x^4}{6} + \frac{(-1 - 4c_1)\, x^2}{2} - 2c_2x - 2c_1 \tag{1}$$

Verification of solutions

$$y = \frac{x^4}{6} + \frac{(-1-4c_1)\,x^2}{2} - 2c_2x - 2c_1$$

Verified OK.

11.16.3 Solving using Kovacic algorithm

Writing the ode as

$$(x^2-1)\,y'' - 2xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2-1 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{(x^2-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= (x^2-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{\left(x^2-1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 300: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = \left(x^2-1\right)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4(x-1)^2} - \frac{3}{4(x-1)} + \frac{3}{4(1+x)} + \frac{3}{4(1+x)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(x^2-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right)\\
&= 1 - (1)\\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty\\
&= -\frac{1}{2(x-1)} + \frac{3}{2(1+x)} + (-)(0)\\
&= -\frac{1}{2(x-1)} + \frac{3}{2(1+x)}\\
&= \frac{-2+x}{x^2-1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-1)} + \frac{3}{2(1+x)}\right)(0) + \left(\left(\frac{1}{2(x-1)^2} - \frac{3}{2(1+x)^2}\right) + \left(-\frac{1}{2(x-1)} + \frac{3}{2(1+x)}\right)^2 - \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)}+\frac{3}{2(1+x)}\right)dx} \\
&= \frac{(1+x)^{\frac{3}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2-1}\, dx} \\
&= z_1 e^{\frac{\ln(x-1)}{2}+\frac{\ln(1+x)}{2}} \\
&= z_1\left(\sqrt{x-1}\,\sqrt{1+x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = (1+x)^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2-1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x-1)+\ln(1+x)}}{(y_1)^2}\, dx \\
&= y_1\left(-\frac{x}{(1+x)^2}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((1+x)^2\right) + c_2\left((1+x)^2\left(-\frac{x}{(1+x)^2}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$\left(x^2-1\right) y'' - 2xy' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1(1+x)^2 - c_2 x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= (1+x)^2 \\ y_2 &= -x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (1+x)^2 & -x \\ \frac{d}{dx}\left((1+x)^2\right) & \frac{d}{dx}(-x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (1+x)^2 & -x \\ 2+2x & -1 \end{vmatrix}$$

Therefore

$$W = \left((1+x)^2\right)(-1) - (-x)(2+2x)$$

Which simplifies to

$$W = x^2 - 1$$

Which simplifies to

$$W = x^2 - 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-x(x^4 - 2x^2 + 1)}{(x^2 - 1)^2}\, dx$$

Which simplifies to

$$u_1 = -\int -x dx$$

Hence

$$u_1 = \frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(1+x)^2 (x^4 - 2x^2 + 1)}{(x^2 - 1)^2}\, dx$$

Which simplifies to

$$u_2 = \int (1+x)^2\, dx$$

Hence

$$u_2 = \frac{(1+x)^3}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2(1+x)^2}{2} - \frac{(1+x)^3 x}{3}$$

Which simplifies to

$$y_p(x) = \frac{x(x^3 - 3x - 2)}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1(1+x)^2 - c_2 x\right) + \left(\frac{x(x^3 - 3x - 2)}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1(1+x)^2 - c_2 x + \frac{x(x^3 - 3x - 2)}{6} \tag{1}$$

Verification of solutions

$$y = c_1(1+x)^2 - c_2 x + \frac{x(x^3 - 3x - 2)}{6}$$

Verified OK.

```

$$\boxed{(x^2+x)\,y''+(-x^2+2)\,y'-(x+2)\,y=x(1+x)^2}$$

11.17.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x^2+x, B=-x^2+2, C=-x-2, f(x)=x(1+x)^2$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$(x^2+x)\,y''+(-x^2+2)\,y'+(-x-2)\,y=0$$

In normal form the ode

$$\left(x^{2}+x\right) y''+\left(-x^{2}+2\right) y'+\left(-x-2\right) y = 0 \tag{1}$$

Becomes

$$y''+p(x) y'+q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= \frac{-x^{2}+2}{x \left(1+x\right)}\\ q(x) &= \frac{-x-2}{x \left(1+x\right)}\end{aligned}$$

Applying change of variables on the depndent variable $y = v(x) x^{n}$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right) v'(x)+\left(\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^{2}}+\frac{n(-x^{2}+2)}{x^{2} \left(1+x\right)}+\frac{-x-2}{x \left(1+x\right)} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned}v''(x)+\left(-\frac{2}{x}+\frac{-x^{2}+2}{x \left(1+x\right)}\right) v'(x) &= 0\\ v''(x)+\frac{\left(-x-2\right) v'(x)}{1+x} &= 0\end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(-x-2)\, u(x)}{1+x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u(x+2)}{1+x}
\end{aligned}$$

Where $f(x) = \frac{x+2}{1+x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= \frac{x+2}{1+x}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{x+2}{1+x}\, dx \\
\ln(u) &= x + \ln(1+x) + c_1 \\
u &= \mathrm{e}^{x+\ln(1+x)+c_1} \\
&= c_1 \mathrm{e}^{x+\ln(1+x)}
\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \frac{x c_1 \mathrm{e}^{x+\ln(1+x)}}{1+x} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\, x^n \\
&= \frac{\frac{x c_1 \mathrm{e}^{x+\ln(1+x)}}{1+x} + c_2}{x} \\
&= \frac{c_1 x\, \mathrm{e}^x + c_2}{x}
\end{aligned}$$

Now the particular solution to this ODE is found

$$(x^2+x)\, y'' + (-x^2+2)\, y' + (-x-2)\, y = x(1+x)^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x} \\ -\frac{1}{x^2} & \frac{2\,\mathrm{e}^{x}}{1+x} - \frac{x\,\mathrm{e}^{x}}{(1+x)^2} + \frac{x\,\mathrm{e}^{x}}{1+x} - \frac{\mathrm{e}^{x}}{(1+x)^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{2\,\mathrm{e}^{x}}{1+x} - \frac{x\,\mathrm{e}^{x}}{(1+x)^2} + \frac{x\,\mathrm{e}^{x}}{1+x} - \frac{\mathrm{e}^{x}}{(1+x)^2}\right) - \left(\frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{(1+x)\,\mathrm{e}^{x}}{x^{2}}$$

Which simplifies to

$$W = \frac{(1+x)\,\mathrm{e}^{x}}{x^{2}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(\frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x}\right) x(1+x)^{2}}{\frac{(x^{2}+x)(1+x)\mathrm{e}^{x}}{x^{2}}}\,dx$$

Which simplifies to

$$u_1 = -\int x^{2}dx$$

Hence

$$u_1 = -\frac{x^{3}}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(1+x)^{2}}{\frac{(x^{2}+x)(1+x)\mathrm{e}^{x}}{x^{2}}}\,dx$$

Which simplifies to

$$u_2 = \int x\,\mathrm{e}^{-x}dx$$

Hence

$$u_2 = -(1+x)\,\mathrm{e}^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^{2}}{3} - (1+x)\,\mathrm{e}^{-x}\left(\frac{x\,\mathrm{e}^{x}}{1+x} + \frac{\mathrm{e}^{x}}{1+x}\right)$$

Which simplifies to

$$y_p(x) = -\frac{1}{3}x^{2} - 1 - x$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{\frac{x c_1 \mathrm{e}^{x+\ln(1+x)}}{1+x} + c_2}{x}\right) + \left(-\frac{1}{3}x^2 - 1 - x\right) \\
&= -\frac{x^2}{3} - 1 - x + \frac{\frac{x c_1 \mathrm{e}^{x+\ln(1+x)}}{1+x} + c_2}{x}
\end{aligned}$$

Which simplifies to

$$y = \frac{3c_1 x\,\mathrm{e}^{x} - x^3 - 3x^2 + 3c_2 - 3x}{3x}$$

Summary

The solution(s) found are the following

$$y = \frac{3c_1 x\,\mathrm{e}^{x} - x^3 - 3x^2 + 3c_2 - 3x}{3x} \tag{1}$$

Verification of solutions

$$y = \frac{3c_1 x\,\mathrm{e}^{x} - x^3 - 3x^2 + 3c_2 - 3x}{3x}$$

Verified OK.

11.17.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(x^2 + x\right) y'' + \left(-x^2 + 2\right) y' + \left(-x - 2\right) y = 0 \tag{1}$$

$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}
A &= x^2 + x \\
B &= -x^2 + 2 \\
C &= -x - 2
\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 + 4x + 6}{4(1+x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 + 4x + 6 \\ t &= 4(1+x)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 + 4x + 6}{4(1+x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 301: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(1+x)^2$. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} + \frac{1}{2+2x} + \frac{3}{4(1+x)^2}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} + \frac{1}{2x} - \frac{1}{x^3} + \frac{11}{4x^4} - \frac{21}{4x^5} + \frac{15}{2x^6} - \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 + 4x + 6}{4x^2 + 8x + 4} \\ &= Q + \frac{R}{4x^2 + 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{2x + 5}{4x^2 + 8x + 4}\right) \\ &= \frac{1}{4} + \frac{2x + 5}{4x^2 + 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 2. Dividing this by leading coefficient in t which is 4 gives $\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{1}{2}\right) - (0) \\ &= \frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 + 4x + 6}{4(1+x)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
-1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\,(1+x)} + (-)\left(\frac{1}{2}\right) \\
&= -\frac{1}{2\,(1+x)} - \frac{1}{2} \\
&= -\frac{x+2}{2\,(1+x)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{2\,(1+x)} - \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2\,(1+x)^2}\right) + \left(-\frac{1}{2\,(1+x)} - \frac{1}{2}\right)^2 - \left(\frac{x^2+4x+6}{4\,(1+x)^2}\right) \right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(1+x)} - \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{-\frac{x}{2}}}{\sqrt{1+x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+2}{x^2+x}\,dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(1+x)}{2}-\ln(x)} \\
&= z_1\left(\frac{\sqrt{1+x}\,\mathrm{e}^{\frac{x}{2}}}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^2+x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x+\ln(1+x)-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(x\,\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}(x\,\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$\left(x^2+x\right)y''+\left(-x^2+2\right)y'+\left(-x-2\right)y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x}+c_2\mathrm{e}^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \mathrm{e}^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \mathrm{e}^x \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\mathrm{e}^x\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & e^x \\ -\frac{1}{x^2} & e^x \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(e^x) - (e^x)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{(1+x)\,e^x}{x^2}$$

Which simplifies to

$$W = \frac{(1+x)\,e^x}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^x x(1+x)^2}{\frac{(x^2+x)(1+x)e^x}{x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int x^2 dx$$

Hence

$$u_1 = -\frac{x^3}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(1+x)^2}{\frac{(x^2+x)(1+x)e^x}{x^2}}\,dx$$

Which simplifies to

$$u_2 = \int x\,e^{-x} dx$$

Hence

$$u_2 = -(1+x)\,e^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2}{3} - (1+x)\,\mathrm{e}^{-x}\mathrm{e}^{x}$$

Which simplifies to

$$y_p(x) = -\frac{1}{3}x^2 - 1 - x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + c_2\mathrm{e}^{x}\right) + \left(-\frac{1}{3}x^2 - 1 - x\right) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{c_1}{x} + c_2\mathrm{e}^{x} - \frac{x^2}{3} - 1 - x \tag{1}$$

<u>Verification of solutions</u>

$$y = \frac{c_1}{x} + c_2\mathrm{e}^{x} - \frac{x^2}{3} - 1 - x$$

Verified OK.

$$\boxed{(1-x)\,y''+xy'-y=(1-x)^2}$$

11.18.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=1-x, B=x, C=-1, f(x)=(x-1)^2$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$(1-x)\,y''+xy'-y=0$$

In normal form the ode

$$(1-x)\,y''+xy'-y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{x}{x-1} \\ q(x) &= \frac{1}{x-1} \end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}-\frac{n}{x-1}+\frac{1}{x-1}=0 \tag{5}$$

Solving (5) for n gives

$$n=1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{2}{x}-\frac{x}{x-1}\right)v'(x) &= 0 \\ v''(x)+\left(\frac{2}{x}-\frac{x}{x-1}\right)v'(x) &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u(x^2 - 2x + 2)}{x\,(x-1)}
\end{aligned}$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{x^2 - 2x + 2}{x\,(x-1)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{x^2 - 2x + 2}{x\,(x-1)}\,dx \\
\ln(u) &= x + \ln(x-1) - 2\ln(x) + c_1 \\
u &= \mathrm{e}^{x + \ln(x-1) - 2\ln(x) + c_1} \\
&= c_1 \mathrm{e}^{x + \ln(x-1) - 2\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{\mathrm{e}^x c_1}{x} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{\mathrm{e}^x c_1}{x} + c_2\right) x \\
&= c_1 \mathrm{e}^x + c_2 x
\end{aligned}$$

Now the particular solution to this ODE is found

$$(1-x)\,y''+xy'-y=(x-1)^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1,u_2 to be determined, and y_1,y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=x$$
$$y_2=\mathrm{e}^x$$

In the Variation of parameters u_1,u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix}y_1 & y_2\\ y_1' & y_2'\end{vmatrix}$. Hence

$$W=\begin{vmatrix}x & \mathrm{e}^x\\ \frac{d}{dx}(x) & \frac{d}{dx}(\mathrm{e}^x)\end{vmatrix}$$

Which gives

$$W=\begin{vmatrix}x & \mathrm{e}^x\\ 1 & \mathrm{e}^x\end{vmatrix}$$

Therefore

$$W=(x)\,(\mathrm{e}^x)-(\mathrm{e}^x)\,(1)$$

Which simplifies to

$$W = x\,\mathrm{e}^{x} - \mathrm{e}^{x}$$

Which simplifies to

$$W = (x-1)\,\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x-1)^2\,\mathrm{e}^{x}}{(1-x)\,(x-1)\,\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int (-1)\,dx$$

Hence

$$u_1 = x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(x-1)^2}{(1-x)\,(x-1)\,\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_2 = \int -x\,\mathrm{e}^{-x} dx$$

Hence

$$u_2 = (1+x)\,\mathrm{e}^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^2 + (1+x)\,\mathrm{e}^{-x}\mathrm{e}^{x}$$

Which simplifies to

$$y_p(x) = x^2 + x + 1$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(\frac{e^x c_1}{x} + c_2\right) x\right) + \left(x^2 + x + 1\right) \\
&= x^2 + x + 1 + \left(\frac{e^x c_1}{x} + c_2\right) x
\end{aligned}
$$

Which simplifies to

$$
y = c_1 e^x + c_2 x + x^2 + x + 1
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^x + c_2 x + x^2 + x + 1 \tag{1}
$$

Verification of solutions

$$
y = c_1 e^x + c_2 x + x^2 + x + 1
$$

Verified OK.

11.18.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0
\end{aligned} \tag{1}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= 1 - x \\
B &= x \\
C &= -1 \\
F &= (x-1)^2
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= (1-x)(0) + (x)(1) + (-1)(x) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-x(x-1) v'' + \left(x^2 - 2x + 2\right) v' = 0$$

Now by applying $v' = u$ the above becomes

$$\left(-x^2 + x\right) u'(x) + \left(x^2 - 2x + 2\right) u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u(x^2 - 2x + 2)}{x(x-1)}
\end{aligned}$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= \frac{x^2 - 2x + 2}{x\,(x-1)}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{x^2 - 2x + 2}{x\,(x-1)}\, dx \\
\ln(u) &= x + \ln(x-1) - 2\ln(x) + c_1 \\
u &= \mathrm{e}^{x+\ln(x-1)-2\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{x+\ln(x-1)-2\ln(x)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1 \left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2} \right)$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1 \left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2} \right)
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{c_1(x-1)\,\mathrm{e}^x}{x^2}\, \mathrm{d}x \\
&= \frac{\mathrm{e}^x c_1}{x} + c_2
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= Bv \\
&= (x) \left(\frac{\mathrm{e}^x c_1}{x} + c_2 \right) \\
&= c_1 \mathrm{e}^x + c_2 x
\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = e^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & e^x \\ \frac{d}{dx}(x) & \frac{d}{dx}(e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & e^x \\ 1 & e^x \end{vmatrix}$$

Therefore

$$W = (x)(e^x) - (e^x)(1)$$

Which simplifies to

$$W = x e^x - e^x$$

Which simplifies to

$$W = (x-1)e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x-1)^2 e^x}{(1-x)(x-1)e^x} \, dx$$

Which simplifies to

$$u_1 = -\int (-1)\, dx$$

Hence

$$u_1 = x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(x-1)^2}{(1-x)\,(x-1)\,\mathrm{e}^x}\, dx$$

Which simplifies to

$$u_2 = \int -x\,\mathrm{e}^{-x} dx$$

Hence

$$u_2 = (1+x)\,\mathrm{e}^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^2 + (1+x)\,\mathrm{e}^{-x}\mathrm{e}^x$$

Which simplifies to

$$y_p(x) = x^2 + x + 1$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (c_1\mathrm{e}^x + c_2 x) + \left(x^2 + x + 1\right) \\ &= c_1\mathrm{e}^x + c_2 x + x^2 + x + 1 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^x + c_2 x + x^2 + x + 1 \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^x + c_2 x + x^2 + x + 1$$

Verified OK.

11.18.3 Solving using Kovacic algorithm

Writing the ode as

$$(1-x)\,y''+xy'-y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=1-x\\B&=x\\C&=-1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\,(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^2-4x+6\\t&=4(x-1)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\,(x-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y=z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 302: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 2 \\
&= 0
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$
L = [1, 2]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{1}{4} + \frac{3}{4(x-1)^2} - \frac{1}{2(x-1)}
$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$
v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{2}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v=0$ or not. Since $v=0$ then starting from $r=\frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2-4x+6}{4x^2-8x+4} \\ &= Q + \frac{R}{4x^2-8x+4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x+5}{4x^2-8x+4}\right) \\ &= \frac{1}{4} + \frac{-2x+5}{4x^2-8x+4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2-4x+6}{4(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\,(x-1)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2\,(x-1)} + \frac{1}{2} \\
&= \frac{-2+x}{2x-2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2\left(x-1\right)}+\frac{1}{2}\right)(0) + \left(\left(\frac{1}{2\left(x-1\right)^{2}}\right) + \left(-\frac{1}{2\left(x-1\right)}+\frac{1}{2}\right)^{2} - \left(\frac{x^{2}-4x+6}{4\left(x-1\right)^{2}}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)}+\frac{1}{2}\right)dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{1-x}\, dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(x-1)}{2}} \\
&= z_1\left(\sqrt{x-1}\, \mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{1-x}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x-1)}}{\left(y_1\right)^2}\, dx \\
&= y_1\left(-x\, \mathrm{e}^{-x}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2\left(\mathrm{e}^x\left(-x\,\mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
(1-x)\,y'' + xy' - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1\mathrm{e}^x - c_2 x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^x \\
y_2 &= -x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{x} & -x \\ \frac{d}{dx}(e^{x}) & \frac{d}{dx}(-x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{x} & -x \\ e^{x} & -1 \end{vmatrix}$$

Therefore

$$W = (e^{x})(-1) - (-x)(e^{x})$$

Which simplifies to

$$W = x\,e^{x} - e^{x}$$

Which simplifies to

$$W = (x-1)\,e^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-x(x-1)^2}{(1-x)(x-1)\,e^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int x\,e^{-x}dx$$

Hence

$$u_1 = (1+x)\,e^{-x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x-1)^2\,e^{x}}{(1-x)(x-1)\,e^{x}}\,dx$$

Which simplifies to

$$u_2 = \int (-1)\, dx$$

Hence

$$u_2 = -x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^2 + (1 + x)\, e^{-x} e^x$$

Which simplifies to

$$y_p(x) = x^2 + x + 1$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^x - c_2 x) + \left(x^2 + x + 1\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x - c_2 x + x^2 + x + 1 \tag{1}$$

Verification of solutions

$$y = c_1 e^x - c_2 x + x^2 + x + 1$$

Verified OK.

Problem number: 5(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' - (1 + x)\, y' + y = x^2 \mathrm{e}^{2x}}$$

11.19.1 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x \\
B &= -1 - x \\
C &= 1 \\
F &= x^2 \mathrm{e}^{2x}
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= (x)\,(0) + (-1 - x)\,(-1) + (1)\,(-1 - x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-x(1 + x)\, v'' + \left(x^2 + 1\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-x(1 + x)\, u'(x) + \left(x^2 + 1\right) u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x) g(u) \\
&= \frac{\left(x^2 + 1\right) u}{x\,(1 + x)}
\end{aligned}
$$

Where $f(x) = \frac{x^2+1}{x(1+x)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{x^2+1}{x\,(1+x)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{x^2+1}{x\,(1+x)}\,dx \\
\ln(u) &= x - 2\ln(1+x) + \ln(x) + c_1 \\
u &= \mathrm{e}^{x-2\ln(1+x)+\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{x-2\ln(1+x)+\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = \frac{c_1 x\,\mathrm{e}^x}{(1+x)^2}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1 x\,\mathrm{e}^x}{(1+x)^2}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1 x\,\mathrm{e}^x}{(1+x)^2}\,\mathrm{d}x \\
&= \frac{c_1 \mathrm{e}^x}{1+x} + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-1-x)\left(\frac{c_1 \mathrm{e}^x}{1+x} + c_2\right) \\
&= -c_1 \mathrm{e}^x - (1+x)\,c_2
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= -1 - x \\
y_2 &= e^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} -1 - x & e^x \\ \frac{d}{dx}(-1 - x) & \frac{d}{dx}(e^x) \end{vmatrix}
$$

Which gives

$$
W = \begin{vmatrix} -1 - x & e^x \\ -1 & e^x \end{vmatrix}
$$

Therefore

$$
W = (-1 - x)(e^x) - (e^x)(-1)
$$

Which simplifies to

$$
W = -x e^x
$$

Which simplifies to

$$
W = -x e^x
$$

Therefore Eq. (2) becomes

$$
u_1 = -\int \frac{e^x x^2 e^{2x}}{-x^2 e^x} \, dx
$$

Which simplifies to

$$u_1 = -\int -e^{2x} dx$$

Hence

$$u_1 = \frac{e^{2x}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(-1-x)\, x^2 e^{2x}}{-x^2 e^x}\, dx$$

Which simplifies to

$$u_2 = \int e^x (1+x)\, dx$$

Hence

$$u_2 = x\, e^x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^{2x}(-1-x)}{2} + e^{2x} x$$

Which simplifies to

$$y_p(x) = \frac{(x-1)\, e^{2x}}{2}$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (-c_1 e^x - (1+x)\, c_2) + \left(\frac{(x-1)\, e^{2x}}{2}\right) \\ &= -c_1 e^x - (1+x)\, c_2 + \frac{(x-1)\, e^{2x}}{2} \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -c_1 e^x - (1+x)\, c_2 + \frac{(x-1)\, e^{2x}}{2} \tag{1}$$

Verification of solutions

$$y = -c_1 e^x - (1+x) c_2 + \frac{(x-1) e^{2x}}{2}$$

Verified OK.

11.19.2 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + (-1-x) y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -1-x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 2x + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 2x + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 2x + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 303: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2x} + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{2x^2} + \frac{1}{2x^3} + \frac{1}{4x^4} - \frac{1}{4x^5} - \frac{3}{4x^6} - \frac{3}{4x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^2 - 2x + 3}{4x^2} \\
&= Q + \frac{R}{4x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-2x+3}{4x^2}\right) \\
&= \frac{1}{4} + \frac{-2x+3}{4x^2}
\end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{1}{2}\right) - (0) \\
&= -\frac{1}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2 - 2x + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + \left(\frac{1}{2}\right) \\
&= \frac{1}{2} - \frac{1}{2x} \\
&= \frac{x-1}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2} - \frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(\frac{1}{2} - \frac{1}{2x}\right)^2 - \left(\frac{x^2 - 2x + 3}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{1}{2} - \frac{1}{2x}\right) dx} \\ &= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-1-x}{x} \, dx} \\ &= z_1 e^{\frac{x}{2} + \frac{\ln(x)}{2}} \\ &= z_1 \left(\sqrt{x}\, \mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1-x}{x} dx}}{(y_1)^2} dx \\
&= y_1 \int \frac{e^{x+\ln(x)}}{(y_1)^2} dx \\
&= y_1 \left(-(1+x)\,\mathrm{e}^{-x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2\left(\mathrm{e}^x\left(-(1+x)\,\mathrm{e}^{-x}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$xy'' + (-1-x)\,y' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^x + (-1-x)\,c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \mathrm{e}^x \\
y_2 &= -1-x
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{x} & -1-x \\ \frac{d}{dx}(e^{x}) & \frac{d}{dx}(-1-x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{x} & -1-x \\ e^{x} & -1 \end{vmatrix}$$

Therefore

$$W = (e^{x})(-1) - (-1-x)(e^{x})$$

Which simplifies to

$$W = x\,e^{x}$$

Which simplifies to

$$W = x\,e^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(-1-x)\,x^2 e^{2x}}{x^2 e^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int -e^{x}(1+x)\,dx$$

Hence

$$u_1 = x\,e^{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^x x^2 e^{2x}}{x^2 e^x} \, dx$$

Which simplifies to

$$u_2 = \int e^{2x} dx$$

Hence

$$u_2 = \frac{e^{2x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^{2x}(-1-x)}{2} + e^{2x} x$$

Which simplifies to

$$y_p(x) = \frac{(x-1)\, e^{2x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 e^x + (-1-x)\, c_2) + \left(\frac{(x-1)\, e^{2x}}{2}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 e^x - (1+x)\, c_2 + \frac{(x-1)\, e^{2x}}{2}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x - (1+x)\, c_2 + \frac{(x-1)\, e^{2x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 e^x - (1+x)\, c_2 + \frac{(x-1)\, e^{2x}}{2}$$

Verified OK.

$$\boxed{x^2y'' - 2xy' + 2y = x\,\mathrm{e}^{-x}}$$

11.20.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = 2, f(x) = x\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2xy' + 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 2xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 2r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 2r + 2 = 0$$

Or

$$r^2 - 3r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^2 + c_1x$$

Next, we find the particular solution to the ODE

$$x^2y'' - 2xy' + 2y = x\,\mathrm{e}^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3 \mathrm{e}^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\mathrm{e}^{-x}}{x} dx$$

Hence

$$u_1 = \mathrm{expIntegral}_1(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2 \mathrm{e}^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\mathrm{e}^{-x}}{x^2} dx$$

Hence

$$u_2 = -\frac{\mathrm{e}^{-x}}{x} + \mathrm{expIntegral}_1(x)$$

Which simplifies to

$$u_1 = \mathrm{expIntegral}_1(x)$$
$$u_2 = \frac{\mathrm{expIntegral}_1(x)\, x - \mathrm{e}^{-x}}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \mathrm{expIntegral}_1(x)\, x + \left(\mathrm{expIntegral}_1(x)\, x - \mathrm{e}^{-x}\right) x$$

Which simplifies to

$$y_p(x) = x\left(-\mathrm{e}^{-x} + (1+x)\, \mathrm{expIntegral}_1(x)\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\left(x\right) + c_2 x + c_1\right) x \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\left(x\right) + c_2 x + c_1\right) x \tag{1}$$

Verification of solutions

$$y = \left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\left(x\right) + c_2 x + c_1\right) x$$

Verified OK.

11.20.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -\frac{2}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{2}{x}\,dx} \\ &= \frac{1}{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \frac{\mathrm{e}^{-x}}{x^2} \\ \left(\frac{y}{x}\right)'' &= \frac{\mathrm{e}^{-x}}{x^2} \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{x}\right)' = \frac{\mathrm{expIntegral}_1\left(x\right) x - \mathrm{e}^{-x}}{x} + c_1$$

Integrating again gives

$$\left(\frac{y}{x}\right) = \text{expIntegral}_1(x)\, x + \text{expIntegral}_1(x) - e^{-x} + c_1 x + c_2$$

Hence the solution is

$$y = \frac{\text{expIntegral}_1(x)\, x + \text{expIntegral}_1(x) - e^{-x} + c_1 x + c_2}{\frac{1}{x}}$$

Or

$$y = c_1 x^2 + x^2 \,\text{expIntegral}_1(x) + c_2 x + x \;\text{expIntegral}_1(x) - x\, e^{-x}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 + x^2 \,\text{expIntegral}_1(x) + c_2 x + x \;\text{expIntegral}_1(x) - x\, e^{-x} \tag{1}$$

Verification of solutions

$$y = c_1 x^2 + x^2 \,\text{expIntegral}_1(x) + c_2 x + x \;\text{expIntegral}_1(x) - x\, e^{-x}$$

Verified OK.

11.20.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2 y'' - 2xy' + 2y = 0$$

In normal form the ode

$$x^2 y'' - 2xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{2}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{2}{x}dx\right)} dx \\
&= \int e^{2\ln(x)}\, dx \\
&= \int x^2 dx \\
&= \frac{x^3}{3} \qquad (6)
\end{aligned}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{x^2}}{x^4} \\
&= \frac{2}{x^6} \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{x^6} = 0$$

But in terms of τ

$$\frac{2}{x^6} = \frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 + 2 = 0$$

Or

$$9r^2 - 9r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{\frac{1}{3}} + c_2 \tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3\right)^{\frac{1}{3}}$$

$$y_2 = \left(x^3\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^3)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^3)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^3\right)^{\frac{1}{3}} & \left(x^3\right)^{\frac{2}{3}} \\ \frac{x^2}{\left(x^3\right)^{\frac{2}{3}}} & \frac{2x^2}{\left(x^3\right)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^3\right)^{\frac{1}{3}}\right)\left(\frac{2x^2}{\left(x^3\right)^{\frac{1}{3}}}\right) - \left(\left(x^3\right)^{\frac{2}{3}}\right)\left(\frac{x^2}{\left(x^3\right)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(x^3\right)^{\frac{2}{3}} x\,\mathrm{e}^{-x}}{x^4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\left(x^3\right)^{\frac{2}{3}} \mathrm{e}^{-x}}{x^3} dx$$

Hence

$$u_1 = \frac{\left(x^3\right)^{\frac{2}{3}} \operatorname{expIntegral}_1(x)}{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\left(x^3\right)^{\frac{1}{3}} x\,\mathrm{e}^{-x}}{x^4}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\left(x^3\right)^{\frac{1}{3}} \mathrm{e}^{-x}}{x^3} dx$$

Hence

$$u_2 = -\frac{(x^3)^{\frac{1}{3}} (-x \text{ expIntegral}_1(x) + e^{-x})}{x^2}$$

Which simplifies to

$$u_1 = \frac{(x^3)^{\frac{2}{3}} \text{ expIntegral}_1(x)}{x^2}$$

$$u_2 = \frac{(x^3)^{\frac{1}{3}} (x \text{ expIntegral}_1(x) - e^{-x})}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x \text{ expIntegral}_1(x) + (x \text{ expIntegral}_1(x) - e^{-x})\, x$$

Which simplifies to

$$y_p(x) = x(-e^{-x} + (1+x) \text{ expIntegral}_1(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3}\right) + (x(-e^{-x} + (1+x) \text{ expIntegral}_1(x))) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3} + x(-e^{-x} + (1+x) \text{ expIntegral}_1(x)) \tag{1}$$

Verification of solutions

$$y = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3} + x(-e^{-x} + (1+x) \text{ expIntegral}_1(x))$$

Verified OK.

11.20.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = 2, f(x) = x\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2xy' + 2y = 0$$

In normal form the ode

$$x^2y'' - 2xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{2}{x}\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{2}\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{3c\sqrt{2}}{2}
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = \mathrm{e}^{\frac{3\sqrt{2}\,c\tau}{4}}\left(c_1 \cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + i c_2 \sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{2}\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{2}\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 2xy' + 2y = x\,\mathrm{e}^{-x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3\right)^{\frac{1}{3}}$$
$$y_2 = \left(x^3\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^3\right)^{\frac{1}{3}} & \left(x^3\right)^{\frac{2}{3}} \\ \frac{d}{dx}\left(\left(x^3\right)^{\frac{1}{3}}\right) & \frac{d}{dx}\left(\left(x^3\right)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^3\right)^{\frac{1}{3}} & \left(x^3\right)^{\frac{2}{3}} \\ \frac{x^2}{\left(x^3\right)^{\frac{2}{3}}} & \frac{2x^2}{\left(x^3\right)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^3\right)^{\frac{1}{3}}\right)\left(\frac{2x^2}{\left(x^3\right)^{\frac{1}{3}}}\right) - \left(\left(x^3\right)^{\frac{2}{3}}\right)\left(\frac{x^2}{\left(x^3\right)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}}\, x\, e^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}}\, e^{-x}}{x^3} dx$$

Hence

$$u_1 = \frac{(x^3)^{\frac{2}{3}}\, \text{expIntegral}_1\left(x\right)}{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}}\, x\, e^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}}\, e^{-x}}{x^3} dx$$

Hence

$$u_2 = -\frac{(x^3)^{\frac{1}{3}}\left(-x\, \text{expIntegral}_1\left(x\right) + e^{-x}\right)}{x^2}$$

Which simplifies to

$$u_1 = \frac{(x^3)^{\frac{2}{3}}\, \text{expIntegral}_1\left(x\right)}{x^2}$$

$$u_2 = \frac{(x^3)^{\frac{1}{3}}\left(x\, \text{expIntegral}_1\left(x\right) - e^{-x}\right)}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\, \text{expIntegral}_1\left(x\right) + \left(x\, \text{expIntegral}_1\left(x\right) - e^{-x}\right) x$$

Which simplifies to

$$y_p(x) = x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1(x)\right)$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)\right) + \left(x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1(x)\right)\right) \\
&= x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1(x)\right) + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)
\end{aligned}$$

Which simplifies to

$$y = x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1(x)\right) + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$y = x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1(x)\right) + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \quad (1)$$

Verification of solutions

$$y = x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1(x)\right) + x^{\frac{3}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)$$

Verified OK.

11.20.5 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 2xy' + 2y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(-\frac{2}{x}\right)'}{2} - \frac{\left(-\frac{2}{x}\right)^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\ &= \frac{2}{x^2} - \left(\frac{1}{x^2}\right) - \frac{1}{x^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\ &= e^{-\int \frac{-\frac{2}{x}}{2}} \\ &= x \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, x \tag{4}$$

Applying this change of variable to the original ode results in

$$x^2 v''(x) = \mathrm{e}^{-x}$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$v''(x) = \frac{e^{-x}}{x^2}$$

Integrating once gives

$$v'(x) = -\frac{e^{-x}}{x} + \text{expIntegral}_1(x) + c_1$$

Integrating again gives

$$v(x) = x \text{ expIntegral}_1(x) - e^{-x} + \text{expIntegral}_1(x) + c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(x \text{ expIntegral}_1(x) + \text{expIntegral}_1(x) - e^{-x} + c_1 x + c_2\right)(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x$$

Hence (7) becomes

$$y = \left(x \text{ expIntegral}_1(x) + \text{expIntegral}_1(x) - e^{-x} + c_1 x + c_2\right) x$$

Therefore the homogeneous solution y_h is

$$y_h = \left(x \text{ expIntegral}_1(x) + \text{expIntegral}_1(x) - e^{-x} + c_1 x + c_2\right) x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3\right)^{\frac{1}{3}}$$

$$y_2 = \left(x^3\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^3)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^3)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^3)^{\frac{1}{3}} & (x^3)^{\frac{2}{3}} \\ \frac{x^2}{(x^3)^{\frac{2}{3}}} & \frac{2x^2}{(x^3)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^3)^{\frac{1}{3}}\right)\left(\frac{2x^2}{(x^3)^{\frac{1}{3}}}\right) - \left((x^3)^{\frac{2}{3}}\right)\left(\frac{x^2}{(x^3)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}}\, x\, \mathrm{e}^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^3)^{\frac{2}{3}}\, \mathrm{e}^{-x}}{x^3} dx$$

Hence

$$u_1 = \frac{(x^3)^{\frac{2}{3}} \operatorname{expIntegral}_1(x)}{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}}\, x\, e^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^3)^{\frac{1}{3}}\, e^{-x}}{x^3} dx$$

Hence

$$u_2 = -\frac{(x^3)^{\frac{1}{3}} (-x \operatorname{expIntegral}_1(x) + e^{-x})}{x^2}$$

Which simplifies to

$$u_1 = \frac{(x^3)^{\frac{2}{3}} \operatorname{expIntegral}_1(x)}{x^2}$$
$$u_2 = \frac{(x^3)^{\frac{1}{3}} (x \operatorname{expIntegral}_1(x) - e^{-x})}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x \operatorname{expIntegral}_1(x) + \left(x \operatorname{expIntegral}_1(x) - e^{-x}\right) x$$

Which simplifies to

$$y_p(x) = x\left(-e^{-x} + (1 + x) \operatorname{expIntegral}_1(x)\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(x \operatorname{expIntegral}_1(x) + \operatorname{expIntegral}_1(x) - e^{-x} + c_1 x + c_2\right) x\right) \\ &\quad + \left(x\left(-e^{-x} + (1 + x) \operatorname{expIntegral}_1(x)\right)\right) \end{aligned}$$

Which simplifies to

$$y = \left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\,(x) + c_1 x + c_2\right) x + x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\,(x)\right)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\,(x) + c_1 x + c_2\right) x \\ & + x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\,(x)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = \left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\,(x) + c_1 x + c_2\right) x + x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\,(x)\right)$$

Verified OK.

11.20.6 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x, C = 2, f(x) = x\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 2xy' + 2y = 0$$

In normal form the ode

$$x^2y'' - 2xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{2n}{x^2} + \frac{2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{2}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{2}{x}\,dx \\
\ln(u) &= -2\ln(x) + c_1 \\
u &= \mathrm{e}^{-2\ln(x)+c_1} \\
&= \frac{c_1}{x^2}
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{c_1}{x} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{c_1}{x} + c_2\right) x^2 \\
&= (c_2 x - c_1)\,x
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 2xy' + 2y = x\,\mathrm{e}^{-x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= x^2
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3 \mathrm{e}^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\mathrm{e}^{-x}}{x} dx$$

Hence

$$u_1 = \operatorname{expIntegral}_1(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2 e^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{e^{-x}}{x^2} dx$$

Hence

$$u_2 = -\frac{e^{-x}}{x} + \text{expIntegral}_1\left(x\right)$$

Which simplifies to

$$u_1 = \text{expIntegral}_1\left(x\right)$$
$$u_2 = \frac{x\ \text{expIntegral}_1\left(x\right) - e^{-x}}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\ \text{expIntegral}_1\left(x\right) + \left(x\ \text{expIntegral}_1\left(x\right) - e^{-x}\right) x$$

Which simplifies to

$$y_p(x) = x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1\left(x\right)\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{x} + c_2\right) x^2\right) + \left(x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1\left(x\right)\right)\right) \\ &= x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1\left(x\right)\right) + \left(-\frac{c_1}{x} + c_2\right) x^2 \end{aligned}$$

Which simplifies to

$$y = x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1\left(x\right) + c_2 x - c_1\right)$$

Summary
The solution(s) found are the following

$$y = x\left(-e^{-x} + (1+x)\operatorname{expIntegral}_1(x) + c_2 x - c_1\right) \tag{1}$$

Verification of solutions

$$y = x\left(-e^{-x} + (1+x)\operatorname{expIntegral}_1(x) + c_2 x - c_1\right)$$

Verified OK.

11.20.7 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v &= 0 \qquad (1)
\end{aligned}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right)u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x^2 \\
B &= -2x \\
C &= 2 \\
F &= x\,\mathrm{e}^{-x}
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(x^2\right)(0) + (-2x)(-2) + (2)(-2x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-2x^3 v'' + (0)\, v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-2x^3 u'(x) = 0
$$

Which is now solved for u. Integrating both sides gives

$$
\begin{aligned}
u(x) &= \int 0 \,\mathrm{d}x \\
&= c_1
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 \,\mathrm{d}x \\
&= c_1 x + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (-2x)\,(c_1 x + c_2) \\
&= -2x(c_1 x + c_2)
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3 \mathrm{e}^{-x}}{x^4} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{\mathrm{e}^{-x}}{x} dx$$

Hence

$$u_1 = \mathrm{expIntegral}_1(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2 \mathrm{e}^{-x}}{x^4} \, dx$$

Which simplifies to

$$u_2 = \int \frac{\mathrm{e}^{-x}}{x^2} dx$$

Hence

$$u_2 = -\frac{\mathrm{e}^{-x}}{x} + \mathrm{expIntegral}_1(x)$$

Which simplifies to

$$u_1 = \mathrm{expIntegral}_1(x)$$

$$u_2 = \frac{x \ \mathrm{expIntegral}_1(x) - \mathrm{e}^{-x}}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x \ \mathrm{expIntegral}_1(x) + \left(x \ \mathrm{expIntegral}_1(x) - \mathrm{e}^{-x}\right) x$$

Which simplifies to

$$y_p(x) = x\left(-\mathrm{e}^{-x} + (1+x) \, \mathrm{expIntegral}_1(x)\right)$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (-2x(c_1x + c_2)) + \left(x\left(-\mathrm{e}^{-x} + (1+x)\,\mathrm{expIntegral}_1\left(x\right)\right)\right) \\ &= -x\left(-x\ \mathrm{expIntegral}_1\left(x\right) + 2c_1x + \mathrm{e}^{-x} - \mathrm{expIntegral}_1\left(x\right) + 2c_2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -x\left(-x\ \mathrm{expIntegral}_1\left(x\right) + 2c_1x + \mathrm{e}^{-x} - \mathrm{expIntegral}_1\left(x\right) + 2c_2\right) \tag{1}$$

Verification of solutions

$$y = -x\left(-x\ \mathrm{expIntegral}_1\left(x\right) + 2c_1x + \mathrm{e}^{-x} - \mathrm{expIntegral}_1\left(x\right) + 2c_2\right)$$

Verified OK.

11.20.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 304: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\, dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\, dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x) + c_2(x(x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 2xy' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_2x^2 + c_1x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^2 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^2 \\ 1 & 2x \end{vmatrix}$$

Therefore

$$W = (x)(2x) - (x^2)(1)$$

Which simplifies to

$$W = x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^3 \mathrm{e}^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\mathrm{e}^{-x}}{x} dx$$

Hence

$$u_1 = \mathrm{expIntegral}_1(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2 \mathrm{e}^{-x}}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\mathrm{e}^{-x}}{x^2} dx$$

Hence

$$u_2 = -\frac{\mathrm{e}^{-x}}{x} + \mathrm{expIntegral}_1(x)$$

Which simplifies to

$$u_1 = \text{expIntegral}_1(x)$$
$$u_2 = \frac{x\ \text{expIntegral}_1(x) - e^{-x}}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\ \text{expIntegral}_1(x) + \left(x\ \text{expIntegral}_1(x) - e^{-x}\right) x$$

Which simplifies to

$$y_p(x) = x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1(x)\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_2 x^2 + c_1 x\right) + \left(x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1(x)\right)\right) \end{aligned}$$

Which simplifies to

$$y = x(c_2 x + c_1) + x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1(x)\right)$$

Summary

The solution(s) found are the following

$$y = x(c_2 x + c_1) + x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1(x)\right) \tag{1}$$

Verification of solutions

$$y = x(c_2 x + c_1) + x\left(-e^{-x} + (1+x)\,\text{expIntegral}_1(x)\right)$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 1(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y = 0}$$

Given that one solution of the ode is

$$y_1 = \sin(x)$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 0$$

Therefore

$$
\begin{aligned}
y_2(x) &= \sin(x)\left(\int \frac{e^{-\left(\int 0 dx\right)}}{\sin(x)^2} dx\right) \\
y_2(x) &= \sin(x)\int \frac{1}{\sin(x)^2}, dx \\
y_2(x) &= \sin(x)\left(\int \csc(x)^2\, dx\right) \\
y_2(x) &= -\sin(x)\cot(x)
\end{aligned}
$$

Hence the solution is

$$
\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= \sin(x)\, c_1 - c_2 \sin(x)\cot(x)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \sin(x)\, c_1 - c_2 \sin(x)\cot(x) \tag{1}
$$

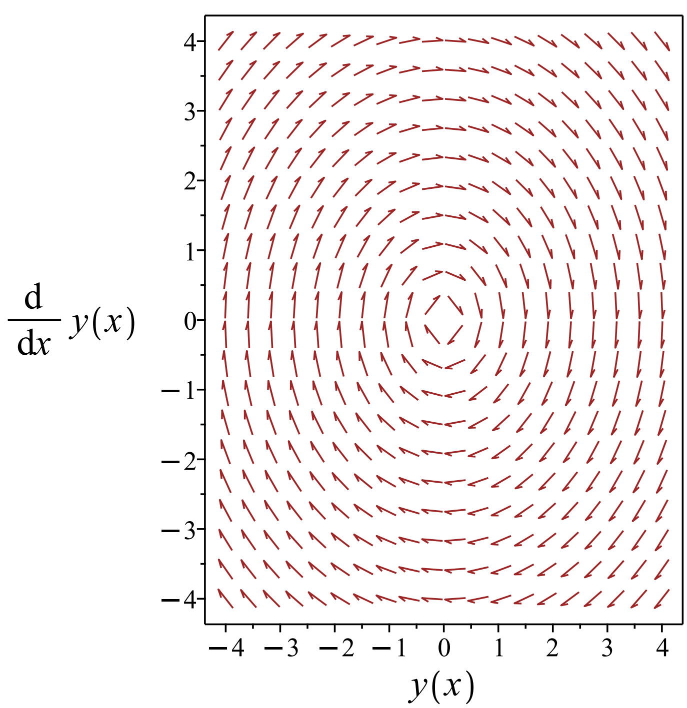

Figure 369: Slope field plot

Verification of solutions

$$y = \sin(x) c_1 - c_2 \sin(x) \cot(x)$$

Verified OK.

12.1.1 Maple step by step solution

Let's solve

$y'' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = \cos(x) c_1 + c_2 \sin(x)$

Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 1(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y = 0}$$

Given that one solution of the ode is

$$y_1 = e^x$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 0$$

Therefore

$$y_2(x) = e^x \left(\int e^{-(\int 0dx)} e^{-2x} dx \right)$$

$$y_2(x) = e^x \int \frac{1}{e^{2x}}, dx$$

$$y_2(x) = e^x \left(\int e^{-2x} dx \right)$$

$$y_2(x) = -\frac{e^x e^{-2x}}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 e^x - \frac{c_2 e^x e^{-2x}}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^x - \frac{c_2 e^x e^{-2x}}{2} \tag{1}$$

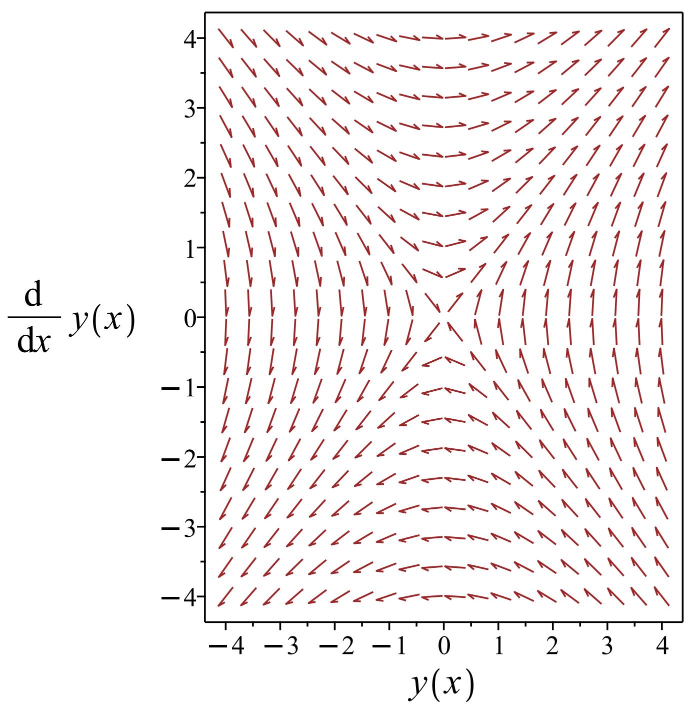

Figure 370: Slope field plot

Verification of solutions

$$y = c_1 e^x - \frac{c_2 e^x e^{-2x}}{2}$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{xy'' + 3y' = 0}$$

Given that one solution of the ode is

$$y_1 = 1$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{3}{x}$$

Therefore

$$y_2(x) = \int e^{-\left(\int \frac{3}{x}dx\right)} dx$$

$$y_2(x) = 1 \int \frac{\frac{1}{x^3}}{1}, dx$$

$$y_2(x) = \int \frac{1}{x^3} dx$$

$$y_2(x) = -\frac{1}{2x^2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 - \frac{c_2}{2x^2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 - \frac{c_2}{2x^2} \tag{1}$$

Verification of solutions

$$y = c_1 - \frac{c_2}{2x^2}$$

Verified OK.

12.3.1 Maple step by step solution

Let's solve

$y''x + 3y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{3y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{3y'}{x} = 0$

- Multiply by denominators of the ODE

$y''x + 3y' = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

- ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

- ◦ Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

- ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

- ◦ Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x + \frac{3\left(\frac{d}{dt}y(t)\right)}{x} = 0$

- Simplify

  $\frac{\frac{d^2}{dt^2}y(t)+2\frac{d}{dt}y(t)}{x} = 0$

- Isolate 2nd derivative

  $\frac{d^2}{dt^2}y(t) = -2\frac{d}{dt}y(t)$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^2}{dt^2}y(t) + 2\frac{d}{dt}y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + 2r = 0$

- Factor the characteristic polynomial

  $r(r+2) = 0$

- Roots of the characteristic polynomial

  $r = (-2, 0)$

- 1st solution of the ODE

  $y_1(t) = e^{-2t}$

- 2nd solution of the ODE

  $y_2(t) = 1$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 e^{-2t} + c_2$

- Change variables back using $t = \ln(x)$

  $y = \frac{c_1}{x^2} + c_2$

Maple trace

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' + xy' - 4y = 0}$$

Given that one solution of the ode is

$$y_1 = x^2$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{1}{x}$$

Therefore

$$y_2(x) = x^2 \left(\int \frac{e^{-\left(\int \frac{1}{x} dx\right)}}{x^4} dx \right)$$

$$y_2(x) = x^2 \int \frac{\frac{1}{x}}{x^4}, dx$$

$$y_2(x) = x^2 \left(\int \frac{1}{x^5} dx \right)$$

$$y_2(x) = -\frac{1}{4x^2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 - \frac{c_2}{4x^2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 - \frac{c_2}{4x^2} \tag{1}$$

Verification of solutions

$$y = c_1 x^2 - \frac{c_2}{4x^2}$$

Verified OK.

12.4.1 Maple step by step solution

Let's solve

$x^2y'' + xy' - 4y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{x} + \frac{4y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} - \frac{4y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'' + xy' - 4y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right)t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{d}{dt}y(t) - 4y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 4y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 4 = 0$

12.5 problem 4

Internal problem ID [6341]
Internal file name [`OUTPUT/5589_Sunday_June_05_2022_03_44_17_PM_96299379/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

`[_Gegenbauer]`

$$\boxed{(-x^2+1)\,y''-2xy'+2y=0}$$

Given that one solution of the ode is

$$y_1 = x$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y''+p(x)\,y'+q(x)\,y=f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{2x}{-x^2+1}$$

Therefore

$$y_2(x) = x\left(\int \frac{\mathrm{e}^{-\left(\int -\frac{2x}{-x^2+1}dx\right)}}{x^2}dx\right)$$

$$y_2(x) = x\int \frac{\mathrm{e}^{-\ln(x-1)-\ln(1+x)}}{x^2}, dx$$

$$y_2(x) = x\left(\int \frac{1}{x^2\left(x^2-1\right)}dx\right)$$

$$y_2(x) = x\left(-\frac{\ln\left(1+x\right)}{2}+\frac{\ln\left(x-1\right)}{2}+\frac{1}{x}\right)$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x)+c_2y_2(x) \\ &= c_1x+c_2x\left(-\frac{\ln\left(1+x\right)}{2}+\frac{\ln\left(x-1\right)}{2}+\frac{1}{x}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1x+c_2x\left(-\frac{\ln\left(1+x\right)}{2}+\frac{\ln\left(x-1\right)}{2}+\frac{1}{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1x+c_2x\left(-\frac{\ln\left(1+x\right)}{2}+\frac{\ln\left(x-1\right)}{2}+\frac{1}{x}\right)$$

Verified OK.

12.5.1 Maple step by step solution

Let's solve

$\left(-x^2+1\right)y''-2xy'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{2xy'}{x^2-1}+\frac{2y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2xy'}{x^2-1} - \frac{2y}{x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{2x}{x^2-1}, P_3(x) = -\frac{2}{x^2-1}\right]$

  - $(1+x) \cdot P_2(x)$ is analytic at $x = -1$

    $\left((1+x) \cdot P_2(x)\right)\bigg|_{x=-1} = 1$

  - $(1+x)^2 \cdot P_3(x)$ is analytic at $x = -1$

    $\left((1+x)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

  - $x = -1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\, y'' + 2xy' - 2y = 0$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^2 - 2u)\left(\frac{d^2}{du^2}y(u)\right) + (2u-2)\left(\frac{d}{du}y(u)\right) - 2y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^{m} \cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right)=\sum_{k =-2+m}^{\infty}a_{k +2-m} \left(k +2-m +r \right) \left(k +1-m +r \right) u^{k +r}$

  Rewrite ODE with series expansions

  $-2a_{0} r^{2} u^{-1+r}+\left(\sum_{k =0}^{\infty}\left(-2a_{k +1} \left(k +1+r \right)^{2}+a_{k} \left(k +r +2\right) \left(k +r -1\right)\right) u^{k +r}\right)=0$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $-2 r^{2}=0$

- Values of r that satisfy the indicial equation

  $r =0$

- Each term in the series must be 0, giving the recursion relation

  $-2 a_{k +1} \left(k +1\right)^{2}+a_{k} \left(k +2\right) \left(k -1\right)=0$

- Recursion relation that defines series solution to ODE

  $a_{k +1}=\frac{a_{k} \left(k +2\right) \left(k -1\right)}{2 \left(k +1\right)^{2}}$

- Recursion relation for $r =0$; series terminates at $k =1$

  $a_{k +1}=\frac{a_{k} \left(k +2\right) \left(k -1\right)}{2 \left(k +1\right)^{2}}$

- Apply recursion relation for $k =0$

  $a_{1}=-a_{0}$

- Terminating series solution of the ODE for $r =0$. Use reduction of order to find the second li

  $y \left(u \right)=a_{0} \cdot \left(-u +1\right)$

- Revert the change of variables $u =1+x$

  $\left[y =-a_{0} x \right]$

12.6 problem 5

Internal problem ID [6342]
Internal file name [OUTPUT/5590_Sunday_June_05_2022_03_44_19_PM_36590290/index.tex]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right)y = 0}$$

Given that one solution of the ode is

$$y_1 = \frac{\sin(x)}{\sqrt{x}}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{1}{x}$$

Therefore

$$y_2(x) = \frac{\sin(x)\left(\int \frac{e^{-\left(\int \frac{1}{x}dx\right)}x}{\sin(x)^2}dx\right)}{\sqrt{x}}$$

$$y_2(x) = \frac{\sin(x)}{\sqrt{x}}\int \frac{\frac{1}{x}}{\frac{\sin(x)^2}{x}}, dx$$

$$y_2(x) = \frac{\sin(x)\left(\int \csc(x)^2\, dx\right)}{\sqrt{x}}$$

$$y_2(x) = -\frac{\sin(x)\cot(x)}{\sqrt{x}}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{\sin(x)\, c_1}{\sqrt{x}} - \frac{c_2 \sin(x)\cot(x)}{\sqrt{x}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sin(x)\, c_1}{\sqrt{x}} - \frac{c_2 \sin(x)\cot(x)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = \frac{\sin(x)\, c_1}{\sqrt{x}} - \frac{c_2 \sin(x)\cot(x)}{\sqrt{x}}$$

Verified OK.

12.6.1 Maple step by step solution

Let's solve

$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right)y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(4x^2-1)y}{4x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(4x^2-1)y}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-1}{4x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -\frac{1}{4}$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2y'' + 4xy' + (4x^2-1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

Rewrite ODE with series expansions

$a_0(1+2r)(-1+2r)x^r + a_1(3+2r)(1+2r)x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)(2k+2r-1)+4a_{k-}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)(-1+2r)=0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)(1+2r)=0$

- Solve for the dependent coefficient(s)

  $a_1=0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2+8kr+4r^2-1)+4a_{k-2}=0$

- Shift index using $k->k+2$

  $a_{k+2}\left(4(k+2)^2+8(k+2)r+4r^2-1\right)+4a_k=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{4a_k}{4k^2+8kr+4r^2+16k+16r+15}$

- Recursion relation for $r=-\frac{1}{2}$

  $a_{k+2}=-\frac{4a_k}{4k^2+12k+8}$

- Solution for $r=-\frac{1}{2}$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2}=-\frac{4a_k}{4k^2+12k+8}, a_1=0\right]$

- Recursion relation for $r=\frac{1}{2}$

  $a_{k+2}=-\frac{4a_k}{4k^2+20k+24}$

- Solution for $r=\frac{1}{2}$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2}=-\frac{4a_k}{4k^2+20k+24}, a_1=0\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2}=-\frac{4a_k}{4k^2+12k+8}, a_1=0, b_{k+2}=-\frac{4b_k}{4k^2+20k+24}, b_1=0\right]$

12.8 problem 6(b)

Internal problem ID [6344]
Internal file name [`OUTPUT/5592_Sunday_June_05_2022_03_44_21_PM_71927023/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 6(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + 2xy' - 2y = 0}$$

Given that one solution of the ode is

$$y_1 = x$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{2}{x}$$

Therefore

$$y_2(x) = x\left(\int \frac{e^{-\left(\int \frac{2}{x}dx\right)}}{x^2}dx\right)$$

$$y_2(x) = x\int \frac{\frac{1}{x^2}}{x^2}, dx$$

$$y_2(x) = x\left(\int \frac{1}{x^4}dx\right)$$

$$y_2(x) = -\frac{1}{3x^2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x - \frac{c_2}{3x^2} \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 x - \frac{c_2}{3x^2} \tag{1}$$

Verification of solutions

$$y = c_1 x - \frac{c_2}{3x^2}$$

Verified OK.

12.8.1 Maple step by step solution

Let's solve

$x^2y'' + 2xy' - 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y'}{x} + \frac{2y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{x} - \frac{2y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2 y'' + 2xy' - 2y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2 \left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + 2\frac{d}{dt}y(t) - 2y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) + \frac{d}{dt}y(t) - 2y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 + r - 2 = 0$

- Factor the characteristic polynomial

  $(r+2)(r-1) = 0$

- Roots of the characteristic polynomial

  $r = (-2, 1)$

- 1st solution of the ODE

  $y_1(t) = e^{-2t}$

- 2nd solution of the ODE

  $y_2(t) = e^{t}$

- General solution of the ODE

$y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 e^{-2t} + c_2 e^{t}$

- Change variables back using $t = \ln(x)$

  $y = \frac{c_1}{x^2} + c_2 x$

- Simplify

  $y = \frac{c_1}{x^2} + c_2 x$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - x(x+2)\,y' + (x+2)\,y = 0}$$

Given that one solution of the ode is

$$y_1 = x$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-x^2 - 2x}{x^2}$$

Therefore

$$y_2(x) = x\left(\int \frac{e^{-\left(\int \frac{-x^2-2x}{x^2}dx\right)}}{x^2}dx\right)$$

$$y_2(x) = x\int \frac{e^{x+2\ln(x)}}{x^2}, dx$$

$$y_2(x) = \left(\int e^x dx\right)x$$

$$y_2(x) = x\,e^x$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= c_1x + c_2x\,e^x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1x + c_2x\,e^x \tag{1}$$

Verification of solutions

$$y = c_1x + c_2x\,e^x$$

Verified OK.

12.9.1 Maple step by step solution

Let's solve

$x^2y'' + (-x^2 - 2x)\,y' + (x + 2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x+2)y}{x^2} + \frac{(x+2)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x+2)y'}{x} + \frac{(x+2)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{x+2}{x}, P_3(x) = \frac{x+2}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\Big|_{x=0} = -2$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 2$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$x^2 y'' - x(x+2)\, y' + (x+2)\, y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

  - Shift index using $k- >k - m$

    $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

  - Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

    $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

  - Shift index using $k- >k + 1 - m$

    $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

  - Convert $x^2 \cdot y''$ to series expansion

    $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

$$a_0(-1+r)(-2+r)x^r + \left(\sum_{k=1}^{\infty} (a_k(k+r-1)(k+r-2) - a_{k-1}(k+r-2))\, x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$
- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)(a_k(k+r-1) - a_{k-1}) = 0$
- Shift index using $k- >k+1$

  $(k+r-1)(a_{k+1}(k+r) - a_k) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+r}$
- Recursion relation for $r = 1$

  $a_{k+1} = \frac{a_k}{k+1}$
- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = \frac{a_k}{k+1}\right]$
- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+2}$
- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = \frac{a_k}{k+2}\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+1} = \frac{a_k}{k+1}, b_{k+1} = \frac{b_k}{k+2}\right]$

Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - xf(x)\, y' + f(x)\, y = 0}$$

12.10.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$y'' - xf(x)\, y' + f(x)\, y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -f(x)\, x \\ q(x) &= f(x) \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - nf(x) + f(x) = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{2}{x} - f(x)\,x\right) v'(x) = 0$$
$$v''(x) + \left(\frac{2}{x} - f(x)\,x\right) v'(x) = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} - f(x)\,x\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u(f(x)\,x^2 - 2)}{x} \end{aligned}$$

Where $f(x) = \frac{f(x)x^2-2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= \frac{f(x)\,x^2 - 2}{x}\,dx \\ \int \frac{1}{u}\,du &= \int \frac{f(x)\,x^2 - 2}{x}\,dx \\ \ln(u) &= \int \frac{f(x)\,x^2 - 2}{x}dx + c_1 \\ u &= e^{\int \frac{f(x)x^2-2}{x}dx + c_1} \\ &= c_1 e^{\int \frac{f(x)x^2-2}{x}dx} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \int c_1 \mathrm{e}^{\int \frac{f(x)x^2-2}{x} dx} dx + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(\int c_1 \mathrm{e}^{\int \frac{f(x)x^2-2}{x} dx} dx + c_2\right) x \\
&= \left(c_1 \left(\int \mathrm{e}^{\int \frac{f(x)x^2-2}{x} dx} dx\right) + c_2\right) x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(\int c_1 \mathrm{e}^{\int \frac{f(x)x^2-2}{x} dx} dx + c_2\right) x \tag{1}
$$

Verification of solutions

$$
y = \left(\int c_1 \mathrm{e}^{\int \frac{f(x)x^2-2}{x} dx} dx + c_2\right) x
$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Second-Order Linear Equations. Section 2.4. THE USE OF A KNOWN SOLUTION TO FIND ANOTHER. Page 74
Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{xy'' - (1+2x)\, y' + (1+x)\, y = 0}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{x}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-1-2x}{x}$$

Therefore

$$y_2(x) = \mathrm{e}^{x} \left(\int \mathrm{e}^{-\left(\int \frac{-1-2x}{x}dx\right)} \mathrm{e}^{-2x} dx\right)$$

$$y_2(x) = \mathrm{e}^{x} \int \frac{\mathrm{e}^{2x+\ln(x)}}{\mathrm{e}^{2x}}, dx$$

$$y_2(x) = \mathrm{e}^{x} \left(\int x dx\right)$$

$$y_2(x) = \frac{x^2 \mathrm{e}^{x}}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \mathrm{e}^{x} + \frac{c_2 x^2 \mathrm{e}^{x}}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{x} + \frac{c_2 x^2 \mathrm{e}^{x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{x} + \frac{c_2 x^2 \mathrm{e}^{x}}{2}$$

Verified OK.

12.11.1 Maple step by step solution

Let's solve

$y''x + (-1-2x)\,y' + (1+x)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(1+x)y}{x} + \frac{(1+2x)y'}{x}$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 1.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 3y'' + 2y' = 0}$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^x + e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^x$$
$$y_3 = e^{2x}$$

Summary
The solution(s) found are the following

$$y = c_1 + c_2 e^x + e^{2x} c_3 \tag{1}$$

Verification of solutions

$$y = c_1 + c_2 e^x + e^{2x} c_3$$

Verified OK.

13.1.1 Maple step by step solution

Let's solve

$y''' - 3y'' + 2y' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 3y_3(x) - 2y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 3y_3(x) - 2y_2(x)]$

- Define vector

  $$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 3 \end{bmatrix} \cdot \overrightarrow{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = c_2 e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + e^{2x} c_3 \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} c_1 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = c_2 e^{x} + \frac{e^{2x} c_3}{4} + c_1$$

13.2 problem 2

Internal problem ID [6349]
Internal file name [`OUTPUT/5597_Sunday_June_05_2022_03_44_29_PM_35554333/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 2.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 3y'' + 4y' - 2y = 0}$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 4\lambda - 2 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 1 - i$$
$$\lambda_3 = 1 + i$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^x + e^{(1+i)x} c_2 + e^{(1-i)x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = e^{(1+i)x}$$
$$y_3 = e^{(1-i)x}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x + e^{(1+i)x} c_2 + e^{(1-i)x} c_3 \tag{1}$$

Verification of solutions

$$y = c_1 e^x + e^{(1+i)x} c_2 + e^{(1-i)x} c_3$$

Verified OK.

13.2.1 Maple step by step solution

Let's solve

$y''' - 3y'' + 4y' - 2y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 3y_3(x) - 4y_2(x) + 2y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 3y_3(x) - 4y_2(x) + 2y_1(x)]$

- Define vector

  $\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$

- System to solve

$$\overrightarrow{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & -4 & 3 \end{bmatrix} \cdot \overrightarrow{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 2 & -4 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[1 - \mathrm{I}, \begin{bmatrix} \frac{\mathrm{I}}{2} \\ \frac{1}{2} + \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[1 + \mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{2} \\ \frac{1}{2} - \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[1 - \mathrm{I}, \begin{bmatrix} \frac{\mathrm{I}}{2} \\ \frac{1}{2} + \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{(1-I)x} \cdot \begin{bmatrix} \frac{I}{2} \\ \frac{1}{2}+\frac{I}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{x} \cdot (\cos(x) - I\sin(x)) \cdot \begin{bmatrix} \frac{I}{2} \\ \frac{1}{2}+\frac{I}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{x} \cdot \begin{bmatrix} \frac{I}{2}(\cos(x) - I\sin(x)) \\ \left(\frac{1}{2}+\frac{I}{2}\right)(\cos(x) - I\sin(x)) \\ \cos(x) - I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(x) = e^{x} \cdot \begin{bmatrix} \frac{\sin(x)}{2} \\ \frac{\sin(x)}{2}+\frac{\cos(x)}{2} \\ \cos(x) \end{bmatrix}, \vec{y}_3(x) = e^{x} \cdot \begin{bmatrix} \frac{\cos(x)}{2} \\ \frac{\cos(x)}{2}-\frac{\sin(x)}{2} \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2(x) + c_3\vec{y}_3(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_2 e^{x} \cdot \begin{bmatrix} \frac{\sin(x)}{2} \\ \frac{\sin(x)}{2}+\frac{\cos(x)}{2} \\ \cos(x) \end{bmatrix} + c_3 e^{x} \cdot \begin{bmatrix} \frac{\cos(x)}{2} \\ \frac{\cos(x)}{2}-\frac{\sin(x)}{2} \\ -\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{e^{x}(c_2\sin(x) + c_3\cos(x) + 2c_1)}{2}$$

Maple trace

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 5.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' + 3y'' + 3y' + y = 0}$$

The characteristic equation is

$$\lambda^3 + 3\lambda^2 + 3\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = -1$$
$$\lambda_2 = -1$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + x\,e^{-x} c_2 + c_3 x^2 e^{-x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = x\,e^{-x}$$
$$y_3 = x^2 e^{-x}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + x\, e^{-x} c_2 + c_3 x^2 e^{-x} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + x\, e^{-x} c_2 + c_3 x^2 e^{-x}$$

Verified OK.

13.7.1 Maple step by step solution

Let's solve

$y'''' - y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - ○ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ○ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ○ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ○ Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - ○ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 1 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = e^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -c_3\sin(x) - c_4\cos(x) \\ -c_3\cos(x) + c_4\sin(x) \\ c_3\sin(x) + c_4\cos(x) \\ c_3\cos(x) - c_4\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} - c_4\cos(x) - c_3\sin(x)$$

Maple trace

Verification of solutions

$$y = c_1 e^{-ix} + e^{-2ix} c_2 + e^{2ix} c_3 + e^{ix} c_4$$

Verified OK.

13.8.1 Maple step by step solution

Let's solve

$y'''' + 5y'' + 4y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - ○ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ○ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ○ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ○ Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - ○ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -5y_3(x) - 4y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -5y_3(x) - 4y_1(x)]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -4 & 0 & -5 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -4 & 0 & -5 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}, \begin{bmatrix} \frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ -\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2\,\mathrm{I}, \begin{bmatrix} -\frac{\mathrm{I}}{8} \\ -\frac{1}{4} \\ \frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-2 I x} \cdot \begin{bmatrix} -\frac{I}{8} \\ -\frac{1}{4} \\ \frac{I}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(2x) - I\sin(2x)) \cdot \begin{bmatrix} -\frac{I}{8} \\ -\frac{1}{4} \\ \frac{I}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\frac{I}{8}(\cos(2x) - I\sin(2x)) \\ -\frac{\cos(2x)}{4} + \frac{I\sin(2x)}{4} \\ \frac{I}{2}(\cos(2x) - I\sin(2x)) \\ \cos(2x) - I\sin(2x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_1(x) = \begin{bmatrix} -\frac{\sin(2x)}{8} \\ -\frac{\cos(2x)}{4} \\ \frac{\sin(2x)}{2} \\ \cos(2x) \end{bmatrix}, \vec{y}_2(x) = \begin{bmatrix} -\frac{\cos(2x)}{8} \\ \frac{\sin(2x)}{4} \\ \frac{\cos(2x)}{2} \\ -\sin(2x) \end{bmatrix}\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$e^{-\mathrm{I}x} \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(x) - \mathrm{I}\sin(x)) \cdot \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = \begin{bmatrix} -c_4\cos(x) - c_3\sin(x) - \frac{c_2\cos(2x)}{8} - \frac{\sin(2x)c_1}{8} \\ -c_3\cos(x) + c_4\sin(x) + \frac{c_2\sin(2x)}{4} - \frac{c_1\cos(2x)}{4} \\ c_3\sin(x) + c_4\cos(x) + \frac{c_2\cos(2x)}{2} + \frac{\sin(2x)c_1}{2} \\ c_3\cos(x) - c_4\sin(x) - c_2\sin(2x) + c_1\cos(2x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = -c_4\cos(x) - c_3\sin(x) - \frac{c_2\cos(2x)}{8} - \frac{\sin(2x)c_1}{8}$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 10.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + 2a^2y'' + ya^4 = 0}$$

The characteristic equation is

$$a^4 + 2a^2\lambda^2 + \lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = ia$$
$$\lambda_2 = -ia$$
$$\lambda_3 = ia$$
$$\lambda_4 = -ia$$

Therefore the homogeneous solution is

$$y_h(x) = \mathrm{e}^{-iax} c_1 + x\,\mathrm{e}^{-iax} c_2 + \mathrm{e}^{iax} c_3 + x\,\mathrm{e}^{iax} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \mathrm{e}^{-iax}$$
$$y_2 = x\,\mathrm{e}^{-iax}$$
$$y_3 = \mathrm{e}^{iax}$$
$$y_4 = x\,\mathrm{e}^{iax}$$

Summary

The solution(s) found are the following

$$y = e^{-iax}c_1 + x\,e^{-iax}c_2 + e^{iax}c_3 + x\,e^{iax}c_4 \tag{1}$$

Verification of solutions

$$y = e^{-iax}c_1 + x\,e^{-iax}c_2 + e^{iax}c_3 + x\,e^{iax}c_4$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 11.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y'''' + 2y''' + 2y'' + 2y' + y = 0}$$

The characteristic equation is

$$\lambda^4 + 2\lambda^3 + 2\lambda^2 + 2\lambda + 1 = 0$$

The roots of the above equation are

$$\lambda_1 = i$$
$$\lambda_2 = -i$$
$$\lambda_3 = -1$$
$$\lambda_4 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 \mathrm{e}^{-x} + x\,\mathrm{e}^{-x} c_2 + \mathrm{e}^{-ix} c_3 + \mathrm{e}^{ix} c_4$$

The fundamental set of solutions for the homogeneous solution are the following

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x} \\
y_2 &= x\,\mathrm{e}^{-x} \\
y_3 &= \mathrm{e}^{-ix} \\
y_4 &= \mathrm{e}^{ix}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{-x} + x\,\mathrm{e}^{-x}c_2 + \mathrm{e}^{-ix}c_3 + \mathrm{e}^{ix}c_4 \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{-x} + x\,\mathrm{e}^{-x}c_2 + \mathrm{e}^{-ix}c_3 + \mathrm{e}^{ix}c_4$$

Verified OK.

13.11.1 Maple step by step solution

Let's solve

$y'''' + 2y''' + 2y'' + 2y' + y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$
  - Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -2y_4(x) - 2y_3(x) - 2y_2(x) - y_1(x)$

  Convert linear ODE into a system of first order ODEs

$$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -2y_4(x) - 2y_3(x) - 2y_2(x) - y_1(x)]$$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -2 & -2 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -2 & -2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[-1, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} \mathrm{I} \\ -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[\begin{array}{c}-1, \left[\begin{array}{c}-1 \\ 1 \\ -1 \\ 1\end{array}\right]\end{array}\right]$$

- First solution from eigenvalue -1

$$\overrightarrow{y}_1(x) = \mathrm{e}^{-x} \cdot \left[\begin{array}{c}-1 \\ 1 \\ -1 \\ 1\end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = -1$ is the eigenvalue, a

$$\overrightarrow{y}_2(x) = \mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_2(x)$ into the homogeneous system

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \left(\mathrm{e}^{\lambda x} A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda\,\mathrm{e}^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + \mathrm{e}^{\lambda x}\overrightarrow{v} = \mathrm{e}^{\lambda x}\left(\lambda x\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_2(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -1

$$\left(\left[\begin{array}{cccc}0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -1 & -2 & -2 & -2\end{array}\right] - (-1) \cdot \left[\begin{array}{cccc}1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1\end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c}-1 \\ 1 \\ -1 \\ 1\end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -1

$$\vec{y}_2(x) = e^{-x} \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-I, \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix} \right]$$

- Solution from eigenpair

$$e^{-Ix} \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$(\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -I \\ -1 \\ I \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ -\cos(x) + \mathrm{I}\sin(x) \\ \mathrm{I}(\cos(x) - \mathrm{I}\sin(x)) \\ \cos(x) - \mathrm{I}\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = \begin{bmatrix} -\sin(x) \\ -\cos(x) \\ \sin(x) \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = \begin{bmatrix} -\cos(x) \\ \sin(x) \\ \cos(x) \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^{-x} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{-x} \cdot \left(x \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right) + \begin{bmatrix} -c_3\sin(x) - c_4\cos(x) \\ -c_3\cos(x) + c_4\sin(x) \\ c_3\sin(x) + c_4\cos(x) \\ c_3\cos(x) - c_4\sin(x) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = ((-1 - x)\, c_2 - c_1)\, \mathrm{e}^{-x} - c_3 \sin(x) - c_4 \cos(x)$$

Verification of solutions

$$y = c_1 e^x + c_2 x\, e^x + e^{(-2+i)x} c_3 + e^{(-2-i)x} c_4$$

Verified OK.

13.12.1 Maple step by step solution

Let's solve

$y'''' + 2y''' - 2y'' - 6y' + 5y = 0$

- Highest derivative means the order of the ODE is 4

  y''''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Define new variable $y_4(x)$

    $y_4(x) = y'''$

  ◦ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = -2y_4(x) + 2y_3(x) + 6y_2(x) - 5y_1(x)$

  Convert linear ODE into a system of first order ODEs

$[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = -2y_4(x) + 2y_3(x) + 6y_2(x) - 5y_1(x)]$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -5 & 6 & 2 & -2 \end{array}\right] \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \left[\begin{array}{cccc} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -5 & 6 & 2 & -2 \end{array}\right]$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \\ 1 \end{array}\right]\right], \left[1, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[-2-\mathrm{I}, \left[\begin{array}{c} -\frac{2}{125}+\frac{11\,\mathrm{I}}{125} \\ \frac{3}{25}-\frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5}+\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right], \left[-2+\mathrm{I}, \left[\begin{array}{c} -\frac{2}{125}-\frac{11\,\mathrm{I}}{125} \\ \frac{3}{25}+\frac{4\,\mathrm{I}}{25} \\ -\frac{2}{5}-\frac{\mathrm{I}}{5} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[\begin{array}{c}1, \left[\begin{array}{c}1 \\ 1 \\ 1 \\ 1\end{array}\right]\end{array}\right]$$

- First solution from eigenvalue 1

$$\vec{y}_1(x) = e^x \cdot \left[\begin{array}{c}1 \\ 1 \\ 1 \\ 1\end{array}\right]$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, an

$$\vec{y}_2(x) = e^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = \left(e^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = e^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{y}_2(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\left[\begin{array}{cccc}0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ -5 & 6 & 2 & -2\end{array}\right] - 1 \cdot \left[\begin{array}{cccc}1 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1\end{array}\right]\right) \cdot \vec{p} = \left[\begin{array}{c}1 \\ 1 \\ 1 \\ 1\end{array}\right]$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 1

$$\vec{y}_2(x) = e^x \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right)$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-2 - I, \begin{bmatrix} -\frac{2}{125} + \frac{11\,I}{125} \\ \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{bmatrix} \right]$$

- Solution from eigenpair

$$e^{(-2-I)x} \cdot \begin{bmatrix} -\frac{2}{125} + \frac{11\,I}{125} \\ \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{-2x} \cdot (\cos(x) - I\sin(x)) \cdot \begin{bmatrix} -\frac{2}{125} + \frac{11\,I}{125} \\ \frac{3}{25} - \frac{4\,I}{25} \\ -\frac{2}{5} + \frac{I}{5} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^{-2x} \cdot \begin{bmatrix} \left(-\frac{2}{125}+\frac{11 I}{125}\right)\left(\cos(x)-I\sin(x)\right) \\ \left(\frac{3}{25}-\frac{4 I}{25}\right)\left(\cos(x)-I\sin(x)\right) \\ \left(-\frac{2}{5}+\frac{I}{5}\right)\left(\cos(x)-I\sin(x)\right) \\ \cos(x)-I\sin(x) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_3(x) = e^{-2x} \cdot \begin{bmatrix} -\frac{2\cos(x)}{125}+\frac{11\sin(x)}{125} \\ \frac{3\cos(x)}{25}-\frac{4\sin(x)}{25} \\ -\frac{2\cos(x)}{5}+\frac{\sin(x)}{5} \\ \cos(x) \end{bmatrix}, \vec{y}_4(x) = e^{-2x} \cdot \begin{bmatrix} \frac{2\sin(x)}{125}+\frac{11\cos(x)}{125} \\ -\frac{3\sin(x)}{25}-\frac{4\cos(x)}{25} \\ \frac{2\sin(x)}{5}+\frac{\cos(x)}{5} \\ -\sin(x) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1(x) + c_2\vec{y}_2(x) + c_3\vec{y}_3(x) + c_4\vec{y}_4(x)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + c_2 e^{x} \cdot \left(x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right) + e^{-2x} c_3 \cdot \begin{bmatrix} -\frac{2\cos(x)}{125}+\frac{11\sin(x)}{125} \\ \frac{3\cos(x)}{25}-\frac{4\sin(x)}{25} \\ -\frac{2\cos(x)}{5}+\frac{\sin(x)}{5} \\ \cos(x) \end{bmatrix} + e^{-2x} c_4 \cdot$$

- First component of the vector is the solution to the ODE

$$y = \left(\left(c_2(x-1)+c_1\right)e^{3x} + \frac{(-2c_3+11c_4)\cos(x)}{125} + \frac{11\left(c_3+\frac{2c_4}{11}\right)\sin(x)}{125}\right)e^{-2x}$$

ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - 6y'' + 11y' - 6y = 0}$$

The characteristic equation is

$$\lambda^3 - 6\lambda^2 + 11\lambda - 6 = 0$$

The roots of the above equation are

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = 3$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^x + c_2 e^{2x} + c_3 e^{3x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^x$$
$$y_2 = e^{2x}$$
$$y_3 = e^{3x}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x + c_2 e^{2x} + c_3 e^{3x} \tag{1}$$

Verification of solutions

$$y = c_1 e^x + c_2 e^{2x} + c_3 e^{3x}$$

Verified OK.

13.13.1 Maple step by step solution

Let's solve

$y''' - 6y'' + 11y' - 6y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

□ Convert linear ODE into a system of first order ODEs

  ◦ Define new variable $y_1(x)$

    $y_1(x) = y$

  ◦ Define new variable $y_2(x)$

    $y_2(x) = y'$

  ◦ Define new variable $y_3(x)$

    $y_3(x) = y''$

  ◦ Isolate for $y_3'(x)$ using original ODE

    $y_3'(x) = 6y_3(x) - 11y_2(x) + 6y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_3'(x) = 6y_3(x) - 11y_2(x) + 6y_1(x)]$

- Define vector

  $$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 6 & -11 & 6 \end{bmatrix}$$

- Rewrite the system as

$$\vec{y}'(x) = A \cdot \vec{y}(x)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = e^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^{3x} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_2 e^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + c_3 e^{3x} \cdot \begin{bmatrix} \frac{1}{9} \\ \frac{1}{3} \\ 1 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = c_1 e^{x} + \frac{c_2 e^{2x}}{4} + \frac{c_3 e^{3x}}{9}$$

Maple gives the following as the ode type

```
[[_high_order, _missing_x]]
```

$$\boxed{y^{(5)}-6y''''-8y'''+48y''+16y'-96y=0}$$

The characteristic equation is

$$\lambda^5-6\lambda^4-8\lambda^3+48\lambda^2+16\lambda-96=0$$

The roots of the above equation are

$$\lambda_1=6$$
$$\lambda_2=2$$
$$\lambda_3=2$$
$$\lambda_4=-2$$
$$\lambda_5=-2$$

Therefore the homogeneous solution is

$$y_h(x)=c_1\mathrm{e}^{-2x}+c_2x\,\mathrm{e}^{-2x}+\mathrm{e}^{2x}c_3+x\,\mathrm{e}^{2x}c_4+\mathrm{e}^{6x}c_5$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-2x}$$
$$y_2 = x\,e^{-2x}$$
$$y_3 = e^{2x}$$
$$y_4 = e^{2x}x$$
$$y_5 = e^{6x}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} + c_2 x\,e^{-2x} + e^{2x}c_3 + x\,e^{2x}c_4 + e^{6x}c_5 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-2x} + c_2 x\,e^{-2x} + e^{2x}c_3 + x\,e^{2x}c_4 + e^{6x}c_5$$

Verified OK.

13.15.1 Maple step by step solution

Let's solve

$y^{(5)} - 6y'''' - 8y''' + 48y'' + 16y' - 96y = 0$

- Highest derivative means the order of the ODE is 5

  $y^{(5)}$

□ Convert linear ODE into a system of first order ODEs

  - Define new variable $y_1(x)$

    $y_1(x) = y$

  - Define new variable $y_2(x)$

    $y_2(x) = y'$

  - Define new variable $y_3(x)$

    $y_3(x) = y''$

  - Define new variable $y_4(x)$

    $y_4(x) = y'''$

  - Define new variable $y_5(x)$

    $y_5(x) = y''''$

- Isolate for $y_5'(x)$ using original ODE

  $y_5'(x) = 6y_5(x) + 8y_4(x) - 48y_3(x) - 16y_2(x) + 96y_1(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_5(x) = y_4'(x), y_5'(x) = 6y_5(x) + 8y_4(x) - 48y_3(x)$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \\ y_5(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 96 & -16 & -48 & 8 & 6 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 96 & -16 & -48 & 8 & 6 \end{bmatrix}$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \left[\begin{array}{c} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right], \left[-2, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[2, \left[\begin{array}{c} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} 0 \\ 0 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[6, \left[\begin{array}{c} \frac{1}{1296} \\ \frac{1}{216} \\ \frac{1}{36} \\ \frac{1}{6} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-2, \left[\begin{array}{c} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right]$$

- First solution from eigenvalue -2

$$\vec{y}_1(x) = e^{-2x} \cdot \left[\begin{array}{c} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = -2$ is the eigenvalue, a

$$\vec{y}_2(x) = e^{\lambda x}\left(x\vec{v} + \vec{p}\right)$$

- Note that the x multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\vec{y}_2(x)$ into the homogeneous system

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = \left(e^{\lambda x}A\right) \cdot \left(x\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda e^{\lambda x}\left(x\vec{v} + \vec{p}\right) + e^{\lambda x}\vec{v} = e^{\lambda x}\left(\lambda x\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$

- Condition $\vec{p}$ must meet for $\vec{y}_2(x)$ to be a solution to the homogeneous system

$(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue -2

$$\left(\begin{bmatrix} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 96 & -16 & -48 & 8 & 6 \end{bmatrix} - (-2) \cdot \begin{bmatrix} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} \frac{1}{32} \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -2

$$\vec{y}_2(x) = \mathrm{e}^{-2x} \cdot \left(x \cdot \begin{bmatrix} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} \frac{1}{32} \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right)$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[2, \begin{bmatrix} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 2

$$\overrightarrow{y}_3(x) = e^{2x} \cdot \left[\begin{array}{c} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 2$ is the eigenvalue, an

$$\overrightarrow{y}_4(x) = e^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Note that the x multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obt
- Substitute $\overrightarrow{y}_4(x)$ into the homogeneous system

$$\lambda e^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda x}\overrightarrow{v} = \left(e^{\lambda x} A\right) \cdot \left(x\overrightarrow{v} + \overrightarrow{p}\right)$$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

$$\lambda e^{\lambda x}\left(x\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda x}\overrightarrow{v} = e^{\lambda x}\left(\lambda x\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$$

- Simplify equation

$$\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{y}_4(x)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 2

$$\left(\left[\begin{array}{ccccc} 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \\ 96 & -16 & -48 & 8 & 6 \end{array}\right] - 2 \cdot \left[\begin{array}{ccccc} 1 & 0 & 0 & 0 & 0 \\ 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 1 \end{array}\right]\right) \cdot \overrightarrow{p} = \left[\begin{array}{c} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\vec{p} = \begin{bmatrix} -\frac{1}{32} \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 2

$$\vec{y}_4(x) = e^{2x} \cdot \left(x \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} -\frac{1}{32} \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right)$$

- Consider eigenpair

$$\begin{bmatrix} 6, & \begin{bmatrix} \frac{1}{1296} \\ \frac{1}{216} \\ \frac{1}{36} \\ \frac{1}{6} \\ 1 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_5 = e^{6x} \cdot \begin{bmatrix} \frac{1}{1296} \\ \frac{1}{216} \\ \frac{1}{36} \\ \frac{1}{6} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1(x) + c_2 \vec{y}_2(x) + c_3 \vec{y}_3(x) + c_4 \vec{y}_4(x) + c_5 \vec{y}_5$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 e^{-2x} \cdot \begin{bmatrix} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + c_2 e^{-2x} \cdot \left(x \cdot \begin{bmatrix} \frac{1}{16} \\ -\frac{1}{8} \\ \frac{1}{4} \\ -\frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} \frac{1}{32} \\ 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \right) + e^{2x} c_3 \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + e^{2x} c_4 \cdot \left(x \cdot \begin{bmatrix} \frac{1}{16} \\ \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right.$$

- First component of the vector is the solution to the ODE

$$y = \frac{(c_2(1+2x)+2c_1)e^{-2x}}{32} + \frac{((2x-1)c_4+2c_3)e^{2x}}{32} + \frac{e^{6x}c_5}{1296}$$

Problem number: 16(a).
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _quadrature]]
```

$$\boxed{y'''' = 0}$$

The characteristic equation is

$$\lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_4x^3 + c_3x^2 + c_2x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$
$$y_4 = x^3$$

Summary
The solution(s) found are the following

$$y = c_4 x^3 + c_3 x^2 + c_2 x + c_1 \tag{1}$$

Verification of solutions

$$y = c_4 x^3 + c_3 x^2 + c_2 x + c_1$$

Verified OK.

13.16.1 Maple step by step solution

Let's solve

$y'''' = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- □ Convert linear ODE into a system of first order ODEs
  - ○ Define new variable $y_1(x)$

    $y_1(x) = y$
  - ○ Define new variable $y_2(x)$

    $y_2(x) = y'$
  - ○ Define new variable $y_3(x)$

    $y_3(x) = y''$
  - ○ Define new variable $y_4(x)$

    $y_4(x) = y'''$
  - ○ Isolate for $y_4'(x)$ using original ODE

    $y_4'(x) = 0$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x), y_3(x) = y_2'(x), y_4(x) = y_3'(x), y_4'(x) = 0]$

- Define vector

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \\ y_4(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix} \cdot \vec{y}(x)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 0 & 0 & 0 \end{bmatrix}$$

- Rewrite the system as

$\vec{y}'(x) = A \cdot \vec{y}(x)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right], \left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\begin{bmatrix} 0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix} \end{bmatrix}$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_4 = \begin{bmatrix} 0 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + c_4\vec{y}_4$$

- Substitute solutions into the general solution

$$\vec{y} = \begin{bmatrix} c_1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = c_1$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 16(b).
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_high_order, _quadrature]]
```

$$\boxed{y'''' = \sin(x) + 24}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y'''' = 0$$

The characteristic equation is

$$\lambda^4 = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 0$$
$$\lambda_3 = 0$$
$$\lambda_4 = 0$$

Therefore the homogeneous solution is

$$y_h(x) = c_4x^3 + c_3x^2 + c_2x + c_1$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = x$$
$$y_3 = x^2$$
$$y_4 = x^3$$

Now the particular solution to the given ODE is found

$$y'''' = \sin(x) + 24$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x) + 24$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, x, x^2, x^3\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{\cos(x), \sin(x)\}]$$

Since x is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^2\}, \{\cos(x), \sin(x)\}]$$

Since x^2 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^3\}, \{\cos(x), \sin(x)\}]$$

Since x^3 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x^4\}, \{\cos(x), \sin(x)\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1x^4 + A_2 \cos(x) + A_3 \sin(x)$$

The unknowns $\{A_1, A_2, A_3\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$24A_1 + A_2 \cos(x) + A_3 \sin(x) = \sin(x) + 24$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1, A_2 = 0, A_3 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = x^4 + \sin(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_4x^3 + c_3x^2 + c_2x + c_1) + (x^4 + \sin(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_4x^3 + c_3x^2 + c_2x + c_1 + x^4 + \sin(x) \tag{1}$$

Verification of solutions

$$y = c_4x^3 + c_3x^2 + c_2x + c_1 + x^4 + \sin(x)$$

Verified OK.

Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 17.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{y''' - 3y'' + 2y' = 10 + 42\,\mathrm{e}^{3x}}$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - 3y'' + 2y' = 0$$

The characteristic equation is

$$\lambda^3 - 3\lambda^2 + 2\lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 2$$
$$\lambda_3 = 1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 + c_2 e^x + e^{2x} c_3$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = 1$$
$$y_2 = e^x$$
$$y_3 = e^{2x}$$

Now the particular solution to the given ODE is found

$$y''' - 3y'' + 2y' = 10 + 42\,e^{3x}$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$10 + 42\,e^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}, \{e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^x, e^{2x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}, \{e^{3x}\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x + A_2 e^{3x}$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$6A_2 e^{3x} + 2A_1 = 10 + 42\,e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 5, A_2 = 7]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = 5x + 7\,\mathrm{e}^{3x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + c_2\mathrm{e}^x + \mathrm{e}^{2x}c_3\right) + \left(5x + 7\,\mathrm{e}^{3x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 + c_2\mathrm{e}^x + \mathrm{e}^{2x}c_3 + 5x + 7\,\mathrm{e}^{3x} \tag{1}$$

Verification of solutions

$$y = c_1 + c_2\mathrm{e}^x + \mathrm{e}^{2x}c_3 + 5x + 7\,\mathrm{e}^{3x}$$

Verified OK.

13.18.1 Maple step by step solution

Let's solve

$y''' - 3y'' + 2y' = 10 + 42\,\mathrm{e}^{3x}$

- Highest derivative means the order of the ODE is 3

  y'''

- □ Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(x)$

    $y_1(x) = y$
  - Define new variable $y_2(x)$

    $y_2(x) = y'$
  - Define new variable $y_3(x)$

    $y_3(x) = y''$

- Isolate for $y_3'(x)$ using original ODE

  $y_3'(x) = 10 + 42\,\mathrm{e}^{3x} + 3y_3(x) - 2y_2(x)$

  Convert linear ODE into a system of first order ODEs

  $[y_2(x) = y_1'(x)\,, y_3(x) = y_2'(x)\,, y_3'(x) = 10 + 42\,\mathrm{e}^{3x} + 3y_3(x) - 2y_2(x)]$

- Define vector

$$\vec{y}(x) = \left[\begin{array}{c} y_1(x) \\ y_2(x) \\ y_3(x) \end{array}\right]$$

- System to solve

$$\vec{y}'(x) = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 3 \end{array}\right] \cdot \vec{y}(x) + \left[\begin{array}{c} 0 \\ 0 \\ 10 + 42\,\mathrm{e}^{3x} \end{array}\right]$$

- Define the forcing function

$$\vec{f}(x) = \left[\begin{array}{c} 0 \\ 0 \\ 10 + 42\,\mathrm{e}^{3x} \end{array}\right]$$

- Define the coefficient matrix

$$A = \left[\begin{array}{ccc} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & -2 & 3 \end{array}\right]$$

- Rewrite the system as

  $\vec{y}'(x) = A \cdot \vec{y}(x) + \vec{f}$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \end{array}\right]\right], \left[1, \left[\begin{array}{c} 1 \\ 1 \\ 1 \end{array}\right]\right], \left[2, \left[\begin{array}{c} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \mathrm{e}^{x} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \mathrm{e}^{2x} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$

□ Fundamental matrix

- Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} 1 & e^x & \frac{e^{2x}}{4} \\ 0 & e^x & \frac{e^{2x}}{2} \\ 0 & e^x & e^{2x} \end{bmatrix}$$

- The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

  $\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(x)$ and $\phi(0)$

  $$\Phi(x) = \begin{bmatrix} 1 & e^x & \frac{e^{2x}}{4} \\ 0 & e^x & \frac{e^{2x}}{2} \\ 0 & e^x & e^{2x} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & \frac{1}{4} \\ 0 & 1 & \frac{1}{2} \\ 0 & 1 & 1 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

  $$\Phi(x) = \begin{bmatrix} 1 & -\frac{3}{2} + 2e^x - \frac{e^{2x}}{2} & \frac{1}{2} - e^x + \frac{e^{2x}}{2} \\ 0 & 2e^x - e^{2x} & -e^x + e^{2x} \\ 0 & 2e^x - 2e^{2x} & -e^x + 2e^{2x} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

  $\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$

- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$

- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$

- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{y}_p(x) = \begin{bmatrix} 5x + 7\,e^{3x} + 11\,e^{x} + \frac{1}{2} - \frac{37\,e^{2x}}{2} \\ 21\,e^{3x} + 5 + 11\,e^{x} - 37\,e^{2x} \\ 63\,e^{3x} + 11\,e^{x} - 74\,e^{2x} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \begin{bmatrix} 5x + 7\,e^{3x} + 11\,e^{x} + \frac{1}{2} - \frac{37\,e^{2x}}{2} \\ 21\,e^{3x} + 5 + 11\,e^{x} - 37\,e^{2x} \\ 63\,e^{3x} + 11\,e^{x} - 74\,e^{2x} \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y = \frac{1}{2} + \frac{(c_3 - 74)\,e^{2x}}{4} + 7\,e^{3x} + (11 + c_2)\,e^{x} + 5x + c_1$$

Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 18.
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_linear_constant_coefficients_ODE"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_x]]
```

$$\boxed{y''' - y' = 1}$$

With initial conditions

$$[y(0) = 4, y'(0) = 4, y''(0) = 4]$$

This is higher order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE And y_p is a particular solution to the nonhomogeneous ODE. y_h is the solution to

$$y''' - y' = 0$$

The characteristic equation is

$$\lambda^3 - \lambda = 0$$

The roots of the above equation are

$$\lambda_1 = 0$$
$$\lambda_2 = 1$$
$$\lambda_3 = -1$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 e^{-x} + c_2 + c_3 e^{x}$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = e^{-x}$$
$$y_2 = 1$$
$$y_3 = e^{x}$$

Now the particular solution to the given ODE is found

$$y''' - y' = 1$$

The particular solution is found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{1, e^{x}, e^{-x}\}$$

Since 1 is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$y_p = A_1 x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 + c_3 e^{x}\right) + (-x) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} + c_2 + c_3 e^{x} - x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 4$ and $x = 0$ in the above gives

$$4 = c_1 + c_2 + c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} + c_3 e^{x} - 1$$

substituting $y' = 4$ and $x = 0$ in the above gives

$$4 = -c_1 + c_3 - 1 \tag{2A}$$

Taking two derivatives of the solution gives

$$y'' = c_1 e^{-x} + c_3 e^{x}$$

substituting $y'' = 4$ and $x = 0$ in the above gives

$$4 = c_1 + c_3 \tag{3A}$$

Equations {1A,2A,3A} are now solved for $\{c_1, c_2, c_3\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -\frac{1}{2} \\
c_2 &= 0 \\
c_3 &= \frac{9}{2}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = -\frac{e^{-x}}{2} + \frac{9 e^{x}}{2} - x
$$

Summary

The solution(s) found are the following

$$
y = -\frac{e^{-x}}{2} + \frac{9 e^{x}}{2} - x \tag{1}
$$

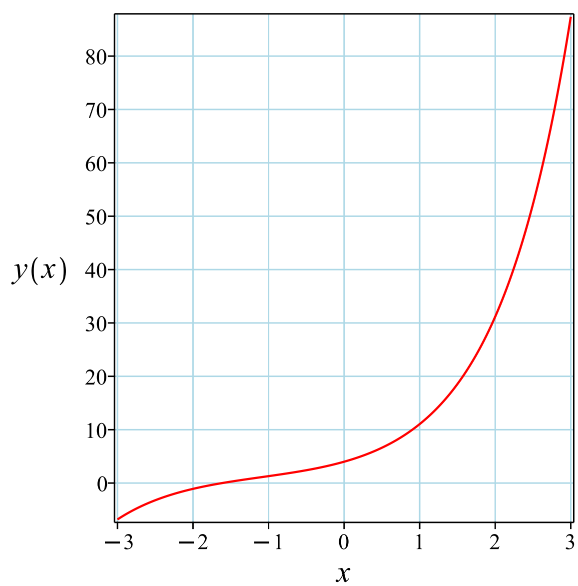

Figure 371: Solution plot

Verification of solutions

$$
y = -\frac{e^{-x}}{2} + \frac{9 e^{x}}{2} - x
$$

Verified OK.

13.19.1 Maple step by step solution

$$\vec{y}(x) = \begin{bmatrix} y_1(x) \\ y_2(x) \\ y_3(x) \end{bmatrix}$$

- System to solve

$$\vec{y}'(x) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \cdot \vec{y}(x) + \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(x) = \begin{bmatrix} 0 \\ 0 \\ 1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{y}'(x) = A \cdot \overrightarrow{y}(x) + \overrightarrow{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^{-x} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_2 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = e^x \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{y}_p($

$\vec{y}(x) = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3 + \vec{y}_p(x)$

☐ Fundamental matrix

◦ Let $\phi(x)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(x) = \begin{bmatrix} e^{-x} & 1 & e^x \\ -e^{-x} & 0 & e^x \\ e^{-x} & 0 & e^x \end{bmatrix}$$

◦ The fundamental matrix, $\Phi(x)$ is a normalized version of $\phi(x)$ satisfying $\Phi(0) = I$ where I is t

$\Phi(x) = \phi(x) \cdot \frac{1}{\phi(0)}$

◦ Substitute the value of $\phi(x)$ and $\phi(0)$

$$\Phi(x) = \begin{bmatrix} e^{-x} & 1 & e^x \\ -e^{-x} & 0 & e^x \\ e^{-x} & 0 & e^x \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} 1 & 1 & 1 \\ -1 & 0 & 1 \\ 1 & 0 & 1 \end{bmatrix}}$$

◦ Evaluate and simplify to get the fundamental matrix

$$\Phi(x) = \begin{bmatrix} 1 & -\frac{e^{-x}}{2} + \frac{e^x}{2} & \frac{e^{-x}}{2} - 1 + \frac{e^x}{2} \\ 0 & \frac{e^{-x}}{2} + \frac{e^x}{2} & -\frac{e^{-x}}{2} + \frac{e^x}{2} \\ 0 & -\frac{e^{-x}}{2} + \frac{e^x}{2} & \frac{e^{-x}}{2} + \frac{e^x}{2} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

◦ Let the particular solution be the fundamental matrix multiplied by $\vec{v}(x)$ and solve for $\vec{v}(x)$

$\vec{y}_p(x) = \Phi(x) \cdot \vec{v}(x)$

- Take the derivative of the particular solution

  $\vec{y}_p'(x) = \Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(x) \cdot \vec{v}(x) + \Phi(x) \cdot \vec{v}'(x) = A \cdot \Phi(x) \cdot \vec{v}(x) + \vec{f}(x)$
- Cancel like terms

  $\Phi(x) \cdot \vec{v}'(x) = \vec{f}(x)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(x) = \frac{1}{\Phi(x)} \cdot \vec{f}(x)$
- Integrate to solve for $\vec{v}(x)$

  $\vec{v}(x) = \int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(x)$ into the equation for the particular solution

  $\vec{y}_p(x) = \Phi(x) \cdot \left(\int_0^x \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{y}_p(x) = \begin{bmatrix} -x - \frac{e^{-x}}{2} + \frac{e^{x}}{2} \\ \frac{e^{-x}}{2} - 1 + \frac{e^{x}}{2} \\ -\frac{e^{-x}}{2} + \frac{e^{x}}{2} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{y}(x) = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + \begin{bmatrix} -x - \frac{e^{-x}}{2} + \frac{e^{x}}{2} \\ \frac{e^{-x}}{2} - 1 + \frac{e^{x}}{2} \\ -\frac{e^{-x}}{2} + \frac{e^{x}}{2} \end{bmatrix}$$
- First component of the vector is the solution to the ODE

  $y = c_1 e^{-x} + c_3 e^{x} - x - \frac{e^{-x}}{2} + \frac{e^{x}}{2} + c_2$
- Use the initial condition $y(0) = 4$

  $4 = c_1 + c_2 + c_3$

- Calculate the 1st derivative of the solution

  $y' = -c_1 e^{-x} + c_3 e^{x} + \frac{e^{-x}}{2} - 1 + \frac{e^{x}}{2}$

- Use the initial condition $y'\Big|_{\{x=0\}} = 4$

  $4 = -c_1 + c_3$

- Calculate the 2nd derivative of the solution

  $y'' = c_1 e^{-x} + c_3 e^{x} - \frac{e^{-x}}{2} + \frac{e^{x}}{2}$

- Use the initial condition $y''\Big|_{\{x=0\}} = 4$

  $4 = c_1 + c_3$

- Solve for the unknown coefficients

  $\{c_1 = 0, c_2 = 0, c_3 = 4\}$

- Solution to the IVP

  $y = -\frac{e^{-x}}{2} + \frac{9\,e^{x}}{2} - x$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 19(a).
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _missing_y]]
```

$$\boxed{x^3y''' + 3x^2y'' = 0}$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned} y' &= \lambda\, x^{\lambda-1} \\ y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\ y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$x^3y''' + 3x^2y'' = 0$$

gives

$$3x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} = 0$$

Which simplifies to

$$3\lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$3\lambda(\lambda-1)+\lambda(\lambda-1)(\lambda-2)=0$$

Simplifying gives the characteristic equation as

$$\lambda^3-\lambda=0$$

Solving the above gives the following roots

$$\lambda_1=0$$
$$\lambda_2=1$$
$$\lambda_3=-1$$

This table summarises the result

root	multiplicity	type of root
-1	1	real root
0	1	real root
1	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a c_1x^λ basis solution. Each real root of multiplicty two, generates c_1x^λ and $c_2x^\lambda\ln(x)$ basis solutions. Each real root of multiplicty three, generates c_1x^λ and $c_2x^\lambda\ln(x)$ and $c_3x^\lambda\ln(x)^2$ basis solutions, and so on. Each complex root $\alpha\pm i\beta$ of multiplicity one generates $x^\alpha(c_1\cos(\beta\ln(x))+c_2\sin(\beta\ln(x)))$ basis solutions. And each complex root $\alpha\pm i\beta$ of multiplicity two generates $\ln(x)\,x^\alpha(c_1\cos(\beta\ln(x))+c_2\sin(\beta\ln(x)))$ basis solutions. And each complex root $\alpha\pm i\beta$ of multiplicity three generates $\ln(x)^2\,x^\alpha(c_1\cos(\beta\ln(x))+c_2$ basis solutions. And so on. Using the above show that the solution is

$$y=\frac{c_1}{x}+c_2+c_3x$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1=\frac{1}{x}$$
$$y_2=1$$
$$y_3=x$$

Summary

The solution(s) found are the following

$$y=\frac{c_1}{x}+c_2+c_3x \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + c_2 + c_3 x$$

Verified OK.

13.20.1 Maple step by step solution

Let's solve

$x^3 y''' + 3x^2 y'' = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = -\frac{3y''}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' + \frac{3y''}{x} = 0$

- Multiply by denominators of the ODE

  $y''' x + 3y'' = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3} y(t)\right) t'(x)^3 + 3t'(x)\, t''(x) \left(\frac{d^2}{dt^2} y(t)\right) + t'''(x) \left(\frac{d}{dt} y(t)\right)$

- Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right)x + \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^2} - \frac{3\left(\frac{d}{dt}y(t)\right)}{x^2} = 0$

- Simplify

  $\frac{\frac{d^3}{dt^3}y(t) - \frac{d}{dt}y(t)}{x^2} = 0$

- Isolate 3rd derivative

  $\frac{d^3}{dt^3}y(t) = \frac{d}{dt}y(t)$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^3}{dt^3}y(t) - \frac{d}{dt}y(t) = 0$

□ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

  $y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

  $\frac{d}{dt}y_3(t) = y_2(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = y_2(t)\right]$

- Define vector

  $\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 0 & 1 & 0 \end{bmatrix}$$

- Rewrite the system as

$$\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \begin{bmatrix} 1 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \mathrm{e}^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2 + c_3\vec{y}_3$$

- Substitute solutions into the general solution

$$\vec{y} = c_1\mathrm{e}^{-t} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + c_3\mathrm{e}^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} c_2 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y(t) = c_1\mathrm{e}^{-t} + c_3\mathrm{e}^t + c_2$$

- Change variables back using $t = \ln(x)$

$$y = \frac{c_1}{x} + c_2 + c_3 x$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 19(b).
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{x^3y''' + x^2y'' - 2xy' + 2y = 0}$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned}
y' &= \lambda\, x^{\lambda-1} \\
y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\
y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3}
\end{aligned}$$

Substituting these back into

$$x^3y''' + x^2y'' - 2xy' + 2y = 0$$

gives

$$-2x\lambda\, x^{\lambda-1} + x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} + 2x^\lambda = 0$$

Which simplifies to

$$-2\lambda\, x^\lambda + \lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda + 2x^\lambda = 0$$

And since $x^\lambda \neq 0$ then dividing through by x^λ, the above becomes

$$-2\lambda + \lambda(\lambda - 1) + \lambda(\lambda - 1)(\lambda - 2) + 2 = 0$$

Simplifying gives the characteristic equation as

$$\lambda^3 - 2\lambda^2 - \lambda + 2 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 1$$
$$\lambda_2 = 2$$
$$\lambda_3 = -1$$

This table summarises the result

root	multiplicity	type of root
-1	1	real root
1	1	real root
2	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^\lambda$ basis solution. Each real root of multiplicty two, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^\lambda$ and $c_2 x^\lambda \ln(x)$ and $c_3 x^\lambda \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^\alpha(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^\alpha(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^\alpha(c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = \frac{c_1}{x} + c_2 x + c_3 x^2$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = \frac{1}{x}$$
$$y_2 = x$$
$$y_3 = x^2$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + c_2 x + c_3 x^2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + c_2 x + c_3 x^2$$

Verified OK.

13.21.1 Maple step by step solution

Let's solve

$x^3 y''' + x^2 y'' - 2xy' + 2y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = -\frac{2y}{x^3} - \frac{y'' x - 2y'}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' + \frac{y''}{x} - \frac{2y'}{x^2} + \frac{2y}{x^3} = 0$

- Multiply by denominators of the ODE

  $x^3 y''' + x^2 y'' - 2xy' + 2y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3} y(t)\right) t'(x)^3 + 3t'(x) t''(x) \left(\frac{d^2}{dt^2} y(t)\right) + t'''(x) \left(\frac{d}{dt} y(t)\right)$

- Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $x^3\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) + x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) - 2\frac{d}{dt}y(t) + 2y(t) = 0$

- Simplify

  $\frac{d^3}{dt^3}y(t) - 2\frac{d^2}{dt^2}y(t) - \frac{d}{dt}y(t) + 2y(t) = 0$

□ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

  $y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

  $\frac{d}{dt}y_3(t) = 2y_3(t) + y_2(t) - 2y_1(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = 2y_3(t) + y_2(t) - 2y_1(t)\right]$

- Define vector

  $\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$

- System to solve

  $\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -2 & 1 & 2 \end{bmatrix} \cdot \vec{y}(t)$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ -2 & 1 & 2 \end{bmatrix}$$

- Rewrite the system as
  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A
  $$\left[\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$
- Consider eigenpair
  $$\left[-1, \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}\right]$$
- Solution to homogeneous system from eigenpair
  $$\vec{y}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix}$$
- Consider eigenpair
  $$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$
- Solution to homogeneous system from eigenpair
  $$\vec{y}_2 = \mathrm{e}^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$
- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_3 = e^{2t} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{y} = c_1 \overrightarrow{y}_1 + c_2 \overrightarrow{y}_2 + c_3 \overrightarrow{y}_3$$

- Substitute solutions into the general solution

$$\overrightarrow{y} = c_1 e^{-t} \cdot \begin{bmatrix} 1 \\ -1 \\ 1 \end{bmatrix} + c_2 e^{t} \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + c_3 e^{2t} \cdot \begin{bmatrix} \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y(t) = c_1 e^{-t} + c_2 e^{t} + \frac{c_3 e^{2t}}{4}$$

- Change variables back using $t = \ln(x)$

$$y = \frac{c_1}{x} + c_2 x + \frac{c_3 x^2}{4}$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 19(c).
ODE order: 3.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_ODE_non_constant_coefficients_of_type_Euler"**

Maple gives the following as the ode type

```
[[_3rd_order, _with_linear_symmetries]]
```

$$\boxed{x^3y''' + 2x^2y'' + xy' - y = 0}$$

This is Euler ODE of higher order. Let $y = x^\lambda$. Hence

$$\begin{aligned} y' &= \lambda\, x^{\lambda-1} \\ y'' &= \lambda(\lambda-1)\, x^{\lambda-2} \\ y''' &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$x^3y''' + 2x^2y'' + xy' - y = 0$$

gives

$$x\lambda\, x^{\lambda-1} + 2x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} - x^\lambda = 0$$

Which simplifies to

$$\lambda\, x^\lambda + 2\lambda(\lambda-1)\, x^\lambda + \lambda(\lambda-1)\,(\lambda-2)\, x^\lambda - x^\lambda = 0$$

And since $x^{\lambda} \neq 0$ then dividing through by x^{λ}, the above becomes

$$\lambda + 2\lambda(\lambda - 1) + \lambda(\lambda - 1)(\lambda - 2) - 1 = 0$$

Simplifying gives the characteristic equation as

$$\lambda^3 - \lambda^2 + \lambda - 1 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 1$$
$$\lambda_2 = i$$
$$\lambda_3 = -i$$

This table summarises the result

root	multiplicity	type of root
1	1	real root
$\pm 1i$	1	complex conjugate root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^{\lambda}$ basis solution. Each real root of multiplicty two, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ and $c_3 x^{\lambda} \ln(x)^2$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^2\, x^{\alpha}(c_1 \cos(\beta \ln(x)) + c_2$ basis solutions. And so on. Using the above show that the solution is

$$y = c_1 x + c_2 \cos(\ln(x)) + c_3 \sin(\ln(x))$$

The fundamental set of solutions for the homogeneous solution are the following

$$y_1 = x$$
$$y_2 = \cos(\ln(x))$$
$$y_3 = \sin(\ln(x))$$

Summary

The solution(s) found are the following

$$y = c_1 x + c_2 \cos(\ln(x)) + c_3 \sin(\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 x + c_2 \cos(\ln(x)) + c_3 \sin(\ln(x))$$

Verified OK.

13.22.1 Maple step by step solution

Let's solve

$x^3 y''' + 2x^2 y'' + x y' - y = 0$

- Highest derivative means the order of the ODE is 3

  y'''

- Isolate 3rd derivative

  $y''' = \frac{y}{x^3} - \frac{2y''x + y'}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''' + \frac{2y''}{x} + \frac{y'}{x^2} - \frac{y}{x^3} = 0$

- Multiply by denominators of the ODE

  $x^3 y''' + 2x^2 y'' + x y' - y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2} y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt} y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2} y(t)}{x^2} - \frac{\frac{d}{dt} y(t)}{x^2}$

  - Calculate the 3rd derivative of y with respect to x , using the chain rule

    $y''' = \left(\frac{d^3}{dt^3} y(t)\right) t'(x)^3 + 3t'(x) t''(x) \left(\frac{d^2}{dt^2} y(t)\right) + t'''(x) \left(\frac{d}{dt} y(t)\right)$

- Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

  Substitute the change of variables back into the ODE

  $x^3\left(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}\right) + 2x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{d}{dt}y(t) - y(t) = 0$

- Simplify

  $\frac{d^3}{dt^3}y(t) - \frac{d^2}{dt^2}y(t) + \frac{d}{dt}y(t) - y(t) = 0$

- [ ] Convert linear ODE into a system of first order ODEs
  - Define new variable $y_1(t)$

    $y_1(t) = y(t)$
  - Define new variable $y_2(t)$

    $y_2(t) = \frac{d}{dt}y(t)$
  - Define new variable $y_3(t)$

    $y_3(t) = \frac{d^2}{dt^2}y(t)$
  - Isolate for $\frac{d}{dt}y_3(t)$ using original ODE

    $\frac{d}{dt}y_3(t) = y_3(t) - y_2(t) + y_1(t)$

    Convert linear ODE into a system of first order ODEs

    $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), \frac{d}{dt}y_3(t) = y_3(t) - y_2(t) + y_1(t)\right]$

- Define vector

  $\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \end{bmatrix}$

- System to solve

  $\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -1 & 1 \end{bmatrix} \cdot \vec{y}(t)$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 \\ 0 & 0 & 1 \\ 1 & -1 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\overrightarrow{y}(t) = A \cdot \overrightarrow{y}(t)$
- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right], \left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right], \left[\mathrm{I}, \begin{bmatrix} -1 \\ -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{y}_1 = \mathrm{e}^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix}$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\mathrm{I}, \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{-\mathrm{I}t} \cdot \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$(\cos(t) - \mathrm{I}\sin(t)) \cdot \begin{bmatrix} -1 \\ \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\begin{bmatrix} -\cos(t) + \mathrm{I}\sin(t) \\ \mathrm{I}(\cos(t) - \mathrm{I}\sin(t)) \\ \cos(t) - \mathrm{I}\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{y}_2(t) = \begin{bmatrix} -\cos(t) \\ \sin(t) \\ \cos(t) \end{bmatrix}, \vec{y}_3(t) = \begin{bmatrix} \sin(t) \\ \cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{y} = c_1\vec{y}_1 + c_2\vec{y}_2(t) + c_3\vec{y}_3(t)$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^t \cdot \begin{bmatrix} 1 \\ 1 \\ 1 \end{bmatrix} + \begin{bmatrix} -c_2\cos(t) + c_3\sin(t) \\ c_2\sin(t) + c_3\cos(t) \\ c_2\cos(t) - c_3\sin(t) \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y(t) = c_1 \mathrm{e}^t + c_3\sin(t) - c_2\cos(t)$$

- Change variables back using $t = \ln(x)$

$$y = c_1 x + c_3\sin(\ln(x)) - c_2\cos(\ln(x))$$

13.23 problem 20

Internal problem ID [6370]
Internal file name [OUTPUT/5618_Sunday_June_05_2022_03_44_58_PM_22166040/index.tex]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Section 2.7. HIGHER ORDER LINEAR EQUATIONS, COUPLED HARMONIC OSCILLATORS Page 98
Problem number: 20.
ODE order: 4.
ODE degree: 1.

The type(s) of ODE detected by this program : **"higher_order_missing_y"**

Maple gives the following as the ode type

```
[[_high_order, _missing_y]]
```

$$\boxed{x^3y'''' + 8x^2y''' + 8xy'' - 8y' = 0}$$

Since y is missing from the ode then we can use the substitution $y' = v(x)$ to reduce the order by one. The ODE becomes

$$x^3v'''(x) + 8x^2v''(x) + 8v'(x)\,x - 8v(x) = 0$$

This is Euler ODE of higher order. Let $v(x) = x^\lambda$. Hence

$$\begin{aligned} v'(x) &= \lambda\, x^{\lambda-1} \\ v''(x) &= \lambda(\lambda-1)\, x^{\lambda-2} \\ v'''(x) &= \lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} \end{aligned}$$

Substituting these back into

$$x^3v'''(x) + 8x^2v''(x) + 8v'(x)\,x - 8v(x) = 0$$

gives

$$8x\lambda\, x^{\lambda-1} + 8x^2\lambda(\lambda-1)\, x^{\lambda-2} + x^3\lambda(\lambda-1)\,(\lambda-2)\, x^{\lambda-3} - 8x^\lambda = 0$$

Which simplifies to

$$8\lambda\, x^{\lambda}+8\lambda(\lambda -1)\, x^{\lambda}+\lambda(\lambda -1)\, (\lambda -2)\, x^{\lambda}-8x^{\lambda} = 0$$

And since $x^{\lambda}\neq 0$ then dividing through by x^{λ}, the above becomes

$$8\lambda +8\lambda(\lambda -1)+\lambda(\lambda -1)\, (\lambda -2)-8 = 0$$

Simplifying gives the characteristic equation as

$$\lambda^{3}+5\lambda^{2}+2\lambda -8 = 0$$

Solving the above gives the following roots

$$\lambda_1 = 1$$
$$\lambda_2 = -4$$
$$\lambda_3 = -2$$

This table summarises the result

root	multiplicity	type of root
-2	1	real root
1	1	real root
-4	1	real root

The solution is generated by going over the above table. For each real root λ of multiplicity one generates a $c_1 x^{\lambda}$ basis solution. Each real root of multiplicty two, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ basis solutions. Each real root of multiplicty three, generates $c_1 x^{\lambda}$ and $c_2 x^{\lambda} \ln(x)$ and $c_3 x^{\lambda} \ln(x)^{2}$ basis solutions, and so on. Each complex root $\alpha \pm i\beta$ of multiplicity one generates $x^{\alpha}(c_1 \cos(\beta \ln(x))+c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity two generates $\ln(x)\, x^{\alpha}(c_1 \cos(\beta \ln(x))+c_2 \sin(\beta \ln(x)))$ basis solutions. And each complex root $\alpha \pm i\beta$ of multiplicity three generates $\ln(x)^{2} x^{\alpha}(c_1 \cos(\beta \ln(x))+c_2$ basis solutions. And so on. Using the above show that the solution is

$$v(x) = \frac{c_1}{x^{2}}+c_2 x +\frac{c_3}{x^{4}}$$

The fundamental set of solutions for the homogeneous solution are the following

$$v_1 = \frac{1}{x^{2}}$$
$$v_2 = x$$
$$v_3 = \frac{1}{x^{4}}$$

But since $y' = v(x)$ then we now need to solve the ode $y' = \frac{c_1}{x^2} + c_2 x + \frac{c_3}{x^4}$. Integrating both sides gives

$$
\begin{aligned}
y &= \int \frac{c_2 x^5 + c_1 x^2 + c_3}{x^4}\, \mathrm{d}x \\
&= \frac{c_2 x^2}{2} - \frac{c_3}{3x^3} - \frac{c_1}{x} + c_1
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_2 x^2}{2} - \frac{c_3}{3x^3} - \frac{c_1}{x} + c_1 \tag{1}
$$

Verification of solutions

$$
y = \frac{c_2 x^2}{2} - \frac{c_3}{3x^3} - \frac{c_1}{x} + c_1
$$

Verified OK.

13.23.1 Maple step by step solution

Let's solve

$x^3 y'''' + 8x^2 y''' + 8y'' x - 8y' = 0$

- Highest derivative means the order of the ODE is 4

  y''''

- Isolate 4th derivative

  $y'''' = -\frac{8(x^2 y''' + y'' x - y')}{x^3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'''' + \frac{8y'''}{x} + \frac{8y''}{x^2} - \frac{8y'}{x^3} = 0$

- Multiply by denominators of the ODE

  $x^3 y'''' + 8x^2 y''' + 8y'' x - 8y' = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ○ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

- Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

- Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$

- Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

- Calculate the 3rd derivative of y with respect to x , using the chain rule

  $y''' = \left(\frac{d^3}{dt^3}y(t)\right)t'(x)^3 + 3t'(x)\,t''(x)\left(\frac{d^2}{dt^2}y(t)\right) + t'''(x)\left(\frac{d}{dt}y(t)\right)$

- Compute derivative

  $y''' = \frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} + \frac{2\left(\frac{d}{dt}y(t)\right)}{x^3}$

- Calculate the 4th derivative of y with respect to x , using the chain rule

  $y'''' = \left(\frac{d^4}{dt^4}y(t)\right)t'(x)^4 + 3t'(x)^2t''(x)\left(\frac{d^3}{dt^3}y(t)\right) + 3t''(x)^2\left(\frac{d^2}{dt^2}y(t)\right) + 3\Big(t'''(x)\left(\frac{d^2}{dt^2}y(t)\right) + \Big(\frac{d^3}{dt^3}y($

- Compute derivative

  $y'''' = \frac{\frac{d^4}{dt^4}y(t)}{x^4} - \frac{3\left(\frac{d^3}{dt^3}y(t)\right)}{x^4} + \frac{5\left(\frac{d^2}{dt^2}y(t)\right)}{x^4} + \frac{3\left(\frac{2\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} - \frac{\frac{d^3}{dt^3}y(t)}{x^3}\right)}{x} - \frac{6\left(\frac{d}{dt}y(t)\right)}{x^4}$

  Substitute the change of variables back into the ODE

  $x^3\left(\frac{\frac{d^4}{dt^4}y(t)}{x^4} - \frac{3\left(\frac{d^3}{dt^3}y(t)\right)}{x^4} + \frac{5\left(\frac{d^2}{dt^2}y(t)\right)}{x^4} + \frac{3\left(\frac{2\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} - \frac{\frac{d^3}{dt^3}y(t)}{x^3}\right)}{x} - \frac{6\left(\frac{d}{dt}y(t)\right)}{x^4}\right) + 8x^2\Big(\frac{\frac{d^3}{dt^3}y(t)}{x^3} - \frac{3\left(\frac{d^2}{dt^2}y(t)\right)}{x^3} -$

- Simplify

  $\frac{\frac{d^4}{dt^4}y(t)+2\frac{d^3}{dt^3}y(t)-5\frac{d^2}{dt^2}y(t)-6\frac{d}{dt}y(t)}{x} = 0$

- Isolate 4th derivative

  $\frac{d^4}{dt^4}y(t) = -2\frac{d^3}{dt^3}y(t) + 5\frac{d^2}{dt^2}y(t) + 6\frac{d}{dt}y(t)$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

  $\frac{d^4}{dt^4}y(t) + 2\frac{d^3}{dt^3}y(t) - 5\frac{d^2}{dt^2}y(t) - 6\frac{d}{dt}y(t) = 0$

☐ Convert linear ODE into a system of first order ODEs

- Define new variable $y_1(t)$

$y_1(t) = y(t)$

- Define new variable $y_2(t)$

  $y_2(t) = \frac{d}{dt}y(t)$

- Define new variable $y_3(t)$

  $y_3(t) = \frac{d^2}{dt^2}y(t)$

- Define new variable $y_4(t)$

  $y_4(t) = \frac{d^3}{dt^3}y(t)$

- Isolate for $\frac{d}{dt}y_4(t)$ using original ODE

  $\frac{d}{dt}y_4(t) = -2y_4(t) + 5y_3(t) + 6y_2(t)$

  Convert linear ODE into a system of first order ODEs

  $\left[y_2(t) = \frac{d}{dt}y_1(t), y_3(t) = \frac{d}{dt}y_2(t), y_4(t) = \frac{d}{dt}y_3(t), \frac{d}{dt}y_4(t) = -2y_4(t) + 5y_3(t) + 6y_2(t)\right]$

- Define vector

$$\vec{y}(t) = \begin{bmatrix} y_1(t) \\ y_2(t) \\ y_3(t) \\ y_4(t) \end{bmatrix}$$

- System to solve

$$\frac{d}{dt}\vec{y}(t) = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 6 & 5 & -2 \end{bmatrix} \cdot \vec{y}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 0 & 1 & 0 & 0 \\ 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 1 \\ 0 & 6 & 5 & -2 \end{bmatrix}$$

- Rewrite the system as

  $\frac{d}{dt}\vec{y}(t) = A \cdot \vec{y}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A

- Eigenpairs of A

$$\left[\left[-3, \left[\begin{array}{c} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]\right], \left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right], \left[0, \left[\begin{array}{c} 1 \\ 0 \\ 0 \\ 0 \end{array}\right]\right], \left[2, \left[\begin{array}{c} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[-3, \left[\begin{array}{c} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_1 = \mathrm{e}^{-3t} \cdot \left[\begin{array}{c} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[-1, \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_2 = \mathrm{e}^{-t} \cdot \left[\begin{array}{c} -1 \\ 1 \\ -1 \\ 1 \end{array}\right]$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_3 = \begin{bmatrix} 1 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{y}_4 = \mathrm{e}^{2t} \cdot \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{y} = c_1 \vec{y}_1 + c_2 \vec{y}_2 + c_3 \vec{y}_3 + c_4 \vec{y}_4$$

- Substitute solutions into the general solution

$$\vec{y} = c_1 \mathrm{e}^{-3t} \cdot \begin{bmatrix} -\frac{1}{27} \\ \frac{1}{9} \\ -\frac{1}{3} \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{-t} \cdot \begin{bmatrix} -1 \\ 1 \\ -1 \\ 1 \end{bmatrix} + c_4 \mathrm{e}^{2t} \cdot \begin{bmatrix} \frac{1}{8} \\ \frac{1}{4} \\ \frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} c_3 \\ 0 \\ 0 \\ 0 \end{bmatrix}$$

- First component of the vector is the solution to the ODE

$$y(t) = -\frac{\left(27c_2 e^{2t} - 27c_3 e^{3t} - \frac{27c_4 e^{5t}}{8} + c_1\right) e^{-3t}}{27}$$

- Change variables back using $t = \ln(x)$

$$y = -\frac{27c_2 x^2 - 27c_3 x^3 - \frac{27}{8} c_4 x^5 + c_1}{27x^3}$$

- Simplify

$$y = \frac{c_4 x^2}{8} + c_3 - \frac{c_2}{x} - \frac{c_1}{27x^3}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 3y' + y = 0}$$

14.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda \,\mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 1$ into the above gives

$$
\begin{aligned}
\lambda_{1,2} &= \frac{3}{(2)(1)} \pm \frac{1}{(2)(1)} \sqrt{-3^2 - (4)(1)(1)} \\
&= \frac{3}{2} \pm \frac{\sqrt{5}}{2}
\end{aligned}
$$

Hence

$$
\lambda_1 = \frac{3}{2} + \frac{\sqrt{5}}{2}
$$
$$
\lambda_2 = \frac{3}{2} - \frac{\sqrt{5}}{2}
$$

Which simplifies to

$$
\lambda_1 = \frac{3}{2} + \frac{\sqrt{5}}{2}
$$
$$
\lambda_2 = \frac{3}{2} - \frac{\sqrt{5}}{2}
$$

Since roots are real and distinct, then the solution is

$$
\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{\left(\frac{3}{2} + \frac{\sqrt{5}}{2}\right)x} + c_2 e^{\left(\frac{3}{2} - \frac{\sqrt{5}}{2}\right)x}
\end{aligned}
$$

Or

$$
y = c_1 \mathrm{e}^{\left(\frac{3}{2} + \frac{\sqrt{5}}{2}\right)x} + c_2 \mathrm{e}^{\left(\frac{3}{2} - \frac{\sqrt{5}}{2}\right)x}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{\left(\frac{3}{2} + \frac{\sqrt{5}}{2}\right)x} + c_2 \mathrm{e}^{\left(\frac{3}{2} - \frac{\sqrt{5}}{2}\right)x} \tag{1}
$$

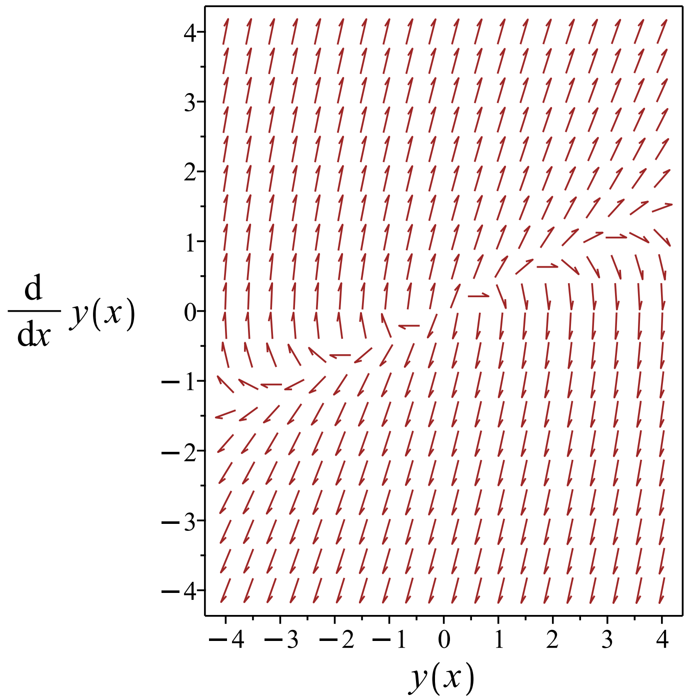

Figure 372: Slope field plot

Verification of solutions

$$y = c_1 e^{\left(\frac{3}{2}+\frac{\sqrt{5}}{2}\right)x} + c_2 e^{\left(\frac{3}{2}-\frac{\sqrt{5}}{2}\right)x}$$

Verified OK.

14.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{5}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 5 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{5z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 332: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{5}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x\sqrt{5}}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\ &= z_1 e^{\frac{3x}{2}} \\ &= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{(\sqrt{5}-3)x}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\sqrt{5}\,\mathrm{e}^{x\sqrt{5}}}{5}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{(\sqrt{5}-3)x}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{(\sqrt{5}-3)x}{2}} \left(\frac{\sqrt{5}\,\mathrm{e}^{x\sqrt{5}}}{5}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{(\sqrt{5}-3)x}{2}} + \frac{c_2 \sqrt{5}\,\mathrm{e}^{\frac{(3+\sqrt{5})x}{2}}}{5} \tag{1}
$$

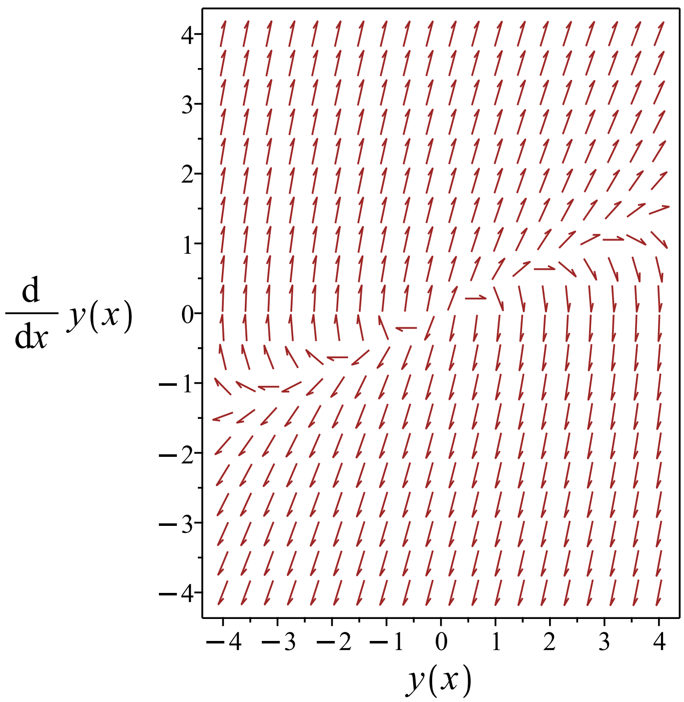

Figure 373: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{(\sqrt{5}-3)x}{2}} + \frac{c_2 \sqrt{5}\,\mathrm{e}^{\frac{(3+\sqrt{5})x}{2}}}{5}
$$

Verified OK.

14.1.3 Maple step by step solution

Let's solve

$y'' - 3y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 3r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{3 \pm (\sqrt{5})}{2}$

- Roots of the characteristic polynomial

  $r = \left(\frac{3}{2} - \frac{\sqrt{5}}{2}, \frac{3}{2} + \frac{\sqrt{5}}{2}\right)$

- 1st solution of the ODE

  $y_1(x) = e^{\left(\frac{3}{2} - \frac{\sqrt{5}}{2}\right)x}$

- 2nd solution of the ODE

  $y_2(x) = e^{\left(\frac{3}{2} + \frac{\sqrt{5}}{2}\right)x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{\left(\frac{3}{2} - \frac{\sqrt{5}}{2}\right)x} + c_2 e^{\left(\frac{3}{2} + \frac{\sqrt{5}}{2}\right)x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + y' + y = 0}$$

14.2.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 1, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + \lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + \lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 1, C = 1$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{-1}{(2)(1)} \pm \frac{1}{(2)(1)} \sqrt{1^2 - (4)(1)(1)} \\
&= -\frac{1}{2} \pm \frac{i\sqrt{3}}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= -\frac{1}{2} + \frac{i\sqrt{3}}{2} \\
\lambda_2 &= -\frac{1}{2} - \frac{i\sqrt{3}}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= -\frac{1}{2} + \frac{i\sqrt{3}}{2} \\
\lambda_2 &= -\frac{1}{2} - \frac{i\sqrt{3}}{2}
\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{1}{2}$ and $\beta = \frac{\sqrt{3}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-\frac{x}{2}} \left(c_1 \cos \left(\frac{\sqrt{3}\,x}{2} \right) + c_2 \sin \left(\frac{\sqrt{3}\,x}{2} \right) \right)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{x}{2}} \left(c_1 \cos \left(\frac{\sqrt{3}\,x}{2} \right) + c_2 \sin \left(\frac{\sqrt{3}\,x}{2} \right) \right) \tag{1}$$

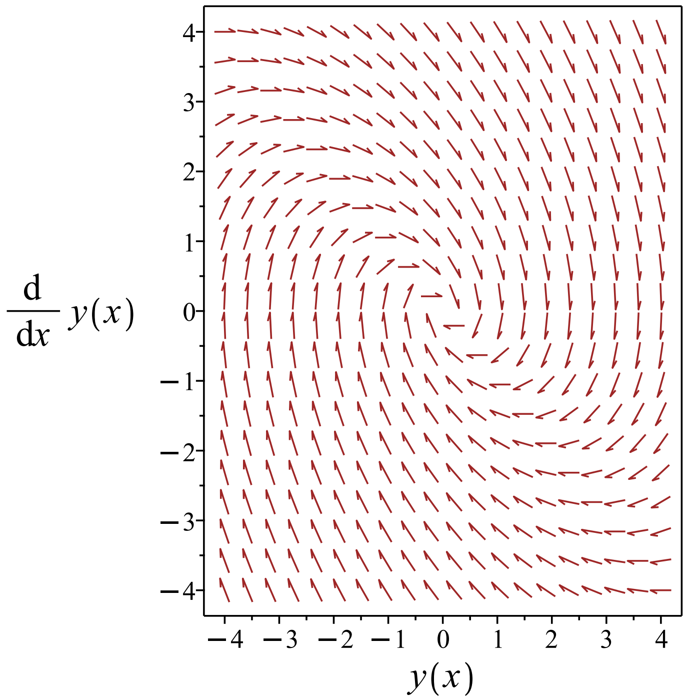

Figure 374: Slope field plot

Verification of solutions

$$y = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{3}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\, x}{2}\right)\right)$$

Verified OK.

14.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{3z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 334: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{3}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{\sqrt{3}\,x}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{2\sqrt{3}\, \tan\left(\frac{\sqrt{3}\, x}{2}\right)}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right)\right) + c_2 \left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right) \left(\frac{2\sqrt{3}\, \tan\left(\frac{\sqrt{3}\, x}{2}\right)}{3}\right)\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right) c_1 + \frac{2 c_2 \mathrm{e}^{-\frac{x}{2}} \sqrt{3}\, \sin\left(\frac{\sqrt{3}\, x}{2}\right)}{3} \tag{1}
$$

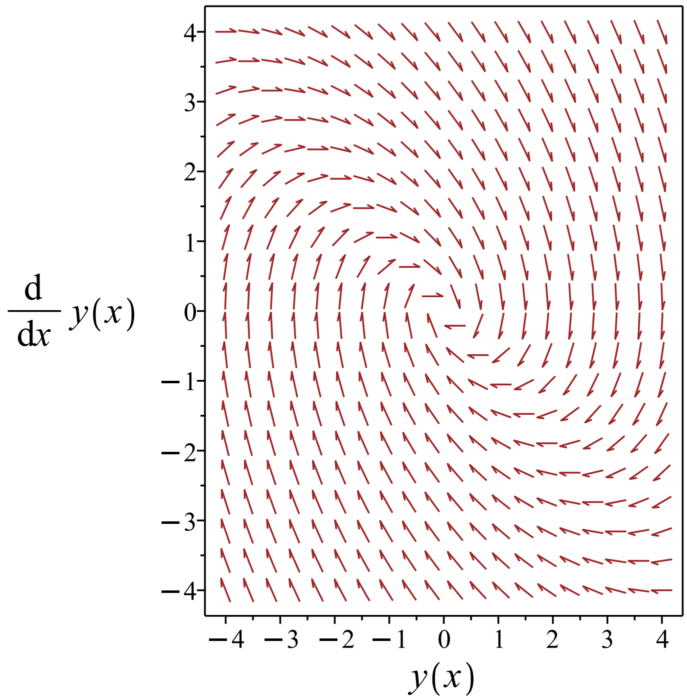

Figure 375: Slope field plot

Verification of solutions

$$y = e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \frac{2c_2 e^{-\frac{x}{2}} \sqrt{3}\, \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{3}$$

Verified OK.

$$\boxed{y'' + 6y' + 9y = 0}$$

14.3.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 6\lambda e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(6)^2 - (4)(1)(9)} \\ &= -3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 3$. Therefore the solution is

$$y = c_1 e^{-3x} + c_2 x\, e^{-3x} \tag{1}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-3x} + x\, e^{-3x} c_2 \tag{1}$$

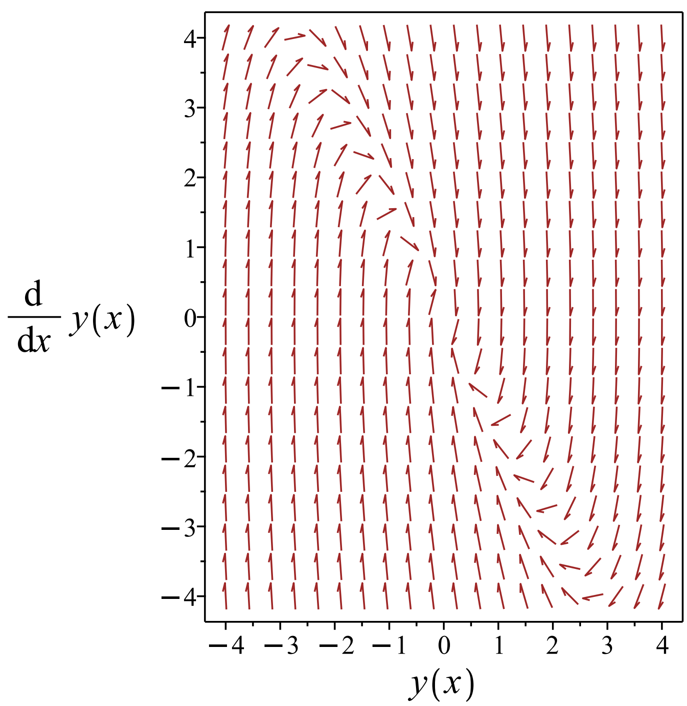

Figure 376: Slope field plot

Verification of solutions

$$y = c_1 e^{-3x} + x\, e^{-3x} c_2$$

Verified OK.

14.3.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = 6$. Therefore, there is an integrating factor given by

$$\begin{aligned}M(x) &= e^{\frac{1}{2}\int p\,dx}\\&= e^{\int 6\,dx}\\&= \mathrm{e}^{3x}\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}(M(x)y)'' &= 0\\\left(\mathrm{e}^{3x}y\right)'' &= 0\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{3x}y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{3x}y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{\mathrm{e}^{3x}}$$

Or

$$y = c_1x\,\mathrm{e}^{-3x} + c_2\mathrm{e}^{-3x}$$

Summary

The solution(s) found are the following

$$y = c_1x\,\mathrm{e}^{-3x} + c_2\mathrm{e}^{-3x} \tag{1}$$

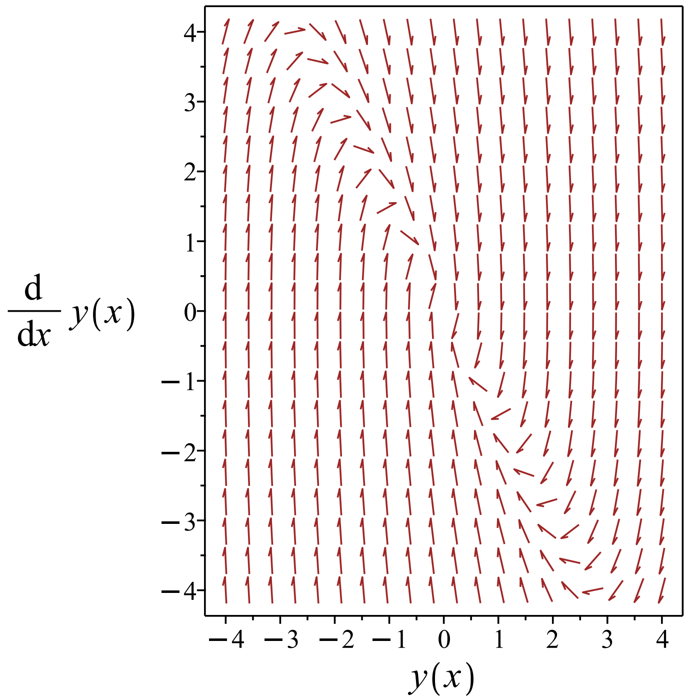

Figure 377: Slope field plot

Verification of solutions

$$y = c_1 x\, e^{-3x} + c_2 e^{-3x}$$

Verified OK.

14.3.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 336: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{6}{1}\,dx} \\ &= z_1 e^{-3x} \\ &= z_1\left(\mathrm{e}^{-3x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{6}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{-6x}}{(y_1)^2}\,dx \\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{-3x}\right) + c_2\left(e^{-3x}(x)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-3x} + x\,e^{-3x} c_2 \tag{1}
$$

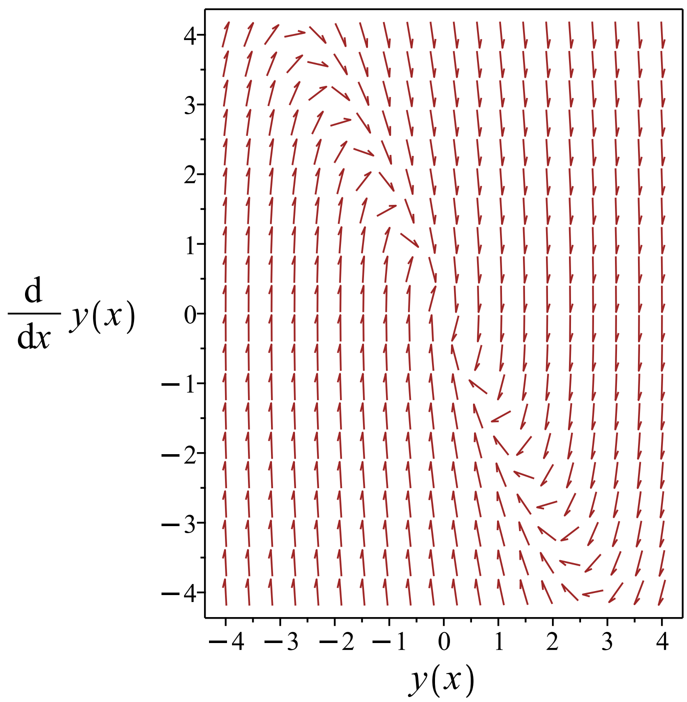

Figure 378: Slope field plot

Verification of solutions

$$
y = c_1 e^{-3x} + x\,e^{-3x} c_2
$$

Verified OK.

14.3.4 Maple step by step solution

Let's solve

$y'' + 6y' + 9y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 6r + 9 = 0$

- Factor the characteristic polynomial

  $(r+3)^2 = 0$

- Root of the characteristic polynomial

  $r = -3$

- 1st solution of the ODE

  $y_1(x) = e^{-3x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,e^{-3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-3x} + x\,e^{-3x} c_2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - y' + 6y = 0}$$

14.4.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = 6$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \lambda e^{\lambda x} + 6 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda + 6 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = 6$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(6)} \\ &= \frac{1}{2} \pm \frac{i\sqrt{23}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= \frac{1}{2} + \frac{i\sqrt{23}}{2} \\ \lambda_2 &= \frac{1}{2} - \frac{i\sqrt{23}}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{1}{2} + \frac{i\sqrt{23}}{2} \\ \lambda_2 &= \frac{1}{2} - \frac{i\sqrt{23}}{2}\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = \frac{1}{2}$ and $\beta = \frac{\sqrt{23}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{\frac{x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right)$$

<u>Summary</u>

The solution(s) found are the following

$$y = \mathrm{e}^{\frac{x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right) \tag{1}$$

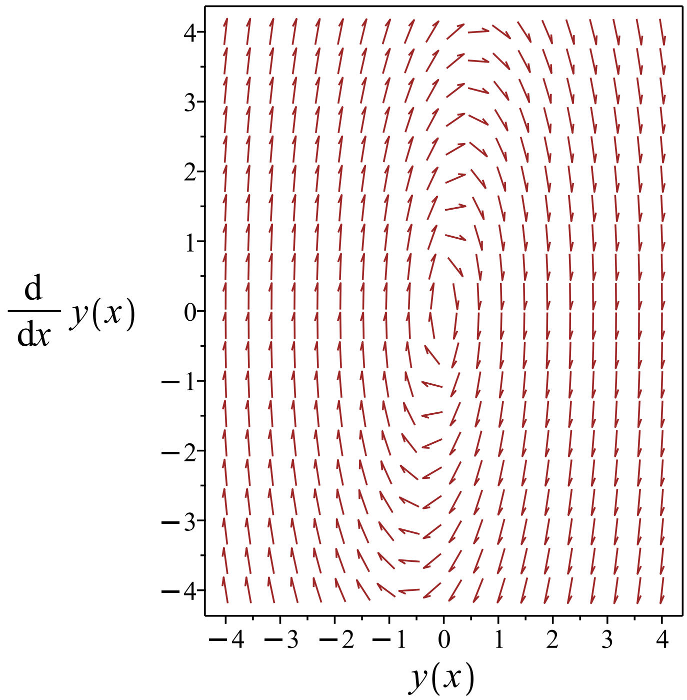

Figure 379: Slope field plot

Verification of solutions

$$y = e^{\frac{x}{2}}\left(c_1 \cos\left(\frac{\sqrt{23}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{23}\, x}{2}\right)\right)$$

Verified OK.

14.4.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-23}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -23 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{23z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 338: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{23}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{\sqrt{23}\,x}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx}\\ &= z_1 e^{\frac{x}{2}}\\ &= z_1\left(\mathrm{e}^{\frac{x}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2\sqrt{23}\,\tan\left(\frac{\sqrt{23}\,x}{2}\right)}{23}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right)\right) + c_2 \left(\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) \left(\frac{2\sqrt{23}\,\tan\left(\frac{\sqrt{23}\,x}{2}\right)}{23}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{23}\,x}{2}\right) + \frac{2 c_2 \mathrm{e}^{\frac{x}{2}} \sqrt{23}\,\sin\left(\frac{\sqrt{23}\,x}{2}\right)}{23} \tag{1}
$$

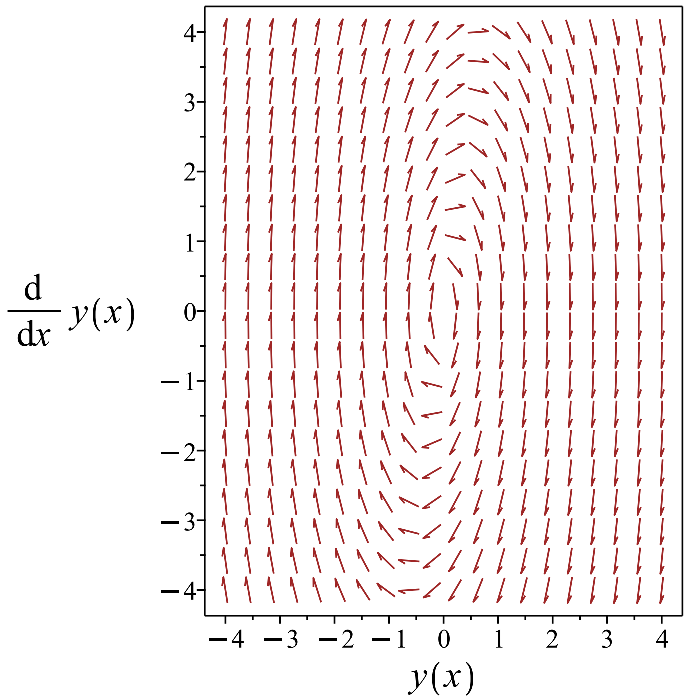

Figure 380: Slope field plot

Verification of solutions

$$y = c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{23}\, x}{2}\right) + \frac{2c_2 e^{\frac{x}{2}} \sqrt{23}\, \sin\left(\frac{\sqrt{23}\, x}{2}\right)}{23}$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 2y' - 5y = x}$$

14.5.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = -5, f(x) = x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' - 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = -5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} - 5 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(-5)} \\ &= 1 \pm \sqrt{6}\end{aligned}$$

Hence

$$\lambda_1 = 1 + \sqrt{6}$$
$$\lambda_2 = 1 - \sqrt{6}$$

Which simplifies to

$$\lambda_1 = 1 + \sqrt{6}$$
$$\lambda_2 = 1 - \sqrt{6}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(1+\sqrt{6}\right)x} + c_2 e^{\left(1-\sqrt{6}\right)x}$$

Or

$$y = c_1 e^{\left(1+\sqrt{6}\right)x} + c_2 e^{\left(1-\sqrt{6}\right)x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\left(1+\sqrt{6}\right)x} + c_2 e^{\left(1-\sqrt{6}\right)x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{\left(1-\sqrt{6}\right)x}, e^{\left(1+\sqrt{6}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-5A_2 x - 5A_1 - 2A_2 = x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{2}{25}, A_2 = -\frac{1}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{5} + \frac{2}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\left(1+\sqrt{6}\right)x} + c_2 e^{\left(1-\sqrt{6}\right)x}\right) + \left(-\frac{x}{5} + \frac{2}{25}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 e^{\left(1+\sqrt{6}\right)x} + c_2 e^{-\left(-1+\sqrt{6}\right)x} - \frac{x}{5} + \frac{2}{25}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{(1+\sqrt{6})x} + c_2 e^{-(-1+\sqrt{6})x} - \frac{x}{5} + \frac{2}{25} \tag{1}$$

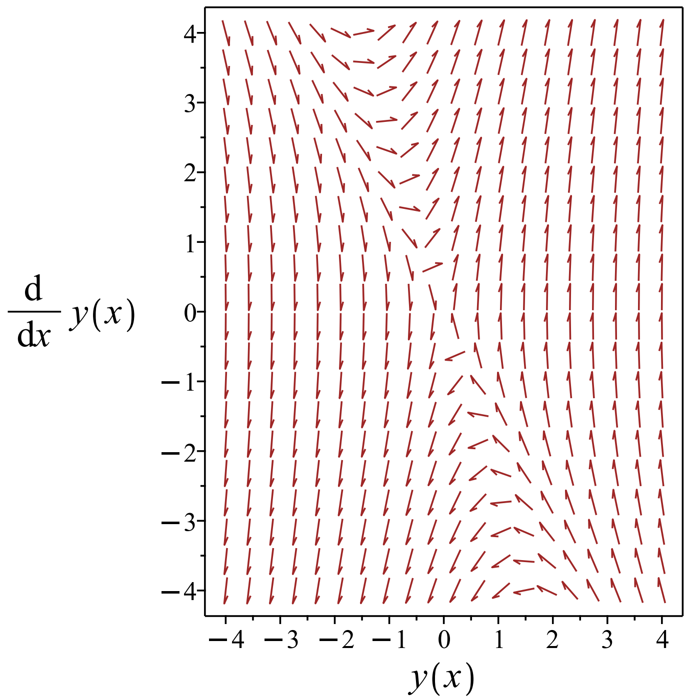

Figure 381: Slope field plot

Verification of solutions

$$y = c_1 e^{(1+\sqrt{6})x} + c_2 e^{-(-1+\sqrt{6})x} - \frac{x}{5} + \frac{2}{25}$$

Verified OK.

14.5.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= -2 \\
C &= -5
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{6}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 6 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 6z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 340: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 6$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-x\sqrt{6}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1 (e^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\left(-1+\sqrt{6}\right)x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\sqrt{6}\,\mathrm{e}^{2x\sqrt{6}}}{12}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\left(-1+\sqrt{6}\right)x}\right) + c_2 \left(\mathrm{e}^{-\left(-1+\sqrt{6}\right)x} \left(\frac{\sqrt{6}\,\mathrm{e}^{2x\sqrt{6}}}{12}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' - 5y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-\left(-1+\sqrt{6}\right)x} + \frac{c_2\sqrt{6}\,\mathrm{e}^{\left(1+\sqrt{6}\right)x}}{12}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{6}\,\mathrm{e}^{\left(1+\sqrt{6}\right)x}}{12}, \mathrm{e}^{-\left(-1+\sqrt{6}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-5A_2 x - 5A_1 - 2A_2 = x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{2}{25}, A_2 = -\frac{1}{5}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{x}{5} + \frac{2}{25}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-\left(-1+\sqrt{6}\right)x} + \frac{c_2 \sqrt{6}\,\mathrm{e}^{\left(1+\sqrt{6}\right)x}}{12}\right) + \left(-\frac{x}{5} + \frac{2}{25}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{-\left(-1+\sqrt{6}\right)x} + \frac{c_2 \sqrt{6}\, e^{\left(1+\sqrt{6}\right)x}}{12} - \frac{x}{5} + \frac{2}{25} \tag{1}
$$

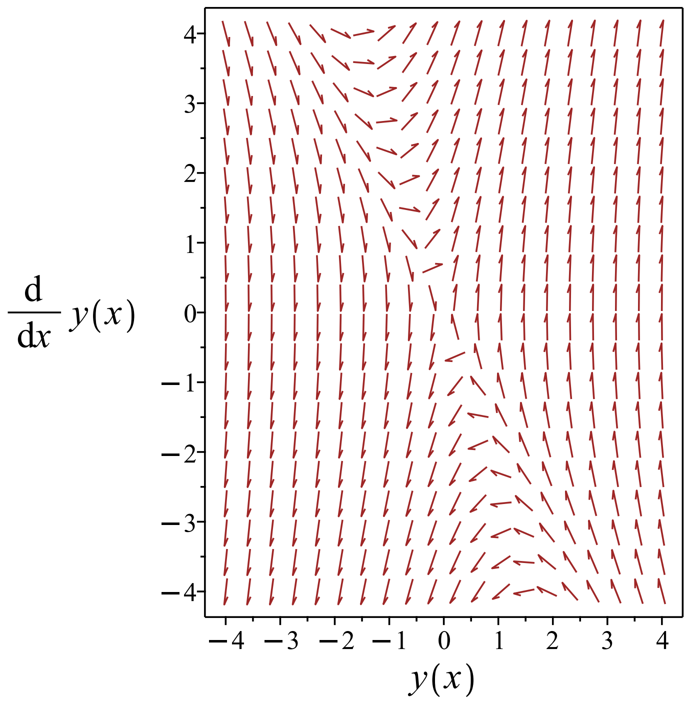

Figure 382: Slope field plot

Verification of solutions

$$
y = c_1 e^{-\left(-1+\sqrt{6}\right)x} + \frac{c_2 \sqrt{6}\, e^{\left(1+\sqrt{6}\right)x}}{12} - \frac{x}{5} + \frac{2}{25}
$$

Verified OK.

14.5.3 Maple step by step solution

Let's solve

$y'' - 2y' - 5y = x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r - 5 = 0$
- Use quadratic formula to solve for r

  $r = \frac{2\pm\left(\sqrt{24}\right)}{2}$
- Roots of the characteristic polynomial

  $r = \left(1-\sqrt{6}, 1+\sqrt{6}\right)$
- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{\left(1-\sqrt{6}\right)x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{\left(1+\sqrt{6}\right)x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{\left(1-\sqrt{6}\right)x} + c_2 \mathrm{e}^{\left(1+\sqrt{6}\right)x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x\right]$
- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{\left(1-\sqrt{6}\right)x} & \mathrm{e}^{\left(1+\sqrt{6}\right)x} \\ \left(1-\sqrt{6}\right)\mathrm{e}^{\left(1-\sqrt{6}\right)x} & \left(1+\sqrt{6}\right)\mathrm{e}^{\left(1+\sqrt{6}\right)x} \end{bmatrix}$
- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2\sqrt{6}\,\mathrm{e}^{2x}$
- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = \frac{\sqrt{6}\left(-\mathrm{e}^{-\left(-1+\sqrt{6}\right)x}\left(\int x\,\mathrm{e}^{\left(-1+\sqrt{6}\right)x}dx\right) + \mathrm{e}^{\left(1+\sqrt{6}\right)x}\left(\int x\,\mathrm{e}^{-\left(1+\sqrt{6}\right)x}dx\right)\right)}{12}$
- ○ Compute integrals

  $y_p(x) = -\frac{x}{5} + \frac{2}{25}$
- Substitute particular solution into general solution to ODE

$$y = c_1 e^{(1-\sqrt{6})x} + c_2 e^{(1+\sqrt{6})x} - \frac{x}{5} + \frac{2}{25}$$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y = e^x}$$

14.6.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(\cos(x) c_1 + c_2 \sin(x))$$

Or

$$y = \cos(x) c_1 + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = \cos(x) c_1 + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x) c_1 + c_2 \sin(x)) + \left(\frac{e^x}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(x) c_1 + c_2 \sin(x) + \frac{e^x}{2} \tag{1}$$

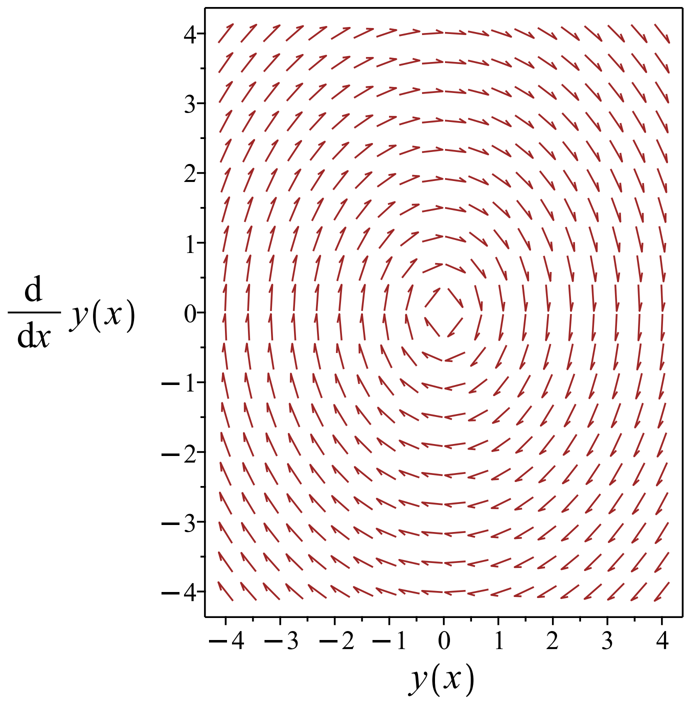

Figure 383: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) + \frac{e^x}{2}$$

Verified OK.

14.6.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 342: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\, dx \\ &= \cos(x) (\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)) + c_2(\cos(x) (\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\, c_1 + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x) c_1 + c_2 \sin(x)) + \left(\frac{e^x}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \cos(x) c_1 + c_2 \sin(x) + \frac{e^x}{2} \tag{1}$$

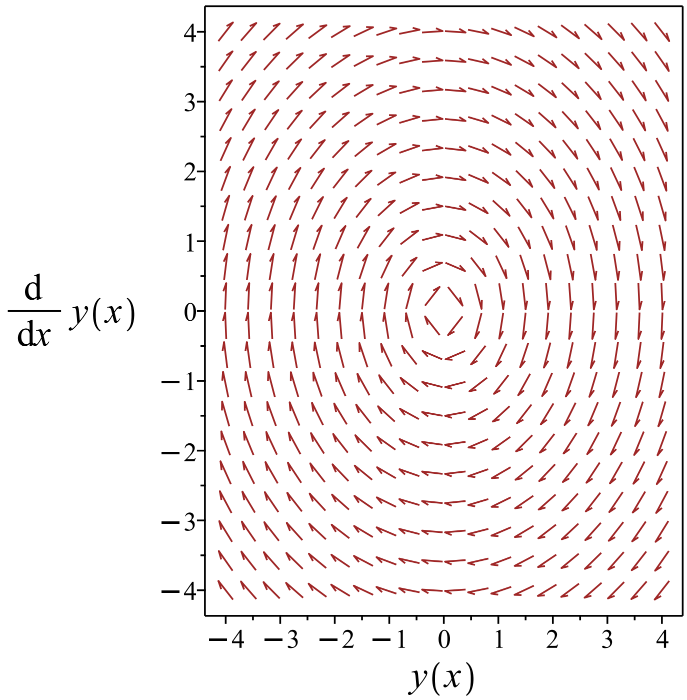

Figure 384: Slope field plot

Verification of solutions

$$y = \cos(x) c_1 + c_2 \sin(x) + \frac{e^x}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' + y = \sin(x)}$$

14.7.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 1, f(x) = \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=1, C=1$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x}+\lambda \mathrm{e}^{\lambda x}+\mathrm{e}^{\lambda x}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2+\lambda+1=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=1, C=1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{1^2-(4)\,(1)\,(1)}\\ &= -\frac{1}{2} \pm \frac{i\sqrt{3}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{1}{2}+\frac{i\sqrt{3}}{2}\\ \lambda_2 &= -\frac{1}{2}-\frac{i\sqrt{3}}{2}\end{aligned}$$

Which simplifies to

$$\lambda_1 = -\frac{1}{2}+\frac{i\sqrt{3}}{2}$$

$$\lambda_2 = -\frac{1}{2}-\frac{i\sqrt{3}}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2}=\alpha \pm i\beta$$

Where $\alpha=-\frac{1}{2}$ and $\beta=\frac{\sqrt{3}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y=e^{\alpha x}(c_1\cos(\beta x)+c_2\sin(\beta x))$$

Which becomes

$$y=e^{-\frac{x}{2}}\left(c_1\cos\left(\frac{\sqrt{3}\,x}{2}\right)+c_2\sin\left(\frac{\sqrt{3}\,x}{2}\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{3}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\, x}{2}\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right), e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\, x}{2}\right)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \sin(x) + A_2 \cos(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{3}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\, x}{2}\right)\right)\right) + (-\cos(x)) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{3}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\, x}{2}\right)\right) - \cos(x) \tag{1}$$

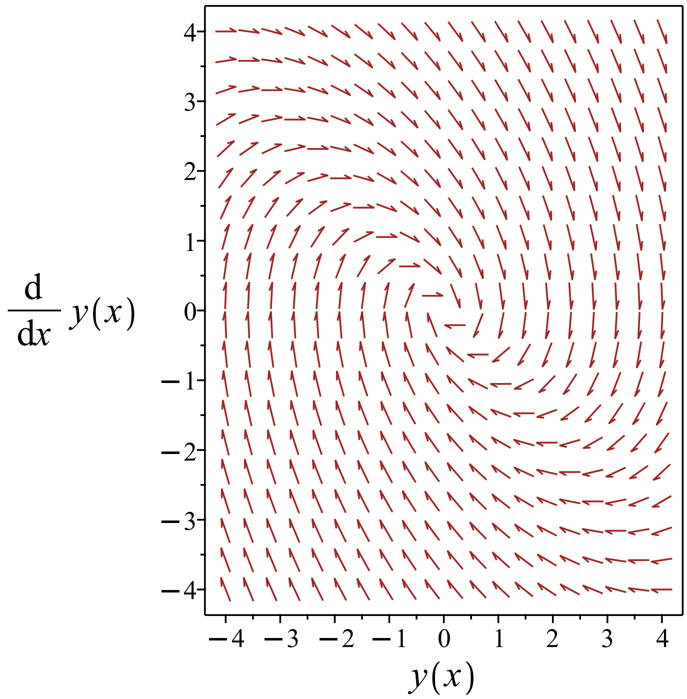

Figure 385: Slope field plot

Verification of solutions

$$y = e^{-\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{3}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{3}\, x}{2}\right)\right) - \cos(x)$$

Verified OK.

14.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 1 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{3z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 344: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\frac{3}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos\left(\frac{\sqrt{3}\,x}{2}\right)
$$

Using the above, the solution for the original ode can now be found. The first solution

to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{1}{1}\,dx} \\
&= z_1 e^{-\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{-\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2\sqrt{3}\,\tan\left(\frac{\sqrt{3}\,x}{2}\right)}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\right) + c_2\left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\left(\frac{2\sqrt{3}\,\tan\left(\frac{\sqrt{3}\,x}{2}\right)}{3}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+y'+y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \frac{2c_2 \mathrm{e}^{-\frac{x}{2}} \sqrt{3}\,\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right), \frac{2\,\mathrm{e}^{-\frac{x}{2}} \sqrt{3}\,\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{3}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_1 \sin(x) + A_2 \cos(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -1, A_2 = 0]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\cos(x)$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \frac{2c_2 \mathrm{e}^{-\frac{x}{2}} \sqrt{3}\, \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{3}\right) + (-\cos(x))
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \frac{2c_2 \mathrm{e}^{-\frac{x}{2}} \sqrt{3}\, \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{3} - \cos(x) \tag{1}
$$

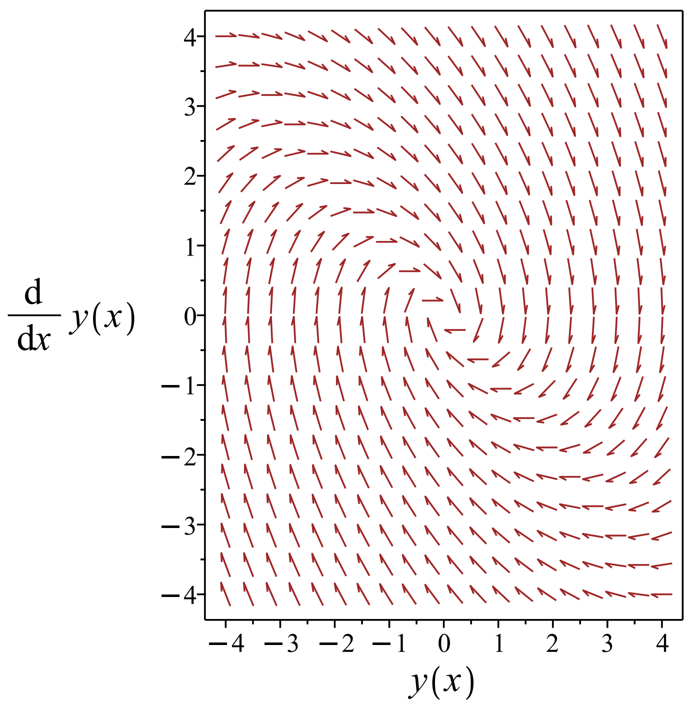

Figure 386: Slope field plot

Verification of solutions

$$
y = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \frac{2c_2 \mathrm{e}^{-\frac{x}{2}} \sqrt{3}\, \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{3} - \cos(x)
$$

Verified OK.

14.7.3 Maple step by step solution

Let's solve

$y'' + y' + y = \sin(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1) \pm (\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - \frac{I\sqrt{3}}{2}, -\frac{1}{2} + \frac{I\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\, x}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right) c_1 + e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\, x}{2}\right) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right) & e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\, x}{2}\right) \\ -\frac{e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right)}{2} - \frac{e^{-\frac{x}{2}} \sqrt{3}\, \sin\left(\frac{\sqrt{3}\, x}{2}\right)}{2} & -\frac{e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\, x}{2}\right)}{2} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\, x}{2}\right) \sqrt{3}}{2} \end{bmatrix}$

  ◦ Compute Wronskian

$W(y_1(x), y_2(x)) = \frac{\sqrt{3}\,e^{-x}}{2}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{2\sqrt{3}\,e^{-\frac{x}{2}}\left(\cos\left(\frac{\sqrt{3}\,x}{2}\right)\left(\int e^{\frac{x}{2}}\sin(x)\sin\left(\frac{\sqrt{3}\,x}{2}\right)dx\right)-\sin\left(\frac{\sqrt{3}\,x}{2}\right)\left(\int e^{\frac{x}{2}}\sin(x)\cos\left(\frac{\sqrt{3}\,x}{2}\right)dx\right)\right)}{3}$

- Compute integrals

  $y_p(x) = -\cos(x)$

- Substitute particular solution into general solution to ODE

  $y = e^{-\frac{x}{2}}\sin\left(\frac{\sqrt{3}\,x}{2}\right)c_2 + e^{-\frac{x}{2}}\cos\left(\frac{\sqrt{3}\,x}{2}\right)c_1 - \cos(x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y = \mathrm{e}^{3x}}$$

14.8.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = \mathrm{e}^{3x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 e^{x} + c_2 e^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{x} + c_2 e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{3x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{3x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{3x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 e^{3x} = e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{3x}}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{x} + c_2 e^{-x}\right) + \left(\frac{e^{3x}}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{x} + c_2 e^{-x} + \frac{e^{3x}}{8} \tag{1}$$

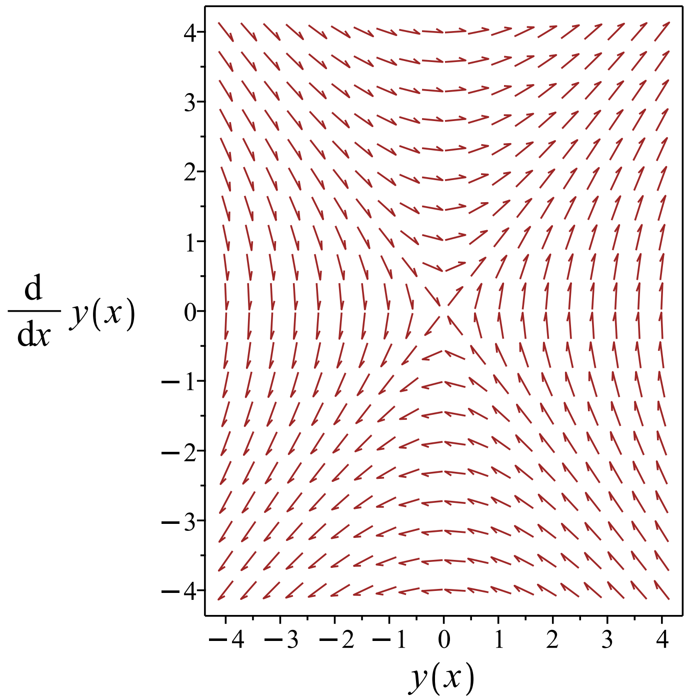

Figure 387: Slope field plot

Verification of solutions

$$y = c_1 e^{x} + c_2 e^{-x} + \frac{e^{3x}}{8}$$

Verified OK.

14.8.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 346: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= e^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= e^{-x} \int \frac{1}{e^{-2x}}\,dx \\ &= e^{-x} \left(\frac{e^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{3x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{3x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{x}}{2}, \mathrm{e}^{-x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{3x}
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 e^{3x} = e^{3x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{3x}}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{c_2 e^{x}}{2}\right) + \left(\frac{e^{3x}}{8}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} + \frac{e^{3x}}{8} \tag{1}$$

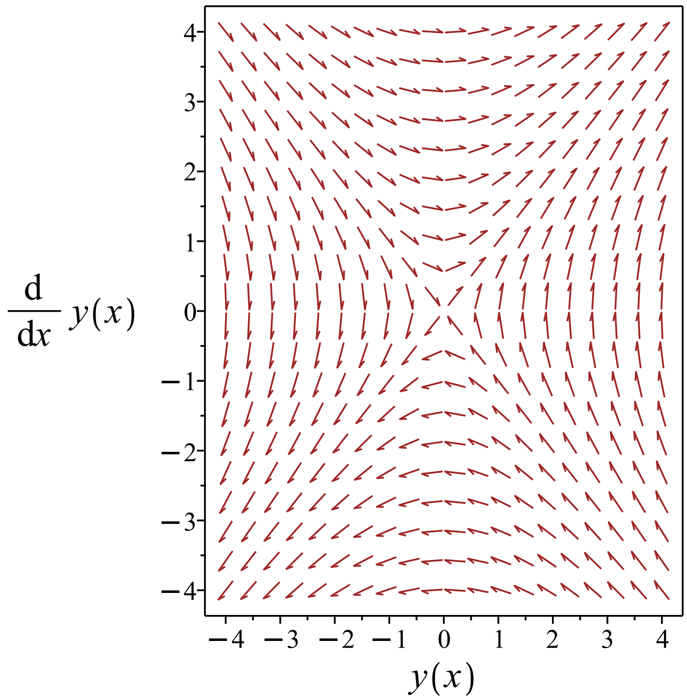

Figure 388: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} + \frac{e^{3x}}{8}$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Problems for Review and Discovery. Drill excercises. Page 105
Problem number: 2(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 9y = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 2]$$

14.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 9 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 9y = 0$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 9$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

14.9.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i \\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\lambda_1 = 3i$$
$$\lambda_2 = -3i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(3x) + c_2 \sin(3x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \sin(3x) + 3c_2 \cos(3x)$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = \frac{2}{3}$$

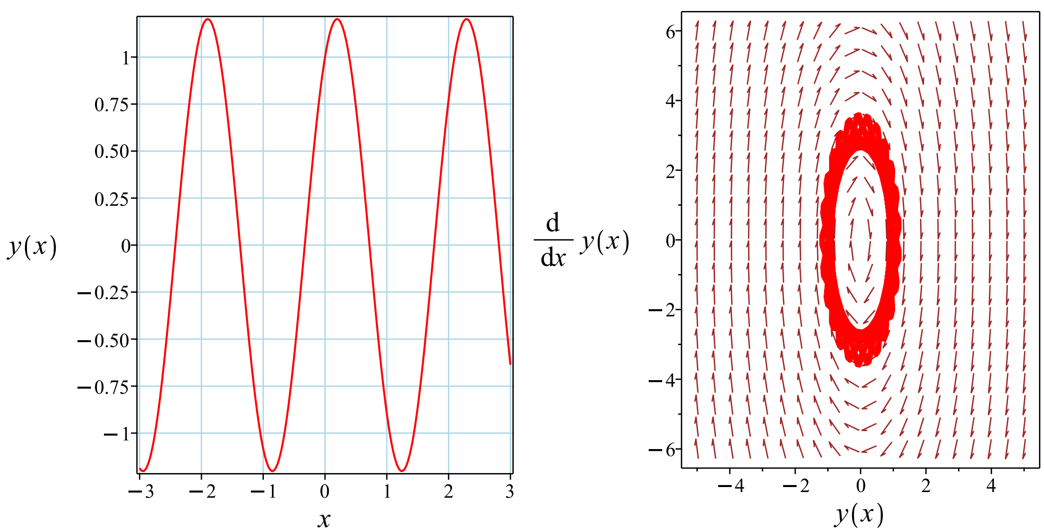
Substituting these values back in above solution results in

$$y = \frac{2\sin(3x)}{3} + \cos(3x)$$

Summary

The solution(s) found are the following

$$y = \frac{2\sin(3x)}{3} + \cos(3x) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{2\sin(3x)}{3} + \cos(3x)$$

Verified OK.

14.9.3 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + 9y'y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + 9y'y)\, dx = 0$$

$$\frac{y'^2}{2} + \frac{9y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-9y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{-9y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-9y^2 + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = c_2 + x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-9y^2 + 2c_1}} dy = \int dx$$
$$-\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+2c_1}}\right)}{3} = c_2 + x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$\frac{\arctan\left(\frac{3}{\sqrt{-9+2c_1}}\right)}{3} = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\left(3 \tan \left(3 c_2 + 3 x\right)^2 + 3\right) \sqrt{2}\, \sqrt{\frac{c_1}{\tan(3 c_2+3 x)^2+1}}}{3} - \frac{\tan \left(3 c_2 + 3 x\right)^2 \sqrt{2}\, c_1 \left(3 \tan \left(3 c_2 + 3 x\right)^2 + 3\right)}{3 \sqrt{\frac{c_1}{\tan(3 c_2+3 x)^2+1}}\, \left(\tan \left(3 c_2 + 3 x\right)^2 + 1\right)^2}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = \frac{\cos \left(3 c_2\right)^2 c_1 \sqrt{2}}{\sqrt{c_1 \cos \left(3 c_2\right)^2}} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{13}{2}$$
$$c_2 = \frac{\arctan \left(\frac{3}{2}\right)}{3}$$

Substituting these values back in above solution results in

$$\frac{\arctan \left(\frac{3 y}{\sqrt{-9 y^2+13}}\right)}{3} = \frac{\arctan \left(\frac{3}{2}\right)}{3} + x$$

Looking at the Second solution

$$-\frac{\arctan \left(\frac{3 y}{\sqrt{-9 y^2+2 c_1}}\right)}{3} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$-\frac{\arctan \left(\frac{3}{\sqrt{-9+2 c_1}}\right)}{3} = c_3 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{\left(3 \tan \left(3 x + 3 c_3\right)^2 + 3\right) \sqrt{2}\, \sqrt{\frac{c_1}{\tan(3 x+3 c_3)^2+1}}}{3} + \frac{\tan \left(3 x + 3 c_3\right)^2 \sqrt{2}\, c_1 \left(3 \tan \left(3 x + 3 c_3\right)^2 + 3\right)}{3 \sqrt{\frac{c_1}{\tan(3 x+3 c_3)^2+1}}\, \left(\tan \left(3 x + 3 c_3\right)^2 + 1\right)^2}$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = -\frac{\cos \left(3 c_3\right)^2 c_1 \sqrt{2}}{\sqrt{c_1 \cos \left(3 c_3\right)^2}} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_3\}$. There is no solution for the constants of integrations. This solution is removed.

Summary

The solution(s) found are the following

$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+13}}\right)}{3} = \frac{\arctan\left(\frac{3}{2}\right)}{3} + x \tag{1}$$

Verification of solutions

$$\frac{\arctan\left(\frac{3y}{\sqrt{-9y^2+13}}\right)}{3} = \frac{\arctan\left(\frac{3}{2}\right)}{3} + x$$

Verified OK.

14.9.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -9$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 348: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(3x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2}\,dx \\ &= \cos(3x) \left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2\left(\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 \sin(3x) + c_2 \cos(3x)$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$2 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

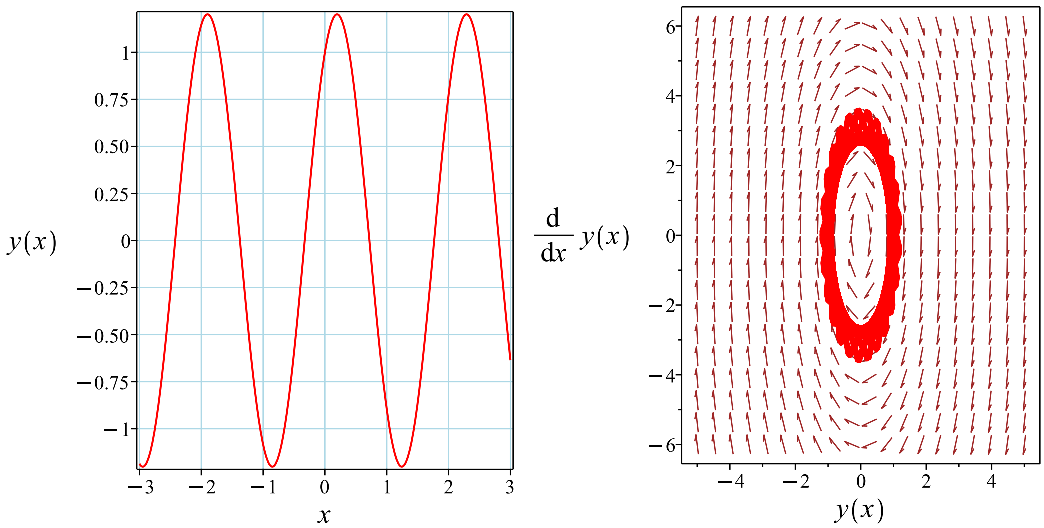
$$c_1 = 1$$
$$c_2 = 2$$

Substituting these values back in above solution results in

$$y = \frac{2\sin(3x)}{3} + \cos(3x)$$

Summary
The solution(s) found are the following

$$y = \frac{2\sin(3x)}{3} + \cos(3x) \tag{1}$$



(a) Solution plot (b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{2\sin(3x)}{3} + \cos(3x)$$

Verified OK.

14.9.5 Maple step by step solution

Let's solve

$\left[y'' + 9y = 0, y(0) = 1, y'\Big|_{\{x=0\}} = 2\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the ODE

$y_1(x) = \cos(3x)$

- 2nd solution of the ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \cos(3x) + c_2 \sin(3x)$

☐ Check validity of solution $y = c_1 \cos(3x) + c_2 \sin(3x)$

  - Use initial condition $y(0) = 1$

    $1 = c_1$

  - Compute derivative of the solution

    $y' = -3c_1 \sin(3x) + 3c_2 \cos(3x)$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 2$

    $2 = 3c_2$

  - Solve for c_1 and c_2

    $\left\{c_1 = 1, c_2 = \frac{2}{3}\right\}$

  - Substitute constant values into general solution and simplify

    $y = \frac{2\sin(3x)}{3} + \cos(3x)$

- Solution to the IVP

  $y = \frac{2\sin(3x)}{3} + \cos(3x)$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y' + 4y = x}$$

With initial conditions

$$[y(1) = 2, y'(1) = 1]$$

14.10.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -1 \\ q(x) &= 4 \\ F &= x \end{aligned}$$

Hence the ode is

$$y'' - y' + 4y = x$$

The domain of $p(x) = -1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. The domain of $F = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

14.10.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = 4, f(x) = x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \,\mathrm{e}^{\lambda x} + 4 \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{1}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-1^2 - (4)(1)(4)}\\ &= \frac{1}{2} \pm \frac{i\sqrt{15}}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{1}{2} + \frac{i\sqrt{15}}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{i\sqrt{15}}{2}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2} + \frac{i\sqrt{15}}{2}$$
$$\lambda_2 = \frac{1}{2} - \frac{i\sqrt{15}}{2}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = \frac{1}{2}$ and $\beta = \frac{\sqrt{15}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{\frac{x}{2}}\left(c_1 \cos\left(\frac{\sqrt{15}\,x}{2}\right) + c_2 \sin\left(\frac{\sqrt{15}\,x}{2}\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{\frac{x}{2}}\left(c_1 \cos\left(\frac{\sqrt{15}\,x}{2}\right) + c_2 \sin\left(\frac{\sqrt{15}\,x}{2}\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{ e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\, x}{2}\right), e^{\frac{x}{2}} \sin\left(\frac{\sqrt{15}\, x}{2}\right) \right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_2 x + 4A_1 - A_2 = x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{16}, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x}{4} + \frac{1}{16}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{15}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{15}\, x}{2}\right)\right)\right) + \left(\frac{x}{4} + \frac{1}{16}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{15}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{15}\, x}{2}\right)\right) + \frac{x}{4} + \frac{1}{16} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 1$ in the above gives

$$2 = e^{\frac{1}{2}} \cos\left(\frac{\sqrt{15}}{2}\right) c_1 + e^{\frac{1}{2}} \sin\left(\frac{\sqrt{15}}{2}\right) c_2 + \frac{5}{16} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{e^{\frac{x}{2}} \left(c_1 \cos\left(\frac{\sqrt{15}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{15}\, x}{2}\right)\right)}{2} + e^{\frac{x}{2}} \left(-\frac{c_1 \sqrt{15}\, \sin\left(\frac{\sqrt{15}\, x}{2}\right)}{2} + \frac{c_2 \sqrt{15}\, \cos\left(\frac{\sqrt{15}\, x}{2}\right)}{2}\right) + \frac{1}{4}$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = \frac{e^{\frac{1}{2}} \left(\sqrt{15}\, c_2 + c_1\right) \cos\left(\frac{\sqrt{15}}{2}\right)}{2} + \frac{1}{4} - \frac{e^{\frac{1}{2}} \left(\sqrt{15}\, c_1 - c_2\right) \sin\left(\frac{\sqrt{15}}{2}\right)}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{e^{-\frac{1}{2}} \sqrt{15} \left(9\sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right) + \sin\left(\frac{\sqrt{15}}{2}\right)\right)}{80}$$
$$c_2 = \frac{e^{-\frac{1}{2}} \sqrt{15} \left(9\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right) - \cos\left(\frac{\sqrt{15}}{2}\right)\right)}{80}$$

Substituting these values back in above solution results in

$$y = \frac{1}{16} + \frac{x}{4} + \frac{27 \sin\left(\frac{\sqrt{15}\, x}{2}\right) e^{\frac{x}{2}-\frac{1}{2}} \sin\left(\frac{\sqrt{15}}{2}\right)}{16} - \frac{\sin\left(\frac{\sqrt{15}\, x}{2}\right) e^{\frac{x}{2}-\frac{1}{2}} \sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right)}{80} + \frac{27 \cos\left(\frac{\sqrt{15}\, x}{2}\right) \cos\left(\frac{\sqrt{15}}{2}\right. \cdots}{16}$$

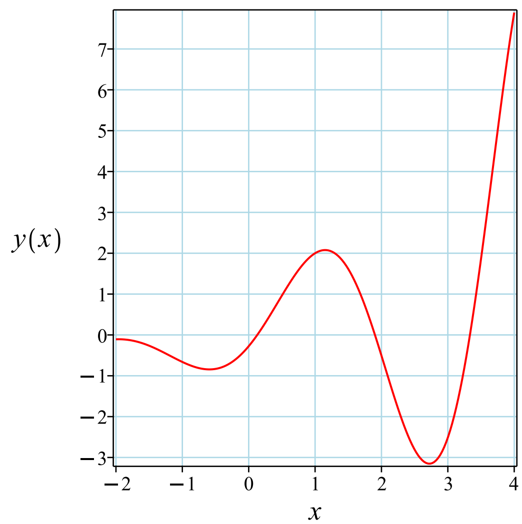
Which simplifies to

$$y = \frac{\left(\left(\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right) + 135 \cos\left(\frac{\sqrt{15}}{2}\right)\right) \cos\left(\frac{\sqrt{15}\, x}{2}\right) - \sin\left(\frac{\sqrt{15}\, x}{2}\right) \left(\sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right) - 135 \sin\left(\frac{\sqrt{15}}{2}\right)\right)\right) e^{\frac{x}{2}-\frac{1}{2}} \cdots}{80} + \frac{x}{4} + \frac{1}{16}$$

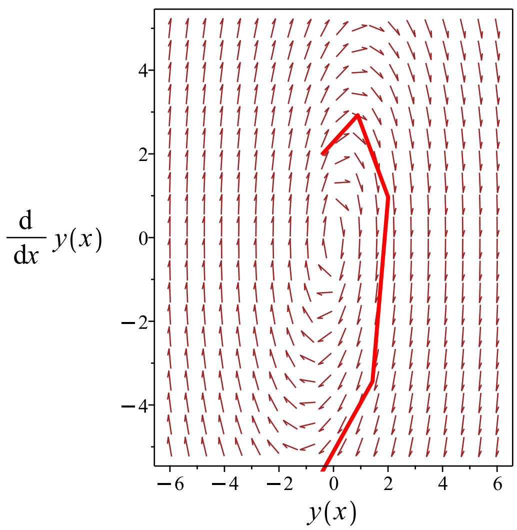
Summary

The solution(s) found are the following

$$y = \frac{\left(\left(\sqrt{15}\,\sin\left(\frac{\sqrt{15}}{2}\right)+135\cos\left(\frac{\sqrt{15}}{2}\right)\right)\cos\left(\frac{\sqrt{15}\,x}{2}\right)-\sin\left(\frac{\sqrt{15}\,x}{2}\right)\left(\sqrt{15}\,\cos\left(\frac{\sqrt{15}}{2}\right)-135\sin\left(\frac{\sqrt{15}}{2}\right)\right)\right)\mathrm{e}^{\frac{x}{2}-\frac{1}{2}}}{80} + \frac{x}{4}+\frac{1}{16} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{\left(\left(\sqrt{15}\,\sin\left(\frac{\sqrt{15}}{2}\right)+135\cos\left(\frac{\sqrt{15}}{2}\right)\right)\cos\left(\frac{\sqrt{15}\,x}{2}\right)-\sin\left(\frac{\sqrt{15}\,x}{2}\right)\left(\sqrt{15}\,\cos\left(\frac{\sqrt{15}}{2}\right)-135\sin\left(\frac{\sqrt{15}}{2}\right)\right)\right)\mathrm{e}^{\frac{x}{2}-\frac{1}{2}}}{80} + \frac{x}{4}+\frac{1}{16}$$

Verified OK.

14.10.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-15}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -15 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{15z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 350: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -\frac{15}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\frac{\sqrt{15}\, x}{2}\right)$$

Using the above, the solution for the original ode can now be found. The first solution

to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\
&= z_1 e^{\frac{x}{2}} \\
&= z_1\left(\mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{2\sqrt{15}\,\tan\left(\frac{\sqrt{15}\,x}{2}\right)}{15}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)\right) + c_2\left(\mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)\left(\frac{2\sqrt{15}\,\tan\left(\frac{\sqrt{15}\,x}{2}\right)}{15}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''-y'+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)+\frac{2c_2 e^{\frac{x}{2}}\sqrt{15}\,\sin\left(\frac{\sqrt{15}\,x}{2}\right)}{15}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1,x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right), \frac{2\,e^{\frac{x}{2}}\sqrt{15}\,\sin\left(\frac{\sqrt{15}\,x}{2}\right)}{15}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2x+A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_2x+4A_1-A_2=x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=\frac{1}{16}, A_2=\frac{1}{4}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{x}{4} + \frac{1}{16}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\, x}{2}\right) + \frac{2 c_2 e^{\frac{x}{2}} \sqrt{15}\, \sin\left(\frac{\sqrt{15}\, x}{2}\right)}{15}\right) + \left(\frac{x}{4} + \frac{1}{16}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\, x}{2}\right) + \frac{2 c_2 e^{\frac{x}{2}} \sqrt{15}\, \sin\left(\frac{\sqrt{15}\, x}{2}\right)}{15} + \frac{x}{4} + \frac{1}{16} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 1$ in the above gives

$$2 = e^{\frac{1}{2}} \cos\left(\frac{\sqrt{15}}{2}\right) c_1 + \frac{2 c_2 e^{\frac{1}{2}} \sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right)}{15} + \frac{5}{16} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\, x}{2}\right)}{2} - \frac{c_1 e^{\frac{x}{2}} \sqrt{15}\, \sin\left(\frac{\sqrt{15}\, x}{2}\right)}{2} + \frac{c_2 e^{\frac{x}{2}} \sqrt{15}\, \sin\left(\frac{\sqrt{15}\, x}{2}\right)}{15} + c_2 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\, x}{2}\right) + \frac{1}{4}$$

substituting $y' = 1$ and $x = 1$ in the above gives

$$1 = \frac{e^{\frac{1}{2}} (c_1 + 2c_2) \cos\left(\frac{\sqrt{15}}{2}\right)}{2} + \frac{1}{4} - \frac{\left(c_1 - \frac{2c_2}{15}\right) \sqrt{15}\, e^{\frac{1}{2}} \sin\left(\frac{\sqrt{15}}{2}\right)}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{\left(\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right) + 135 \cos\left(\frac{\sqrt{15}}{2}\right)\right) e^{-\frac{1}{2}}}{80} \\ c_2 &= \frac{3\left(9\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right) - \cos\left(\frac{\sqrt{15}}{2}\right)\right) e^{-\frac{1}{2}}}{32} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{1}{16} + \frac{x}{4} + \frac{27 \sin\left(\frac{\sqrt{15}\,x}{2}\right) e^{\frac{x}{2}-\frac{1}{2}} \sin\left(\frac{\sqrt{15}}{2}\right)}{16} - \frac{\sin\left(\frac{\sqrt{15}\,x}{2}\right) e^{\frac{x}{2}-\frac{1}{2}} \sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right)}{80} + \frac{27 \cos\left(\frac{\sqrt{15}\,x}{2}\right) \cos\left(\frac{\sqrt{15}}{2}\right.}{16}$$

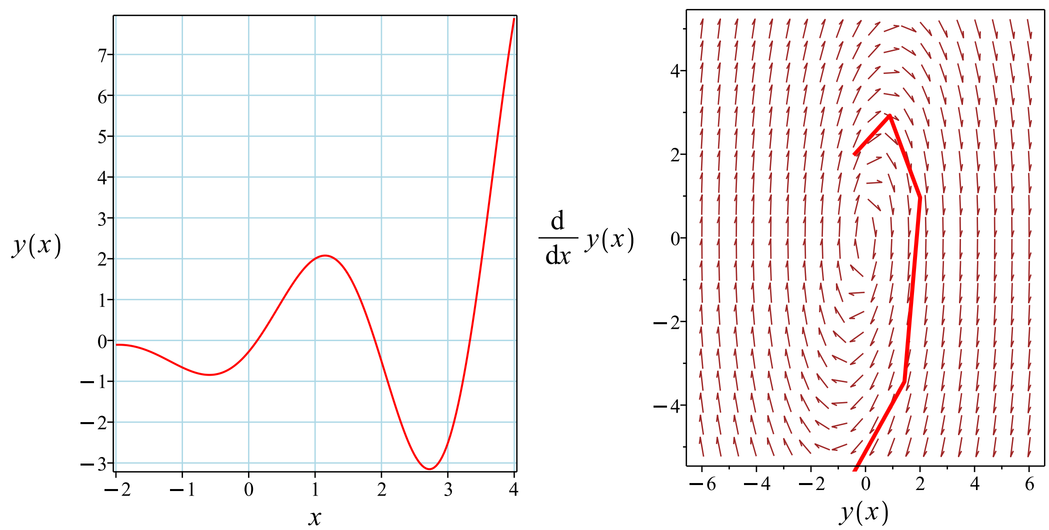
Which simplifies to

$$y = \frac{\left(\left(\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right) + 135 \cos\left(\frac{\sqrt{15}}{2}\right)\right) \cos\left(\frac{\sqrt{15}\,x}{2}\right) - \sin\left(\frac{\sqrt{15}\,x}{2}\right) \left(\sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right) - 135 \sin\left(\frac{\sqrt{15}}{2}\right)\right)\right) e^{\frac{x}{2}-\frac{1}{2}}}{80} + \frac{x}{4} + \frac{1}{16}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\left(\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right) + 135 \cos\left(\frac{\sqrt{15}}{2}\right)\right) \cos\left(\frac{\sqrt{15}\,x}{2}\right) - \sin\left(\frac{\sqrt{15}\,x}{2}\right) \left(\sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right) - 135 \sin\left(\frac{\sqrt{15}}{2}\right)\right)\right) e^{\frac{x}{2}-\frac{1}{2}}}{80} + \frac{x}{4} + \frac{1}{16} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{\left(\left(\sqrt{15}\,\sin\left(\frac{\sqrt{15}}{2}\right) + 135\cos\left(\frac{\sqrt{15}}{2}\right)\right)\cos\left(\frac{\sqrt{15}\,x}{2}\right) - \sin\left(\frac{\sqrt{15}\,x}{2}\right)\left(\sqrt{15}\,\cos\left(\frac{\sqrt{15}}{2}\right) - 135\sin\left(\frac{\sqrt{15}}{2}\right)\right)\right)\mathrm{e}^{\frac{x}{2}-\frac{1}{2}}}{80} + \frac{x}{4} + \frac{1}{16}$$

Verified OK.

14.10.4 Maple step by step solution

Let's solve

$$\left[y'' - y' + 4y = x, y(1) = 2, y'\Big|_{\{x=1\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{1 \pm (\sqrt{-15})}{2}$

- Roots of the characteristic polynomial

  $r = \left(\frac{1}{2} - \frac{\mathrm{I}\sqrt{15}}{2}, \frac{1}{2} + \frac{\mathrm{I}\sqrt{15}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{\frac{x}{2}} \sin\left(\frac{\sqrt{15}\,x}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right) + \mathrm{e}^{\frac{x}{2}} c_2 \sin\left(\frac{\sqrt{15}\,x}{2}\right) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = x\right]$$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right) & e^{\frac{x}{2}} \sin\left(\frac{\sqrt{15}\,x}{2}\right) \\ \frac{e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)}{2} - \frac{e^{\frac{x}{2}} \sqrt{15}\,\sin\left(\frac{\sqrt{15}\,x}{2}\right)}{2} & \frac{e^{\frac{x}{2}} \sin\left(\frac{\sqrt{15}\,x}{2}\right)}{2} + \frac{e^{\frac{x}{2}} \sqrt{15}\,\cos\left(\frac{\sqrt{15}\,x}{2}\right)}{2} \end{bmatrix}$$

- Compute Wronskian

$$W(y_1(x), y_2(x)) = \frac{\sqrt{15}\,e^{x}}{2}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{2\,e^{\frac{x}{2}} \sqrt{15}\left(\cos\left(\frac{\sqrt{15}\,x}{2}\right)\left(\int x\,e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{15}\,x}{2}\right) dx\right) - \sin\left(\frac{\sqrt{15}\,x}{2}\right)\left(\int x\,e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right) dx\right)\right)}{15}$$

- Compute integrals

$$y_p(x) = \frac{x}{4} + \frac{1}{16}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right) + e^{\frac{x}{2}} c_2 \sin\left(\frac{\sqrt{15}\,x}{2}\right) + \frac{x}{4} + \frac{1}{16}$$

☐ Check validity of solution $y = c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right) + e^{\frac{x}{2}} c_2 \sin\left(\frac{\sqrt{15}\,x}{2}\right) + \frac{x}{4} + \frac{1}{16}$

- Use initial condition $y(1) = 2$

$$2 = e^{\frac{1}{2}} \cos\left(\frac{\sqrt{15}}{2}\right) c_1 + e^{\frac{1}{2}} \sin\left(\frac{\sqrt{15}}{2}\right) c_2 + \frac{5}{16}$$

- Compute derivative of the solution

$$y' = \frac{c_1 e^{\frac{x}{2}} \cos\left(\frac{\sqrt{15}\,x}{2}\right)}{2} - \frac{c_1 e^{\frac{x}{2}} \sqrt{15}\,\sin\left(\frac{\sqrt{15}\,x}{2}\right)}{2} + \frac{e^{\frac{x}{2}} c_2 \sin\left(\frac{\sqrt{15}\,x}{2}\right)}{2} + \frac{e^{\frac{x}{2}} c_2 \sqrt{15}\,\cos\left(\frac{\sqrt{15}\,x}{2}\right)}{2} + \frac{1}{4}$$

- Use the initial condition $y'\Big|_{\{x=1\}} = 1$

$$1 = \frac{1}{4} + \frac{e^{\frac{1}{2}} \cos\left(\frac{\sqrt{15}}{2}\right) c_1}{2} - \frac{e^{\frac{1}{2}} c_1 \sqrt{15}\,\sin\left(\frac{\sqrt{15}}{2}\right)}{2} + \frac{e^{\frac{1}{2}} \sin\left(\frac{\sqrt{15}}{2}\right) c_2}{2} + \frac{c_2 e^{\frac{1}{2}} \sqrt{15}\,\cos\left(\frac{\sqrt{15}}{2}\right)}{2}$$

- Solve for c_1 and c_2

$$\left\{c_1 = \frac{\left(9\sqrt{15}\,\cos\left(\frac{\sqrt{15}}{2}\right) + \sin\left(\frac{\sqrt{15}}{2}\right)\right)\sqrt{15}}{80\,e^{\frac{1}{2}}\left(\sin\left(\frac{\sqrt{15}}{2}\right)^2 + \cos\left(\frac{\sqrt{15}}{2}\right)^2\right)}, c_2 = \frac{\sqrt{15}\left(9\sqrt{15}\,\sin\left(\frac{\sqrt{15}}{2}\right) - \cos\left(\frac{\sqrt{15}}{2}\right)\right)}{80\,e^{\frac{1}{2}}\left(\sin\left(\frac{\sqrt{15}}{2}\right)^2 + \cos\left(\frac{\sqrt{15}}{2}\right)^2\right)}\right\}$$

- Substitute constant values into general solution and simplify

$$y = \frac{\left(\left(\sqrt{15}\,\sin\left(\frac{\sqrt{15}}{2}\right) + 135\cos\left(\frac{\sqrt{15}}{2}\right)\right)\cos\left(\frac{\sqrt{15}\,x}{2}\right) - \sin\left(\frac{\sqrt{15}\,x}{2}\right)\left(\sqrt{15}\,\cos\left(\frac{\sqrt{15}}{2}\right) - 135\sin\left(\frac{\sqrt{15}}{2}\right)\right)\right)e^{\frac{x}{2}-\frac{1}{2}}}{80} + \frac{x}{4} + \frac{1}{16}$$

- Solution to the IVP

$$y = \frac{\left(\left(\sqrt{15}\, \sin\left(\frac{\sqrt{15}}{2}\right)+135 \cos\left(\frac{\sqrt{15}}{2}\right)\right) \cos\left(\frac{\sqrt{15}\, x}{2}\right)-\sin\left(\frac{\sqrt{15}\, x}{2}\right) \left(\sqrt{15}\, \cos\left(\frac{\sqrt{15}}{2}\right)-135 \sin\left(\frac{\sqrt{15}}{2}\right)\right)\right) e^{\frac{x}{2}-\frac{1}{2}}}{80}+\frac{x}{4}+\frac{1}{16}$$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 2y' + 5y = e^x}$$

With initial conditions

$$[y(0) = -1, y'(0) = 1]$$

14.11.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 2 \\ q(x) &= 5 \\ F &= e^x \end{aligned}$$

Hence the ode is

$$y'' + 2y' + 5y = e^x$$

The domain of $p(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 5$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = e^x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

14.11.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = 5, f(x) = e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' + 5y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = 5$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda e^{\lambda x} + 5 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda + 5 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = 5$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{2^2 - (4)(1)(5)}\\ &= -1 \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -1 + 2i\\ \lambda_2 &= -1 - 2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -1$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{-x}(c_1 \cos(2x) + c_2 \sin(2x))$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}\cos(2x), e^{-x}\sin(2x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-x}(c_1\cos(2x) + c_2\sin(2x))\right) + \left(\frac{e^x}{8}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-x}(c_1\cos(2x) + c_2\sin(2x)) + \frac{e^x}{8} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 + \frac{1}{8} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\mathrm{e}^{-x}(c_1 \cos(2x) + c_2 \sin(2x)) + \mathrm{e}^{-x}(-2\sin(2x)\, c_1 + 2c_2 \cos(2x)) + \frac{\mathrm{e}^{x}}{8}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 + \frac{1}{8} + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{9}{8}$$
$$c_2 = -\frac{1}{8}$$

Substituting these values back in above solution results in

$$y = -\frac{9\,\mathrm{e}^{-x}\cos(2x)}{8} - \frac{\mathrm{e}^{-x}\sin(2x)}{8} + \frac{\mathrm{e}^{x}}{8}$$

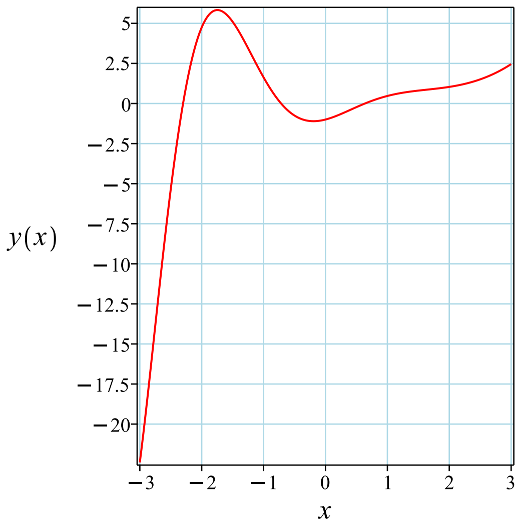
Which simplifies to

$$y = \frac{(-9\cos(2x) - \sin(2x))\,\mathrm{e}^{-x}}{8} + \frac{\mathrm{e}^{x}}{8}$$

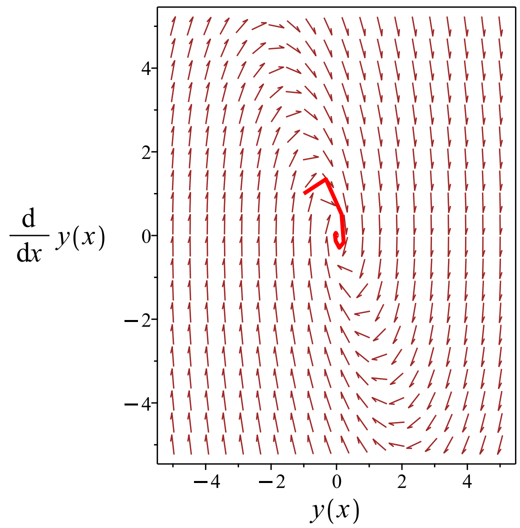
Summary

The solution(s) found are the following

$$y = \frac{(-9\cos(2x) - \sin(2x))\,\mathrm{e}^{-x}}{8} + \frac{\mathrm{e}^{x}}{8} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{(-9\cos(2x) - \sin(2x))\,e^{-x}}{8} + \frac{e^{x}}{8}$$

Verified OK.

14.11.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' + 5y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= 5 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-4}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -4 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -4z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 352: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(2x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2}{1} \, dx} \\
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-x} \cos(2x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-2x}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{\tan(2x)}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-x}\cos(2x)\right) + c_2\left(\mathrm{e}^{-x}\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' + 5y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1\mathrm{e}^{-x}\cos(2x) + \frac{\mathrm{e}^{-x}c_2\sin(2x)}{2}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\mathrm{e}^{-x}\cos(2x), \frac{\mathrm{e}^{-x}\sin(2x)}{2}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1\mathrm{e}^{x}
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$8A_1 e^x = e^x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{8}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^x}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} \cos(2x) + \frac{e^{-x} c_2 \sin(2x)}{2}\right) + \left(\frac{e^x}{8}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-x} \cos(2x) + \frac{e^{-x} c_2 \sin(2x)}{2} + \frac{e^x}{8} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 + \frac{1}{8} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 e^{-x} \cos(2x) - 2c_1 e^{-x} \sin(2x) - \frac{e^{-x} c_2 \sin(2x)}{2} + e^{-x} c_2 \cos(2x) + \frac{e^x}{8}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 + \frac{1}{8} + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{9}{8}$$
$$c_2 = -\frac{1}{4}$$

Substituting these values back in above solution results in

$$y = -\frac{9\,\mathrm{e}^{-x}\cos(2x)}{8} - \frac{\mathrm{e}^{-x}\sin(2x)}{8} + \frac{\mathrm{e}^{x}}{8}$$

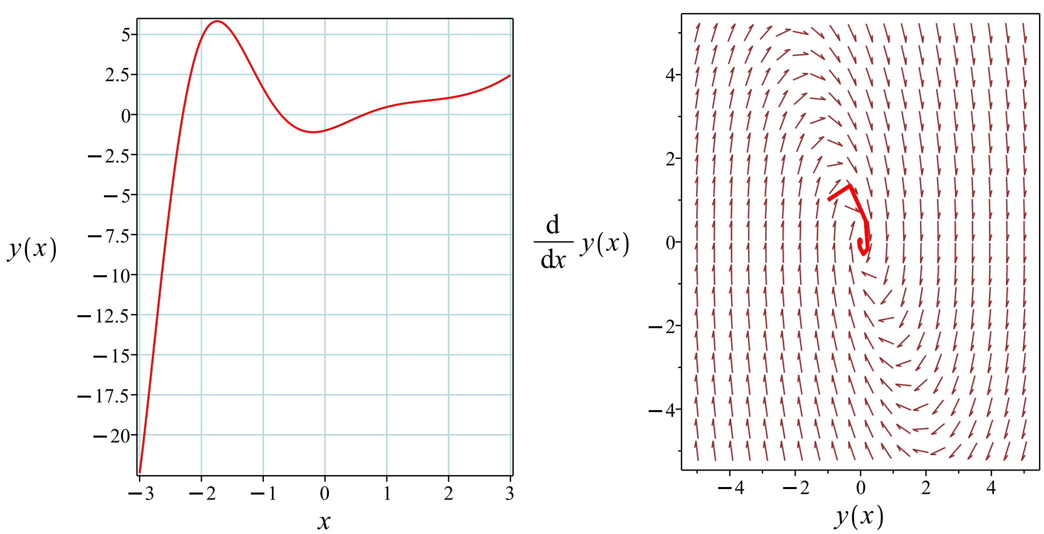
Which simplifies to

$$y = \frac{(-9\cos(2x) - \sin(2x))\,\mathrm{e}^{-x}}{8} + \frac{\mathrm{e}^{x}}{8}$$

Summary

The solution(s) found are the following

$$y = \frac{(-9\cos(2x) - \sin(2x))\,\mathrm{e}^{-x}}{8} + \frac{\mathrm{e}^{x}}{8} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{(-9\cos(2x) - \sin(2x))\,\mathrm{e}^{-x}}{8} + \frac{\mathrm{e}^{x}}{8}$$

Verified OK.

14.11.4 Maple step by step solution

Let's solve

$\left[y'' + 2y' + 5y = e^{x}, y(0) = -1, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm(\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

  $r = (-1 - 2\,\mathrm{I}, -1 + 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x} \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-x} \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} \cos(2x) + e^{-x} c_2 \sin(2x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{x}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x}\cos(2x) & e^{-x}\sin(2x) \\ -e^{-x}\cos(2x) - 2\,e^{-x}\sin(2x) & -e^{-x}\sin(2x) + 2\,e^{-x}\cos(2x) \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,e^{-2x}$

  ◦ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{e^{-x} \left(\cos(2x) \left(\int e^{2x} \sin(2x) dx\right) - \sin(2x) \left(\int e^{2x} \cos(2x) dx\right)\right)}{2}$$

- Compute integrals

  $$y_p(x) = \frac{e^x}{8}$$

- Substitute particular solution into general solution to ODE

  $$y = c_1 e^{-x} \cos(2x) + e^{-x} c_2 \sin(2x) + \frac{e^x}{8}$$

□ Check validity of solution $y = c_1 e^{-x} \cos(2x) + e^{-x} c_2 \sin(2x) + \frac{e^x}{8}$

- Use initial condition $y(0) = -1$

  $$-1 = c_1 + \frac{1}{8}$$

- Compute derivative of the solution

  $$y' = -c_1 e^{-x} \cos(2x) - 2c_1 e^{-x} \sin(2x) - e^{-x} c_2 \sin(2x) + 2 e^{-x} c_2 \cos(2x) + \frac{e^x}{8}$$

- Use the initial condition $y'\Big|_{\{x=0\}} = 1$

  $$1 = -c_1 + \frac{1}{8} + 2c_2$$

- Solve for c_1 and c_2

  $$\left\{c_1 = -\frac{9}{8}, c_2 = -\frac{1}{8}\right\}$$

- Substitute constant values into general solution and simplify

  $$y = \frac{(-9\cos(2x) - \sin(2x)) e^{-x}}{8} + \frac{e^x}{8}$$

- Solution to the IVP

  $$y = \frac{(-9\cos(2x) - \sin(2x)) e^{-x}}{8} + \frac{e^x}{8}$$

Problem number: 2(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 3y' + 4y = \sin(x)}$$

With initial conditions

$$\left[y\left(\frac{\pi}{2}\right) = 1, y'\left(\frac{\pi}{2}\right) = -1\right]$$

14.12.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 3 \\ q(x) &= 4 \\ F &= \sin(x) \end{aligned}$$

Hence the ode is

$$y'' + 3y' + 4y = \sin(x)$$

The domain of $p(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \frac{\pi}{2}$ is inside this domain. The domain of $q(x) = 4$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \frac{\pi}{2}$ is also inside this domain. The domain of $F = \sin(x)$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = \frac{\pi}{2}$ is also inside this domain. Hence solution exists and is unique.

14.12.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 4, f(x) = \sin(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 3\lambda e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-3}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{3^2 - (4)(1)(4)} \\ &= -\frac{3}{2} \pm \frac{i\sqrt{7}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{i\sqrt{7}}{2} \\ \lambda_2 &= -\frac{3}{2} - \frac{i\sqrt{7}}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -\frac{3}{2} + \frac{i\sqrt{7}}{2} \\ \lambda_2 &= -\frac{3}{2} - \frac{i\sqrt{7}}{2}\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = -\frac{3}{2}$ and $\beta = \frac{\sqrt{7}}{2}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{-\frac{3x}{2}}\left(c_1 \cos\left(\frac{\sqrt{7}\,x}{2}\right) + c_2 \sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{-\frac{3x}{2}}\left(c_1 \cos\left(\frac{\sqrt{7}\,x}{2}\right) + c_2 \sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{ e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right), e^{-\frac{3x}{2}} \sin\left(\frac{\sqrt{7}\, x}{2}\right) \right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 \cos(x) + 3A_2 \sin(x) - 3A_1 \sin(x) + 3A_2 \cos(x) = \sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{6}, A_2 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(e^{-\frac{3x}{2}} \left(c_1 \cos\left(\frac{\sqrt{7}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right)\right) + \left(-\frac{\cos(x)}{6} + \frac{\sin(x)}{6}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{-\frac{3x}{2}} \left(c_1 \cos\left(\frac{\sqrt{7}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right) - \frac{\cos(x)}{6} + \frac{\sin(x)}{6} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \frac{\pi}{2}$ in the above gives

$$1 = e^{-\frac{3\pi}{4}} \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) c_1 + e^{-\frac{3\pi}{4}} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) c_2 + \frac{1}{6} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{3\, e^{-\frac{3x}{2}} \left(c_1 \cos\left(\frac{\sqrt{7}\, x}{2}\right) + c_2 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right)}{2} + e^{-\frac{3x}{2}} \left(-\frac{c_1 \sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{2} + \frac{c_2 \sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right)}{2}\right) + \frac{\sin(x)}{6} +$$

substituting $y' = -1$ and $x = \frac{\pi}{2}$ in the above gives

$$-1 = -\frac{3\left(-\frac{\sqrt{7}\, c_2}{3} + c_1\right) e^{-\frac{3\pi}{4}} \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)}{2} + \frac{1}{6} - \frac{e^{-\frac{3\pi}{4}} \left(\sqrt{7}\, c_1 + 3 c_2\right) \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{e^{\frac{3\pi}{4}} \sqrt{7} \left(5\sqrt{7}\, \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) - \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)\right)}{42}$$
$$c_2 = \frac{e^{\frac{3\pi}{4}} \sqrt{7} \left(5\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) + \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)\right)}{42}$$

Substituting these values back in above solution results in

$$y = \frac{\sin(x)}{6} - \frac{\cos(x)}{6} + \frac{5 \cos\left(\frac{\sqrt{7}\, x}{2}\right) \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) e^{-\frac{3x}{2} + \frac{3\pi}{4}}}{6} - \frac{\cos\left(\frac{\sqrt{7}\, x}{2}\right) \sqrt{7}\, \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) e^{-\frac{3x}{2} + \frac{3\pi}{4}}}{42} + \frac{5 \sin\left(\frac{\sqrt{7}\, x}{2}\right.}{}$$

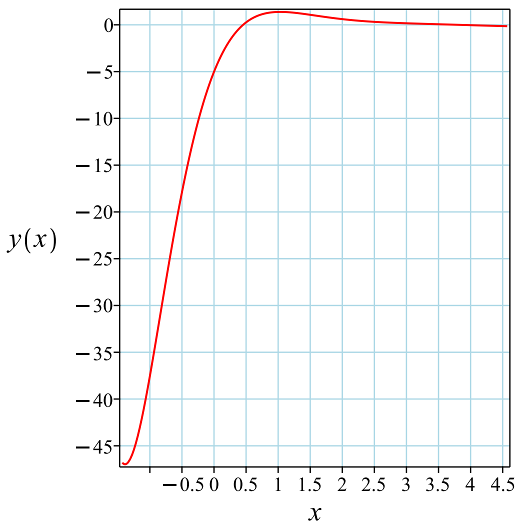
Which simplifies to

$$y = \frac{\left(\left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right) + 35 \cos\left(\frac{\sqrt{7}\, x}{2}\right)\right) \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) - \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) \left(\sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right) - 35 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right)\right) e^{-\frac{3x}{2} + \frac{3\pi}{4}}}{42} - \frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

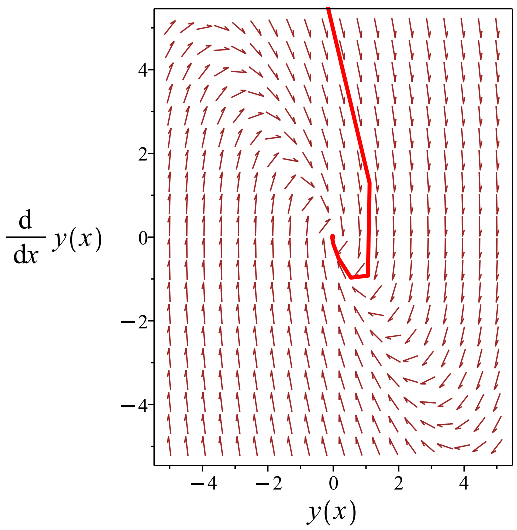
Summary

The solution(s) found are the following

$$y = \frac{\left(\left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right)+35 \cos\left(\frac{\sqrt{7}\, x}{2}\right)\right) \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)-\sin\left(\frac{\sqrt{7}\, \pi}{4}\right) \left(\sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right)-35 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right)\right) {\mathrm e}^{-\frac{3 x}{2}+\frac{3 \pi}{4}}}{42} - \frac{\cos\left(x\right)}{6}+\frac{\sin\left(x\right)}{6} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{\left(\left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right)+35 \cos\left(\frac{\sqrt{7}\, x}{2}\right)\right) \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)-\sin\left(\frac{\sqrt{7}\, \pi}{4}\right) \left(\sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right)-35 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right)\right) {\mathrm e}^{-\frac{3 x}{2}+\frac{3 \pi}{4}}}{42} - \frac{\cos\left(x\right)}{6}+\frac{\sin\left(x\right)}{6}$$

Verified OK.

14.12.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-7}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -7 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -\frac{7z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 354: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -\frac{7}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos\left(\frac{\sqrt{7}\,x}{2}\right)
$$

Using the above, the solution for the original ode can now be found. The first solution

to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\,x}{2}\right)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{2\sqrt{7}\,\tan\left(\frac{\sqrt{7}\,x}{2}\right)}{7}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\,x}{2}\right)\right) + c_2 \left(\mathrm{e}^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\,x}{2}\right) \left(\frac{2\sqrt{7}\,\tan\left(\frac{\sqrt{7}\,x}{2}\right)}{7}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+3y'+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\,x}{2}\right)+\frac{2c_2 \mathrm{e}^{-\frac{3x}{2}} \sqrt{7}\, \sin\left(\frac{\sqrt{7}\,x}{2}\right)}{7}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\,x}{2}\right), \frac{2\,\mathrm{e}^{-\frac{3x}{2}} \sqrt{7}\, \sin\left(\frac{\sqrt{7}\,x}{2}\right)}{7}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x)+A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$3A_1 \cos(x)+3A_2 \sin(x)-3A_1 \sin(x)+3A_2 \cos(x)=\sin(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1=-\frac{1}{6}, A_2=\frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) + \frac{2c_2 e^{-\frac{3x}{2}} \sqrt{7} \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{7}\right) + \left(-\frac{\cos(x)}{6} + \frac{\sin(x)}{6}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) + \frac{2c_2 e^{-\frac{3x}{2}} \sqrt{7} \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{7} - \frac{\cos(x)}{6} + \frac{\sin(x)}{6} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = \frac{\pi}{2}$ in the above gives

$$1 = e^{-\frac{3\pi}{4}} \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) c_1 + \frac{2c_2 e^{-\frac{3\pi}{4}} \sqrt{7} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)}{7} + \frac{1}{6} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{3c_1 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right)}{2} - \frac{c_1 e^{-\frac{3x}{2}} \sqrt{7} \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{2} - \frac{3c_2 e^{-\frac{3x}{2}} \sqrt{7} \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{7} + c_2 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) + \frac{\sin(x)}{6}$$

substituting $y' = -1$ and $x = \frac{\pi}{2}$ in the above gives

$$-1 = -\frac{3\left(c_1 - \frac{2c_2}{3}\right) e^{-\frac{3\pi}{4}} \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)}{2} + \frac{1}{6} - \frac{\sqrt{7}\left(c_1 + \frac{6c_2}{7}\right) e^{-\frac{3\pi}{4}} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)}{2} \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -\frac{\left(\sqrt{7} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) - 35 \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)\right) e^{\frac{3\pi}{4}}}{42} \\ c_2 &= \frac{\left(5\sqrt{7} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) + \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)\right) e^{\frac{3\pi}{4}}}{12} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{\sin(x)}{6} - \frac{\cos(x)}{6} + \frac{5\cos\left(\frac{\sqrt{7}\,x}{2}\right)\cos\left(\frac{\sqrt{7}\,\pi}{4}\right)\mathrm{e}^{-\frac{3x}{2}+\frac{3\pi}{4}}}{6} - \frac{\cos\left(\frac{\sqrt{7}\,x}{2}\right)\sqrt{7}\,\sin\left(\frac{\sqrt{7}\,\pi}{4}\right)\mathrm{e}^{-\frac{3x}{2}+\frac{3\pi}{4}}}{42} + \frac{5\sin\left(\frac{\sqrt{7}\,x}{2}\right.}{}$$

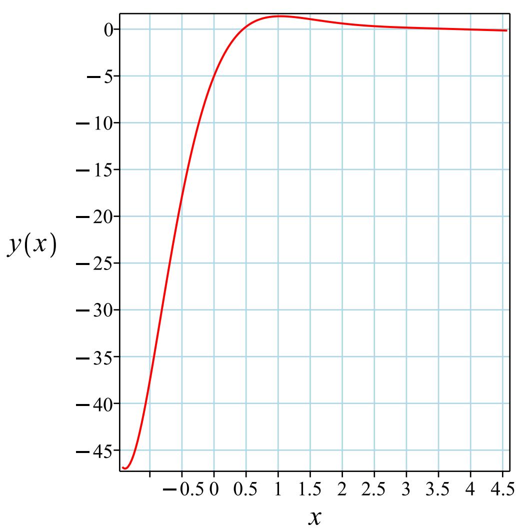
Which simplifies to

$$y = \frac{\left(\left(\sqrt{7}\,\sin\left(\frac{\sqrt{7}\,x}{2}\right) + 35\cos\left(\frac{\sqrt{7}\,x}{2}\right)\right)\cos\left(\frac{\sqrt{7}\,\pi}{4}\right) - \sin\left(\frac{\sqrt{7}\,\pi}{4}\right)\left(\sqrt{7}\,\cos\left(\frac{\sqrt{7}\,x}{2}\right) - 35\sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)\right)\mathrm{e}^{-\frac{3x}{2}+\frac{3\pi}{4}}}{42} - \frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

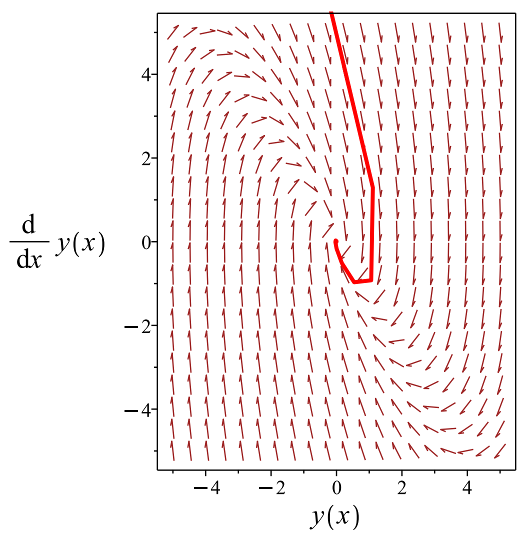
Summary

The solution(s) found are the following

$$y = \frac{\left(\left(\sqrt{7}\,\sin\left(\frac{\sqrt{7}\,x}{2}\right) + 35\cos\left(\frac{\sqrt{7}\,x}{2}\right)\right)\cos\left(\frac{\sqrt{7}\,\pi}{4}\right) - \sin\left(\frac{\sqrt{7}\,\pi}{4}\right)\left(\sqrt{7}\,\cos\left(\frac{\sqrt{7}\,x}{2}\right) - 35\sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)\right)\mathrm{e}^{-\frac{3x}{2}+\frac{3\pi}{4}}}{42} - \frac{\cos(x)}{6} + \frac{\sin(x)}{6} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{\left(\left(\sqrt{7}\,\sin\left(\frac{\sqrt{7}\,x}{2}\right)+35\cos\left(\frac{\sqrt{7}\,x}{2}\right)\right)\cos\left(\frac{\sqrt{7}\,\pi}{4}\right)-\sin\left(\frac{\sqrt{7}\,\pi}{4}\right)\left(\sqrt{7}\,\cos\left(\frac{\sqrt{7}\,x}{2}\right)-35\sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)\right)\mathrm{e}^{-\frac{3x}{2}+\frac{3\pi}{4}}}{42} - \frac{\cos(x)}{6}+\frac{\sin(x)}{6}$$

Verified OK.

14.12.4 Maple step by step solution

Let's solve

$$\left[y''+3y'+4y=\sin(x), y\left(\frac{\pi}{2}\right)=1, y'\Big|_{\left\{x=\frac{\pi}{2}\right\}}=-1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2+3r+4=0$

- Use quadratic formula to solve for r

  $r=\frac{(-3)\pm(\sqrt{-7})}{2}$

- Roots of the characteristic polynomial

  $r=\left(-\frac{3}{2}-\frac{\mathrm{I}\sqrt{7}}{2}, -\frac{3}{2}+\frac{\mathrm{I}\sqrt{7}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{-\frac{3x}{2}}\cos\left(\frac{\sqrt{7}\,x}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\mathrm{e}^{-\frac{3x}{2}}\sin\left(\frac{\sqrt{7}\,x}{2}\right)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\mathrm{e}^{-\frac{3x}{2}}\cos\left(\frac{\sqrt{7}\,x}{2}\right)+\mathrm{e}^{-\frac{3x}{2}}c_2\sin\left(\frac{\sqrt{7}\,x}{2}\right)+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \sin(x)\right]$$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) & e^{-\frac{3x}{2}} \sin\left(\frac{\sqrt{7}\, x}{2}\right) \\ -\frac{3\, e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right)}{2} - \frac{e^{-\frac{3x}{2}} \sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{2} & -\frac{3\, e^{-\frac{3x}{2}} \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{2} + \frac{e^{-\frac{3x}{2}} \sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right)}{2} \end{bmatrix}$$

- Compute Wronskian

$$W(y_1(x), y_2(x)) = \frac{\sqrt{7}\, e^{-3x}}{2}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{2\, e^{-\frac{3x}{2}} \sqrt{7}\left(\cos\left(\frac{\sqrt{7}\, x}{2}\right)\left(\int \sin(x) e^{\frac{3x}{2}} \sin\left(\frac{\sqrt{7}\, x}{2}\right) dx\right) - \sin\left(\frac{\sqrt{7}\, x}{2}\right)\left(\int \sin(x) e^{\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) dx\right)\right)}{7}$$

- Compute integrals

$$y_p(x) = -\frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) + e^{-\frac{3x}{2}} c_2 \sin\left(\frac{\sqrt{7}\, x}{2}\right) - \frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

☐ Check validity of solution $y = c_1 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right) + e^{-\frac{3x}{2}} c_2 \sin\left(\frac{\sqrt{7}\, x}{2}\right) - \frac{\cos(x)}{6} + \frac{\sin(x)}{6}$

- Use initial condition $y\left(\frac{\pi}{2}\right) = 1$

$$1 = e^{-\frac{3\pi}{4}} \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) c_1 + e^{-\frac{3\pi}{4}} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) c_2 + \frac{1}{6}$$

- Compute derivative of the solution

$$y' = -\frac{3 c_1 e^{-\frac{3x}{2}} \cos\left(\frac{\sqrt{7}\, x}{2}\right)}{2} - \frac{c_1 e^{-\frac{3x}{2}} \sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{2} - \frac{3\, e^{-\frac{3x}{2}} c_2 \sin\left(\frac{\sqrt{7}\, x}{2}\right)}{2} + \frac{e^{-\frac{3x}{2}} c_2 \sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right)}{2} + \frac{\sin(x)}{6} + \frac{\cos(x)}{6}$$

- Use the initial condition $y'\Big|_{\{x=\frac{\pi}{2}\}} = -1$

$$-1 = \frac{1}{6} - \frac{c_1 e^{-\frac{3\pi}{4}} \sqrt{7}\, \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)}{2} - \frac{3\, e^{-\frac{3\pi}{4}} \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) c_1}{2} + \frac{e^{-\frac{3\pi}{4}} c_2 \sqrt{7}\, \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)}{2} - \frac{3\, e^{-\frac{3\pi}{4}} \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) c_2}{2}$$

- Solve for c_1 and c_2

$$\left\{c_1 = \frac{\left(5\sqrt{7}\, \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) - \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)\right)\sqrt{7}}{42\, e^{-\frac{3\pi}{4}}\left(\cos\left(\frac{\sqrt{7}\, \pi}{4}\right)^2 + \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)^2\right)}, c_2 = \frac{\sqrt{7}\left(5\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, \pi}{4}\right) + \cos\left(\frac{\sqrt{7}\, \pi}{4}\right)\right)}{42\, e^{-\frac{3\pi}{4}}\left(\cos\left(\frac{\sqrt{7}\, \pi}{4}\right)^2 + \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)^2\right)}\right\}$$

- Substitute constant values into general solution and simplify

$$y = \frac{\left(\left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, x}{2}\right) + 35 \cos\left(\frac{\sqrt{7}\, x}{2}\right)\right) \cos\left(\frac{\sqrt{7}\, \pi}{4}\right) - \sin\left(\frac{\sqrt{7}\, \pi}{4}\right)\left(\sqrt{7}\, \cos\left(\frac{\sqrt{7}\, x}{2}\right) - 35 \sin\left(\frac{\sqrt{7}\, x}{2}\right)\right)\right) e^{-\frac{3x}{2} + \frac{3\pi}{4}}}{42} - \frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

- Solution to the IVP

$$y = \frac{\left(\left(\sqrt{7}\,\sin\left(\frac{\sqrt{7}\,x}{2}\right)+35\cos\left(\frac{\sqrt{7}\,x}{2}\right)\right)\cos\left(\frac{\sqrt{7}\,\pi}{4}\right)-\sin\left(\frac{\sqrt{7}\,\pi}{4}\right)\left(\sqrt{7}\,\cos\left(\frac{\sqrt{7}\,x}{2}\right)-35\sin\left(\frac{\sqrt{7}\,x}{2}\right)\right)\right)\mathrm{e}^{-\frac{3x}{2}+\frac{3\pi}{4}}}{42} - \frac{\cos(x)}{6} + \frac{\sin(x)}{6}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y = \mathrm{e}^{-x}}$$

With initial conditions

$$[y(2) = 0, y'(2) = -2]$$

14.13.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 1 \\ F &= \mathrm{e}^{-x} \end{aligned}$$

Hence the ode is

$$y'' + y = e^{-x}$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is also inside this domain. The domain of $F = e^{-x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 2$ is also inside this domain. Hence solution exists and is unique.

14.13.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = e^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(1)}\\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i\\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i\\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(\cos(x)\,c_1 + c_2 \sin(x))$$

Or

$$y = \cos(x)\,c_1 + c_2 \sin(x)$$

Therefore the homogeneous solution y_h is

$$y_h = \cos(x)\,c_1 + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x) c_1 + c_2 \sin(x)) + \left(\frac{e^{-x}}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \cos(x) c_1 + c_2 \sin(x) + \frac{e^{-x}}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = \cos(2) c_1 + c_2 \sin(2) + \frac{e^{-2}}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\sin(x) c_1 + c_2 \cos(x) - \frac{e^{-x}}{2}$$

substituting $y' = -2$ and $x = 2$ in the above gives

$$-2 = -\sin(2) c_1 + c_2 \cos(2) - \frac{e^{-2}}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{e^{-2}\cos(2)}{2} - \frac{\sin(2)e^{-2}}{2} + 2\sin(2)$$
$$c_2 = \frac{e^{-2}\cos(2)}{2} - \frac{\sin(2)e^{-2}}{2} - 2\cos(2)$$

Substituting these values back in above solution results in

$$y = -\frac{\cos(x)e^{-2}\cos(2)}{2} - \frac{\cos(x)\sin(2)e^{-2}}{2} + 2\cos(x)\sin(2) + \frac{\sin(x)e^{-2}\cos(2)}{2} - \frac{\sin(x)\sin(2)e^{-2}}{2} -$$

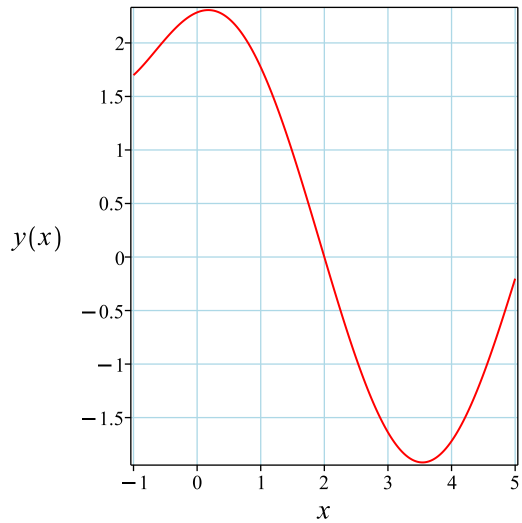
Which simplifies to

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x) - \cos(x))\cos(2) - \cos(x)\sin(2) - \sin(x)\sin(2))e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2)$$

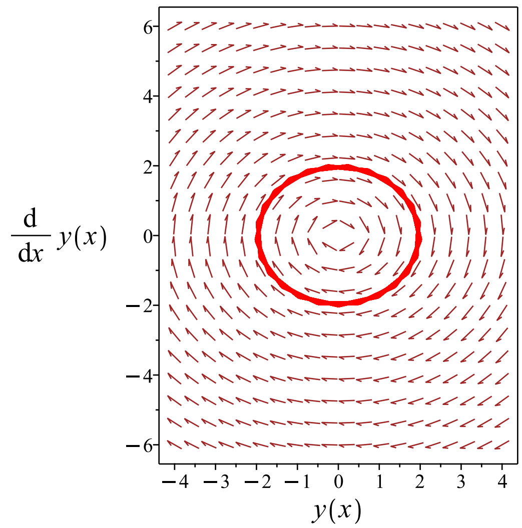
Summary

The solution(s) found are the following

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x) - \cos(x))\cos(2) - \cos(x)\sin(2) - \sin(x)\sin(2))e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2) \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x) - \cos(x))\cos(2) - \cos(x)\sin(2) - \sin(x)\sin(2))\,e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2)$$

Verified OK.

14.13.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 356: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1 \\ &= \cos(x)\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(x) \int \frac{1}{\cos(x)^2}\,dx \\ &= \cos(x)(\tan(x))\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(x)) + c_2(\cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \cos(x)\, c_1 + c_2 \sin(x)
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{-x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\cos(x), \sin(x)\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{-x}
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
2A_1 \mathrm{e}^{-x} = \mathrm{e}^{-x}
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-x}}{2}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p \\ &= (\cos(x) c_1 + c_2 \sin(x)) + \left(\frac{e^{-x}}{2}\right)\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \cos(x) c_1 + c_2 \sin(x) + \frac{e^{-x}}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 2$ in the above gives

$$0 = \cos(2) c_1 + c_2 \sin(2) + \frac{e^{-2}}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\sin(x) c_1 + c_2 \cos(x) - \frac{e^{-x}}{2}$$

substituting $y' = -2$ and $x = 2$ in the above gives

$$-2 = -\sin(2) c_1 + c_2 \cos(2) - \frac{e^{-2}}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}c_1 &= -\frac{e^{-2}\cos(2)}{2} - \frac{\sin(2) e^{-2}}{2} + 2\sin(2) \\ c_2 &= \frac{e^{-2}\cos(2)}{2} - \frac{\sin(2) e^{-2}}{2} - 2\cos(2)\end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{\cos(x)\,e^{-2}\cos(2)}{2} - \frac{\cos(x)\sin(2)\,e^{-2}}{2} + 2\cos(x)\sin(2) + \frac{\sin(x)\,e^{-2}\cos(2)}{2} - \frac{\sin(x)\sin(2)\,e^{-2}}{2} -$$

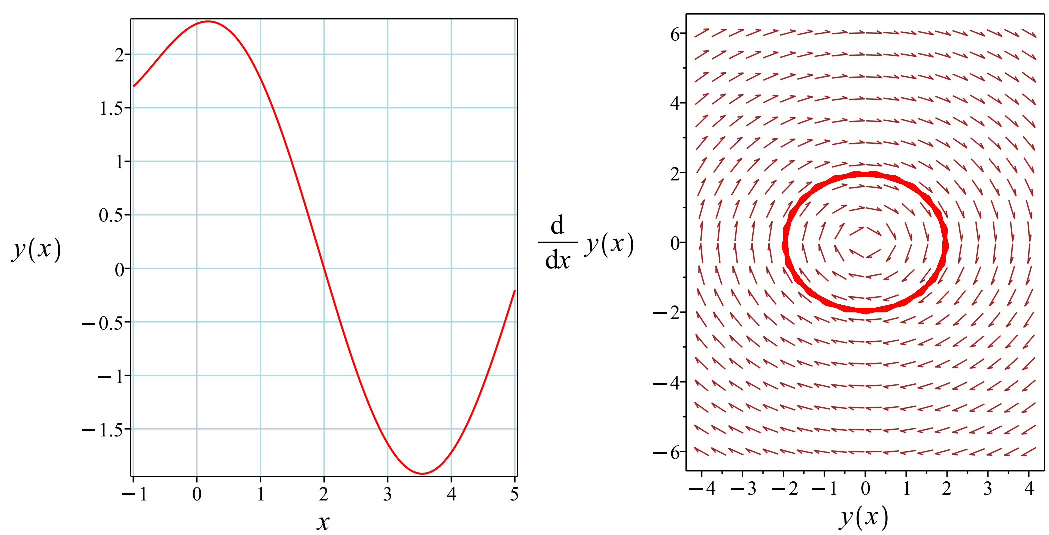
Which simplifies to

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x) - \cos(x))\cos(2) - \cos(x)\sin(2) - \sin(x)\sin(2))\,e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2)$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x) - \cos(x))\cos(2) - \cos(x)\sin(2) - \sin(x)\sin(2))\,e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x) - \cos(x))\cos(2) - \cos(x)\sin(2) - \sin(x)\sin(2))\,e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2)$$

Verified OK.

14.13.4 Maple step by step solution

Let's solve

$$\left[y'' + y = e^{-x}, y(2) = 0, y'\Big|_{\{x=2\}} = -2\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (-\mathrm{I}, \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x) c_1 + c_2 \sin(x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = e^{-x}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x) & \sin(x) \\ -\sin(x) & \cos(x) \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 1$

  - Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\cos(x)\left(\int e^{-x}\sin(x)\,dx\right) + \sin(x)\left(\int e^{-x}\cos(x)\,dx\right)$$

- Compute integrals

$$y_p(x) = \frac{e^{-x}}{2}$$

- Substitute particular solution into general solution to ODE

$$y = \cos(x)\,c_1 + c_2\sin(x) + \frac{e^{-x}}{2}$$

☐ Check validity of solution $y = \cos(x)\,c_1 + c_2\sin(x) + \frac{e^{-x}}{2}$

- Use initial condition $y(2) = 0$

$$0 = \cos(2)\,c_1 + c_2\sin(2) + \frac{e^{-2}}{2}$$

- Compute derivative of the solution

$$y' = -\sin(x)\,c_1 + c_2\cos(x) - \frac{e^{-x}}{2}$$

- Use the initial condition $y'\Big|_{\{x=2\}} = -2$

$$-2 = -\sin(2)\,c_1 + c_2\cos(2) - \frac{e^{-2}}{2}$$

- Solve for c_1 and c_2

$$\left\{c_1 = -\frac{e^{-2}\cos(2)+\sin(2)e^{-2}-4\sin(2)}{2\left(\cos(2)^2+\sin(2)^2\right)}, c_2 = \frac{e^{-2}\cos(2)-\sin(2)e^{-2}-4\cos(2)}{2\left(\cos(2)^2+\sin(2)^2\right)}\right\}$$

- Substitute constant values into general solution and simplify

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x)-\cos(x))\cos(2)-\cos(x)\sin(2)-\sin(x)\sin(2))e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2)$$

- Solution to the IVP

$$y = \frac{e^{-x}}{2} + \frac{((\sin(x)-\cos(x))\cos(2)-\cos(x)\sin(2)-\sin(x)\sin(2))e^{-2}}{2} - 2\sin(x)\cos(2) + 2\cos(x)\sin(2)$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' - y = \cos(x)}$$

With initial conditions

$$[y(0) = 3, y'(2) = 2]$$

14.14.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\lambda_1 = +1$$
$$\lambda_2 = -1$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(1)x} + c_2 e^{(-1)x}$$

Or

$$y = c_1 e^{x} + c_2 e^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{x} + c_2 e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \cos(x) - 2A_2 \sin(x) = \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{x} + c_2 e^{-x}\right) + \left(-\frac{\cos(x)}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x} - \frac{\cos(x)}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 + c_2 - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \mathrm{e}^{x} - c_2 \mathrm{e}^{-x} + \frac{\sin(x)}{2}$$

substituting $y' = 2$ and $x = 2$ in the above gives

$$2 = c_1 \mathrm{e}^{2} - c_2 \mathrm{e}^{-2} + \frac{\sin(2)}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -\frac{\sin(2)\,\mathrm{e}^{2} - 4\,\mathrm{e}^{2} - 7}{2\,(\mathrm{e}^{4} + 1)} \\ c_2 &= \frac{(7\,\mathrm{e}^{2} + \sin(2) - 4)\,\mathrm{e}^{2}}{2\,\mathrm{e}^{4} + 2} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{-\cos(x)\,\mathrm{e}^{8} - 2\cos(x)\,\mathrm{e}^{4} + \sin(2)\,\mathrm{e}^{2-x} + \sin(2)\,\mathrm{e}^{-x+6} - \sin(2)\,\mathrm{e}^{x+6} - \sin(2)\,\mathrm{e}^{x+2} - \cos(x) + 7\,\mathrm{e}^{8-x}}{2\,\mathrm{e}^{8} + 4\,\mathrm{e}^{4} + 2}$$

Which simplifies to

$$y = \frac{(\sin(2) - 4)\,\mathrm{e}^{2-x} + (\sin(2) - 4)\,\mathrm{e}^{-x+6} + 7\,\mathrm{e}^{4-x} + 7\,\mathrm{e}^{8-x} + (4 - \sin(2))\,\mathrm{e}^{x+2} + (4 - \sin(2))\,\mathrm{e}^{x+6} + 7\,\mathrm{e}^{x+}}{2\,\mathrm{e}^{8} + 4\,\mathrm{e}^{4} + 2}$$

Summary
The solution(s) found are the following

$$y = \frac{(\sin(2) - 4)\,\mathrm{e}^{2-x} + (\sin(2) - 4)\,\mathrm{e}^{-x+6} + 7\,\mathrm{e}^{4-x} + 7\,\mathrm{e}^{8-x} + (4 - \sin(2))\,\mathrm{e}^{x+2} + (4 - \sin(2))\,\mathrm{e}^{x+6} + 7\,\mathrm{e}^{x+}}{2\,\mathrm{e}^{8} + 4\,\mathrm{e}^{4} + 2} \tag{1}$$

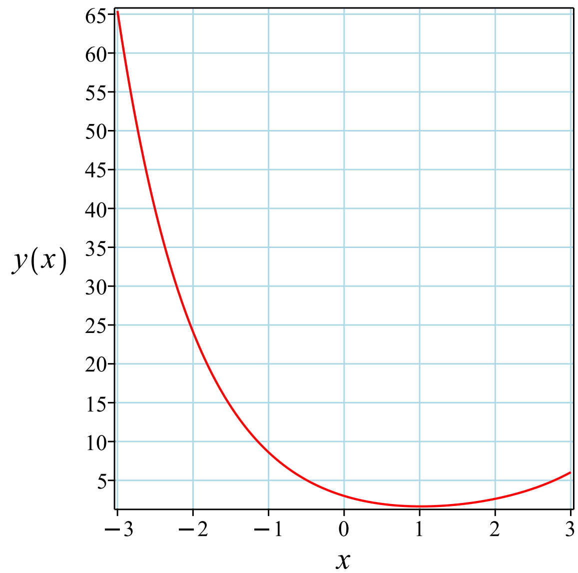

Figure 399: Solution plot

Verification of solutions

$$y = \frac{(\sin(2)-4)\,e^{2-x} + (\sin(2)-4)\,e^{-x+6} + 7\,e^{4-x} + 7\,e^{8-x} + (4-\sin(2))\,e^{x+2} + (4-\sin(2))\,e^{x+6} + 7\,e^{x+}}{2\,e^{8} + 4\,e^{4} + 2}$$

Verified OK.

14.14.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 358: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= e^{-x} \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= e^{-x} \int \frac{1}{e^{-2x}}\,dx \\ &= e^{-x}\left(\frac{e^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\mathrm{e}^{x}}{2}, \mathrm{e}^{-x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \cos(x) - 2A_2 \sin(x) = \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{\cos(x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}\right) + \left(-\frac{\cos(x)}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} - \frac{\cos(x)}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 + \frac{c_2}{2} - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2} + \frac{\sin(x)}{2}$$

substituting $y' = 2$ and $x = 2$ in the above gives

$$2 = -c_1 \mathrm{e}^{-2} + \frac{c_2 \mathrm{e}^{2}}{2} + \frac{\sin(2)}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= \frac{(7\,\mathrm{e}^2 + \sin(2) - 4)\,\mathrm{e}^2}{2\,\mathrm{e}^4 + 2} \\
c_2 &= -\frac{\sin(2)\,\mathrm{e}^2 - 4\,\mathrm{e}^2 - 7}{\mathrm{e}^4 + 1}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \frac{-\cos(x)\,\mathrm{e}^8 - 2\cos(x)\,\mathrm{e}^4 + \sin(2)\,\mathrm{e}^{2-x} + \sin(2)\,\mathrm{e}^{-x+6} - \sin(2)\,\mathrm{e}^{x+6} - \sin(2)\,\mathrm{e}^{x+2} - \cos(x) + 7\,\mathrm{e}^{8-x}}{2\,\mathrm{e}^8 + 4\,\mathrm{e}^4 + 2}
$$

Which simplifies to

$$
y = \frac{(\sin(2) - 4)\,\mathrm{e}^{2-x} + (\sin(2) - 4)\,\mathrm{e}^{-x+6} + 7\,\mathrm{e}^{4-x} + 7\,\mathrm{e}^{8-x} + (4 - \sin(2))\,\mathrm{e}^{x+2} + (4 - \sin(2))\,\mathrm{e}^{x+6} + 7\,\mathrm{e}^{x+}}{2\,\mathrm{e}^8 + 4\,\mathrm{e}^4 + 2}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(\sin(2) - 4)\,\mathrm{e}^{2-x} + (\sin(2) - 4)\,\mathrm{e}^{-x+6} + 7\,\mathrm{e}^{4-x} + 7\,\mathrm{e}^{8-x} + (4 - \sin(2))\,\mathrm{e}^{x+2} + (4 - \sin(2))\,\mathrm{e}^{x+6} + 7\,\mathrm{e}^{x+}}{2\,\mathrm{e}^8 + 4\,\mathrm{e}^4 + 2} \tag{1}
$$

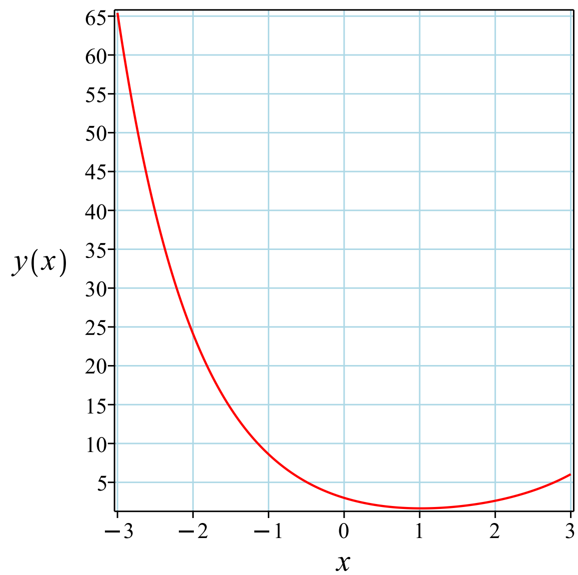

Figure 400: Solution plot

Verification of solutions

$$y = \frac{(\sin(2)-4)\,\mathrm{e}^{2-x}+(\sin(2)-4)\,\mathrm{e}^{-x+6}+7\,\mathrm{e}^{4-x}+7\,\mathrm{e}^{8-x}+(4-\sin(2))\,\mathrm{e}^{x+2}+(4-\sin(2))\,\mathrm{e}^{x+6}+7\,\mathrm{e}^{x+}}{2\,\mathrm{e}^{8}+4\,\mathrm{e}^{4}+2}$$

Verified OK.

14.14.3 Maple step by step solution

Let's solve

$$\left[y''-y=\cos(x),y(0)=3,y'\Big|_{\{x=2\}}=2\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2-1=0$

- Factor the characteristic polynomial

  $(r-1)(r+1)=0$

- Roots of the characteristic polynomial

  $r=(-1,1)$

- 1st solution of the homogeneous ODE

  $y_1(x)=\mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\mathrm{e}^{x}$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\mathrm{e}^{-x}+c_2\mathrm{e}^{x}+y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $$\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=\cos(x)\right]$$

- ◦ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{x} \\ -e^{-x} & e^{x} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{e^{-x}\left(\int \cos(x)e^{x}dx\right)}{2} + \frac{e^{x}\left(\int e^{-x}\cos(x)dx\right)}{2}$

- Compute integrals

  $y_p(x) = -\frac{\cos(x)}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 e^{x} - \frac{\cos(x)}{2}$

☐ Check validity of solution $y = c_1 e^{-x} + c_2 e^{x} - \frac{\cos(x)}{2}$

- Use initial condition $y(0) = 3$

  $3 = c_1 + c_2 - \frac{1}{2}$

- Compute derivative of the solution

  $y' = -c_1 e^{-x} + c_2 e^{x} + \frac{\sin(x)}{2}$

- Use the initial condition $y'\Big|_{\{x=2\}} = 2$

  $2 = -c_1 e^{-2} + c_2 e^{2} + \frac{\sin(2)}{2}$

- Solve for c_1 and c_2

  $\left\{c_1 = \frac{7e^{2}+\sin(2)-4}{2(e^{2}+e^{-2})}, c_2 = \frac{7e^{-2}-\sin(2)+4}{2(e^{2}+e^{-2})}\right\}$

- Substitute constant values into general solution and simplify

  $y = \frac{(\sin(2)-4)e^{2-x}+7e^{4-x}+(4-\sin(2))e^{x+2}+(-e^{4}-1)\cos(x)+7e^{x}}{2e^{4}+2}$

- Solution to the IVP

  $y = \frac{(\sin(2)-4)e^{2-x}+7e^{4-x}+(4-\sin(2))e^{x+2}+(-e^{4}-1)\cos(x)+7e^{x}}{2e^{4}+2}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_ode_quadrature", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _quadrature]]
```

$$\boxed{y'' = \tan(x)}$$

With initial conditions

$$[y(1) = 1, y'(1) = -1]$$

14.15.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 0 \\ F &= \tan(x) \end{aligned}$$

Hence the ode is

$$y'' = \tan(x)$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $F = \tan(x)$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z416 \vee \frac{1}{2}\pi + \pi\_Z416 < x\right\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

14.15.2 Solving as second order ode quadrature ode

Integrating once gives

$$y' = -\ln(\cos(x)) + c_1$$

Integrating again gives

$$y = -\frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(e^{2ix} + 1\right) - \frac{i\,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} + c_1 x + c_2$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(e^{2ix} + 1\right) - \frac{i\,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} + c_1 x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -\frac{i}{2} - \ln(\cos(1)) + \ln\left(e^{2i} + 1\right) - \frac{i\,\mathrm{dilog}\left(e^{2i} + 1\right)}{2} + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -ix - \ln(\cos(x)) + \frac{x\sin(x)}{\cos(x)} + \frac{2ix\,e^{2ix}}{e^{2ix} + 1} + c_1$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{(i - \ln(\cos(1)) + \tan(1) + c_1)\,e^{2i} - i + c_1 + \tan(1) - \ln(\cos(1))}{e^{2i} + 1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{e^{2i}\ln(\cos(1)) - ie^{2i} - e^{2i}\tan(1) - 1 + i - e^{2i} + \ln(\cos(1)) - \tan(1)}{e^{2i} + 1}$$

$$c_2 = -\frac{-ie^{2i}\,\mathrm{dilog}\left(e^{2i} + 1\right) + 2\ln\left(e^{2i} + 1\right)e^{2i} - 3ie^{2i} - 2\,e^{2i}\tan(1) - i\,\mathrm{dilog}\left(e^{2i} + 1\right) - 4\,e^{2i} + 2\ln\left(e^{2i} + 1\right)}{2\left(e^{2i} + 1\right)}$$

Substituting these values back in above solution results in

$$y = \frac{4 - 2\,e^{2i}x - 2x + 2\tan(1) - i + 4\,e^{2i} - 2\ln\left(e^{2i} + 1\right) + 2ix + ie^{2i}\,\mathrm{dilog}\left(e^{2i} + 1\right) + 3ie^{2i} + 2\,e^{2i}\tan(1)}{}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-ie^{2i} - i\right)\mathrm{polylog}\left(2, -e^{2ix}\right) + 2x\left(e^{2i} + 1\right)\ln\left(e^{2ix} + 1\right) + \left(ie^{2i} + i\right)\mathrm{dilog}\left(e^{2i} + 1\right) + \left(-2\,e^{2i} - 2\right)\ln\left(e^{2i}\right.}{} \tag{1}$$

Verification of solutions

$$y = \frac{\left(-ie^{2i} - i\right)\mathrm{polylog}\left(2, -e^{2ix}\right) + 2x\left(e^{2i} + 1\right)\ln\left(e^{2ix} + 1\right) + \left(ie^{2i} + i\right)\mathrm{dilog}\left(e^{2i} + 1\right) + \left(-2\,e^{2i} - 2\right)\ln\left(e^{2i}\right.}{}$$

Verified OK.

14.15.3 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 0, f(x) = \tan(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(0)^2 - (4)(1)(0)} \\ &= 0\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 0$. Therefore the solution is

$$y = c_1 1 + c_2 x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x \tan(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int x \tan(x) dx$$

Hence

$$u_1 = -\frac{i\pi^2}{24} - \frac{i x^2}{2} + x \ln\left(e^{2ix} + 1\right) - \frac{i \,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \tan(x) dx$$

Hence

$$u_2 = -\ln(\cos(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{i\pi^2}{24} - \frac{i x^2}{2} + x \ln\left(e^{2ix} + 1\right) - \frac{i \,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} - x \ln(\cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(-\frac{i\pi^2}{24} - \frac{i x^2}{2} + x \ln\left(e^{2ix} + 1\right) - \frac{i \,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} - x \ln(\cos(x))\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 - \frac{i\pi^2}{24} - \frac{i x^2}{2} + x \ln\left(e^{2ix}+1\right) - \frac{i \operatorname{polylog}\left(2, -e^{2ix}\right)}{2} - x \ln\left(\cos\left(x\right)\right) \quad (1)$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_2 + c_1 - \frac{i\pi^2}{24} - \frac{i}{2} + \ln\left(e^{2i}+1\right) - \frac{i \operatorname{dilog}\left(e^{2i}+1\right)}{2} - \ln\left(\cos\left(1\right)\right) \quad (1A)$$

Taking derivative of the solution gives

$$y' = c_2 - ix + \frac{2ix\, e^{2ix}}{e^{2ix}+1} - \ln\left(\cos\left(x\right)\right) + \frac{x \sin\left(x\right)}{\cos\left(x\right)}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{\left(i - \ln\left(\cos\left(1\right)\right) + \tan\left(1\right) + c_2\right) e^{2i} - i + c_2 + \tan\left(1\right) - \ln\left(\cos\left(1\right)\right)}{e^{2i}+1} \quad (2A)$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{-i\pi^2 e^{2i} - 12i e^{2i} \operatorname{dilog}\left(e^{2i}+1\right) - i\pi^2 + 24\ln\left(e^{2i}+1\right) e^{2i} - 36i e^{2i} - 24\, e^{2i}\tan\left(1\right) - 12i \operatorname{dilog}\left(e^{2i} + \right.}{24\left(e^{2i}+1\right)}$$

$$c_2 = \frac{e^{2i}\ln\left(\cos\left(1\right)\right) - i e^{2i} - e^{2i}\tan\left(1\right) - 1 + i - e^{2i} + \ln\left(\cos\left(1\right)\right) - \tan\left(1\right)}{e^{2i}+1}$$

Substituting these values back in above solution results in

$$y = \frac{4 - 2\, e^{2i} x - 2x + 2\tan\left(1\right) - i + 4\, e^{2i} - 2\ln\left(e^{2i}+1\right) + 2ix + i e^{2i} \operatorname{dilog}\left(e^{2i}+1\right) + 3i e^{2i} + 2\, e^{2i}\tan\left(1\right)}{}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-i e^{2i} - i\right) \operatorname{polylog}\left(2, -e^{2ix}\right) + 2x\left(e^{2i}+1\right)\ln\left(e^{2ix}+1\right) + \left(i e^{2i} + i\right) \operatorname{dilog}\left(e^{2i}+1\right) + \left(-2\, e^{2i} - 2\right)\ln\left(e^{2i} \right.}{} \quad (1)$$

Verification of solutions

$$y = \frac{\left(-i e^{2i} - i\right) \operatorname{polylog}\left(2, -e^{2ix}\right) + 2x\left(e^{2i}+1\right)\ln\left(e^{2ix}+1\right) + \left(i e^{2i} + i\right) \operatorname{dilog}\left(e^{2i}+1\right) + \left(-2\, e^{2i} - 2\right)\ln\left(e^{2i} \right.}{}$$

Verified OK.

14.15.4 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int y'' dx = \int \tan(x)\, dx$$
$$y' = -\ln(\cos(x)) + c_1$$

Which is now solved for y. Integrating both sides gives

$$\begin{aligned} y &= \int -\ln(\cos(x)) + c_1 \, \mathrm{d}x \\ &= -\frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2ix}+1\right) - \frac{i\,\mathrm{polylog}(2, -\mathrm{e}^{2ix})}{2} + c_1 x + c_2 \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2ix}+1\right) - \frac{i\,\mathrm{polylog}(2, -\mathrm{e}^{2ix})}{2} + c_1 x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -\frac{i}{2} - \ln(\cos(1)) + \ln\left(\mathrm{e}^{2i}+1\right) - \frac{i\,\mathrm{dilog}(\mathrm{e}^{2i}+1)}{2} + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -ix - \ln(\cos(x)) + \frac{x\sin(x)}{\cos(x)} + \frac{2ix\,\mathrm{e}^{2ix}}{\mathrm{e}^{2ix}+1} + c_1$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{(i - \ln(\cos(1)) + \tan(1) + c_1)\,\mathrm{e}^{2i} - i + c_1 + \tan(1) - \ln(\cos(1))}{\mathrm{e}^{2i}+1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{\mathrm{e}^{2i}\ln(\cos(1)) - i\mathrm{e}^{2i} - \mathrm{e}^{2i}\tan(1) - 1 + i - \mathrm{e}^{2i} + \ln(\cos(1)) - \tan(1)}{\mathrm{e}^{2i}+1} \\ c_2 &= -\frac{-i\mathrm{e}^{2i}\,\mathrm{dilog}(\mathrm{e}^{2i}+1) + 2\ln(\mathrm{e}^{2i}+1)\,\mathrm{e}^{2i} - 3i\mathrm{e}^{2i} - 2\,\mathrm{e}^{2i}\tan(1) - i\,\mathrm{dilog}(\mathrm{e}^{2i}+1) - 4\,\mathrm{e}^{2i} + 2\ln(\mathrm{e}^{2i}+ }{2(\mathrm{e}^{2i}+1)} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{4 - 2\,\mathrm{e}^{2i}x - 2x + 2\tan(1) - i + 4\,\mathrm{e}^{2i} - 2\ln(\mathrm{e}^{2i}+1) + 2ix + i\mathrm{e}^{2i}\,\mathrm{dilog}(\mathrm{e}^{2i}+1) + 3i\mathrm{e}^{2i} + 2\,\mathrm{e}^{2i}\tan(1)}{}$$

Summary
The solution(s) found are the following

$$y = \frac{(-i e^{2i} - i) \operatorname{polylog}(2, -e^{2ix}) + 2x(e^{2i} + 1) \ln(e^{2ix} + 1) + (i e^{2i} + i) \operatorname{dilog}(e^{2i} + 1) + (-2 e^{2i} - 2) \ln(e^{2i} -}{} \quad (1)$$

Verification of solutions

$$y = \frac{(-i e^{2i} - i) \operatorname{polylog}(2, -e^{2ix}) + 2x(e^{2i} + 1) \ln(e^{2ix} + 1) + (i e^{2i} + i) \operatorname{dilog}(e^{2i} + 1) + (-2 e^{2i} - 2) \ln(e^{2i} -}{}$$

Verified OK.

14.15.5 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - \tan(x) = 0$$

Which is now solve for $p(x)$ as first order ode. Integrating both sides gives

$$\begin{aligned} p(x) &= \int \tan(x)\, dx \\ &= -\ln(\cos(x)) + c_1 \end{aligned}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $p = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -\ln(\cos(1)) + c_1$$

$$c_1 = \ln(\cos(1)) - 1$$

Substituting c_1 found above in the general solution gives

$$p(x) = -\ln(\cos(x)) + \ln(\cos(1)) - 1$$

Since $p = y'$ then the new first order ode to solve is

$$y' = -\ln(\cos(x)) + \ln(\cos(1)) - 1$$

Integrating both sides gives

$$\begin{aligned} y &= \int -\ln(\cos(x)) + \ln(\cos(1)) - 1 \, dx \\ &= -x - \frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(e^{2ix}+1\right) - \frac{i\,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} + \ln(\cos(1))\,x + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = -1 - \frac{i}{2} + \ln\left(e^{2i}+1\right) - \frac{i\,\mathrm{dilog}\left(e^{2i}+1\right)}{2} + c_2$$

$$c_2 = 2 + \frac{i}{2} - \ln\left(e^{2i}+1\right) + \frac{i\,\mathrm{dilog}\left(e^{2i}+1\right)}{2}$$

Substituting c_2 found above in the general solution gives

$$y = -x - \frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(e^{2ix}+1\right) - \frac{i\,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} + \ln(\cos(1))\,x + 2 + \frac{i}{2} - \ln\left(e^{2i}+1\right.$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$\begin{aligned} y = -x - \frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(e^{2ix}+1\right) - \frac{i\,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} \\ + \ln(\cos(1))\,x + 2 + \frac{i}{2} - \ln\left(e^{2i}+1\right) + \frac{i\,\mathrm{dilog}\left(e^{2i}+1\right)}{2} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = -x - \frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(e^{2ix}+1\right) - \frac{i\,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} \\ + \ln(\cos(1))\,x + 2 + \frac{i}{2} - \ln\left(e^{2i}+1\right) + \frac{i\,\mathrm{dilog}\left(e^{2i}+1\right)}{2} \end{aligned}$$

Verified OK.

14.15.6 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{aligned}
y'' &= 0 & (1)\\
Ay'' + By' + Cy &= 0 & (2)
\end{aligned}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1\\
B &= 0 \qquad (3)\\
C &= 0
\end{aligned}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \qquad (5)\\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{0}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 0\\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 360: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= 1 \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= 1 \int \frac{1}{1}\, dx \\ &= 1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(1) + c_2(1(x)) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_2 x + c_1$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = 1$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & x \\ \frac{d}{dx}(1) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & x \\ 0 & 1 \end{vmatrix}$$

Therefore

$$W = (1)(1) - (x)(0)$$

Which simplifies to

$$W = 1$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x \tan(x)}{1} dx$$

Which simplifies to

$$u_1 = -\int x \tan(x)\, dx$$

Hence

$$u_1 = -\frac{i\pi^2}{24} - \frac{ix^2}{2} + x \ln\left(e^{2ix} + 1\right) - \frac{i \,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)}{1} dx$$

Which simplifies to

$$u_2 = \int \tan(x)\, dx$$

Hence

$$u_2 = -\ln(\cos(x))$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{i\pi^2}{24} - \frac{ix^2}{2} + x \ln\left(e^{2ix} + 1\right) - \frac{i \,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} - x \ln(\cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x + c_1) + \left(-\frac{i\pi^2}{24} - \frac{ix^2}{2} + x \ln\left(e^{2ix} + 1\right) - \frac{i \,\mathrm{polylog}\left(2, -e^{2ix}\right)}{2} - x \ln(\cos(x))\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x + c_1 - \frac{i\pi^2}{24} - \frac{i x^2}{2} + x \ln\left(e^{2ix}+1\right) - \frac{i \operatorname{polylog}\left(2, -e^{2ix}\right)}{2} - x \ln\left(\cos\left(x\right)\right) \quad (1)$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_2 + c_1 - \frac{i\pi^2}{24} - \frac{i}{2} + \ln\left(e^{2i}+1\right) - \frac{i \operatorname{dilog}\left(e^{2i}+1\right)}{2} - \ln\left(\cos\left(1\right)\right) \quad (1A)$$

Taking derivative of the solution gives

$$y' = c_2 - ix + \frac{2ix\, e^{2ix}}{e^{2ix}+1} - \ln\left(\cos\left(x\right)\right) + \frac{x \sin\left(x\right)}{\cos\left(x\right)}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{\left(i - \ln\left(\cos\left(1\right)\right) + \tan\left(1\right) + c_2\right) e^{2i} - i + c_2 + \tan\left(1\right) - \ln\left(\cos\left(1\right)\right)}{e^{2i}+1} \quad (2A)$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{-i\pi^2 e^{2i} - 12ie^{2i} \operatorname{dilog}\left(e^{2i}+1\right) - i\pi^2 + 24 \ln\left(e^{2i}+1\right) e^{2i} - 36ie^{2i} - 24\, e^{2i} \tan\left(1\right) - 12i \operatorname{dilog}\left(e^{2i} +\right.}{24\left(e^{2i}+1\right)}$$

$$c_2 = \frac{e^{2i} \ln\left(\cos\left(1\right)\right) - ie^{2i} - e^{2i} \tan\left(1\right) - 1 + i - e^{2i} + \ln\left(\cos\left(1\right)\right) - \tan\left(1\right)}{e^{2i}+1}$$

Substituting these values back in above solution results in

$$y = \frac{4 - 2\, e^{2i} x - 2x + 2\tan\left(1\right) - i + 4\, e^{2i} - 2\ln\left(e^{2i}+1\right) + 2ix + ie^{2i} \operatorname{dilog}\left(e^{2i}+1\right) + 3ie^{2i} + 2\, e^{2i} \tan\left(1\right)}{}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-ie^{2i} - i\right) \operatorname{polylog}\left(2, -e^{2ix}\right) + 2x\left(e^{2i}+1\right) \ln\left(e^{2ix}+1\right) + \left(ie^{2i}+i\right) \operatorname{dilog}\left(e^{2i}+1\right) + \left(-2\, e^{2i} - 2\right) \ln\left(e^{2i}\right.}{} \quad (1)$$

Verification of solutions

$$y = \frac{\left(-ie^{2i} - i\right) \operatorname{polylog}\left(2, -e^{2ix}\right) + 2x\left(e^{2i}+1\right) \ln\left(e^{2ix}+1\right) + \left(ie^{2i}+i\right) \operatorname{dilog}\left(e^{2i}+1\right) + \left(-2\, e^{2i} - 2\right) \ln\left(e^{2i}\right.}{}$$

Verified OK.

14.15.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= 0 \\ r(x) &= 0 \\ s(x) &= \tan(x) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y' = \int \tan(x)\, dx$$

We now have a first order ode to solve which is

$$y' = -\ln(\cos(x)) + c_1$$

Integrating both sides gives

$$\begin{aligned}y &= \int -\ln(\cos(x)) + c_1\, \mathrm{d}x \\ &= -\frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2ix}+1\right) - \frac{i\,\mathrm{polylog}\left(2, -\mathrm{e}^{2ix}\right)}{2} + c_1 x + c_2\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{i x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2ix}+1\right) - \frac{i\,\mathrm{polylog}\left(2, -\mathrm{e}^{2ix}\right)}{2} + c_1 x + c_2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -\frac{i}{2} - \ln(\cos(1)) + \ln\left(\mathrm{e}^{2i}+1\right) - \frac{i\,\mathrm{dilog}\left(\mathrm{e}^{2i}+1\right)}{2} + c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -ix - \ln(\cos(x)) + \frac{x\sin(x)}{\cos(x)} + \frac{2ix\,\mathrm{e}^{2ix}}{\mathrm{e}^{2ix}+1} + c_1$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{(i - \ln(\cos(1)) + \tan(1) + c_1)\,\mathrm{e}^{2i} - i + c_1 + \tan(1) - \ln(\cos(1))}{\mathrm{e}^{2i}+1} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}c_1 &= \frac{\mathrm{e}^{2i}\ln(\cos(1)) - i\mathrm{e}^{2i} - \mathrm{e}^{2i}\tan(1) - 1 + i - \mathrm{e}^{2i} + \ln(\cos(1)) - \tan(1)}{\mathrm{e}^{2i}+1} \\ c_2 &= -\frac{-i\mathrm{e}^{2i}\,\mathrm{dilog}\left(\mathrm{e}^{2i}+1\right) + 2\ln\left(\mathrm{e}^{2i}+1\right)\mathrm{e}^{2i} - 3i\mathrm{e}^{2i} - 2\,\mathrm{e}^{2i}\tan(1) - i\,\mathrm{dilog}\left(\mathrm{e}^{2i}+1\right) - 4\,\mathrm{e}^{2i} + 2\ln\left(\mathrm{e}^{2i} + \right.}{2\left(\mathrm{e}^{2i}+1\right)}\end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{4 - 2\,\mathrm{e}^{2i}x - 2x + 2\tan(1) - i + 4\,\mathrm{e}^{2i} - 2\ln\left(\mathrm{e}^{2i}+1\right) + 2ix + i\mathrm{e}^{2i}\,\mathrm{dilog}\left(\mathrm{e}^{2i}+1\right) + 3i\mathrm{e}^{2i} + 2\,\mathrm{e}^{2i}\tan(1)}{}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(-i\mathrm{e}^{2i} - i\right)\mathrm{polylog}\left(2, -\mathrm{e}^{2ix}\right) + 2x\left(\mathrm{e}^{2i}+1\right)\ln\left(\mathrm{e}^{2ix}+1\right) + \left(i\mathrm{e}^{2i}+i\right)\mathrm{dilog}\left(\mathrm{e}^{2i}+1\right) + \left(-2\,\mathrm{e}^{2i}-2\right)\ln\left(\mathrm{e}^{2i}\right.}{} \tag{1}$$

Verification of solutions

$$y = \frac{(-i\mathrm{e}^{2i} - i)\,\mathrm{polylog}\left(2, -\mathrm{e}^{2ix}\right) + 2x(\mathrm{e}^{2i} + 1)\ln\left(\mathrm{e}^{2ix} + 1\right) + (i\mathrm{e}^{2i} + i)\,\mathrm{dilog}\left(\mathrm{e}^{2i} + 1\right) + (-2\,\mathrm{e}^{2i} - 2)\ln\left(\mathrm{e}^{2i}\right.}{}$$

Verified OK.

14.15.8 Maple step by step solution

Let's solve

$$\left[y'' = \tan(x), y(1) = 1, y'\Big|_{\{x=1\}} = -1\right]$$

- Highest derivative means the order of the ODE is 2

  y''
- Characteristic polynomial of homogeneous ODE

  $r^2 = 0$
- Use quadratic formula to solve for r

  $r = \frac{0 \pm \left(\sqrt{0}\right)}{2}$
- Roots of the characteristic polynomial

  $r = 0$
- 1st solution of the homogeneous ODE

  $y_1(x) = 1$
- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 x + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \tan(x)\right]$
- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & x \\ 0 & 1 \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = 1$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\left(\int x \tan(x)\, dx\right) + x\left(\int \tan(x)\, dx\right)$

- Compute integrals

  $y_p(x) = -\frac{\mathrm{I}x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2\mathrm{I}x}+1\right) - \frac{\mathrm{I}polylog(2, -\mathrm{e}^{2\mathrm{I}x})}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 x - \frac{\mathrm{I}x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2\mathrm{I}x}+1\right) - \frac{\mathrm{I}polylog(2, -\mathrm{e}^{2\mathrm{I}x})}{2}$

□ Check validity of solution $y = c_1 + c_2 x - \frac{\mathrm{I}x^2}{2} - x\ln(\cos(x)) + x\ln\left(\mathrm{e}^{2\mathrm{I}x}+1\right) - \frac{\mathrm{I}polylog(2, -\mathrm{e}^{2\mathrm{I}x})}{2}$

- Use initial condition $y(1) = 1$

  $1 = c_1 + c_2 - \frac{\mathrm{I}}{2} - \ln(\cos(1)) + \ln\left(\mathrm{e}^{2\mathrm{I}}+1\right) - \frac{\mathrm{I}polylog(2, -\mathrm{e}^{2\mathrm{I}})}{2}$

- Compute derivative of the solution

  $y' = c_2 - \mathrm{I}x + \frac{2\mathrm{I}x\,\mathrm{e}^{2\mathrm{I}x}}{\mathrm{e}^{2\mathrm{I}x}+1} - \ln(\cos(x)) + \frac{x\sin(x)}{\cos(x)}$

- Use the initial condition $y'\Big|_{\{x=1\}} = -1$

  $-1 = c_2 - \mathrm{I} + \frac{2\mathrm{I}\,\mathrm{e}^{2\mathrm{I}}}{\mathrm{e}^{2\mathrm{I}}+1} - \ln(\cos(1)) + \frac{\sin(1)}{\cos(1)}$

- Solve for c_1 and c_2

  $\left\{c_1 = -\frac{-\mathrm{I}polylog(2,-\mathrm{e}^{2\mathrm{I}})\cos(1)\mathrm{e}^{2\mathrm{I}}+2\ln(\mathrm{e}^{2\mathrm{I}}+1)\mathrm{e}^{2\mathrm{I}}\cos(1)-3\mathrm{I}\,\mathrm{e}^{2\mathrm{I}}\cos(1)-\mathrm{I}polylog(2,-\mathrm{e}^{2\mathrm{I}})\cos(1)-2\,\mathrm{e}^{2\mathrm{I}}\sin(1)-4\,\mathrm{e}^{2\mathrm{I}}\cos(1)+2}{2\cos(1)(\mathrm{e}^{2\mathrm{I}}+1)}\right.$

- Substitute constant values into general solution and simplify

  $y = \frac{(-\mathrm{I}\,\mathrm{e}^{2\mathrm{I}}-\mathrm{I})polylog(2,-\mathrm{e}^{2\mathrm{I}x})+2x(\mathrm{e}^{2\mathrm{I}}+1)\ln(\mathrm{e}^{2\mathrm{I}x}+1)+(\mathrm{I}\,\mathrm{e}^{2\mathrm{I}}+\mathrm{I})polylog(2,-\mathrm{e}^{2\mathrm{I}})+(-2\,\mathrm{e}^{2\mathrm{I}}-2)\ln(\mathrm{e}^{2\mathrm{I}}+1)+(2\ln(\cos(1))x-2x\ln}{2\,\mathrm{e}^{2\mathrm{I}}-}$

- Solution to the IVP

  $y = \frac{(-\mathrm{I}\,\mathrm{e}^{2\mathrm{I}}-\mathrm{I})polylog(2,-\mathrm{e}^{2\mathrm{I}x})+2x(\mathrm{e}^{2\mathrm{I}}+1)\ln(\mathrm{e}^{2\mathrm{I}x}+1)+(\mathrm{I}\,\mathrm{e}^{2\mathrm{I}}+\mathrm{I})polylog(2,-\mathrm{e}^{2\mathrm{I}})+(-2\,\mathrm{e}^{2\mathrm{I}}-2)\ln(\mathrm{e}^{2\mathrm{I}}+1)+(2\ln(\cos(1))x-2x\ln}{2\,\mathrm{e}^{2\mathrm{I}}-}$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' - 2y' = \ln(x)}$$

With initial conditions

$$[y(1) = \mathrm{e}, y'(1) = \mathrm{e}^{-1}]$$

14.16.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 0 \\ F &= \ln(x) \end{aligned}$$

Hence the ode is

$$y'' - 2y' = \ln(x)$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $F = \ln(x)$ is

$$\{0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

14.16.2 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 0, f(x) = \ln(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 0$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda \, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 0$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(0)} \\ &= 1 \pm 1\end{aligned}$$

Hence

$$\lambda_1 = 1 + 1$$
$$\lambda_2 = 1 - 1$$

Which simplifies to

$$\lambda_1 = 2$$
$$\lambda_2 = 0$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(2)x} + c_2 e^{(0)x}$$

Or

$$y = c_1 \mathrm{e}^{2x} + c_2$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^{2x} \\ y_2 &= 1 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{2x} & 1 \\ \frac{d}{dx}(\mathrm{e}^{2x}) & \frac{d}{dx}(1) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{2x} & 1 \\ 2\,\mathrm{e}^{2x} & 0 \end{vmatrix}$$

Therefore

$$W = (\mathrm{e}^{2x})\,(0) - (1)\,(2\,\mathrm{e}^{2x})$$

Which simplifies to

$$W = -2\,\mathrm{e}^{2x}$$

Which simplifies to

$$W = -2\,\mathrm{e}^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\ln(x)}{-2\,e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\ln(x)\,e^{-2x}}{2}dx$$

Hence

$$u_1 = -\frac{\ln(x)\,e^{-2x}}{4} - \frac{\operatorname{expIntegral}_1(2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\ln(x)\,e^{2x}}{-2\,e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\ln(x)}{2}dx$$

Hence

$$u_2 = -\frac{\ln(x)\,x}{2} + \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\ln(x)\,e^{-2x}}{4} - \frac{\operatorname{expIntegral}_1(2x)}{4}\right)e^{2x} - \frac{\ln(x)\,x}{2} + \frac{x}{2}$$

Which simplifies to

$$y_p(x) = -\frac{e^{2x}\operatorname{expIntegral}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2\right) + \left(-\frac{e^{2x}\operatorname{expIntegral}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{2x} + c_2 - \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \mathrm{e}$ and $x = 1$ in the above gives

$$\mathrm{e} = c_1 \mathrm{e}^2 + c_2 - \frac{\mathrm{e}^2 \operatorname{expIntegral}_1(2)}{4} + \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2c_1 \mathrm{e}^{2x} - \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{2} + \frac{\mathrm{e}^{2x}\mathrm{e}^{-2x}}{4x} - \frac{\ln(x)}{2} + \frac{-1-2x}{4x} + \frac{1}{2}$$

substituting $y' = \mathrm{e}^{-1}$ and $x = 1$ in the above gives

$$\mathrm{e}^{-1} = \mathrm{e}^2 \left(2c_1 - \frac{\operatorname{expIntegral}_1(2)}{2}\right) \tag{2A}$$

Equations $\{1\mathrm{A}, 2\mathrm{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{\operatorname{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{-3}}{2} \\ c_2 &= \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} \end{aligned}$$

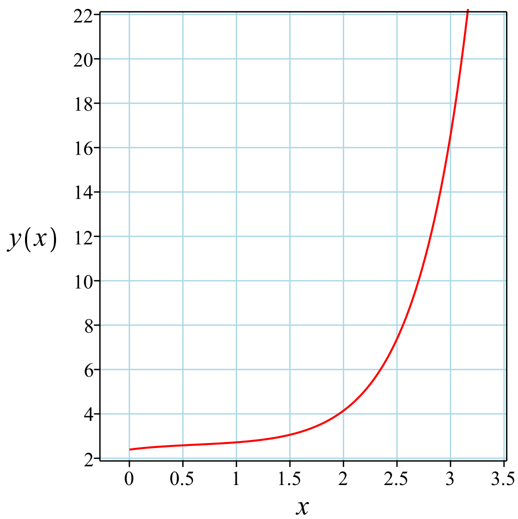
Substituting these values back in above solution results in

$$y = \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{2x-3}}{2} + \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} - \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

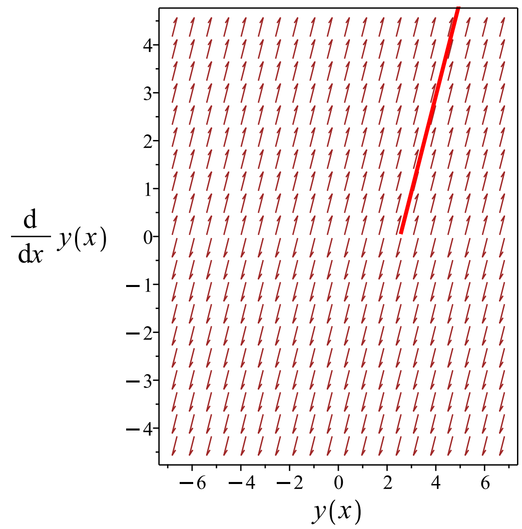
Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{2x-3}}{2} + \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} \\ & - \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2} \end{aligned} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{e^{2x}\,\text{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

Verified OK.

14.16.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 2y')\,dx = \int \ln(x)\,dx$$

$$y' - 2y = \ln(x)\,x - x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -2$$
$$q(x) = \ln(x)\,x - x + c_1$$

Hence the ode is

$$y' - 2y = \ln(x)\, x - x + c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int (-2)dx} \\ &= \mathrm{e}^{-2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\,(\ln(x)\, x - x + c_1) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(y\,\mathrm{e}^{-2x}\right) &= \left(\mathrm{e}^{-2x}\right)(\ln(x)\, x - x + c_1) \\ \mathrm{d}\left(y\,\mathrm{e}^{-2x}\right) &= \left((\ln(x)\, x - x + c_1)\,\mathrm{e}^{-2x}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}y\,\mathrm{e}^{-2x} &= \int (\ln(x)\, x - x + c_1)\,\mathrm{e}^{-2x}\,\mathrm{d}x \\ y\,\mathrm{e}^{-2x} &= \left(-\frac{1}{4} - \frac{x}{2}\right)\mathrm{e}^{-2x}\ln(x) - \frac{c_1\mathrm{e}^{-2x}}{2} + \frac{x\,\mathrm{e}^{-2x}}{2} - \frac{\mathrm{expIntegral}_1(2x)}{4} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-2x}$ results in

$$y = \mathrm{e}^{2x}\left(\left(-\frac{1}{4} - \frac{x}{2}\right)\mathrm{e}^{-2x}\ln(x) - \frac{c_1\mathrm{e}^{-2x}}{2} + \frac{x\,\mathrm{e}^{-2x}}{2} - \frac{\mathrm{expIntegral}_1(2x)}{4}\right) + c_2\mathrm{e}^{2x}$$

which simplifies to

$$y = -\frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{4} + c_2\mathrm{e}^{2x} + \frac{(-1 - 2x)\ln(x)}{4} + \frac{x}{2} - \frac{c_1}{2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{4} + c_2\mathrm{e}^{2x} + \frac{(-1 - 2x)\ln(x)}{4} + \frac{x}{2} - \frac{c_1}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \mathrm{e}$ and $x = 1$ in the above gives

$$\mathrm{e} = -\frac{\mathrm{e}^2\,\mathrm{expIntegral}_1(2)}{4} + c_2\mathrm{e}^2 + \frac{1}{2} - \frac{c_1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{e^{2x}\,\text{expIntegral}_1(2x)}{2} + \frac{e^{2x}e^{-2x}}{4x} + 2c_2 e^{2x} - \frac{\ln(x)}{2} + \frac{-1-2x}{4x} + \frac{1}{2}$$

substituting $y' = e^{-1}$ and $x = 1$ in the above gives

$$e^{-1} = e^{2}\left(-\frac{\text{expIntegral}_1(2)}{2} + 2c_2\right) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

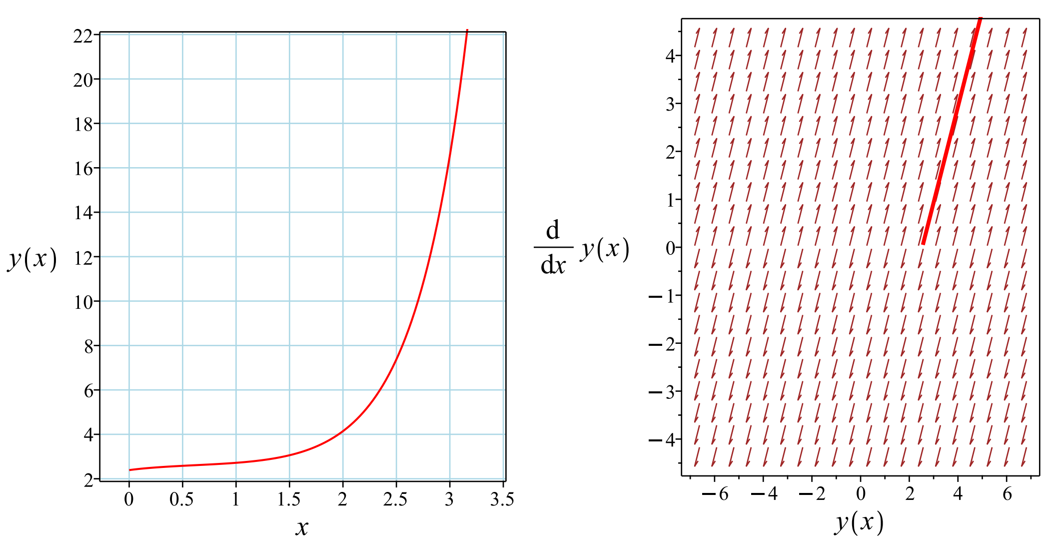
$$\begin{aligned} c_1 &= -2\,e + 1 + e^{-1} \\ c_2 &= \frac{\text{expIntegral}_1(2)}{4} + \frac{e^{-3}}{2} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{e^{2x}\,\text{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

<u>Summary</u>
The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{e^{2x}\,\text{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} \\ & - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2} \end{aligned} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \frac{e^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

Verified OK.

14.16.4 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) - 2p(x) - \ln(x) = 0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-2)dx} \\ &= e^{-2x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu p) &= (\mu)(\ln(x)) \\ \frac{d}{dx}\left(e^{-2x} p\right) &= \left(e^{-2x}\right)(\ln(x)) \\ d\left(e^{-2x} p\right) &= \left(\ln(x)\, e^{-2x}\right) dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-2x} p &= \int \ln(x)\, e^{-2x}\, dx \\ e^{-2x} p &= -\frac{\ln(x)\, e^{-2x}}{2} - \frac{\operatorname{expIntegral}_1(2x)}{2} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-2x}$ results in

$$p(x) = \mathrm{e}^{2x}\left(-\frac{\ln(x)\,\mathrm{e}^{-2x}}{2} - \frac{\mathrm{expIntegral}_1(2x)}{2}\right) + c_1 \mathrm{e}^{2x}$$

which simplifies to

$$p(x) = -\frac{\ln(x)}{2} - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{2} + c_1 \mathrm{e}^{2x}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $p = \mathrm{e}^{-1}$ in the above solution gives an equation to solve for the constant of integration.

$$\mathrm{e}^{-1} = -\frac{\mathrm{e}^2\,\mathrm{expIntegral}_1(2)}{2} + c_1 \mathrm{e}^2$$

$$c_1 = \frac{(\mathrm{e}^2\,\mathrm{expIntegral}_1(2) + 2\,\mathrm{e}^{-1})\,\mathrm{e}^{-2}}{2}$$

Substituting c_1 found above in the general solution gives

$$p(x) = \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2)}{2} + \mathrm{e}^{2x-3} - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2)}{2} + \mathrm{e}^{2x-3} - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}$$

Integrating both sides gives

$$\begin{aligned} y &= \int \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2)}{2} + \mathrm{e}^{2x-3} - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}\,\mathrm{d}x \\ &= \int \left(\frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2)}{2} + \mathrm{e}^{2x-3} - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}\right) dx + c_2 \end{aligned}$$

Initial conditions are used to solve for c_2. Substituting $x = 1$ and $y = \mathrm{e}$ in the above solution gives an equation to solve for the constant of integration.

$$\mathrm{e} = \int^1 \left(\frac{\mathrm{e}^{2\_a}\,\mathrm{expIntegral}_1(2)}{2} + \mathrm{e}^{2\_a-3} - \frac{\mathrm{e}^{2\_a}\,\mathrm{expIntegral}_1(2\_a)}{2} - \frac{\ln(\_a)}{2}\right) d\_a + c_2$$

$$c_2 = -\frac{\left(\int^1 (-\mathrm{e}^{2\_a}\,\mathrm{expIntegral}_1(2\_a) + \mathrm{e}^{2\_a}\,\mathrm{expIntegral}_1(2) + 2\,\mathrm{e}^{2\_a-3} - \ln(\_a))\,d\_a\right)}{2} + \mathrm{e}$$

Substituting c_2 found above in the general solution gives

$$y = \int \left(\frac{e^{2x}\,\text{expIntegral}_1(2)}{2} + e^{2x-3} - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}\right) dx - \frac{\left(\int^1 (-e^{2\_a}\,\text{expIntegral}_1(2\_$$

Initial conditions are used to solve for the constants of integration.

Summary

The solution(s) found are the following

$$\begin{aligned} y &= \int \left(\frac{e^{2x}\,\text{expIntegral}_1(2)}{2} + e^{2x-3} - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}\right) dx \\ &\quad - \frac{\left(\int^1 \left(-e^{2\_a}\,\text{expIntegral}_1(2\_a) + e^{2\_a}\,\text{expIntegral}_1(2) + 2\,e^{2\_a-3} - \ln(\_a)\right) d\_a\right)}{2} \\ &\quad + e \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y &= \int \left(\frac{e^{2x}\,\text{expIntegral}_1(2)}{2} + e^{2x-3} - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{2} - \frac{\ln(x)}{2}\right) dx \\ &\quad - \frac{\left(\int^1 \left(-e^{2\_a}\,\text{expIntegral}_1(2\_a) + e^{2\_a}\,\text{expIntegral}_1(2) + 2\,e^{2\_a-3} - \ln(\_a)\right) d\_a\right)}{2} \\ &\quad + e \end{aligned}$$

Verified OK.

14.16.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' - 2y' = \ln(x)$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' - 2y')\, dx = \int \ln(x)\, dx$$

$$y' - 2y = \ln(x)\, x - x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -2 \\
q(x) &= \ln(x)\, x - x + c_1
\end{aligned}
$$

Hence the ode is

$$
y' - 2y = \ln(x)\, x - x + c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int (-2)dx} \\
&= e^{-2x}
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\ln(x)\, x - x + c_1\right) \\
\frac{d}{dx}\left(y\, e^{-2x}\right) &= \left(e^{-2x}\right)\left(\ln(x)\, x - x + c_1\right) \\
d\left(y\, e^{-2x}\right) &= \left(\left(\ln(x)\, x - x + c_1\right) e^{-2x}\right)\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
y\, e^{-2x} &= \int \left(\ln(x)\, x - x + c_1\right) e^{-2x}\, dx \\
y\, e^{-2x} &= \left(-\frac{1}{4} - \frac{x}{2}\right) e^{-2x} \ln(x) - \frac{c_1 e^{-2x}}{2} + \frac{x\, e^{-2x}}{2} - \frac{\operatorname{expIntegral}_1(2x)}{4} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{-2x}$ results in

$$
y = e^{2x}\left(\left(-\frac{1}{4} - \frac{x}{2}\right) e^{-2x} \ln(x) - \frac{c_1 e^{-2x}}{2} + \frac{x\, e^{-2x}}{2} - \frac{\operatorname{expIntegral}_1(2x)}{4}\right) + c_2 e^{2x}
$$

which simplifies to

$$
y = -\frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} + c_2 e^{2x} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} - \frac{c_1}{2}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = -\frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} + c_2 e^{2x} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} - \frac{c_1}{2} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \mathrm{e}$ and $x = 1$ in the above gives

$$\mathrm{e} = -\frac{\mathrm{e}^2 \operatorname{expIntegral}_1(2)}{4} + c_2 \mathrm{e}^2 + \frac{1}{2} - \frac{c_1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{2} + \frac{\mathrm{e}^{2x}\mathrm{e}^{-2x}}{4x} + 2c_2 \mathrm{e}^{2x} - \frac{\ln(x)}{2} + \frac{-1-2x}{4x} + \frac{1}{2}$$

substituting $y' = \mathrm{e}^{-1}$ and $x = 1$ in the above gives

$$\mathrm{e}^{-1} = \mathrm{e}^2 \left(-\frac{\operatorname{expIntegral}_1(2)}{2} + 2c_2\right) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -2\,\mathrm{e} + 1 + \mathrm{e}^{-1} \\ c_2 &= \frac{\operatorname{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{-3}}{2} \end{aligned}$$

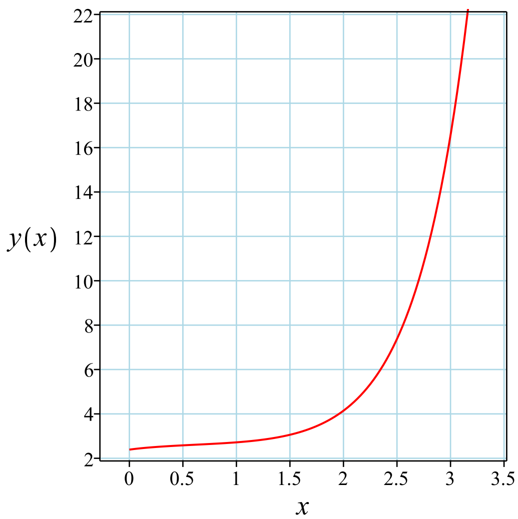
Substituting these values back in above solution results in

$$y = \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{2x-3}}{2} + \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} - \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

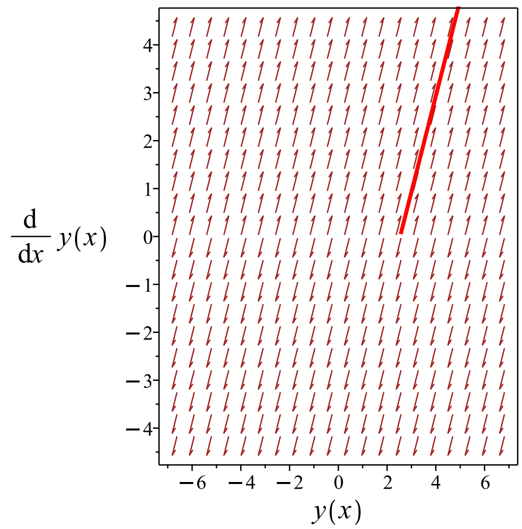
<u>Summary</u>

The solution(s) found are the following

$$\begin{aligned} y = {}& \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{2x-3}}{2} + \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} \\ & - \frac{\mathrm{e}^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2} \end{aligned} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{e^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

Verified OK.

14.16.6 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 0 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 362: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = 1$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1(1) + c_2\left(1\left(\frac{e^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 + \frac{c_2 e^{2x}}{2}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= 1 \\
y_2 &= \frac{e^{2x}}{2}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} 1 & \frac{e^{2x}}{2} \\ \frac{d}{dx}(1) & \frac{d}{dx}\left(\frac{e^{2x}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} 1 & \frac{e^{2x}}{2} \\ 0 & e^{2x} \end{vmatrix}$$

Therefore

$$W = (1)\left(e^{2x}\right) - \left(\frac{e^{2x}}{2}\right)(0)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\ln(x) e^{2x}}{2}}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\ln(x)}{2} dx$$

Hence

$$u_1 = -\frac{\ln(x)\,x}{2} + \frac{x}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\ln(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int \ln(x)\, \mathrm{e}^{-2x} dx$$

Hence

$$u_2 = -\frac{\ln(x)\, \mathrm{e}^{-2x}}{2} - \frac{\mathrm{expIntegral}_1(2x)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(x)\, x}{2} + \frac{x}{2} + \frac{\mathrm{e}^{2x}\left(-\frac{\ln(x)\mathrm{e}^{-2x}}{2} - \frac{\mathrm{expIntegral}_1(2x)}{2}\right)}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^{2x}\, \mathrm{expIntegral}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 + \frac{c_2 \mathrm{e}^{2x}}{2}\right) + \left(-\frac{\mathrm{e}^{2x}\, \mathrm{expIntegral}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 + \frac{c_2 \mathrm{e}^{2x}}{2} - \frac{\mathrm{e}^{2x}\, \mathrm{expIntegral}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \mathrm{e}$ and $x = 1$ in the above gives

$$\mathrm{e} = c_1 + \frac{c_2 \mathrm{e}^2}{2} - \frac{\mathrm{e}^2\, \mathrm{expIntegral}_1(2)}{4} + \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 \mathrm{e}^{2x} - \frac{\mathrm{e}^{2x}\, \mathrm{expIntegral}_1(2x)}{2} + \frac{\mathrm{e}^{2x}\mathrm{e}^{-2x}}{4x} - \frac{\ln(x)}{2} + \frac{-1-2x}{4x} + \frac{1}{2}$$

substituting $y' = \mathrm{e}^{-1}$ and $x = 1$ in the above gives

$$\mathrm{e}^{-1} = \mathrm{e}^{2}\left(c_2 - \frac{\mathrm{expIntegral}_1(2)}{2}\right) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2}$$
$$c_2 = \frac{\mathrm{expIntegral}_1(2)}{2} + \mathrm{e}^{-3}$$

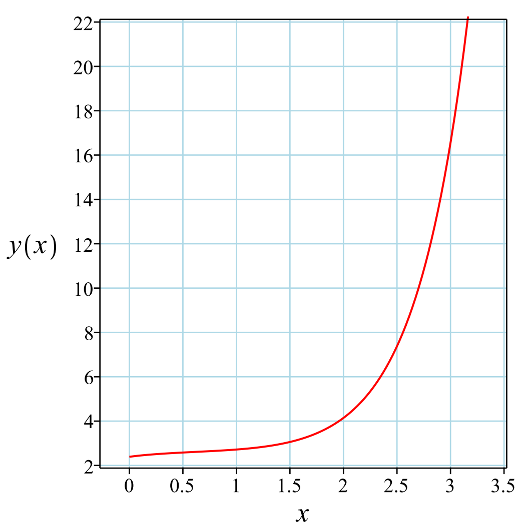
Substituting these values back in above solution results in

$$y = \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{2x-3}}{2} + \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

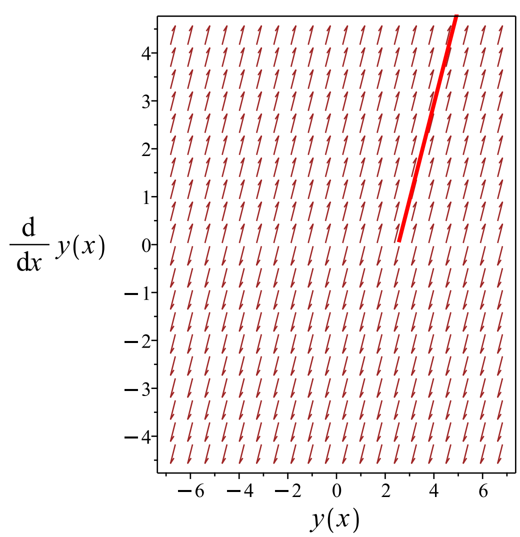
Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2)}{4} + \frac{\mathrm{e}^{2x-3}}{2} + \mathrm{e} - \frac{1}{2} - \frac{\mathrm{e}^{-1}}{2} \\ & - \frac{\mathrm{e}^{2x}\,\mathrm{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2} \end{aligned} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{e^{2x}\,\text{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x}\,\text{expIntegral}_1(2x)}{4} - \frac{\ln(x)\,x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

Verified OK.

14.16.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -2 \\ r(x) &= 0 \\ s(x) &= \ln(x) \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$0 - (0) + (0) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$y' - 2y = \int \ln(x)\, dx$$

We now have a first order ode to solve which is

$$y' - 2y = \ln(x)\, x - x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= \ln(x)\, x - x + c_1 \end{aligned}$$

Hence the ode is

$$y' - 2y = \ln(x)\, x - x + c_1$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int (-2)dx} \\ &= \mathrm{e}^{-2x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\ln(x)\, x - x + c_1\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(y\,\mathrm{e}^{-2x}\right) &= \left(\mathrm{e}^{-2x}\right)\left(\ln(x)\, x - x + c_1\right) \\ \mathrm{d}\left(y\,\mathrm{e}^{-2x}\right) &= \left(\left(\ln(x)\, x - x + c_1\right)\mathrm{e}^{-2x}\right)\, \mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} y\,\mathrm{e}^{-2x} &= \int \left(\ln(x)\, x - x + c_1\right)\mathrm{e}^{-2x}\, \mathrm{d}x \\ y\,\mathrm{e}^{-2x} &= \left(-\frac{1}{4} - \frac{x}{2}\right)\mathrm{e}^{-2x}\ln(x) - \frac{c_1\mathrm{e}^{-2x}}{2} + \frac{x\,\mathrm{e}^{-2x}}{2} - \frac{\operatorname{expIntegral}_1(2x)}{4} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{-2x}$ results in

$$y = \mathrm{e}^{2x}\left(\left(-\frac{1}{4} - \frac{x}{2}\right)\mathrm{e}^{-2x}\ln(x) - \frac{c_1\mathrm{e}^{-2x}}{2} + \frac{x\,\mathrm{e}^{-2x}}{2} - \frac{\operatorname{expIntegral}_1(2x)}{4}\right) + c_2\mathrm{e}^{2x}$$

which simplifies to

$$y = -\frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} + c_2 e^{2x} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} - \frac{c_1}{2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} + c_2 e^{2x} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} - \frac{c_1}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = e$ and $x = 1$ in the above gives

$$e = -\frac{e^2 \operatorname{expIntegral}_1(2)}{4} + c_2 e^2 + \frac{1}{2} - \frac{c_1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{e^{2x} \operatorname{expIntegral}_1(2x)}{2} + \frac{e^{2x} e^{-2x}}{4x} + 2c_2 e^{2x} - \frac{\ln(x)}{2} + \frac{-1-2x}{4x} + \frac{1}{2}$$

substituting $y' = e^{-1}$ and $x = 1$ in the above gives

$$e^{-1} = e^2 \left(-\frac{\operatorname{expIntegral}_1(2)}{2} + 2c_2\right) \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2e + 1 + e^{-1}$$
$$c_2 = \frac{\operatorname{expIntegral}_1(2)}{4} + \frac{e^{-3}}{2}$$

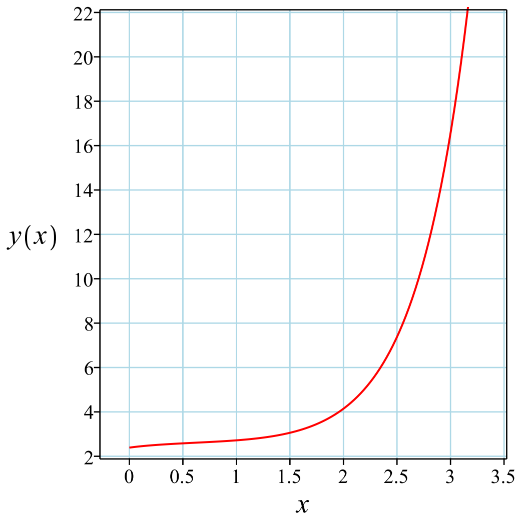
Substituting these values back in above solution results in

$$y = \frac{e^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

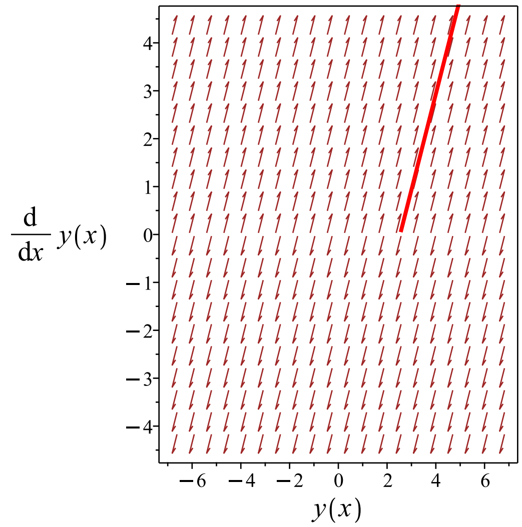
Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \frac{e^{2x} \operatorname{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} \\ & - \frac{e^{2x} \operatorname{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2} \end{aligned} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{e^{2x} \text{expIntegral}_1(2)}{4} + \frac{e^{2x-3}}{2} + e - \frac{1}{2} - \frac{e^{-1}}{2} - \frac{e^{2x} \text{expIntegral}_1(2x)}{4} - \frac{\ln(x)\, x}{2} - \frac{\ln(x)}{4} + \frac{x}{2}$$

Verified OK.

14.16.8 Maple step by step solution

Let's solve

$$\left[y'' - 2y' = \ln(x), y(1) = e, y'\Big|_{\{x=1\}} = \frac{1}{e}\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r = 0$

- Factor the characteristic polynomial

  $r(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (0, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = 1$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 + c_2 e^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \ln(x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} 1 & e^{2x} \\ 0 & 2\,e^{2x} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = 2\,e^{2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -\frac{\left(\int \ln(x)dx\right)}{2} + \frac{e^{2x}\left(\int \ln(x)e^{-2x}dx\right)}{2}$

  - Compute integrals

    $y_p(x) = -\frac{e^{2x}\mathrm{Ei}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 + c_2 e^{2x} - \frac{e^{2x}\mathrm{Ei}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}$

☐ Check validity of solution $y = c_1 + c_2 e^{2x} - \frac{e^{2x}\mathrm{Ei}_1(2x)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2}$

  - Use initial condition $y(1) = e$

    $e = c_1 + c_2 e^2 - \frac{e^2\mathrm{Ei}_1(2)}{4} + \frac{1}{2}$

  - Compute derivative of the solution

    $y' = -\frac{e^{2x}\mathrm{Ei}_1(2x)}{2} + \frac{e^{2x}e^{-2x}}{4x} + 2c_2 e^{2x} - \frac{\ln(x)}{2} + \frac{-1-2x}{4x} + \frac{1}{2}$

  - Use the initial condition $y'\Big|_{\{x=1\}} = \frac{1}{e}$

$$\frac{1}{e} = -\frac{e^2 \mathrm{Ei}_1(2)}{2} + \frac{e^2 e^{-2}}{4} + 2c_2 e^2 - \frac{1}{4}$$

- Solve for c_1 and c_2

$$\left\{c_1 = \frac{e^2 e^{-2} e + 8(e)^2 - 5e - 4}{8e}, c_2 = -\frac{e^2 e^{-2} e - 2e^2 e \mathrm{Ei}_1(2) - e - 4}{8e^2 e}\right\}$$

- Substitute constant values into general solution and simplify

$$y = \frac{e^{2x-3}}{2} - \frac{e^{2x} \mathrm{Ei}_1(2x)}{4} + \frac{e^{2x} \mathrm{Ei}_1(2)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} - \frac{e^{-1}}{2} + e - \frac{1}{2}$$

- Solution to the IVP

$$y = \frac{e^{2x-3}}{2} - \frac{e^{2x} \mathrm{Ei}_1(2x)}{4} + \frac{e^{2x} \mathrm{Ei}_1(2)}{4} + \frac{(-1-2x)\ln(x)}{4} + \frac{x}{2} - \frac{e^{-1}}{2} + e - \frac{1}{2}$$

```

$$\boxed{y'' + 3y' + 2y = 2x - 1}$$

14.17.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 3, C = 2, f(x) = 2x - 1$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 3\lambda\,\mathrm{e}^{\lambda x} + 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 3, C = 2$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{-3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{3^2 - (4)\,(1)\,(2)} \\
&= -\frac{3}{2} \pm \frac{1}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= -\frac{3}{2} + \frac{1}{2} \\
\lambda_2 &= -\frac{3}{2} - \frac{1}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= -1 \\
\lambda_2 &= -2
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(-1)x} + c_2 e^{(-2)x}
\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1 + x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$2A_2 x + 2A_1 + 3A_2 = 2x - 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2 + x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + c_2 e^{-2x}\right) + (-2 + x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 e^{-2x} - 2 + x \tag{1}$$

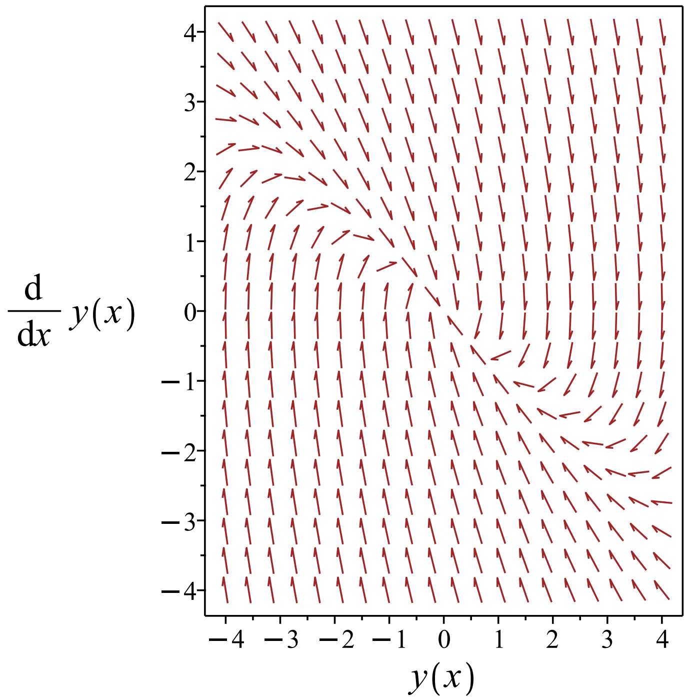

Figure 406: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + c_2 e^{-2x} - 2 + x$$

Verified OK.

14.17.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 364: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3}{1}\,dx} \\
&= z_1 e^{-\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\right) + c_2\left(\mathrm{e}^{-2x}\left(\mathrm{e}^{x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1\mathrm{e}^{-2x} + c_2\mathrm{e}^{-x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
1 + x
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{1, x\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\mathrm{e}^{-2x}, \mathrm{e}^{-x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_2 x + A_1
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
2A_2 x + 2A_1 + 3A_2 = 2x - 1
$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = -2, A_2 = 1]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -2 + x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x}\right) + (-2 + x) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} - 2 + x \tag{1}$$

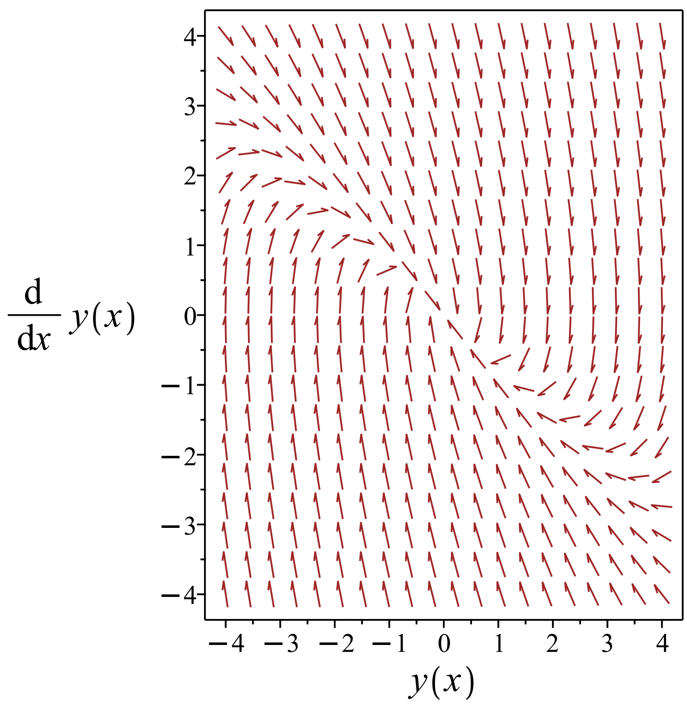

Figure 407: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-2x} + c_2 \mathrm{e}^{-x} - 2 + x$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 3y' + 2y = \mathrm{e}^{-x}}$$

14.18.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = \mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 3\lambda\, \mathrm{e}^{\lambda x} + 2\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 2$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(2)} \\
&= \frac{3}{2} \pm \frac{1}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= \frac{3}{2} + \frac{1}{2} \\
\lambda_2 &= \frac{3}{2} - \frac{1}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 2 \\
\lambda_2 &= 1
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(2)x} + c_2 e^{(1)x}
\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$e^{-x}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{e^{-x}\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 e^{-x}$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$6A_1 e^{-x} = e^{-x}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2 e^{x}\right) + \left(\frac{e^{-x}}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^{x} + \frac{e^{-x}}{6} \tag{1}$$

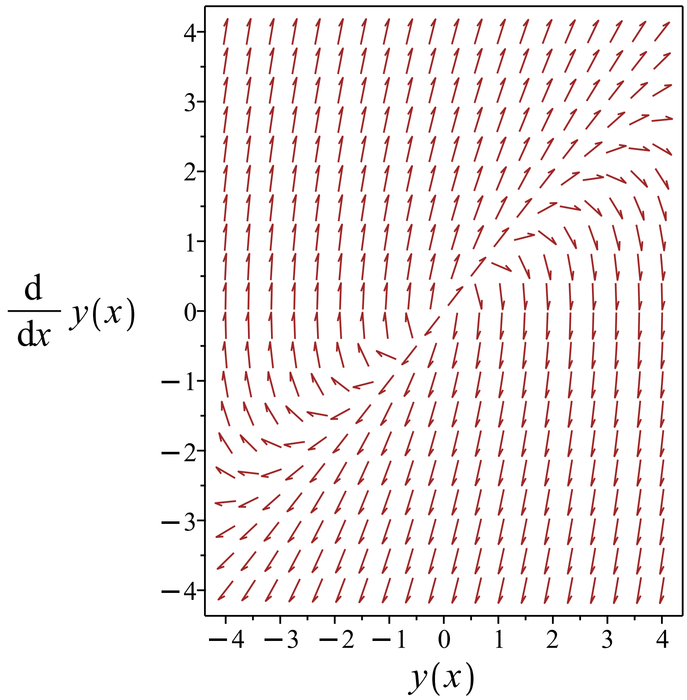

Figure 408: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 e^{2x} + c_2 e^{x} + \frac{e^{-x}}{6}$$

Verified OK.

14.18.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 366: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\, dx} \\
&= z_1 e^{\frac{3x}{2}} \\
&= z_1 \left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{3x}}{(y_1)^2}\, dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(\mathrm{e}^x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 3y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^x + c_2 \mathrm{e}^{2x}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\mathrm{e}^{-x}
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\mathrm{e}^{-x}\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\{\mathrm{e}^x, \mathrm{e}^{2x}\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \mathrm{e}^{-x}
$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$
6A_1 \mathrm{e}^{-x} = \mathrm{e}^{-x}
$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{6}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{e^{-x}}{6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^x + c_2 e^{2x}\right) + \left(\frac{e^{-x}}{6}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^x + c_2 e^{2x} + \frac{e^{-x}}{6} \tag{1}$$

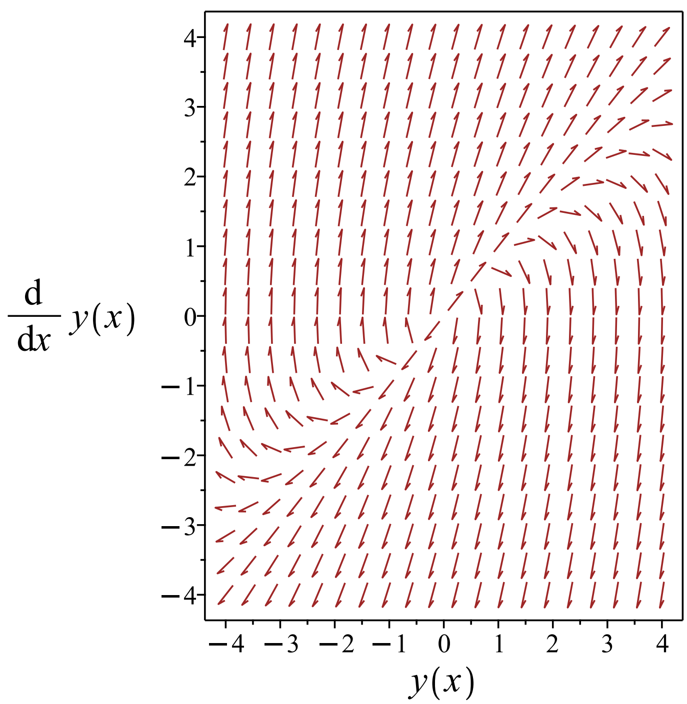

Figure 409: Slope field plot

Verification of solutions

$$y = c_1 e^{x} + c_2 e^{2x} + \frac{e^{-x}}{6}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y' - 2y = \cos(x)}$$

14.19.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -1, C = -2, f(x) = \cos(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y' - 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -1, C = -2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \lambda \,\mathrm{e}^{\lambda x} - 2 \,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \lambda - 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -1, C = -2$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{1}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-1^2 - (4)\,(1)\,(-2)} \\
&= \frac{1}{2} \pm \frac{3}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= \frac{1}{2} + \frac{3}{2} \\
\lambda_2 &= \frac{1}{2} - \frac{3}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= 2 \\
\lambda_2 &= -1
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\
y &= c_1 e^{(2)x} + c_2 e^{(-1)x}
\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(x) + A_2 \sin(x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-3A_1 \cos(x) - 3A_2 \sin(x) + A_1 \sin(x) - A_2 \cos(x) = \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{10}, A_2 = -\frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(x)}{10} - \frac{\sin(x)}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2 e^{-x}\right) + \left(-\frac{3\cos(x)}{10} - \frac{\sin(x)}{10}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^{-x} - \frac{3\cos(x)}{10} - \frac{\sin(x)}{10} \tag{1}$$

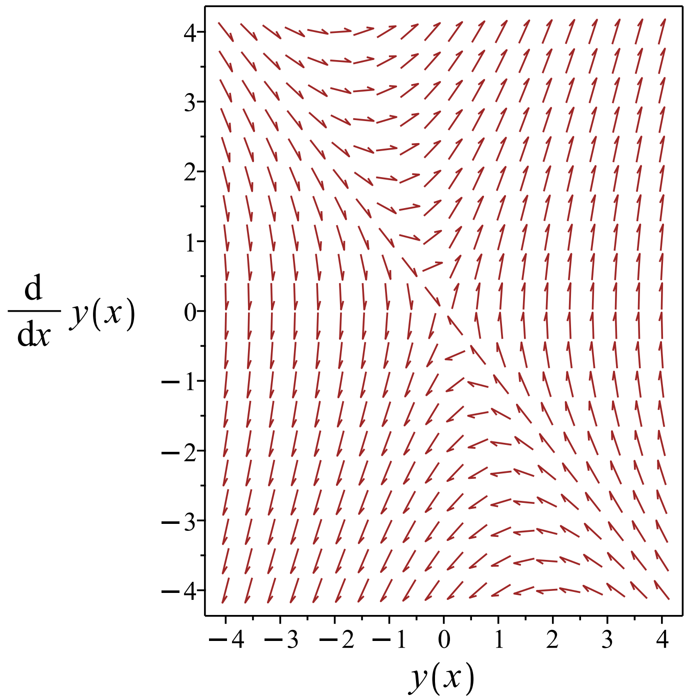

Figure 410: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{-x} - \frac{3\cos(x)}{10} - \frac{\sin(x)}{10}$$

Verified OK.

14.19.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -1 \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 368: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-1}{1}\,dx} \\ &= z_1 e^{\frac{x}{2}} \\ &= z_1 \left(e^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{e^{3x}}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - y' - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{2x}}{3}
$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$
\cos(x)
$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$
[\{\cos(x), \sin(x)\}]
$$

While the set of the basis functions for the homogeneous solution found earlier is

$$
\left\{\frac{\mathrm{e}^{2x}}{3}, \mathrm{e}^{-x}\right\}
$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$
y_p = A_1 \cos(x) + A_2 \sin(x)
$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-3A_1 \cos(x) - 3A_2 \sin(x) + A_1 \sin(x) - A_2 \cos(x) = \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{10}, A_2 = -\frac{1}{10}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(x)}{10} - \frac{\sin(x)}{10}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{c_2 e^{2x}}{3}\right) + \left(-\frac{3\cos(x)}{10} - \frac{\sin(x)}{10}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{2x}}{3} - \frac{3\cos(x)}{10} - \frac{\sin(x)}{10} \tag{1}$$

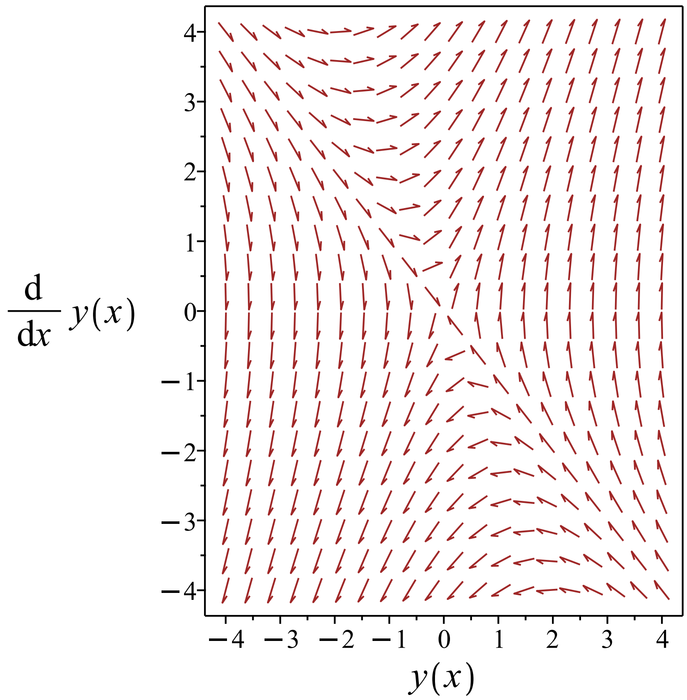

Figure 411: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{2x}}{3} - \frac{3\cos(x)}{10} - \frac{\sin(x)}{10}$$

Verified OK.

14.19.3 Maple step by step solution

Let's solve

$y'' - y' - 2y = \cos(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r - 2 = 0$

- Factor the characteristic polynomial

  $(r+1)(r-2) = 0$

- Roots of the characteristic polynomial

$r = (-1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{2x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \cos(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{2x} \\ -\mathrm{e}^{-x} & 2\,\mathrm{e}^{2x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3\,\mathrm{e}^{x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\mathrm{e}^{-x}\left(\int \cos(x)\mathrm{e}^{x} dx\right)}{3} + \frac{\mathrm{e}^{2x}\left(\int \mathrm{e}^{-2x}\cos(x) dx\right)}{3}$

  ◦ Compute integrals

  $y_p(x) = -\frac{3\cos(x)}{10} - \frac{\sin(x)}{10}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{2x} - \frac{3\cos(x)}{10} - \frac{\sin(x)}{10}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 2y' - y = \sin(x)\,\mathrm{e}^{x} x}$$

14.20.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 2, C = -1, f(x) = \sin(x)\,\mathrm{e}^{x} x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 2y' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 2, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 2\lambda e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 2\lambda - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 2, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{2^2 - (4)(1)(-1)} \\ &= -1 \pm \sqrt{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= -1 + \sqrt{2} \\ \lambda_2 &= -1 - \sqrt{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{2} - 1 \\ \lambda_2 &= -1 - \sqrt{2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{\left(\sqrt{2}-1\right)x} + c_2 e^{\left(-1-\sqrt{2}\right)x}\end{aligned}$$

Or

$$y = c_1 e^{\left(\sqrt{2}-1\right)x} + c_2 e^{\left(-1-\sqrt{2}\right)x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{\left(\sqrt{2}-1\right)x} + c_2 e^{\left(-1-\sqrt{2}\right)x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin(x)\,\mathrm{e}^{x} x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x)\,\mathrm{e}^{x}, \sin(x)\,\mathrm{e}^{x}, \cos(x)\,\mathrm{e}^{x} x, \sin(x)\,\mathrm{e}^{x} x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{\left(-1-\sqrt{2}\right)x}, \mathrm{e}^{\left(\sqrt{2}-1\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(x)\,\mathrm{e}^{x} + A_2\sin(x)\,\mathrm{e}^{x} + A_3\cos(x)\,\mathrm{e}^{x} x + A_4\sin(x)\,\mathrm{e}^{x} x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-4A_1\sin(x)\,\mathrm{e}^{x} + 4A_2\cos(x)\,\mathrm{e}^{x} - 4A_3\sin(x)\,\mathrm{e}^{x} x - 2A_3\sin(x)\,\mathrm{e}^{x}\\ &+ 4A_3\cos(x)\,\mathrm{e}^{x} + 4A_4\cos(x)\,\mathrm{e}^{x} x + 2A_4\cos(x)\,\mathrm{e}^{x} + 4A_4\sin(x)\,\mathrm{e}^{x}\\ &+ A_1\cos(x)\,\mathrm{e}^{x} + A_2\sin(x)\,\mathrm{e}^{x} + A_3\cos(x)\,\mathrm{e}^{x} x + A_4\sin(x)\,\mathrm{e}^{x} x = \sin(x)\,\mathrm{e}^{x} x\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{62}{289}, A_2 = \frac{44}{289}, A_3 = -\frac{4}{17}, A_4 = \frac{1}{17}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{62\cos(x)\,\mathrm{e}^{x}}{289} + \frac{44\sin(x)\,\mathrm{e}^{x}}{289} - \frac{4\cos(x)\,\mathrm{e}^{x} x}{17} + \frac{\sin(x)\,\mathrm{e}^{x} x}{17}$$

Therefore the general solution is

$$\begin{aligned}y &= y_h + y_p\\ &= \left(c_1\mathrm{e}^{\left(\sqrt{2}-1\right)x} + c_2\mathrm{e}^{\left(-1-\sqrt{2}\right)x}\right)\\ &\quad + \left(\frac{62\cos(x)\,\mathrm{e}^{x}}{289} + \frac{44\sin(x)\,\mathrm{e}^{x}}{289} - \frac{4\cos(x)\,\mathrm{e}^{x} x}{17} + \frac{\sin(x)\,\mathrm{e}^{x} x}{17}\right)\end{aligned}$$

Which simplifies to

$$y = c_1 e^{(\sqrt{2}-1)x} + c_2 e^{-(1+\sqrt{2})x} + \frac{62\cos(x)\, e^{x}}{289} + \frac{44\sin(x)\, e^{x}}{289} - \frac{4\cos(x)\, e^{x} x}{17} + \frac{\sin(x)\, e^{x} x}{17}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{(\sqrt{2}-1)x} + c_2 e^{-(1+\sqrt{2})x} + \frac{62\cos(x)\, e^{x}}{289} + \frac{44\sin(x)\, e^{x}}{289} - \frac{4\cos(x)\, e^{x} x}{17} + \frac{\sin(x)\, e^{x} x}{17} \tag{1}$$

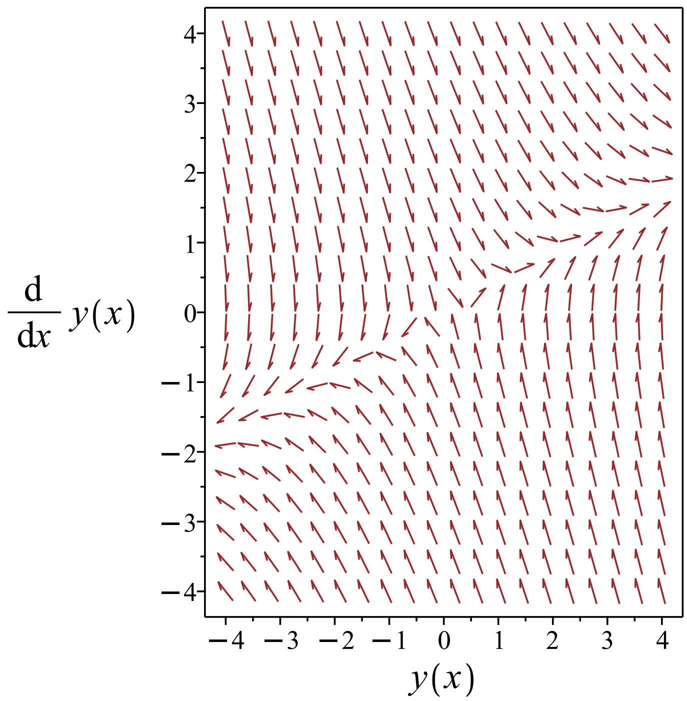

Figure 412: Slope field plot

Verification of solutions

$$y = c_1 e^{(\sqrt{2}-1)x} + c_2 e^{-(1+\sqrt{2})x} + \frac{62\cos(x)\, e^{x}}{289} + \frac{44\sin(x)\, e^{x}}{289} - \frac{4\cos(x)\, e^{x} x}{17} + \frac{\sin(x)\, e^{x} x}{17}$$

Verified OK.

14.20.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 2y' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 2z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 370: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x\sqrt{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-x} \\
&= z_1 \left(\mathrm{e}^{-x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\left(1+\sqrt{2}\right)x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2}{1}\, dx}}{\left(y_1\right)^2}\, dx \\
&= y_1 \int \frac{e^{-2x}}{\left(y_1\right)^2}\, dx \\
&= y_1 \left(\frac{\sqrt{2}\, \mathrm{e}^{2x\sqrt{2}}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\left(1+\sqrt{2}\right)x}\right) + c_2 \left(\mathrm{e}^{-\left(1+\sqrt{2}\right)x} \left(\frac{\sqrt{2}\, \mathrm{e}^{2x\sqrt{2}}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 2y' - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-\left(1+\sqrt{2}\right)x} + \frac{c_2\sqrt{2}\,\mathrm{e}^{\left(\sqrt{2}-1\right)x}}{4}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\sin\left(x\right)\mathrm{e}^{x} x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos\left(x\right)\mathrm{e}^{x}, \sin\left(x\right)\mathrm{e}^{x}, \cos\left(x\right)\mathrm{e}^{x} x, \sin\left(x\right)\mathrm{e}^{x} x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sqrt{2}\,\mathrm{e}^{\left(\sqrt{2}-1\right)x}}{4}, \mathrm{e}^{-\left(1+\sqrt{2}\right)x}\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos\left(x\right)\mathrm{e}^{x} + A_2\sin\left(x\right)\mathrm{e}^{x} + A_3\cos\left(x\right)\mathrm{e}^{x} x + A_4\sin\left(x\right)\mathrm{e}^{x} x$$

The unknowns $\{A_1, A_2, A_3, A_4\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$\begin{aligned}&-4A_1\sin\left(x\right)\mathrm{e}^{x} + 4A_2\cos\left(x\right)\mathrm{e}^{x} - 4A_3\sin\left(x\right)\mathrm{e}^{x} x - 2A_3\sin\left(x\right)\mathrm{e}^{x}\\ &+ 4A_3\cos\left(x\right)\mathrm{e}^{x} + 4A_4\cos\left(x\right)\mathrm{e}^{x} x + 2A_4\cos\left(x\right)\mathrm{e}^{x} + 4A_4\sin\left(x\right)\mathrm{e}^{x}\\ &+ A_1\cos\left(x\right)\mathrm{e}^{x} + A_2\sin\left(x\right)\mathrm{e}^{x} + A_3\cos\left(x\right)\mathrm{e}^{x} x + A_4\sin\left(x\right)\mathrm{e}^{x} x = \sin\left(x\right)\mathrm{e}^{x} x\end{aligned}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{62}{289}, A_2 = \frac{44}{289}, A_3 = -\frac{4}{17}, A_4 = \frac{1}{17}\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = \frac{62\cos\left(x\right)\mathrm{e}^{x}}{289} + \frac{44\sin\left(x\right)\mathrm{e}^{x}}{289} - \frac{4\cos\left(x\right)\mathrm{e}^{x} x}{17} + \frac{\sin\left(x\right)\mathrm{e}^{x} x}{17}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 e^{-\left(1+\sqrt{2}\right)x} + \frac{c_2\sqrt{2}\, e^{\left(\sqrt{2}-1\right)x}}{4}\right) \\
&\quad + \left(\frac{62\cos\left(x\right) e^{x}}{289} + \frac{44\sin\left(x\right) e^{x}}{289} - \frac{4\cos\left(x\right) e^{x} x}{17} + \frac{\sin\left(x\right) e^{x} x}{17}\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = c_1 e^{-\left(1+\sqrt{2}\right)x} + \frac{c_2\sqrt{2}\, e^{\left(\sqrt{2}-1\right)x}}{4} + \frac{62\cos\left(x\right) e^{x}}{289} \\
+ \frac{44\sin\left(x\right) e^{x}}{289} - \frac{4\cos\left(x\right) e^{x} x}{17} + \frac{\sin\left(x\right) e^{x} x}{17}
\end{aligned} \tag{1}
$$

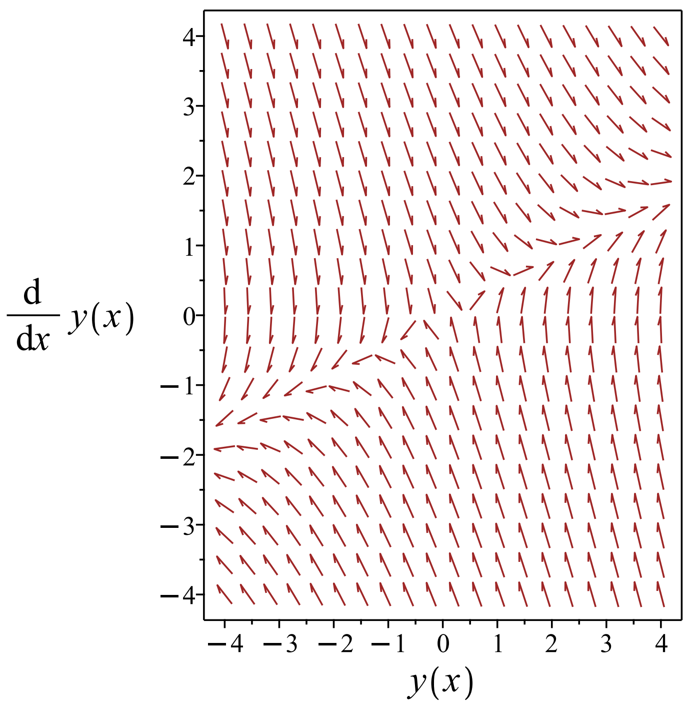

Figure 413: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-\left(1+\sqrt{2}\right)x} + \frac{c_2\sqrt{2}\,\mathrm{e}^{\left(\sqrt{2}-1\right)x}}{4} + \frac{62\cos\left(x\right)\mathrm{e}^{x}}{289} + \frac{44\sin\left(x\right)\mathrm{e}^{x}}{289} - \frac{4\cos\left(x\right)\mathrm{e}^{x}x}{17} + \frac{\sin\left(x\right)\mathrm{e}^{x}x}{17}$$

Verified OK.

14.20.3 Maple step by step solution

Let's solve

$y'' + 2y' - y = \sin\left(x\right)\mathrm{e}^{x}x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r - 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm\left(\sqrt{8}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-1-\sqrt{2}, \sqrt{2}-1\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{\left(-1-\sqrt{2}\right)x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{\left(\sqrt{2}-1\right)x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{\left(-1-\sqrt{2}\right)x} + c_2 \mathrm{e}^{\left(\sqrt{2}-1\right)x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \sin\left(x\right)\mathrm{e}^{x}x\right]$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{(-1-\sqrt{2})x} & e^{(\sqrt{2}-1)x} \\ (-1-\sqrt{2})\, e^{(-1-\sqrt{2})x} & (\sqrt{2}-1)\, e^{(\sqrt{2}-1)x} \end{bmatrix}$$

- Compute Wronskian

$$W(y_1(x), y_2(x)) = 2\sqrt{2}\, e^{-2x}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\sqrt{2}\left(e^{-(1+\sqrt{2})x}\left(\int x\, e^{(2+\sqrt{2})x} \sin(x)dx\right) - e^{(\sqrt{2}-1)x}\left(\int x\, e^{-(-2+\sqrt{2})x} \sin(x)dx\right)\right)}{4}$$

- Compute integrals

$$y_p(x) = \frac{e^x(17\sin(x)x - 68\cos(x)x + 44\sin(x) + 62\cos(x))}{289}$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^{(-1-\sqrt{2})x} + c_2 e^{(\sqrt{2}-1)x} + \frac{e^x(17\sin(x)x - 68\cos(x)x + 44\sin(x) + 62\cos(x))}{289}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 9y = \sec(2x)}$$

14.21.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = \sec(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 9\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i \\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i \\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(3x) \\ y_2 &= \sin(3x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(3x) & \sin(3x) \\ \frac{d}{dx}(\cos(3x)) & \frac{d}{dx}(\sin(3x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{vmatrix}$$

Therefore

$$W = (\cos(3x))(3\cos(3x)) - (\sin(3x))(-3\sin(3x))$$

Which simplifies to

$$W = 3\cos(3x)^2 + 3\sin(3x)^2$$

Which simplifies to

$$W = 3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(3x)\sec(2x)}{3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(3x)\sec(2x)}{3}dx$$

Hence

$$u_1 = -\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{2\cos(x)}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(3x)\sec(2x)}{3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\cos(3x)\sec(2x)}{3}dx$$

Hence

$$u_2 = -\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{2\sin(x)}{3}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned}y_p(x) = &\left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{2\cos(x)}{3}\right)\cos(3x)\\&+\left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{2\sin(x)}{3}\right)\sin(3x)\end{aligned}$$

Which simplifies to

$$y_p(x) = -\frac{2}{3} + \frac{\left(-4\cos(x)^3 + 3\cos(x)\right)\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2 + 1\right)\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{4\cos(x)^2}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(3x) + c_2\sin(3x)) + \left(-\frac{2}{3} + \frac{\left(-4\cos(x)^3 + 3\cos(x)\right)\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2 + 1\right)\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{4\cos(x)^2}{3}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(3x) + c_2\sin(3x) - \frac{2}{3} + \frac{\left(-4\cos(x)^3 + 3\cos(x)\right)\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2 + 1\right)\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{4\cos(x)^2}{3} \tag{1}$$

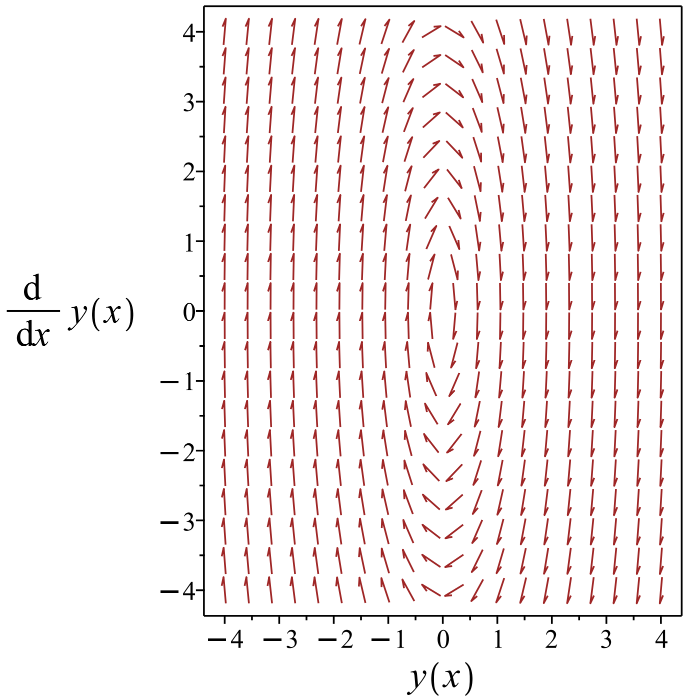

Figure 414: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + c_2 \sin(3x) - \frac{2}{3} + \frac{(-4\cos(x)^3 + 3\cos(x))\sqrt{2}\,\mathrm{arctanh}\left(\sqrt{2}\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2 + 1\right)\sqrt{2}\,\mathrm{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{4\cos(x)^2}{3}$$

Verified OK.

14.21.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 372: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\&= 0 - 0\\&= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1\\&= \cos(3x)\end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2}\, dx \\ &= \cos(3x) \left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2\left(\cos(3x) \left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(3x)$$
$$y_2 = \frac{\sin(3x)}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(3x) & \frac{\sin(3x)}{3} \\ \frac{d}{dx}(\cos(3x)) & \frac{d}{dx}\left(\frac{\sin(3x)}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(3x) & \frac{\sin(3x)}{3} \\ -3\sin(3x) & \cos(3x) \end{vmatrix}$$

Therefore

$$W = (\cos(3x))(\cos(3x)) - \left(\frac{\sin(3x)}{3}\right)(-3\sin(3x))$$

Which simplifies to

$$W = \cos(3x)^2 + \sin(3x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(3x)\sec(2x)}{3}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(3x)\sec(2x)}{3} dx$$

Hence

$$u_1 = -\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{2\cos(x)}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(3x)\sec(2x)}{1} dx$$

Which simplifies to

$$u_2 = \int \cos(3x)\sec(2x)\, dx$$

Hence

$$u_2 = -\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{2} + 2\sin(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{2\cos(x)}{3}\right)\cos(3x) + \frac{\left(-\frac{\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{2} + 2\sin(x)\right)\sin(3x)}{3}$$

Which simplifies to

$$y_p(x) = -\frac{2}{3}+\frac{\left(-4 \cos \left(x \right)^{3}+3 \cos \left(x \right)\right) \sqrt{2}\, \operatorname{arctanh}\left(\sqrt{2}\, \cos \left(x \right)\right)}{6} + \frac{\sin \left(x \right) \left(-4 \cos \left(x \right)^{2}+1\right) \sqrt{2}\, \operatorname{arctanh}\left(\sin \left(x \right) \sqrt{2}\right)}{6}+\frac{4 \cos \left(x \right)^{2}}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_{1} \cos \left(3 x \right)+\frac{c_{2} \sin \left(3 x \right)}{3}\right) \\ &\quad + \left(-\frac{2}{3}+\frac{\left(-4 \cos \left(x \right)^{3}+3 \cos \left(x \right)\right) \sqrt{2}\, \operatorname{arctanh}\left(\sqrt{2}\, \cos \left(x \right)\right)}{6} \right. \\ &\quad \left. + \frac{\sin \left(x \right) \left(-4 \cos \left(x \right)^{2}+1\right) \sqrt{2}\, \operatorname{arctanh}\left(\sin \left(x \right) \sqrt{2}\right)}{6}+\frac{4 \cos \left(x \right)^{2}}{3}\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_{1} \cos \left(3 x \right)+\frac{c_{2} \sin \left(3 x \right)}{3}-\frac{2}{3}+\frac{\left(-4 \cos \left(x \right)^{3}+3 \cos \left(x \right)\right) \sqrt{2}\, \operatorname{arctanh}\left(\sqrt{2}\, \cos \left(x \right)\right)}{6} + \frac{\sin \left(x \right) \left(-4 \cos \left(x \right)^{2}+1\right) \sqrt{2}\, \operatorname{arctanh}\left(\sin \left(x \right) \sqrt{2}\right)}{6}+\frac{4 \cos \left(x \right)^{2}}{3} \tag{1}$$

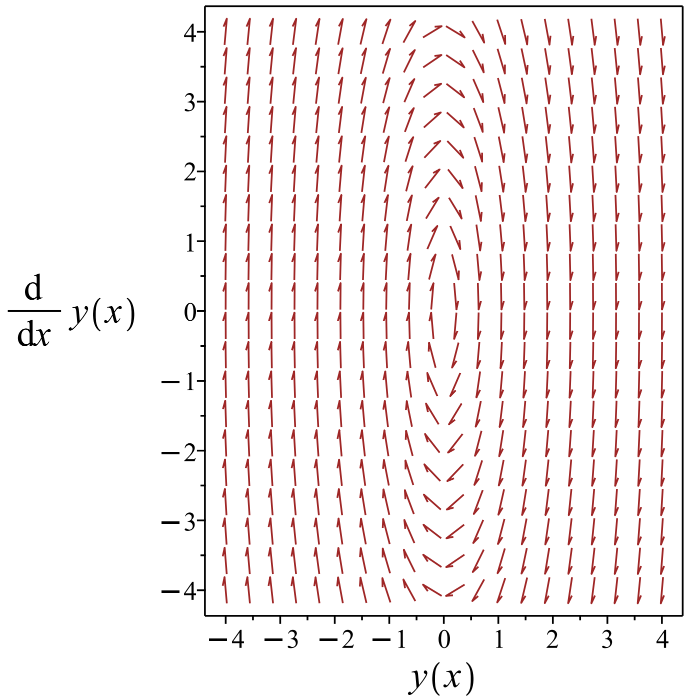

Figure 415: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} - \frac{2}{3} + \frac{\left(-4\cos(x)^3 + 3\cos(x)\right)\sqrt{2}\,\operatorname{arctanh}\left(\sqrt{2}\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2 + 1\right)\sqrt{2}\,\operatorname{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{4\cos(x)^2}{3}$$

Verified OK.

14.21.3 Maple step by step solution

Let's solve

$y'' + 9y = \sec(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

$r = \frac{0\pm(\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \sec(2x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{\cos(3x)\left(\int \sin(3x)\sec(2x)dx\right)}{3} + \frac{\sin(3x)\left(\int \cos(3x)\sec(2x)dx\right)}{3}$

  ◦ Compute integrals

  $y_p(x) = -\frac{2}{3} + \frac{\left(-4\cos(x)^3+3\cos(x)\right)\sqrt{2}\,\mathrm{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2+1\right)\sqrt{2}\,\mathrm{arctanh}\left(\sin(x)\sqrt{2}\right)}{6} + \frac{4\cos(x)^2}{3}$

- Substitute particular solution into general solution to ODE

  $y = c_1\cos(3x) + c_2\sin(3x) - \frac{2}{3} + \frac{\left(-4\cos(x)^3+3\cos(x)\right)\sqrt{2}\,\mathrm{arctanh}\left(\sqrt{2}\,\cos(x)\right)}{6} + \frac{\sin(x)\left(-4\cos(x)^2+1\right)\sqrt{2}\,\mathrm{arctan}}{6}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y' + 4y = \ln(x)\, x}$$

14.22.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4, C = 4, f(x) = \ln(x)\, x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 4, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\lambda\,\mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4\lambda + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 4, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{-4}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{(4)^2 - (4)\,(1)\,(4)}\\ &= -2\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = 2$. Therefore the solution is

$$y = c_1\mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x} \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1\mathrm{e}^{-2x} + c_2 x\,\mathrm{e}^{-2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= \mathrm{e}^{-2x}\\ y_2 &= x\,\mathrm{e}^{-2x}\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-2x} & x\,e^{-2x} \\ \frac{d}{dx}\left(e^{-2x}\right) & \frac{d}{dx}\left(x\,e^{-2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-2x} & x\,e^{-2x} \\ -2\,e^{-2x} & e^{-2x} - 2x\,e^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(e^{-2x}\right)\left(e^{-2x} - 2x\,e^{-2x}\right) - \left(x\,e^{-2x}\right)\left(-2\,e^{-2x}\right)$$

Which simplifies to

$$W = e^{-4x}$$

Which simplifies to

$$W = e^{-4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 e^{-2x} \ln(x)}{e^{-4x}}\,dx$$

Which simplifies to

$$u_1 = -\int x^2 \ln(x)\,e^{2x}\,dx$$

Hence

$$u_1 = -\left(\frac{1}{4}-\frac{1}{2}x+\frac{1}{2}x^2\right)\mathrm{e}^{2x}\ln(x)+\frac{\mathrm{e}^{2x}x}{4}-\frac{3\,\mathrm{e}^{2x}}{8}-\frac{\mathrm{expIntegral}_1(-2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{-2x}\ln(x)\,x}{\mathrm{e}^{-4x}}\,dx$$

Which simplifies to

$$u_2 = \int x\ln(x)\,\mathrm{e}^{2x}dx$$

Hence

$$u_2 = \left(-\frac{1}{4}+\frac{x}{2}\right)\mathrm{e}^{2x}\ln(x)-\frac{\mathrm{expIntegral}_1(-2x)}{4}-\frac{\mathrm{e}^{2x}}{4}$$

Which simplifies to

$$u_1 = -\frac{\mathrm{expIntegral}_1(-2x)}{4}+\frac{((-4x^2+4x-2)\ln(x)+2x-3)\,\mathrm{e}^{2x}}{8}$$
$$u_2 = -\frac{\mathrm{expIntegral}_1(-2x)}{4}+\frac{(-1+(2x-1)\ln(x))\,\mathrm{e}^{2x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\mathrm{expIntegral}_1(-2x)}{4}+\frac{((-4x^2+4x-2)\ln(x)+2x-3)\,\mathrm{e}^{2x}}{8}\right)\mathrm{e}^{-2x} + \left(-\frac{\mathrm{expIntegral}_1(-2x)}{4}+\frac{(-1+(2x-1)\ln(x))\,\mathrm{e}^{2x}}{4}\right)x\,\mathrm{e}^{-2x}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^{-2x}(1+x)\,\mathrm{expIntegral}_1(-2x)}{4}-\frac{3}{8}+\frac{(2x-2)\ln(x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-2x}+c_2x\,\mathrm{e}^{-2x}\right)+\left(-\frac{\mathrm{e}^{-2x}(1+x)\,\mathrm{expIntegral}_1(-2x)}{4}-\frac{3}{8}+\frac{(2x-2)\ln(x)}{8}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_2 x + c_1) - \frac{e^{-2x}(1 + x) \operatorname{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x - 2)\ln(x)}{8}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_2 x + c_1) - \frac{e^{-2x}(1 + x) \operatorname{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x - 2)\ln(x)}{8} \tag{1}$$

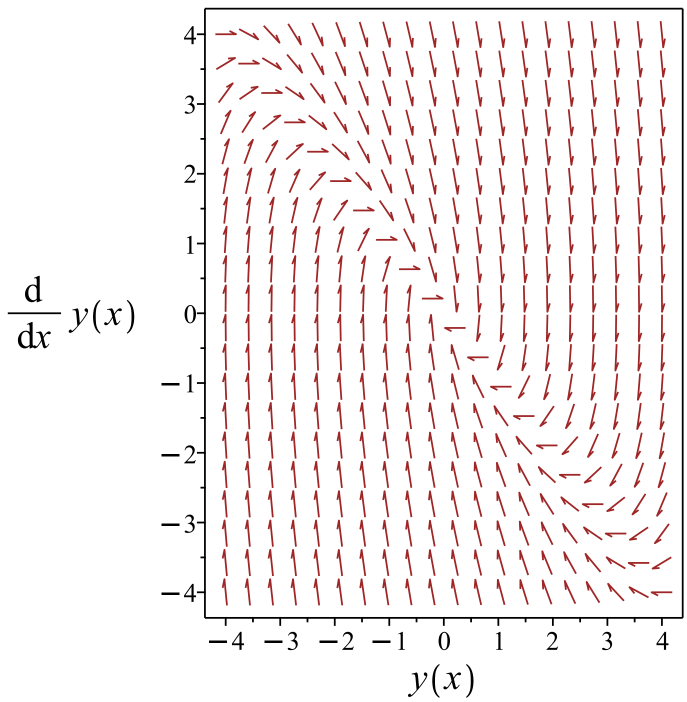

Figure 416: Slope field plot

Verification of solutions

$$y = e^{-2x}(c_2 x + c_1) - \frac{e^{-2x}(1 + x) \operatorname{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x - 2)\ln(x)}{8}$$

Verified OK.

14.22.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^{2} + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 4$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int 4\, dx} \\ &= \mathrm{e}^{2x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= x \ln(x)\, \mathrm{e}^{2x} \\ \left(\mathrm{e}^{2x} y\right)'' &= x \ln(x)\, \mathrm{e}^{2x} \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{2x} y\right)' = -\frac{\mathrm{expIntegral}_{1}(-2x)}{4} + \frac{(-1 + (2x - 1)\ln(x))\, \mathrm{e}^{2x}}{4} + c_1$$

Integrating again gives

$$\left(\mathrm{e}^{2x} y\right) = \frac{(-2 - 2x)\, \mathrm{expIntegral}_{1}(-2x)}{8} + \frac{(-3 + (2x - 2)\ln(x))\, \mathrm{e}^{2x}}{8} + c_1 x + c_2$$

Hence the solution is

$$y = \frac{\frac{(-2-2x)\, \mathrm{expIntegral}_{1}(-2x)}{8} + \frac{(-3+(2x-2)\ln(x))\mathrm{e}^{2x}}{8} + c_1 x + c_2}{\mathrm{e}^{2x}}$$

Or

$$\begin{aligned} y = {} & \frac{x \ln(x)}{4} - \frac{\ln(x)}{4} + c_1 x\, \mathrm{e}^{-2x} - \frac{x\, \mathrm{e}^{-2x}\, \mathrm{expIntegral}_{1}(-2x)}{4} \\ & + c_2 \mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x}\, \mathrm{expIntegral}_{1}(-2x)}{4} - \frac{3}{8} \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{x \ln(x)}{4} - \frac{\ln(x)}{4} + c_1 x \,\mathrm{e}^{-2x} - \frac{x \,\mathrm{e}^{-2x} \operatorname{expIntegral}_1(-2x)}{4} + c_2 \mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x} \operatorname{expIntegral}_1(-2x)}{4} - \frac{3}{8} \tag{1}$$

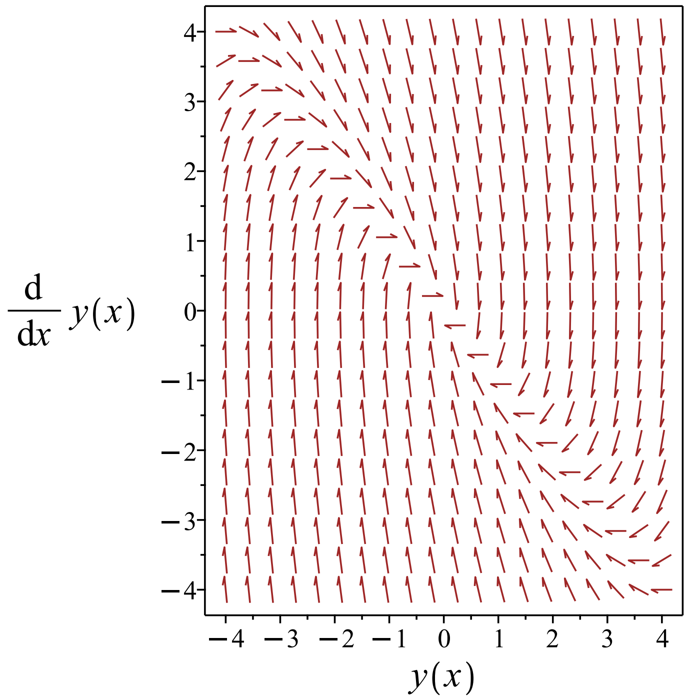

Figure 417: Slope field plot

Verification of solutions

$$y = \frac{x \ln(x)}{4} - \frac{\ln(x)}{4} + c_1 x \,\mathrm{e}^{-2x} - \frac{x \,\mathrm{e}^{-2x} \operatorname{expIntegral}_1(-2x)}{4} + c_2 \mathrm{e}^{-2x} - \frac{\mathrm{e}^{-2x} \operatorname{expIntegral}_1(-2x)}{4} - \frac{3}{8}$$

Verified OK.

14.22.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 4y' + 4y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 4 \\ C &= 4 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 374: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4}{1}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{-2x}\\
&= z_1 \left(\mathrm{e}^{-2x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4}{1}\, dx}}{(y_1)^2}\, dx\\
&= y_1 \int \frac{e^{-4x}}{(y_1)^2}\, dx\\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2\\
&= c_1 \left(\mathrm{e}^{-2x}\right) + c_2 \left(\mathrm{e}^{-2x}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 4y' + 4y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^{-2x} + c_2 x\, \mathrm{e}^{-2x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-2x}$$
$$y_2 = x\,\mathrm{e}^{-2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-2x} & x\,\mathrm{e}^{-2x} \\ \frac{d}{dx}(\mathrm{e}^{-2x}) & \frac{d}{dx}(x\,\mathrm{e}^{-2x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-2x} & x\,\mathrm{e}^{-2x} \\ -2\,\mathrm{e}^{-2x} & \mathrm{e}^{-2x} - 2x\,\mathrm{e}^{-2x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-2x}\right)\left(\mathrm{e}^{-2x} - 2x\,\mathrm{e}^{-2x}\right) - \left(x\,\mathrm{e}^{-2x}\right)\left(-2\,\mathrm{e}^{-2x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-4x}$$

Which simplifies to

$$W = \mathrm{e}^{-4x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2 \mathrm{e}^{-2x} \ln(x)}{\mathrm{e}^{-4x}} dx$$

Which simplifies to

$$u_1 = -\int x^2 \ln(x)\,\mathrm{e}^{2x} dx$$

Hence

$$u_1 = -\left(\frac{1}{4} - \frac{1}{2}x + \frac{1}{2}x^2\right) \mathrm{e}^{2x} \ln(x) + \frac{\mathrm{e}^{2x} x}{4} - \frac{3\,\mathrm{e}^{2x}}{8} - \frac{\mathrm{expIntegral}_1(-2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{-2x} \ln(x)\, x}{\mathrm{e}^{-4x}} dx$$

Which simplifies to

$$u_2 = \int x \ln(x)\,\mathrm{e}^{2x} dx$$

Hence

$$u_2 = \left(-\frac{1}{4} + \frac{x}{2}\right) \mathrm{e}^{2x} \ln(x) - \frac{\mathrm{expIntegral}_1(-2x)}{4} - \frac{\mathrm{e}^{2x}}{4}$$

Which simplifies to

$$u_1 = -\frac{\mathrm{expIntegral}_1(-2x)}{4} + \frac{((-4x^2 + 4x - 2)\ln(x) + 2x - 3)\,\mathrm{e}^{2x}}{8}$$

$$u_2 = -\frac{\mathrm{expIntegral}_1(-2x)}{4} + \frac{(-1 + (2x - 1)\ln(x))\,\mathrm{e}^{2x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\mathrm{expIntegral}_1(-2x)}{4} + \frac{((-4x^2 + 4x - 2)\ln(x) + 2x - 3)\,\mathrm{e}^{2x}}{8}\right) \mathrm{e}^{-2x} + \left(-\frac{\mathrm{expIntegral}_1(-2x)}{4} + \frac{(-1 + (2x - 1)\ln(x))\,\mathrm{e}^{2x}}{4}\right) x\,\mathrm{e}^{-2x}$$

Which simplifies to

$$y_p(x) = -\frac{e^{-2x}(1+x)\,\text{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x-2)\ln(x)}{8}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} + c_2 x\, e^{-2x}\right) + \left(-\frac{e^{-2x}(1+x)\,\text{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x-2)\ln(x)}{8}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-2x}(c_2 x + c_1) - \frac{e^{-2x}(1+x)\,\text{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x-2)\ln(x)}{8}$$

Summary

The solution(s) found are the following

$$y = e^{-2x}(c_2 x + c_1) - \frac{e^{-2x}(1+x)\,\text{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x-2)\ln(x)}{8} \tag{1}$$

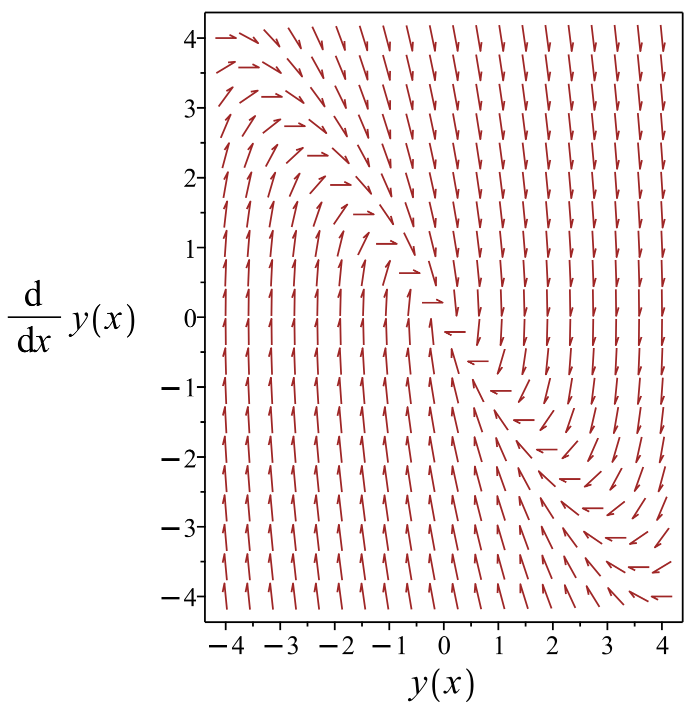

Figure 418: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-2x}(c_2x + c_1) - \frac{\mathrm{e}^{-2x}(1 + x)\,\mathrm{expIntegral}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x - 2)\ln(x)}{8}$$

Verified OK.

14.22.4 Maple step by step solution

Let's solve

$y'' + 4y' + 4y = x\ln(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4r + 4 = 0$

- Factor the characteristic polynomial

  $(r + 2)^2 = 0$

- Root of the characteristic polynomial

  $r = -2$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-2x}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{-2x}$

- General solution of the ODE

  $y = c_1y_1(x) + c_2y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1\mathrm{e}^{-2x} + c_2x\,\mathrm{e}^{-2x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x\ln(x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-2x} & x e^{-2x} \\ -2 e^{-2x} & e^{-2x} - 2x e^{-2x} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{-4x}$

- Substitute functions into equation for $y_p(x)$

  $y_p(x) = e^{-2x}\left(-\left(\int x^2 \ln(x) e^{2x} dx\right) + \left(\int x \ln(x) e^{2x} dx\right) x\right)$

- Compute integrals

  $y_p(x) = -\frac{e^{-2x}(1+x)\mathrm{Ei}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x-2)\ln(x)}{8}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-2x} + c_2 x e^{-2x} - \frac{e^{-2x}(1+x)\mathrm{Ei}_1(-2x)}{4} - \frac{3}{8} + \frac{(2x-2)\ln(x)}{8}$

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$x^2y'' + 3xy' + y = \frac{2}{x}$$

14.23.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 3x, C = 1, f(x) = \frac{2}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 3xy' + y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 3xrx^{r-1} + x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 3r\,x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 3r + 1 = 0$$

Or

$$r^2 + 2r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = -1$$

Since the roots are equal, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

Next, we find the particular solution to the ODE

$$x^2y'' + 3xy' + y = \frac{2}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{\ln(x)}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{\ln(x)}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ -\frac{1}{x^2} & -\frac{\ln(x)}{x^2} + \frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(-\frac{\ln(x)}{x^2} + \frac{1}{x^2}\right) - \left(\frac{\ln(x)}{x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\ln(x)}{x^2}}{\frac{1}{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{2\ln(x)}{x}dx$$

Hence

$$u_1 = -\ln(x)^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2}{x^2}}{\frac{1}{x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x}dx$$

Hence

$$u_2 = 2\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\ln(x)^2}{x}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \frac{\ln(x)^2 + c_1 + c_2 \ln(x)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{\ln(x)^2 + c_1 + c_2 \ln(x)}{x} \tag{1}
$$

Verification of solutions

$$
y = \frac{\ln(x)^2 + c_1 + c_2 \ln(x)}{x}
$$

Verified OK.

14.23.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + 3xy' + y = 0
$$

In normal form the ode

$$
x^2y'' + 3xy' + y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{3}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int \frac{3}{x}dx\right)} dx \\
&= \int e^{-3\ln(x)}\, dx \\
&= \int \frac{1}{x^3} dx \\
&= -\frac{1}{2x^2}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{1}{x^2}}{\frac{1}{x^6}} \\
&= x^4
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + x^4 y(\tau) = 0$$

But in terms of τ

$$x^4 = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\left(c_1 - c_2\ln(2) + c_2\ln\left(-\frac{1}{x^2}\right)\right)}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2 \ln\left(2\right) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-\frac{1}{x^2}}$$

$$y_2 = -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(2\right)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{d}{dx}\left(\sqrt{-\frac{1}{x^2}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3} & -\frac{\sqrt{2}\,\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\,\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}}{x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-\frac{1}{x^2}}\right)\left(-\frac{\sqrt{2}\,\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\,\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}}{x}\right) - \left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right)\left(\frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{-\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)+\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{x}}{\frac{\sqrt{2}}{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \left(-\ln(2) + \ln\left(-\frac{1}{x^2}\right)\right)\sqrt{-\frac{1}{x^2}}dx$$

Hence

$$u_1 = x\sqrt{-\frac{1}{x^2}}\,\ln(2)\ln(x) + \frac{x\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)^2}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2\sqrt{-\frac{1}{x^2}}}{x}}{\frac{\sqrt{2}}{x}}\, dx$$

Which simplifies to

$$u_2 = \int \sqrt{2}\sqrt{-\frac{1}{x^2}} dx$$

Hence

$$u_2 = \sqrt{2}\sqrt{-\frac{1}{x^2}}\, x \ln(x)$$

Which simplifies to

$$u_1 = \sqrt{-\frac{1}{x^2}}\, x \left(\ln(2)\ln(x) + \frac{\ln\left(-\frac{1}{x^2}\right)^2}{4}\right)$$

$$u_2 = \sqrt{2}\sqrt{-\frac{1}{x^2}}\, x \ln(x)$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) = &-\frac{\ln(2)\ln(x) + \frac{\ln\left(-\frac{1}{x^2}\right)^2}{4}}{x} \\ &+ \sqrt{2}\sqrt{-\frac{1}{x^2}}\, x \ln(x) \left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\, \ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\, \ln\left(-\frac{1}{x^2}\right)}{2}\right) \end{aligned}$$

Which simplifies to

$$y_p(x) = -\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\left(c_1 - c_2\ln(2) + c_2\ln\left(-\frac{1}{x^2}\right)\right)}{2}\right) + \left(-\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2} - \frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\left(c_1 - c_2 \ln(2) + c_2 \ln\left(-\frac{1}{x^2}\right)\right)}{2} - \frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x}$$

Verified OK.

14.23.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 3x, C = 1, f(x) = \frac{2}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 3xy' + y = 0$$

In normal form the ode

$$x^2y'' + 3xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{3}{x}$$
$$q(x) = \frac{1}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\, x^3} + \frac{3}{x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= 2c \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2} y(\tau) + 2c\left(\frac{d}{d\tau} y(\tau)\right) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{-c\tau} c_1$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\, dx \\ &= \frac{\int \sqrt{\frac{1}{x^2}} dx}{c} \\ &= \frac{\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \frac{c_1}{x}$$

Now the particular solution to this ODE is found

$$x^2y'' + 3xy' + y = \frac{2}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{-\frac{1}{x^2}}$$

$$y_2 = -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{d}{dx}\left(\sqrt{-\frac{1}{x^2}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln(2)}{2} + \frac{\sqrt{2}\sqrt{-\frac{1}{x^2}}\ln\left(-\frac{1}{x^2}\right)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{-\frac{1}{x^2}} & -\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2} \\ \frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3} & -\frac{\sqrt{2}\,\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\,\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}}{x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{-\frac{1}{x^2}}\right)\left(-\frac{\sqrt{2}\,\ln(2)}{2\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{\sqrt{2}\,\ln\left(-\frac{1}{x^2}\right)}{2\sqrt{-\frac{1}{x^2}}\,x^3} - \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}}{x}\right) - \left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{2}\right)\left(\frac{1}{\sqrt{-\frac{1}{x^2}}\,x^3}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Which simplifies to

$$W = \frac{\sqrt{2}}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{-\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln(2)+\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)}{x}}{\frac{\sqrt{2}}{x}}\,dx$$

Which simplifies to

$$u_1 = -\int \left(-\ln(2) + \ln\left(-\frac{1}{x^2}\right)\right)\sqrt{-\frac{1}{x^2}}dx$$

Hence

$$u_1 = x\sqrt{-\frac{1}{x^2}}\,\ln(2)\ln(x) + \frac{x\sqrt{-\frac{1}{x^2}}\,\ln\left(-\frac{1}{x^2}\right)^2}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2\sqrt{-\frac{1}{x^2}}}{x}}{\frac{\sqrt{2}}{x}} \, dx$$

Which simplifies to

$$u_2 = \int \sqrt{2}\,\sqrt{-\frac{1}{x^2}} dx$$

Hence

$$u_2 = \sqrt{2}\,\sqrt{-\frac{1}{x^2}}\, x \ln(x)$$

Which simplifies to

$$u_1 = \sqrt{-\frac{1}{x^2}}\, x \left(\ln(2)\ln(x) + \frac{\ln\left(-\frac{1}{x^2}\right)^2}{4}\right)$$

$$u_2 = \sqrt{2}\,\sqrt{-\frac{1}{x^2}}\, x \ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\ln(2)\ln(x) + \frac{\ln\left(-\frac{1}{x^2}\right)^2}{4}}{x} + \sqrt{2}\,\sqrt{-\frac{1}{x^2}}\, x \ln(x) \left(-\frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\, \ln(2)}{2} + \frac{\sqrt{2}\,\sqrt{-\frac{1}{x^2}}\, \ln\left(-\frac{1}{x^2}\right)}{2}\right)$$

Which simplifies to

$$y_p(x) = -\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x}\right) + \left(-\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x}\right) \\ &= -\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x) + \ln\left(-\frac{1}{x^2}\right)\right)}{4x} + \frac{c_1}{x} \end{aligned}$$

Which simplifies to

$$y = \frac{-\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x)+\ln\left(-\frac{1}{x^2}\right)\right)}{4} + c_1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{-\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x)+\ln\left(-\frac{1}{x^2}\right)\right)}{4} + c_1}{x} \tag{1}$$

Verification of solutions

$$y = \frac{-\frac{\ln\left(-\frac{1}{x^2}\right)\left(4\ln(x)+\ln\left(-\frac{1}{x^2}\right)\right)}{4} + c_1}{x}$$

Verified OK.

14.23.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 3x, C = 1, f(x) = \frac{2}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 3xy' + y = 0$$

In normal form the ode

$$x^2y'' + 3xy' + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{3}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} + \frac{3n}{x^2} + \frac{1}{x^2} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = -1 \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \frac{v'(x)}{x} &= 0 \\
v''(x) + \frac{v'(x)}{x} &= 0 \qquad (7)
\end{aligned}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \frac{u(x)}{x} = 0 \tag{8}
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{1}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\
\ln(u) &= -\ln(x) + c_1 \\
u &= e^{-\ln(x)+c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \frac{c_1 \ln(x) + c_2}{x} \\
&= \frac{c_1 \ln(x) + c_2}{x}
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2y'' + 3xy' + y = \frac{2}{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{\ln(x)}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{\ln(x)}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ -\frac{1}{x^2} & -\frac{\ln(x)}{x^2} + \frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(-\frac{\ln(x)}{x^2} + \frac{1}{x^2}\right) - \left(\frac{\ln(x)}{x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\left(\int \frac{\frac{2\ln(x)}{x^2}}{\frac{1}{x}}\, dx\right)$$

Which simplifies to

$$u_1 = -\left(\int \frac{2\ln(x)}{x} dx\right)$$

Hence

$$u_1 = -\ln(x)^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2}{x^2}}{\frac{1}{x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x} dx$$

Hence

$$u_2 = 2\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\ln(x)^2}{x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 \ln(x) + c_2}{x}\right) + \left(\frac{\ln(x)^2}{x}\right) \\ &= \frac{\ln(x)^2}{x} + \frac{c_1 \ln(x) + c_2}{x} \end{aligned}$$

Which simplifies to

$$y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x}$$

Verified OK.

14.23.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2 y'' + 3xy' + y)\, dx = \int \frac{2}{x} dx$$
$$x^2 y' + xy = 2\ln(x) + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{2\ln(x) + c_1}{x^2}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{2\ln(x) + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{x} dx}$$
$$= x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2\ln(x) + c_1}{x^2}\right)$$
$$\frac{d}{dx}(xy) = (x)\left(\frac{2\ln(x) + c_1}{x^2}\right)$$
$$d(xy) = \left(\frac{2\ln(x) + c_1}{x}\right) dx$$

Integrating gives

$$
\begin{aligned}
xy &= \int \frac{2\ln(x) + c_1}{x}\,\mathrm{d}x \\
xy &= \ln(x)^2 + c_1 \ln(x) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$
y = \frac{\ln(x)^2 + c_1 \ln(x)}{x} + \frac{c_2}{x}
$$

which simplifies to

$$
y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x}
$$

Summary

The solution(s) found are the following

$$
y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x} \tag{1}
$$

Verification of solutions

$$
y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x}
$$

Verified OK.

14.23.6 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$
x^2 y'' + 3xy' + y = \frac{2}{x}
$$

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int \left(x^2 y'' + 3xy' + y\right) dx &= \int \frac{2}{x} dx \\
x^2 y' + xy &= 2\ln(x) + c_1
\end{aligned}
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{2\ln(x) + c_1}{x^2}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{2\ln(x) + c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{x}dx}$$
$$= x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2\ln(x) + c_1}{x^2}\right)$$
$$\frac{d}{dx}(xy) = (x)\left(\frac{2\ln(x) + c_1}{x^2}\right)$$
$$d(xy) = \left(\frac{2\ln(x) + c_1}{x}\right) dx$$

Integrating gives

$$xy = \int \frac{2\ln(x) + c_1}{x} dx$$
$$xy = \ln(x)^2 + c_1\ln(x) + c_2$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{\ln(x)^2 + c_1\ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{\ln(x)^2 + c_1\ln(x) + c_2}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\ln(x)^2 + c_1\ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{\ln(x)^2 + c_1\ln(x) + c_2}{x}$$

Verified OK.

14.23.7 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 3xy' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 3x \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 376: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{1}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{1}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3x}{x^2}\,dx} \\
&= z_1 e^{-\frac{3\ln(x)}{2}} \\
&= z_1\left(\frac{1}{x^{\frac{3}{2}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-3\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x}\right) + c_2\left(\frac{1}{x}(\ln(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + 3xy' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1}{x} + \frac{c_2 \ln(x)}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{\ln(x)}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{\ln(x)}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{\ln(x)}{x} \\ -\frac{1}{x^2} & -\frac{\ln(x)}{x^2} + \frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(-\frac{\ln(x)}{x^2} + \frac{1}{x^2}\right) - \left(\frac{\ln(x)}{x}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Which simplifies to

$$W = \frac{1}{x^3}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\ln(x)}{x^2}}{\frac{1}{x}} dx$$

Which simplifies to

$$u_1 = -\int \frac{2\ln(x)}{x} dx$$

Hence

$$u_1 = -\ln(x)^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2}{x^2}}{\frac{1}{x}} dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x} dx$$

Hence

$$u_2 = 2\ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\ln(x)^2}{x}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1}{x} + \frac{c_2 \ln(x)}{x}\right) + \left(\frac{\ln(x)^2}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y = \frac{c_1 + c_2 \ln(x)}{x} + \frac{\ln(x)^2}{x}
$$

Summary
The solution(s) found are the following

$$
y = \frac{c_1 + c_2 \ln(x)}{x} + \frac{\ln(x)^2}{x} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 + c_2 \ln(x)}{x} + \frac{\ln(x)^2}{x}
$$

Verified OK.

14.23.8 Solving as exact linear second order ode ode

An ode of the form

$$
p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)
$$

is exact if

$$
p''(x) - q'(x) + r(x) = 0 \tag{1}
$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x^2 \\
q(x) &= 3x \\
r(x) &= 1 \\
s(x) &= \frac{2}{x}
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 3
\end{aligned}
$$

Therefore (1) becomes

$$2 - (3) + (1) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\; dx$$

Substituting the above values for p, q, r, s gives

$$x^2 y' + xy = \int \frac{2}{x}\, dx$$

We now have a first order ode to solve which is

$$x^2 y' + xy = 2\ln(x) + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= \frac{2\ln(x) + c_1}{x^2} \end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = \frac{2\ln(x) + c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int \frac{1}{x} dx} \\ &= x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{2\ln(x) + c_1}{x^2}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}(xy) &= (x)\left(\frac{2\ln(x) + c_1}{x^2}\right) \\ \mathrm{d}(xy) &= \left(\frac{2\ln(x) + c_1}{x}\right)\, \mathrm{d}x \end{aligned}$$

Integrating gives

$$xy = \int \frac{2\ln(x) + c_1}{x} \, \mathrm{d}x$$
$$xy = \ln(x)^2 + c_1 \ln(x) + c_2$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{\ln(x)^2 + c_1 \ln(x)}{x} + \frac{c_2}{x}$$

which simplifies to

$$y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{\ln(x)^2 + c_1 \ln(x) + c_2}{x}$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 4y = \tan(x)^2}$$

14.24.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \tan(x)^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A=1, B=0, C=4$. Let the solution be $y=e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A=1, B=0, C=4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(4)}\\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i\\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i\\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{0}(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(2x) \\ y_2 &= \sin(2x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2x) & \sin(2x) \\ \frac{d}{dx}(\cos(2x)) & \frac{d}{dx}(\sin(2x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{vmatrix}$$

Therefore

$$W = (\cos(2x))(2\cos(2x)) - (\sin(2x))(-2\sin(2x))$$

Which simplifies to

$$W = 2\cos(2x)^2 + 2\sin(2x)^2$$

Which simplifies to

$$W = 2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(2x)\tan(x)^2}{2}dx$$

Which simplifies to

$$u_1 = -\int \sin(x)^2 \tan(x)\,dx$$

Hence

$$u_1 = \frac{\sin(x)^2}{2} + \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)^2 \cos(2x)}{2}dx$$

Which simplifies to

$$u_2 = \int \left(\sin(x)^2 - \frac{\tan(x)^2}{2}\right)dx$$

Hence

$$u_2 = -\frac{\cos(x)\sin(x)}{2} + x - \frac{\tan(x)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\sin(x)^2}{2} + \ln(\cos(x))\right)\cos(2x) + \left(-\frac{\cos(x)\sin(x)}{2} + x - \frac{\tan(x)}{2}\right)\sin(2x)$$

Which simplifies to

$$y_p(x) = \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= (c_1\cos(2x) + c_2\sin(2x)) + \left(\left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\cos(2x) + c_2\sin(2x) + \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2} \tag{1}$$

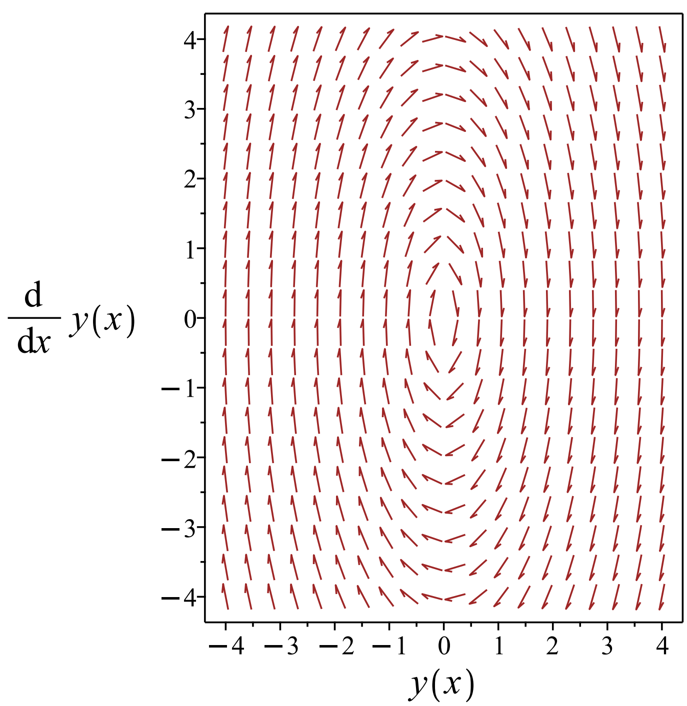

Figure 419: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\, x - \frac{3\sin(x)^2}{2}$$

Verified OK.

14.24.2 Solving using Kovacic algorithm

Writing the ode as

$$\begin{align*} y'' + 4y &= 0 \tag{1} \\ Ay'' + By' + Cy &= 0 \tag{2} \end{align*}$$

Comparing (1) and (2) shows that

$$\begin{align*} A &= 1 \\ B &= 0 \tag{3} \\ C &= 4 \end{align*}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{align*} r &= \frac{s}{t} \tag{5} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{align*}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{align*} s &= -4 \\ t &= 1 \end{align*}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 377: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(2x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\,dx \\ &= \cos(2x)\left(\frac{\tan(2x)}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(2x) \\ y_2 &= \frac{\sin(2x)}{2} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2x) & \frac{\sin(2x)}{2} \\ \frac{d}{dx}(\cos(2x)) & \frac{d}{dx}\left(\frac{\sin(2x)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2x) & \frac{\sin(2x)}{2} \\ -2\sin(2x) & \cos(2x) \end{vmatrix}$$

Therefore

$$W = (\cos(2x))(\cos(2x)) - \left(\frac{\sin(2x)}{2}\right)(-2\sin(2x))$$

Which simplifies to

$$W = \cos(2x)^2 + \sin(2x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(2x)\tan(x)^2}{2}}{1} dx$$

Which simplifies to

$$u_1 = -\int \sin(x)^2 \tan(x) \, dx$$

Hence

$$u_1 = \frac{\sin(x)^2}{2} + \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\tan(x)^2 \cos(2x)}{1} dx$$

Which simplifies to

$$u_2 = \int \left(2\sin(x)^2 - \tan(x)^2\right) dx$$

Hence

$$u_2 = -\cos(x)\sin(x) - \tan(x) + 2x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\sin(x)^2}{2} + \ln(\cos(x))\right)\cos(2x) + \frac{(-\cos(x)\sin(x) - \tan(x) + 2x)\sin(2x)}{2}$$

Which simplifies to

$$y_p(x) = \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) \\ &\quad + \left(\left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) \\ & + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2} \end{aligned} \tag{1}$$

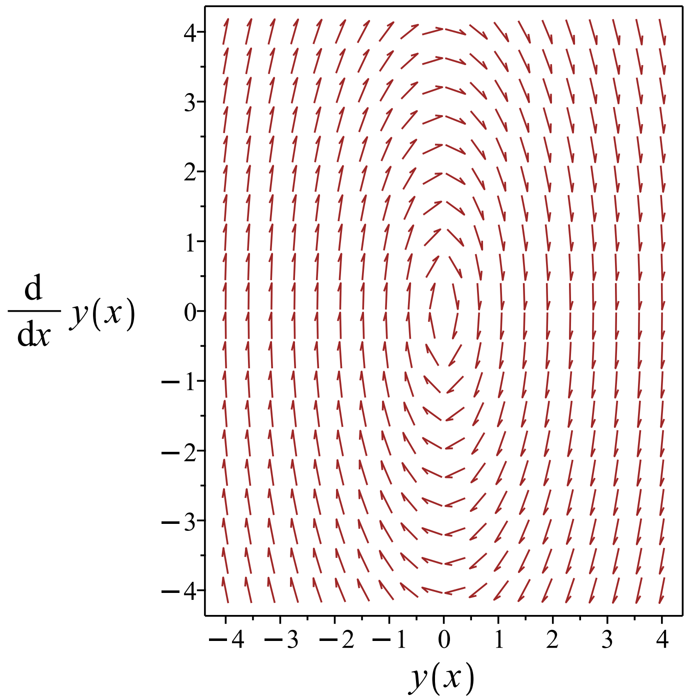

Figure 420: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}$$

Verified OK.

14.24.3 Maple step by step solution

Let's solve

$y'' + 4y = \tan(x)^2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

- Roots of the characteristic polynomial

$r = (-2\,\mathrm{I}, 2\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(2x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(2x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \tan(x)^2\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\cos(2x)\left(\int \sin(x)^2 \tan(x)\,dx\right) + \frac{\sin(2x)\left(\int \left(2\sin(x)^2 - \tan(x)^2\right)dx\right)}{2}$

  ◦ Compute integrals

  $y_p(x) = \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos(2x) + c_2 \sin(2x) + \left(2\cos(x)^2 - 1\right)\ln(\cos(x)) + 2\cos(x)\sin(x)\,x - \frac{3\sin(x)^2}{2}$

Problem number: 4(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y = 3\,\mathrm{e}^{2x}}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{2x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = 3\,\mathrm{e}^{2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 0$$

Therefore

$$\begin{aligned}
y_2(x) &= \mathrm{e}^{2x}\left(\int \mathrm{e}^{-\left(\int 0dx\right)}\mathrm{e}^{-4x}dx\right)\\
y_2(x) &= \mathrm{e}^{2x}\int \frac{1}{\mathrm{e}^{4x}},dx\\
y_2(x) &= \mathrm{e}^{2x}\left(\int \mathrm{e}^{-4x}dx\right)\\
y_2(x) &= -\frac{\mathrm{e}^{2x}\mathrm{e}^{-4x}}{4}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1y_1(x) + c_2y_2(x)\\
&= c_1\mathrm{e}^{2x} - \frac{c_2\mathrm{e}^{2x}\mathrm{e}^{-4x}}{4}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1\mathrm{e}^{2x} - \frac{c_2\mathrm{e}^{2x}\mathrm{e}^{-4x}}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \mathrm{e}^{2x}\\
y_2 &= -\frac{\mathrm{e}^{2x}\mathrm{e}^{-4x}}{4}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & -\frac{e^{2x}e^{-4x}}{4} \\ \frac{d}{dx}\left(e^{2x}\right) & \frac{d}{dx}\left(-\frac{e^{2x}e^{-4x}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & -\frac{e^{2x}e^{-4x}}{4} \\ 2\,e^{2x} & \frac{e^{2x}e^{-4x}}{2} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\right)\left(\frac{e^{2x}e^{-4x}}{2}\right) - \left(-\frac{e^{2x}e^{-4x}}{4}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = e^{4x}e^{-4x}$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{3\,e^{4x}e^{-4x}}{4}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{3}{4}dx$$

Hence

$$u_1 = \frac{3x}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{3\,\mathrm{e}^{4x}}{1}\,dx$$

Which simplifies to

$$u_2 = \int 3\,\mathrm{e}^{4x} dx$$

Hence

$$u_2 = \frac{3\,\mathrm{e}^{4x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{3\,\mathrm{e}^{2x} x}{4} - \frac{3\,\mathrm{e}^{4x} \mathrm{e}^{2x} \mathrm{e}^{-4x}}{16}$$

Which simplifies to

$$y_p(x) = \frac{3(4x-1)\,\mathrm{e}^{2x}}{16}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{2x} - \frac{c_2 \mathrm{e}^{2x} \mathrm{e}^{-4x}}{4}\right) + \left(\frac{3(4x-1)\,\mathrm{e}^{2x}}{16}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 \mathrm{e}^{2x} - \frac{c_2 \mathrm{e}^{-2x}}{4} + \frac{3(4x-1)\,\mathrm{e}^{2x}}{16}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{2x} - \frac{c_2 \mathrm{e}^{-2x}}{4} + \frac{3(4x-1)\,\mathrm{e}^{2x}}{16} \tag{1}$$

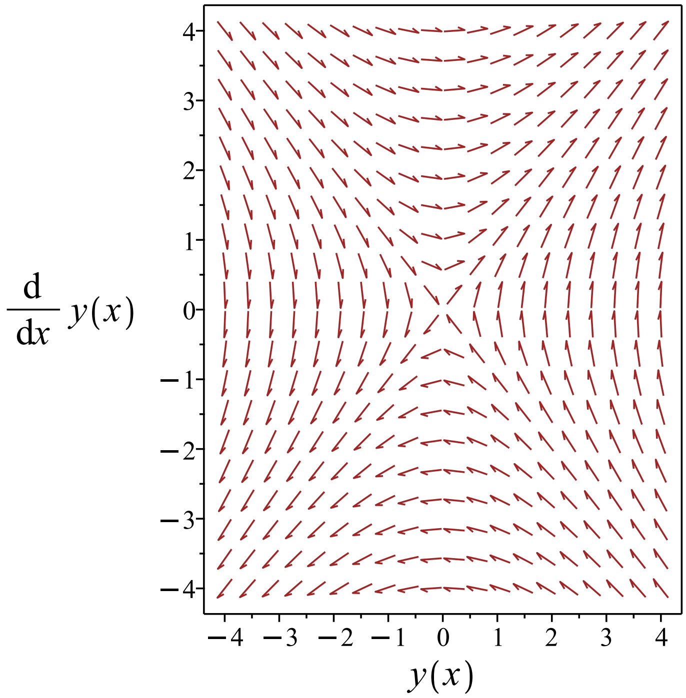

Figure 421: Slope field plot

Verification of solutions

$$y = c_1 e^{2x} - \frac{c_2 e^{-2x}}{4} + \frac{3(4x-1)\,e^{2x}}{16}$$

Verified OK.

14.25.1 Maple step by step solution

Let's solve

$y'' - y = 3\,e^{2x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

$r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-x}$
- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{x}$
- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-x} + c_2 e^{x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 3\,e^{2x}\right]$
- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-x} & e^{x} \\ -e^{-x} & e^{x} \end{bmatrix}$
- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$
- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{3\,e^{-x}\left(\int e^{3x}dx\right)}{2} + \frac{3\,e^{x}\left(\int e^{x}dx\right)}{2}$
- ○ Compute integrals

  $y_p(x) = e^{2x}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-x} + c_2 e^{x} + e^{2x}$

Problem number: 4(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y = -8\sin(3x)}$$

Given that one solution of the ode is

$$y_1 = \sin(3x)$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 1, f(x) = -8\sin(3x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 0$$

Therefore

$$\begin{aligned}
y_2(x) &= \sin(3x)\left(\int \frac{e^{-\left(\int 0dx\right)}}{\sin(3x)^2} dx\right) \\
y_2(x) &= \sin(3x) \int \frac{1}{\sin(3x)^2}, dx \\
y_2(x) &= \sin(3x)\left(\int \csc(3x)^2\, dx\right) \\
y_2(x) &= -\frac{\sin(3x)\cot(3x)}{3}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \sin(3x) - \frac{c_2 \sin(3x)\cot(3x)}{3}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \sin(3x) - \frac{c_2 \sin(3x)\cot(3x)}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \sin(3x) \\
y_2 &= -\frac{\sin(3x)\cot(3x)}{3}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sin(3x) & -\frac{\sin(3x)\cot(3x)}{3} \\ \frac{d}{dx}(\sin(3x)) & \frac{d}{dx}\left(-\frac{\sin(3x)\cot(3x)}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sin(3x) & -\frac{\sin(3x)\cot(3x)}{3} \\ 3\cos(3x) & -\cos(3x)\cot(3x) - \frac{\sin(3x)\left(-3-3\cot(3x)^2\right)}{3} \end{vmatrix}$$

Therefore

$$W = (\sin(3x))\left(-\cos(3x)\cot(3x) - \frac{\sin(3x)\left(-3 - 3\cot(3x)^2\right)}{3}\right) - \left(-\frac{\sin(3x)\cot(3x)}{3}\right)(3\cos(3x))$$

Which simplifies to

$$W = \sin(3x)^2 \cot(3x)^2 + \sin(3x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{8\sin(3x)^2\cot(3x)}{3}}{1}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{4\sin(6x)}{3} dx$$

Hence

$$u_1 = \frac{2\cos(6x)}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-8\sin(3x)^2}{1} dx$$

Which simplifies to

$$u_2 = \int (-4 + 4\cos(6x))\, dx$$

Hence

$$u_2 = -4x + \frac{2\sin(6x)}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{2\cos(6x)\sin(3x)}{9} - \frac{\left(-4x + \frac{2\sin(6x)}{3}\right)\sin(3x)\cot(3x)}{3}$$

Which simplifies to

$$y_p(x) = -\frac{2\sin(3x)}{9} + \frac{4x\cos(3x)}{3}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1\sin(3x) - \frac{c_2\sin(3x)\cot(3x)}{3}\right) + \left(-\frac{2\sin(3x)}{9} + \frac{4x\cos(3x)}{3}\right)
\end{aligned}$$

Which simplifies to

$$y = c_1\sin(3x) - \frac{c_2\cos(3x)}{3} - \frac{2\sin(3x)}{9} + \frac{4x\cos(3x)}{3}$$

Summary

The solution(s) found are the following

$$y = c_1 \sin(3x) - \frac{c_2 \cos(3x)}{3} - \frac{2\sin(3x)}{9} + \frac{4x\cos(3x)}{3} \tag{1}$$

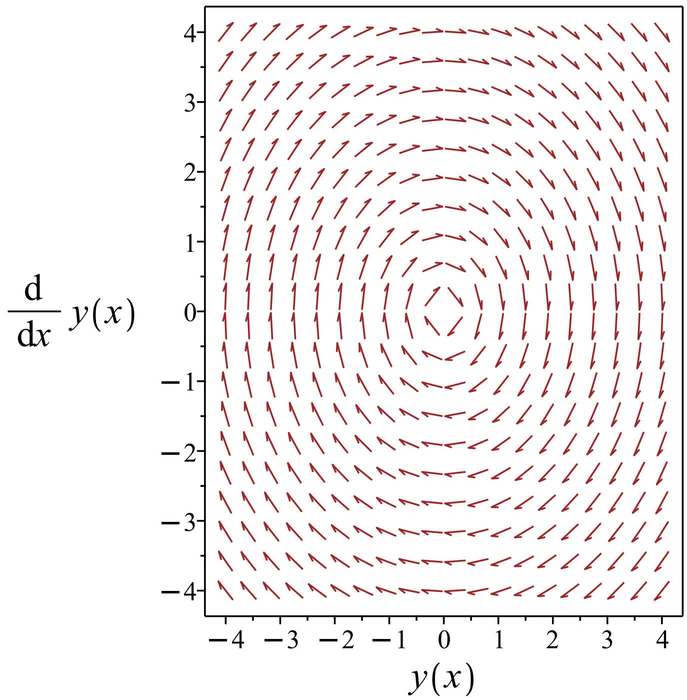

Figure 422: Slope field plot

Verification of solutions

$$y = c_1 \sin(3x) - \frac{c_2 \cos(3x)}{3} - \frac{2\sin(3x)}{9} + \frac{4x\cos(3x)}{3}$$

Verified OK.

14.26.1 Maple step by step solution

Let's solve

$y'' + y = -8\sin(3x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2+1=0$

- Use quadratic formula to solve for r

  $r=\frac{0\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r=(-\mathrm{I},\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x)=\cos(x)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\sin(x)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=\cos(x)\,c_1+c_2\sin(x)+y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=-8\sin(3x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x),y_2(x))=\left[\begin{array}{cc}\cos(x) & \sin(x)\\ -\sin(x) & \cos(x)\end{array}\right]$

  ◦ Compute Wronskian

    $W(y_1(x),y_2(x))=1$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x)=-4\cos(x)\left(\int(-\cos(2x)+\cos(4x))\,dx\right)+4\sin(x)\left(\int(-\sin(4x)-\sin(2x))\,dx\right)$

  ◦ Compute integrals

    $y_p(x)=\sin(3x)$

- Substitute particular solution into general solution to ODE

  $y=\cos(x)\,c_1+c_2\sin(x)+\sin(3x)$

Problem number: 4(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + y' + y = x^2 + 2x + 2}$$

Given that one solution of the ode is

$$y_1 = x^2$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 1, f(x) = x^2 + 2x + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' + y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 1$$

Therefore

$$y_2(x) = x^2 \left(\int \frac{\mathrm{e}^{-\left(\int 1 dx\right)}}{x^4} dx \right)$$

$$y_2(x) = x^2 \int \frac{\mathrm{e}^{-x}}{x^4}, dx$$

$$y_2(x) = x^2 \left(\int \frac{\mathrm{e}^{-x}}{x^4} dx \right)$$

$$y_2(x) = x^2 \left(-\frac{\mathrm{e}^{-x}}{3x^3} + \frac{\mathrm{e}^{-x}}{6x^2} - \frac{\mathrm{e}^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6} \right)$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 + c_2 x^2 \left(-\frac{\mathrm{e}^{-x}}{3x^3} + \frac{\mathrm{e}^{-x}}{6x^2} - \frac{\mathrm{e}^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6} \right) \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x^2 + c_2 x^2 \left(-\frac{\mathrm{e}^{-x}}{3x^3} + \frac{\mathrm{e}^{-x}}{6x^2} - \frac{\mathrm{e}^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6} \right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^2\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x^2 & x^2\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right) \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(x^2\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right)\right) \end{vmatrix}
$$

Which gives

$$
W = \begin{vmatrix} x^2 & x^2\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right) \\ 2x & 2x\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right) + \frac{e^{-x}}{x^2} \end{vmatrix}
$$

Therefore

$$
\begin{aligned}
W = (x^2)\left(2x\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right) + \frac{e^{-x}}{x^2}\right) \\
- \left(x^2\left(-\frac{e^{-x}}{3x^3} + \frac{e^{-x}}{6x^2} - \frac{e^{-x}}{6x} + \frac{\text{expIntegral}_1(x)}{6}\right)\right)(2x)
\end{aligned}
$$

Which simplifies to

$$
W = e^{-x}
$$

Which simplifies to

$$W = \mathrm{e}^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^2\left(-\frac{\mathrm{e}^{-x}}{3x^3} + \frac{\mathrm{e}^{-x}}{6x^2} - \frac{\mathrm{e}^{-x}}{6x} + \frac{\mathrm{expIntegral}_1(x)}{6}\right)(x^2+2x+2)}{\mathrm{e}^{-x}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^2+2x+2)\left(\mathrm{e}^x \,\mathrm{expIntegral}_1\left(x\right) x^3 - x^2 + x - 2\right)}{6x} dx$$

Hence

$$u_1 = -\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(\mathrm{e}^\alpha \,\mathrm{expIntegral}_1\left(\alpha\right) \alpha^3 - \alpha^2 + \alpha - 2\right)}{6\alpha} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^2+2x+2)\, x^2}{\mathrm{e}^{-x}}\, dx$$

Which simplifies to

$$u_2 = \int x^2\left(x^2+2x+2\right) \mathrm{e}^x dx$$

Hence

$$u_2 = \left(x^4 - 2x^3 + 8x^2 - 16x + 16\right) \mathrm{e}^x$$

Which simplifies to

$$u_1 = -\frac{\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(\mathrm{e}^\alpha \,\mathrm{expIntegral}_1(\alpha)\alpha^3-\alpha^2+\alpha-2\right)}{\alpha} d\alpha\right)}{6}$$

$$u_2 = \left(x^4 - 2x^3 + 8x^2 - 16x + 16\right) \mathrm{e}^x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(e^{\alpha} \operatorname{expIntegral}_1(\alpha)\alpha^3-\alpha^2+\alpha-2\right)}{\alpha}d\alpha\right)x^2}{6} + \left(x^4-2x^3+8x^2-16x+16\right)e^x x^2\left(-\frac{e^{-x}}{3x^3}+\frac{e^{-x}}{6x^2}-\frac{e^{-x}}{6x}+\frac{\operatorname{expIntegral}_1(x)}{6}\right)$$

Which simplifies to

$$y_p(x) = \frac{-\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(e^{\alpha} \operatorname{expIntegral}_1(\alpha)\alpha^3-\alpha^2+\alpha-2\right)}{\alpha}d\alpha\right)x^3+\left(x^4-2x^3+8x^2-16x+16\right)\left(e^x \operatorname{expIntegral}_1(x)\,x^3 -\right.}{6x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1x^2+c_2x^2\left(-\frac{e^{-x}}{3x^3}+\frac{e^{-x}}{6x^2}-\frac{e^{-x}}{6x}+\frac{\operatorname{expIntegral}_1(x)}{6}\right)\right)+\left(\frac{-\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(e^{\alpha} \operatorname{expIntegral}_1(\alpha)\alpha^3-\alpha^2+\alpha-\right.}{\alpha}\right.}{}\right. \end{aligned}$$

Which simplifies to

$$y = \frac{-c_2(x^2-x+2)e^{-x}+6\left(\frac{c_2 \operatorname{expIntegral}_1(x)}{6}+c_1\right)x^3}{6x}+\frac{-\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(e^{\alpha} \operatorname{expIntegral}_1(\alpha)\alpha^3-\alpha^2+\alpha-2\right)}{\alpha}d\alpha\right)x^3+}{}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{-c_2(x^2-x+2)e^{-x}+6\left(\frac{c_2 \operatorname{expIntegral}_1(x)}{6}+c_1\right)x^3}{6x} + \frac{-\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(e^{\alpha} \operatorname{expIntegral}_1(\alpha)\alpha^3-\alpha^2+\alpha-2\right)}{\alpha}d\alpha\right)x^3+\left(x^4-2x^3+8x^2-16x+16\right)\left(e^x \operatorname{expIntegral}_1(x)\,x\right.}{6x} \tag{1}$$

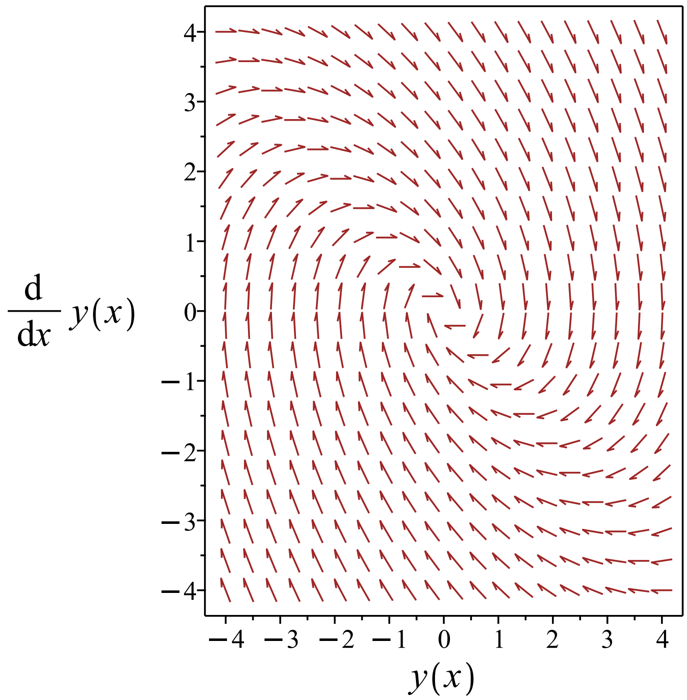

Figure 423: Slope field plot

Verification of solutions

$$y = \frac{-c_2(x^2 - x + 2)\,\mathrm{e}^{-x} + 6\left(\frac{c_2 \operatorname{expIntegral}_1(x)}{6} + c_1\right)x^3}{6x}$$
$$+ \frac{-\left(\int_0^x \frac{(\alpha^2+2\alpha+2)\left(\mathrm{e}^{\alpha} \operatorname{expIntegral}_1(\alpha)\alpha^3 - \alpha^2 + \alpha - 2\right)}{\alpha} d\alpha\right) x^3 + (x^4 - 2x^3 + 8x^2 - 16x + 16)\left(\mathrm{e}^{x} \operatorname{expIntegral}_1(x)\, x\right.}{6x}$$

Verified OK.

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r + 1 = 0$

- Use quadratic formula to solve for r

$r = \frac{(-1)\pm(\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}, -\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x^2+2x+2\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) & \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) \\ -\frac{\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{\mathrm{e}^{-\frac{x}{2}} \sqrt{3}\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} & -\frac{\mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{\mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = \frac{\sqrt{3}\,\mathrm{e}^{-x}}{2}$

- ○ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -\frac{2\sqrt{3}\,\mathrm{e}^{-\frac{x}{2}}\left(\cos\left(\frac{\sqrt{3}\,x}{2}\right)\left(\int \mathrm{e}^{\frac{x}{2}}(x^2+2x+2)\sin\left(\frac{\sqrt{3}\,x}{2}\right)dx\right) - \sin\left(\frac{\sqrt{3}\,x}{2}\right)\left(\int \mathrm{e}^{\frac{x}{2}}(x^2+2x+2)\cos\left(\frac{\sqrt{3}\,x}{2}\right)dx\right)\right)}{3}$

- ○ Compute integrals

  $y_p(x) = x^2$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + \mathrm{e}^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) c_2 + x^2$

The type(s) of ODE detected by this program : **"reduction_of_order", "exact linear second order ode", "second_order_integrable_as_is", "second_order_ode_missing_y", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + y' = \frac{x - 1}{x}}$$

Given that one solution of the ode is

$$y_1 = \ln(x)$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 1, C = 0, f(x) = 1 - \frac{1}{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + y' = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 1$$

Therefore

$$y_2(x) = \ln(x) \left(\int \frac{e^{-\left(\int 1 dx\right)}}{\ln(x)^2} dx \right)$$

$$y_2(x) = \ln(x) \int \frac{e^{-x}}{\ln(x)^2}, dx$$

$$y_2(x) = \ln(x) \left(\int \frac{e^{-x}}{\ln(x)^2} dx \right)$$

$$y_2(x) = \ln(x) \left(-\frac{x e^{-x}}{\ln(x)} + \int -\frac{e^{-x}(x-1)}{\ln(x)} dx \right)$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \ln(x) + c_2 \ln(x) \left(-\frac{x e^{-x}}{\ln(x)} + \int -\frac{e^{-x}(x-1)}{\ln(x)} dx \right) \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \ln(x) + c_2 \ln(x) \left(-\frac{x e^{-x}}{\ln(x)} + \int -\frac{e^{-x}(x-1)}{\ln(x)} dx \right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \ln(x) \\
y_2 &= \ln(x)\left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \ln(x) & \ln(x)\left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right) \\ \frac{d}{dx}(\ln(x)) & \frac{d}{dx}\left(\ln(x)\left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \ln(x) & \ln(x)\left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right) \\ \frac{1}{x} & \frac{-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx}{x} + \ln(x)\left(-\frac{\mathrm{e}^{-x}}{\ln(x)} + \frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \frac{\mathrm{e}^{-x}}{\ln(x)^2} - \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}\right) \end{vmatrix}$$

Therefore

$$W = (\ln(x)) \left(\frac{-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)} dx}{x} \right.$$
$$\left. + \ln(x) \left(-\frac{\mathrm{e}^{-x}}{\ln(x)} + \frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \frac{\mathrm{e}^{-x}}{\ln(x)^2} - \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)} \right) \right)$$
$$- \left(\ln(x) \left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)} dx \right) \right) \left(\frac{1}{x} \right)$$

Which simplifies to

$$W = \mathrm{e}^{-x}$$

Which simplifies to

$$W = \mathrm{e}^{-x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\ln(x) \left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)} + \int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)} dx \right) \left(1 - \frac{1}{x}\right)}{\mathrm{e}^{-x}} dx$$

Which simplifies to

$$u_1 = -\int -\frac{(x-1) \left(\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)} dx \right) \mathrm{e}^{x} \ln(x) + x \right)}{x} dx$$

Hence

$$u_1 = -\left(\int_0^x -\frac{(\alpha-1) \left(\left(\int \frac{\mathrm{e}^{-\alpha}(\alpha-1)}{\ln(\alpha)} d\alpha \right) \mathrm{e}^{\alpha} \ln(\alpha) + \alpha \right)}{\alpha} d\alpha \right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\ln(x) \left(1 - \frac{1}{x}\right)}{\mathrm{e}^{-x}} dx$$

Which simplifies to

$$u_2 = \int \frac{\ln(x)(x-1)\,\mathrm{e}^{x}}{x} dx$$

Hence

$$u_2 = \int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha$$

Which simplifies to

$$u_1 = \int_0^x \frac{(\alpha-1)\left(\left(\int \frac{\mathrm{e}^{-\alpha}(\alpha-1)}{\ln(\alpha)}d\alpha\right)\mathrm{e}^{\alpha}\ln(\alpha)+\alpha\right)}{\alpha}d\alpha$$
$$u_2 = \int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\int_0^x \frac{(\alpha-1)\left(\left(\int \frac{\mathrm{e}^{-\alpha}(\alpha-1)}{\ln(\alpha)}d\alpha\right)\mathrm{e}^{\alpha}\ln(\alpha)+\alpha\right)}{\alpha}d\alpha\right)\ln(x) + \left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)\ln(x)\left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)}+\int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)$$

Which simplifies to

$$y_p(x) = -\mathrm{e}^{-x}\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)x - \ln(x)\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right) + \left(\int_0^x \frac{(\alpha-1)\left(\left(\int \frac{\mathrm{e}^{-\alpha}(\alpha-1)}{\ln(\alpha)}d\alpha\right)\mathrm{e}^{\alpha}\ln(\alpha)+\alpha\right)}{\alpha}d\alpha\right)\ln(x)$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(c_1\ln(x) + c_2\ln(x)\left(-\frac{x\,\mathrm{e}^{-x}}{\ln(x)}+\int -\frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)\right) + \left(-\mathrm{e}^{-x}\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)x - \ln(x\right.$$

Which simplifies to

$$y = -x\,\mathrm{e}^{-x}c_2 - \ln(x)\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)c_2 + c_1\ln(x) - \mathrm{e}^{-x}\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)x - \ln(x)\left(\int_0^x \frac{\ln(\alpha\right.$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = & -x\,\mathrm{e}^{-x} c_2 - \ln(x)\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)c_2 \\
& + c_1\ln(x) - \mathrm{e}^{-x}\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)x \\
& - \ln(x)\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right) \\
& + \left(\int_0^x \frac{(\alpha-1)\left(\left(\int \frac{\mathrm{e}^{-\alpha}(\alpha-1)}{\ln(\alpha)}d\alpha\right)\mathrm{e}^{\alpha}\ln(\alpha)+\alpha\right)}{\alpha}d\alpha\right)\ln(x)
\end{aligned}
\tag{1}
$$

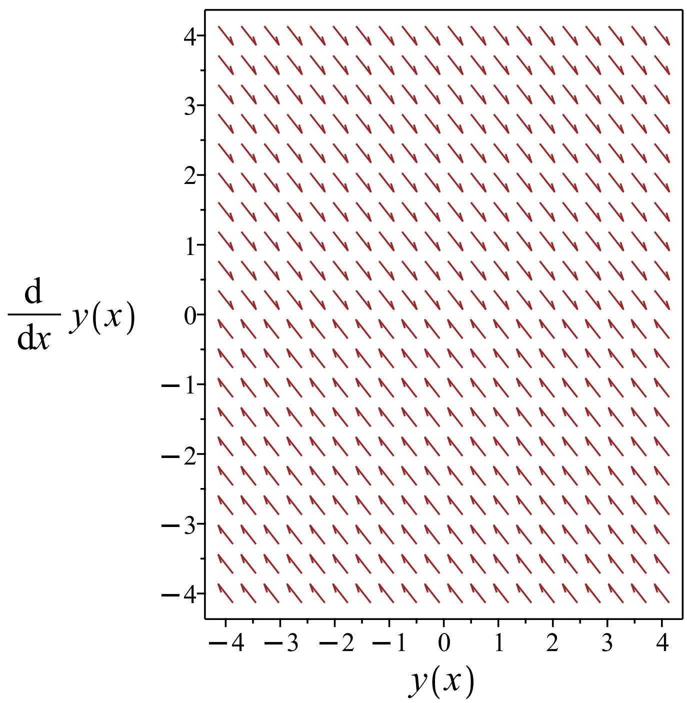

Figure 424: Slope field plot

Verification of solutions

$$y = -x\,\mathrm{e}^{-x} c_2 - \ln(x)\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)c_2 + c_1 \ln(x) - \mathrm{e}^{-x}\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)x$$
$$- \ln(x)\left(\int_0^x \frac{\ln(\alpha)(\alpha-1)\,\mathrm{e}^{\alpha}}{\alpha}d\alpha\right)\left(\int \frac{\mathrm{e}^{-x}(x-1)}{\ln(x)}dx\right)$$
$$+ \left(\int_0^x \frac{(\alpha-1)\left(\left(\int \frac{\mathrm{e}^{-\alpha}(\alpha-1)}{\ln(\alpha)}d\alpha\right)\mathrm{e}^{\alpha}\ln(\alpha)+\alpha\right)}{\alpha}d\alpha\right)\ln(x)$$

Verified OK.

14.28.1 Maple step by step solution

Let's solve

$y' + y'' = \frac{x-1}{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r = 0$

- Factor the characteristic polynomial

  $r(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 0)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = 1$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

$$\left[y_p(x)=-y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x)=\frac{x-1}{x}\right]$$

- Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x))=\left[\begin{array}{cc} e^{-x} & 1 \\ -e^{-x} & 0 \end{array}\right]$$

- Compute Wronskian

$$W(y_1(x), y_2(x))=e^{-x}$$

- Substitute functions into equation for $y_p(x)$

$$y_p(x)=-e^{-x}\left(\int \frac{e^{x}(x-1)}{x}dx\right)+\int \frac{x-1}{x}dx$$

- Compute integrals

$$y_p(x)=-e^{-x}\mathrm{Ei}_1(-x)-1-\ln(x)+x$$

- Substitute particular solution into general solution to ODE

$$y=c_1e^{-x}+c_2-e^{-x}\mathrm{Ei}_1(-x)-1-\ln(x)+x$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2", "linear_second_order_ode_solved_by_an_integrating_factor", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' - 2xy' + 2y = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

15.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{2}{x^2}$$
$$F = 0$$

Hence the ode is

$$y'' - \frac{2y'}{x} + \frac{2y}{x^2} = 0$$

The domain of $p(x) = -\frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

But the point $x_0 = 0$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

15.1.2 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 2xrx^{r-1} + 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 2r\,x^r + 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 2r + 2 = 0$$

Or

$$r^2 - 3r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2 x^2 + c_1 x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x^2 + c_1 x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 0 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2c_2 x + c_1$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$

Substituting these values back in above solution results in

$$y = c_2 x^2$$

Summary
The solution(s) found are the following

$$y = c_2 x^2 \tag{1}$$

Verification of solutions

$$y = c_2 x^2$$

Verified OK.

15.1.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -\frac{2}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2} \int p\, dx} \\ &= e^{\int -\frac{2}{x}\, dx} \\ &= \frac{1}{x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ \left(\frac{y}{x}\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{x}\right)' = c_1$$

Integrating again gives

$$\left(\frac{y}{x}\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\frac{1}{x}}$$

Or

$$y = c_1 x^2 + c_2 x$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x^2 + c_2 x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 0 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2c_1x + c_2$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = c_1x^2$$

Summary

The solution(s) found are the following

$$y = c_1x^2 \tag{1}$$

Verification of solutions

$$y = c_1x^2$$

Verified OK.

15.1.4 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' - 2xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{2}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{2}{x}dx\right)} dx \\
&= \int e^{2\ln(x)}\, dx \\
&= \int x^2 dx \\
&= \frac{x^3}{3}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{x^2}}{x^4} \\
&= \frac{2}{x^6}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{x^6} &= 0
\end{aligned}$$

But in terms of τ

$$\frac{2}{x^6} = \frac{2}{9\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0$$

Simplifying gives

$$9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$9r(r-1) + 0 + 2 = 0$$

Or

$$9r^2 - 9r + 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{3}} + c_2\tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}}(x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}}(x^3)^{\frac{2}{3}}}{3}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 3^{\frac{2}{3}} (x^3)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} (x^3)^{\frac{2}{3}}}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 0 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 3^{\frac{2}{3}} x^2}{3 (x^3)^{\frac{2}{3}}} + \frac{2c_2 3^{\frac{1}{3}} x^2}{3 (x^3)^{\frac{1}{3}}}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{3^{\frac{1}{3}} \left(\lim_{x \to 0} \frac{x^2 \left(2c_2 (x^3)^{\frac{1}{3}} + c_1 3^{\frac{1}{3}}\right)}{(x^3)^{\frac{2}{3}}}\right)}{3} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Warning, unable to solve for constants of integrations.

Verification of solutions N/A

15.1.5 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' - 2xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{2}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{2}{x}\frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{3c\sqrt{2}}{2}\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - \frac{3c\sqrt{2}\left(\frac{d}{d\tau}y(\tau)\right)}{2} + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{3\sqrt{2}\,c\tau}{4}}\left(c_1\cosh\left(\frac{\sqrt{2}\,c\tau}{4}\right) + ic_2\sinh\left(\frac{\sqrt{2}\,c\tau}{4}\right)\right)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{2}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{2}\,\sqrt{\frac{1}{x^2}}\, x\ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = x^{\frac{3}{2}}\left(c_1\cosh\left(\frac{\ln(x)}{2}\right) + ic_2\sinh\left(\frac{\ln(x)}{2}\right)\right)
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = x^{\frac{3}{2}}\left(c_1\cosh\left(\frac{\ln(x)}{2}\right) + ic_2\sinh\left(\frac{\ln(x)}{2}\right)\right) \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = 0 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{3\sqrt{x}\left(c_1\cosh\left(\frac{\ln(x)}{2}\right) + ic_2\sinh\left(\frac{\ln(x)}{2}\right)\right)}{2} + x^{\frac{3}{2}}\left(\frac{c_1\sinh\left(\frac{\ln(x)}{2}\right)}{2x} + \frac{ic_2\cosh\left(\frac{\ln(x)}{2}\right)}{2x}\right)
$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$
0 = \frac{c_1}{2} - \frac{ic_2}{2} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
c_1 = ic_2
$$

Substituting these values back in above solution results in

$$
y = ic_2x^{\frac{3}{2}}\cosh\left(\frac{\ln(x)}{2}\right) + ix^{\frac{3}{2}}\sinh\left(\frac{\ln(x)}{2}\right)c_2
$$

Summary
The solution(s) found are the following

$$y = i\left(\cosh\left(\frac{\ln\left(x\right)}{2}\right)+\sinh\left(\frac{\ln\left(x\right)}{2}\right)\right) c_2 x^{\frac{3}{2}} \tag{1}$$

Verification of solutions

$$y = i\left(\cosh\left(\frac{\ln\left(x\right)}{2}\right)+\sinh\left(\frac{\ln\left(x\right)}{2}\right)\right) c_2 x^{\frac{3}{2}}$$

Verified OK.

15.1.6 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(-\frac{2}{x}\right)'}{2} - \frac{\left(-\frac{2}{x}\right)^2}{4} \\ &= \frac{2}{x^2} - \frac{\left(\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\ &= \frac{2}{x^2} - \left(\frac{1}{x^2}\right) - \frac{1}{x^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2}{x}}{2}} \\
&= x
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x \tag{4}
$$

Applying this change of variable to the original ode results in

$$
x^3 v''(x) = 0
$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$
v(x) = c_1 x + c_2
$$

Now that $v(x)$ is known, then

$$
\begin{aligned}
y &= v(x)\, z(x) \\
&= (c_1 x + c_2)\, (z(x))
\end{aligned} \tag{7}
$$

But from (5)

$$
z(x) = x
$$

Hence (7) becomes

$$
y = x(c_1 x + c_2)
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = x(c_1 x + c_2) \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$
0 = 0 \tag{1A}
$$

Taking derivative of the solution gives

$$y' = 2c_1x + c_2$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = c_1x^2$$

Summary
The solution(s) found are the following

$$y = c_1x^2 \tag{1}$$

Verification of solutions

$$y = c_1x^2$$

Verified OK.

15.1.7 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' - 2xy' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2}{x} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{2n}{x^2} + \frac{2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{2}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{2}{x}\,dx \\ \ln(u) &= -2\ln(x) + c_1 \\ u &= \mathrm{e}^{-2\ln(x)+c_1} \\ &= \frac{c_1}{x^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1}{x} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(-\frac{c_1}{x} + c_2\right) x^2 \\ &= (c_2 x - c_1)\, x \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \left(-\frac{c_1}{x} + c_2\right) x^2 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 0 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 + 2\left(-\frac{c_1}{x} + c_2\right) x$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$

Substituting these values back in above solution results in

$$y = c_2 x^2$$

Summary
The solution(s) found are the following

$$y = c_2 x^2 \tag{1}$$

Verification of solutions

$$y = c_2 x^2$$

Verified OK.

15.1.8 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x^2 \\
B &= -2x \\
C &= 2 \\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(x^2\right)(0) + (-2x)(-2) + (2)(-2x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
-2x^3v'' + (0)\, v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
-2x^3u'(x) = 0
$$

Which is now solved for u. Integrating both sides gives

$$
\begin{aligned}
u(x) &= \int 0 \, \mathrm{d}x \\
&= c_1
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1 \, \mathrm{d}x \\
&= c_1x + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (-2x)(c_1x + c_2) \\
&= -2x(c_1x + c_2)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -2x(c_1x + c_2) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 0 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -4c_1x - 2c_2$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = -2c_1x^2$$

Summary
The solution(s) found are the following

$$y = -2c_1x^2 \tag{1}$$

Verification of solutions

$$y = -2c_1x^2$$

Verified OK.

15.1.9 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2xy' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= -2x \\
C &= 2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{0}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 0 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = 0 \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 383: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\ &= z_1 e^{\ln(x)} \\ &= z_1(x) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\, dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x) + c_2(x(x)) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_2 x^2 + c_1 x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = 0 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2c_2 x + c_1$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$

Substituting these values back in above solution results in

$$y = c_2 x^2$$

Summary
The solution(s) found are the following

$$y = c_2 x^2 \tag{1}$$

Verification of solutions

$$y = c_2 x^2$$

Verified OK.

15.1.10 Maple step by step solution

Let's solve

$\left[x^2 y'' - 2xy' + 2y = 0, y(0) = 0, y'\Big|_{\{x=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{2y'}{x} - \frac{2y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{x} + \frac{2y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2 y'' - 2xy' + 2y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

  $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

- Compute derivative

  $y' = \frac{\frac{d}{dt}y(t)}{x}$

- Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

- Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2 \left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) - 2\frac{d}{dt}y(t) + 2y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 3\frac{d}{dt}y(t) + 2y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (1, 2)$

- 1st solution of the ODE

  $y_1(t) = \mathrm{e}^t$

- 2nd solution of the ODE

  $y_2(t) = \mathrm{e}^{2t}$

- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 \mathrm{e}^t + c_2 \mathrm{e}^{2t}$

- Change variables back using $t = \ln(x)$

  $y = c_2 x^2 + c_1 x$

- Simplify

  $y = x(c_2 x + c_1)$

□ Check validity of solution $y = x(c_2x + c_1)$

- Use initial condition $y(0) = 0$

  $0 = 0$

- Compute derivative of the solution

  $y' = 2c_2x + c_1$

- Use the initial condition $y'\big|_{\{x=0\}} = 0$

  $0 = c_1$

- Solve for c_1 and c_2

  $\{c_1 = 0, c_2 = c_2\}$

- Substitute constant values into general solution and simplify

  $y = c_2x^2$

- Solution to the IVP

  $y = c_2x^2$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 9y = -3\cos(2x)}$$

15.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = -3\cos(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i \\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i \\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-3\cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(3x), \sin(3x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1 \cos(2x) + A_2 \sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$5A_1 \cos(2x) + 5A_2 \sin(2x) = -3\cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{5}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(2x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \cos(3x) + c_2 \sin(3x)) + \left(-\frac{3\cos(2x)}{5}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \cos(3x) + c_2 \sin(3x) - \frac{3\cos(2x)}{5} \tag{1}$$

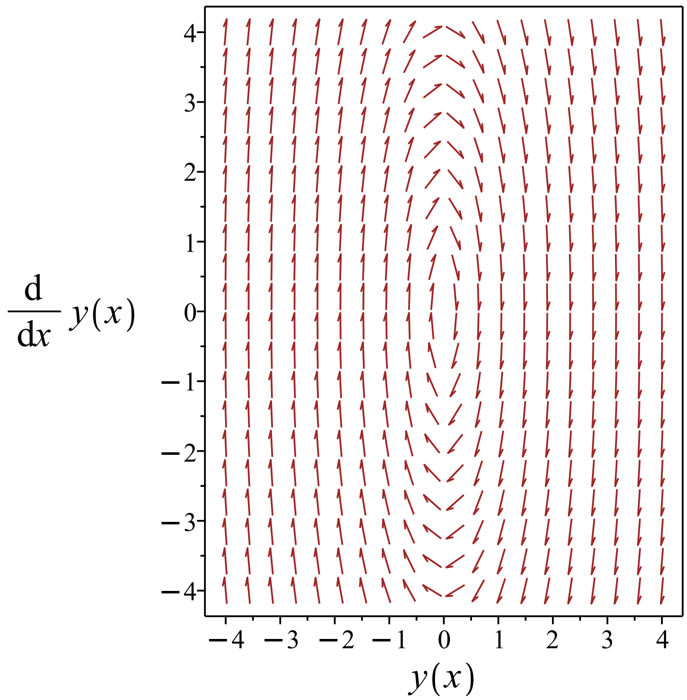

Figure 425: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + c_2 \sin(3x) - \frac{3\cos(2x)}{5}$$

Verified OK.

15.2.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 0 \\
C &= 9
\end{aligned}
\tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned}
\tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{-9}{1} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -9 \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = -9z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 385: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(3x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \cos(3x) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(3x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(3x) \int \frac{1}{\cos(3x)^2}\,dx \\ &= \cos(3x)\left(\frac{\tan(3x)}{3}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(3x)) + c_2\left(\cos(3x)\left(\frac{\tan(3x)}{3}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$-3\cos(2x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(2x), \sin(2x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\frac{\sin(3x)}{3}, \cos(3x)\right\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$y_p = A_1\cos(2x) + A_2\sin(2x)$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution y_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$5A_1\cos(2x) + 5A_2\sin(2x) = -3\cos(2x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{3}{5}, A_2 = 0\right]$$

Substituting the above back in the above trial solution y_p, gives the particular solution

$$y_p = -\frac{3\cos(2x)}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(3x) + \frac{c_2\sin(3x)}{3}\right) + \left(-\frac{3\cos(2x)}{5}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} - \frac{3\cos(2x)}{5} \tag{1}$$

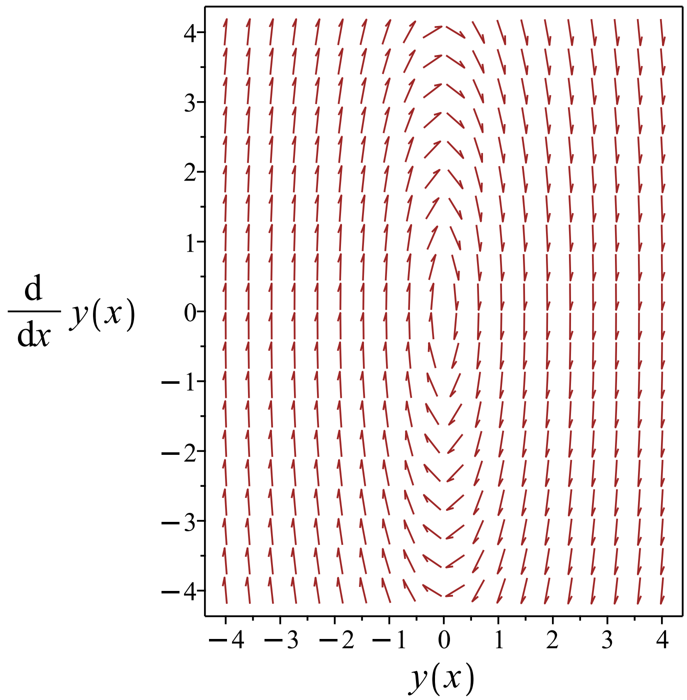

Figure 426: Slope field plot

Verification of solutions

$$y = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3} - \frac{3\cos(2x)}{5}$$

Verified OK.

15.2.3 Maple step by step solution

Let's solve

$y'' + 9y = -3\cos(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2+9=0$

- Use quadratic formula to solve for r

  $r=\frac{0\pm(\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r=(-3\,\mathrm{I},3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x)=\cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x)=\sin(3x)$

- General solution of the ODE

  $y=c_1y_1(x)+c_2y_2(x)+y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y=c_1\cos(3x)+c_2\sin(3x)+y_p(x)$

- ☐ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x)=-y_1(x)\left(\int\frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right)+y_2(x)\left(\int\frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right),f(x)=-3\cos(2x)\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x),y_2(x))=\begin{bmatrix}\cos(3x) & \sin(3x)\\ -3\sin(3x) & 3\cos(3x)\end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x),y_2(x))=3$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x)=-\frac{\cos(3x)\left(\int(-\sin(5x)-\sin(x))dx\right)}{2}+\frac{\sin(3x)\left(\int(-\cos(x)-\cos(5x))dx\right)}{2}$

  - Compute integrals

    $y_p(x)=-\frac{3\cos(2x)}{5}$

- Substitute particular solution into general solution to ODE

  $y=c_1\cos(3x)+c_2\sin(3x)-\frac{3\cos(2x)}{5}$

Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + y' = \cos(x)}$$

16.1.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = \cos(x)$$

Hence the ode is

$$y + y' = \cos(x)$$

The integrating factor μ is

$$\mu = e^{\int 1dx}$$
$$= e^{x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(\cos(x))$$
$$\frac{d}{dx}(y\,e^{x}) = (e^{x})(\cos(x))$$
$$d(y\,e^{x}) = (\cos(x)\,e^{x})\,dx$$

Integrating gives

$$y\,e^{x} = \int \cos(x)\,e^{x}\,dx$$
$$y\,e^{x} = \frac{\cos(x)\,e^{x}}{2} + \frac{\sin(x)\,e^{x}}{2} + c_1$$

Dividing both sides by the integrating factor $\mu = e^{x}$ results in

$$y = e^{-x}\left(\frac{\cos(x)\,e^{x}}{2} + \frac{\sin(x)\,e^{x}}{2}\right) + c_1 e^{-x}$$

which simplifies to

$$y = \frac{\sin(x)}{2} + \frac{\cos(x)}{2} + c_1 e^{-x}$$

Summary

The solution(s) found are the following

$$y = \frac{\sin(x)}{2} + \frac{\cos(x)}{2} + c_1 e^{-x} \tag{1}$$

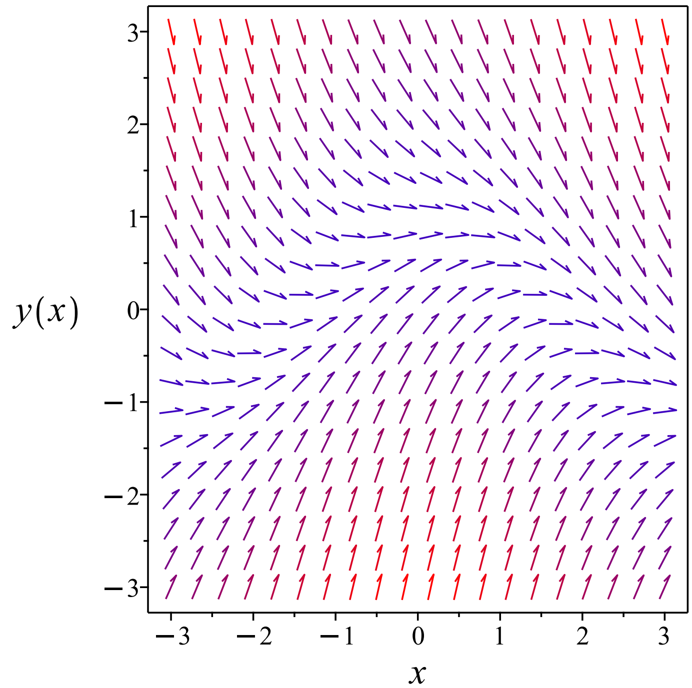

Figure 427: Slope field plot

Verification of solutions

$$y = \frac{\sin(x)}{2} + \frac{\cos(x)}{2} + c_1 \mathrm{e}^{-x}$$

Verified OK.

16.1.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -y + \cos(x)$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 387: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^{-x}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-x}} dy \end{aligned}$$

Which results in

$$S = y\,e^{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -y + \cos(x)$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y\,e^{x} \\ S_y &= e^{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \cos(x)\,e^{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \cos(R)\,e^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 + \frac{e^{R}(\cos(R) + \sin(R))}{2} \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{x} y = \frac{e^{x}(\sin(x) + \cos(x))}{2} + c_1$$

Which simplifies to

$$e^{x} y = \frac{e^{x}(\sin(x) + \cos(x))}{2} + c_1$$

Which gives

$$y = \frac{e^{-x}(\cos(x) e^{x} + \sin(x) e^{x} + 2c_1)}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -y + \cos(x)$ 	$R = x$ $S = y e^{x}$	$\frac{dS}{dR} = \cos(R) e^{R}$ 
Summary

The solution(s) found are the following

$$y = \frac{e^{-x}(\cos(x) e^{x} + \sin(x) e^{x} + 2c_1)}{2} \tag{1}$$

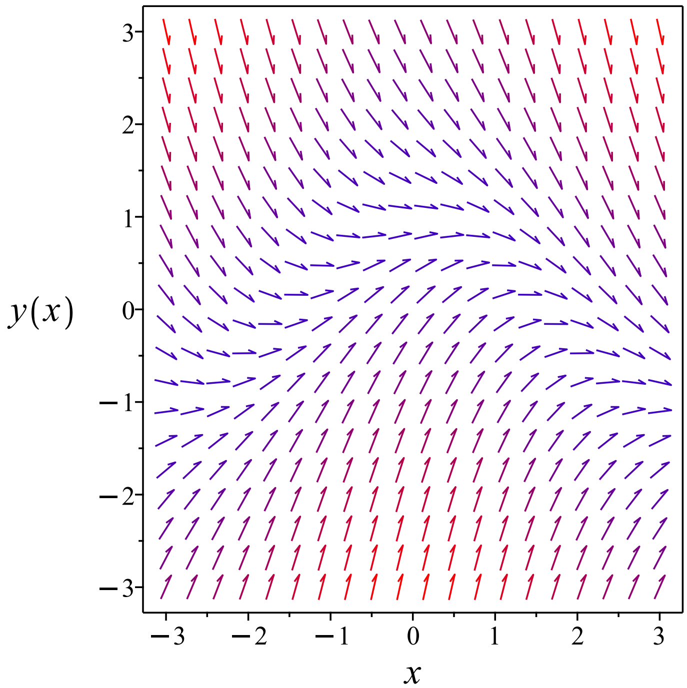

Figure 428: Slope field plot

Verification of solutions

$$y = \frac{e^{-x}(\cos(x) e^{x} + \sin(x) e^{x} + 2c_1)}{2}$$

Verified OK.

16.1.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= (-y + \cos(x))\,\mathrm{d}x\\ (y - \cos(x))\,\mathrm{d}x + \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = y - \cos(x)$$
$$N(x,y) = 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(y - \cos(x))\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((1) - (0)) \\ &= 1 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int 1 \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{x} \\ &= \mathrm{e}^{x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{x}(y - \cos(x)) \\ &= (y - \cos(x))\,\mathrm{e}^{x} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{x}(1) \\ &= \mathrm{e}^{x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ ((y - \cos(x))\,\mathrm{e}^{x}) + (\mathrm{e}^{x})\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int (y - \cos(x)) \mathrm{e}^{x} \mathrm{d}x$$

$$\phi = -\frac{\mathrm{e}^{x}(-2y + \cos(x) + \sin(x))}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{x}$. Therefore equation (4) becomes

$$\mathrm{e}^{x} = \mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\mathrm{e}^{x}(-2y + \cos(x) + \sin(x))}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\mathrm{e}^{x}(-2y + \cos(x) + \sin(x))}{2}$$

The solution becomes

$$y = \frac{\mathrm{e}^{-x}(\cos(x) \mathrm{e}^{x} + \sin(x) \mathrm{e}^{x} + 2c_1)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-x}(\cos(x)e^{x} + \sin(x)e^{x} + 2c_1)}{2} \tag{1}$$

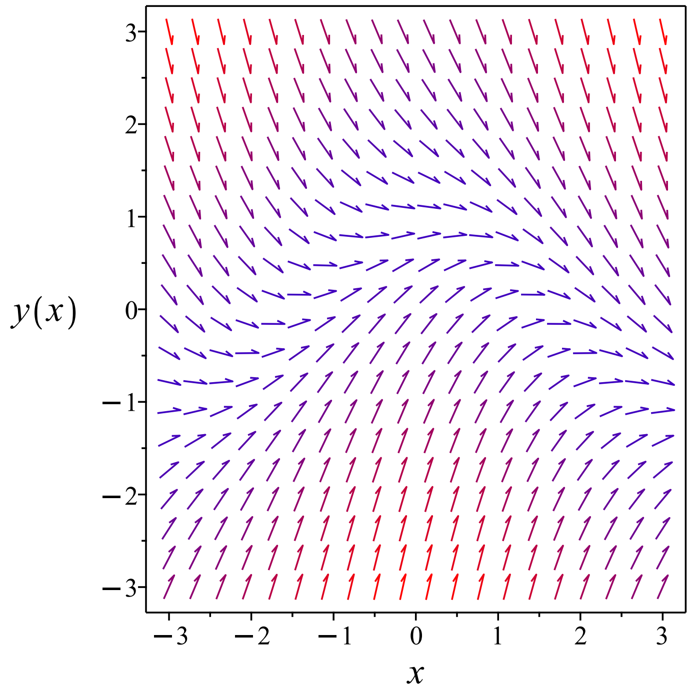

Figure 429: Slope field plot

Verification of solutions

$$y = \frac{e^{-x}(\cos(x)e^{x} + \sin(x)e^{x} + 2c_1)}{2}$$

Verified OK.

16.1.4 Maple step by step solution

Let's solve

$y + y' = \cos(x)$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

$$y' = -y + \cos(x)$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

$$y + y' = \cos(x)$$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$$\mu(x)(y + y') = \mu(x)\cos(x)$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

$$\mu(x)(y + y') = \mu'(x)\, y + \mu(x)\, y'$$

- Isolate $\mu'(x)$

$$\mu'(x) = \mu(x)$$

- Solve to find the integrating factor

$$\mu(x) = \mathrm{e}^{x}$$

- Integrate both sides with respect to x

$$\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x)\cos(x)\, dx + c_1$$

- Evaluate the integral on the lhs

$$\mu(x)\, y = \int \mu(x)\cos(x)\, dx + c_1$$

- Solve for y

$$y = \frac{\int \mu(x)\cos(x)dx + c_1}{\mu(x)}$$

- Substitute $\mu(x) = \mathrm{e}^{x}$

$$y = \frac{\int \cos(x)\mathrm{e}^{x}dx + c_1}{\mathrm{e}^{x}}$$

- Evaluate the integrals on the rhs

$$y = \frac{\frac{\cos(x)\mathrm{e}^{x}}{2} + \frac{\sin(x)\mathrm{e}^{x}}{2} + c_1}{\mathrm{e}^{x}}$$

- Simplify

$$y = \frac{\sin(x)}{2} + \frac{\cos(x)}{2} + c_1\mathrm{e}^{-x}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 3y = 0}$$

With initial conditions

$$[y(0) = -1]$$

16.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= 3 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + 3y = 0$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 3$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

16.2.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + 3\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 3$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(3)} \\ &= \pm i\sqrt{3} \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= +i\sqrt{3} \\ \lambda_2 &= -i\sqrt{3} \end{aligned}$$

Which simplifies to

$$\lambda_1 = i\sqrt{3}$$
$$\lambda_2 = -i\sqrt{3}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = \sqrt{3}$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{0}\left(c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)\right)$$

Or

$$y = c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$

Substituting these values back in above solution results in

$$y = -\cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)$$

Summary
The solution(s) found are the following

$$y = -\cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right) \tag{1}$$

Verification of solutions

$$y = -\cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)$$

Verified OK.

16.2.3 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + 3y'y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + 3y'y)\, dx = 0$$
$$\frac{y'^2}{2} + \frac{3y^2}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-3y^2 + 2c_1} \tag{1}$$
$$y' = -\sqrt{-3y^2 + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-3y^2 + 2c_1}} dy = \int dx$$
$$\frac{\sqrt{3}\, \arctan\left(\frac{\sqrt{3}\, y}{\sqrt{-3y^2+2c_1}}\right)}{3} = c_2 + x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-3y^2+2c_1}}dy = \int dx$$

$$-\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = x + c_3$$

Initial conditions are used to solve for the constants of integration.

Looking at the First solution

$$\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = c_2 + x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-\frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3} = c_2 \tag{1A}$$

Equations $\{1A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_2 = -\frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3}$$

Substituting these values back in above solution results in

$$\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = -\frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3} + x$$

Looking at the Second solution

$$-\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = x + c_3 \tag{2}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$\frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3} = c_3 \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_3\}$. Solving for the constants gives

$$c_3 = \frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3}$$

Substituting these values back in above solution results in

$$-\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = x + \frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3}$$

Summary
The solution(s) found are the following

$$\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = -\frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3} + x \tag{1}$$

$$-\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = x + \frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3} \tag{2}$$

Verification of solutions

$$\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = -\frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3} + x$$

Verified OK.

$$-\frac{\sqrt{3}\,\arctan\left(\frac{\sqrt{3}\,y}{\sqrt{-3y^2+2c_1}}\right)}{3} = x + \frac{\arctan\left(\frac{\sqrt{3}}{\sqrt{-3+2c_1}}\right)\sqrt{3}}{3}$$

Verified OK.

16.2.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 3y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-3}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -3 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -3z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 390: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -3$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos\left(\sqrt{3}\, x\right)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= \cos\left(\sqrt{3}\, x\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \cos\left(\sqrt{3}\, x\right)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos\left(\sqrt{3}\, x\right) \int \frac{1}{\cos\left(\sqrt{3}\, x\right)^2}\, dx \\
&= \cos\left(\sqrt{3}\, x\right) \left(\frac{\sqrt{3}\, \tan\left(\sqrt{3}\, x\right)}{3}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\cos\left(\sqrt{3}\, x\right)\right) + c_2\left(\cos\left(\sqrt{3}\, x\right)\left(\frac{\sqrt{3}\, \tan\left(\sqrt{3}\, x\right)}{3}\right)\right)
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos\left(\sqrt{3}\, x\right) + \frac{c_2 \sqrt{3}\, \sin\left(\sqrt{3}\, x\right)}{3} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 \tag{1A}$$

Equations {1A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$

Substituting these values back in above solution results in

$$y = -\cos\left(\sqrt{3}\, x\right) + \frac{c_2\sqrt{3}\, \sin\left(\sqrt{3}\, x\right)}{3}$$

Summary

The solution(s) found are the following

$$y = -\cos\left(\sqrt{3}\, x\right) + \frac{c_2\sqrt{3}\, \sin\left(\sqrt{3}\, x\right)}{3} \tag{1}$$

Verification of solutions

$$y = -\cos\left(\sqrt{3}\, x\right) + \frac{c_2\sqrt{3}\, \sin\left(\sqrt{3}\, x\right)}{3}$$

Verified OK.

16.2.5 Maple step by step solution

Let's solve

$[y'' + 3y = 0, y(0) = -1]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + 3 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-12})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\mathrm{I}\sqrt{3}, \mathrm{I}\sqrt{3}\right)$

- 1st solution of the ODE

  $y_1(x) = \cos\left(\sqrt{3}\, x\right)$

- 2nd solution of the ODE

  $y_2(x) = \sin\left(\sqrt{3}\, x\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

$$y = c_1 \cos\left(\sqrt{3}\, x\right) + c_2 \sin\left(\sqrt{3}\, x\right)$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 2. Problems for Review and Discovery. Problems for Discussion and Exploration. Page 105
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_x", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x], [_2nd_order, _reducible, _mu_x_y1]]
```

$$\boxed{y'' + \sin(y) = 0}$$

16.3.1 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + y' \sin(y) = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + y' \sin(y))\, dx = 0$$
$$\frac{y'^2}{2} - \cos(y) = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{2\cos(y) + 2c_1} \tag{1}$$
$$y' = -\sqrt{2\cos(y) + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{2\cos(y)+2c_1}}dy = \int dx$$

$$\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\mathrm{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = c_2 + x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{2\cos(y)+2c_1}}dy = \int dx$$

$$-\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\mathrm{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = x + c_3$$

Summary

The solution(s) found are the following

$$\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\mathrm{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = c_2 + x \tag{1}$$

$$-\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\mathrm{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = x + c_3 \tag{2}$$

Verification of solutions

$$\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\mathrm{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = c_2 + x$$

Verified OK.

$$-\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\mathrm{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = x + c_3$$

Verified OK.

16.3.2 Solving as second order ode missing x ode

This is missing independent variable second order ode. Solved by reduction of order by using substitution which makes the dependent variable y an independent variable. Using

$$y' = p(y)$$

Then

$$\begin{aligned} y'' &= \frac{dp}{dx} \\ &= \frac{dy}{dx}\frac{dp}{dy} \\ &= p\frac{dp}{dy} \end{aligned}$$

Hence the ode becomes

$$p(y)\left(\frac{d}{dy}p(y)\right) = -\sin\left(y\right)$$

Which is now solved as first order ode for $p(y)$. In canonical form the ODE is

$$\begin{aligned} p' &= F(y,p) \\ &= f(y)g(p) \\ &= -\frac{\sin\left(y\right)}{p} \end{aligned}$$

Where $f(y) = -\sin\left(y\right)$ and $g(p) = \frac{1}{p}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{1}{p}}\,dp &= -\sin\left(y\right)\,dy \\ \int \frac{1}{\frac{1}{p}}\,dp &= \int -\sin\left(y\right)\,dy \\ \frac{p^2}{2} &= \cos\left(y\right) + c_1 \end{aligned}$$

The solution is

$$\frac{p(y)^2}{2} - \cos\left(y\right) - c_1 = 0$$

For solution (1) found earlier, since $p = y'$ then we now have a new first order ode to solve which is

$$\frac{y'^2}{2} - \cos(y) - c_1 = 0$$

Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{2\cos(y) + 2c_1} \tag{1}$$
$$y' = -\sqrt{2\cos(y) + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{2\cos(y) + 2c_1}} dy = \int dx$$

$$\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\ \text{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y) + 2c_1}} = c_2 + x$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{2\cos(y) + 2c_1}} dy = \int dx$$

$$-\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\ \text{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y) + 2c_1}} = x + c_3$$

Summary

The solution(s) found are the following

$$\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\ \text{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y) + 2c_1}} = c_2 + x \tag{1}$$

$$-\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\ \text{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y) + 2c_1}} = x + c_3 \tag{2}$$

Verification of solutions

$$\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\operatorname{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = c_2 + x$$

Verified OK.

$$-\frac{2\sqrt{\frac{\cos(y)+c_1}{c_1+1}}\,\operatorname{InverseJacobiAM}\left(\frac{y}{2}, \frac{2}{\sqrt{2+2c_1}}\right)}{\sqrt{2\cos(y)+2c_1}} = x + c_3$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2xy = 0}$$

With the expansion point for the power series method at $x = 0$.

17.1.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f && (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y) && (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 && (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n\big|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= 2xy \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= \left(4x^2 + 2\right) y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= \left(8x^3 + 12x\right) y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= 4y\left(4x^4 + 12x^2 + 3\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= 32y\left(x^4 + 5x^2 + \frac{15}{4}\right) x \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= \left(64x^6 + 480x^4 + 720x^2 + 120\right) y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= \left(128x^7 + 1344x^5 + 3360x^3 + 1680x\right) y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 2y(0) \\
F_2 &= 0 \\
F_3 &= 12y(0) \\
F_4 &= 0 \\
F_5 &= 120y(0) \\
F_6 &= 0
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = \left(1 + x^2 + \frac{1}{2}x^4 + \frac{1}{6}x^6\right) y(0) + O(x^8)
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x) \\
y' - 2xy &= 0
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= -2x \\
p(x) &= 0
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 2x\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-2x^{1+n} a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n$$

$$\sum_{n=0}^{\infty} \left(-2x^{1+n} a_n\right) = \sum_{n=1}^{\infty} \left(-2a_{n-1} x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n\right) + \sum_{n=1}^{\infty} \left(-2a_{n-1} x^n\right) = 0 \tag{3}$$

For $1 \leq n$, the recurrence equation is

$$(1+n)\, a_{1+n} - 2a_{n-1} = 0 \tag{4}$$

Solving for a_{1+n}, gives

$$a_{1+n} = \frac{2a_{n-1}}{1+n} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$2a_2 - 2a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = a_0$$

For $n = 2$ the recurrence equation gives

$$3a_3 - 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = 0$$

For $n = 3$ the recurrence equation gives

$$4a_4 - 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{2}$$

For $n = 4$ the recurrence equation gives

$$5a_5 - 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 5$ the recurrence equation gives

$$6a_6 - 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{6}$$

For $n = 6$ the recurrence equation gives

$$7a_7 - 2a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

For $n = 7$ the recurrence equation gives

$$8a_8 - 2a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{24}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_0 x^2 + \frac{1}{2} a_0 x^4 + \frac{1}{6} a_0 x^6 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x^2 + \frac{1}{2} x^4 + \frac{1}{6} x^6\right) a_0 + O(x^8) \tag{3}$$

Summary
The solution(s) found are the following

$$y = \left(1 + x^2 + \frac{1}{2} x^4 + \frac{1}{6} x^6\right) y(0) + O(x^8) \tag{1}$$

$$y = \left(1 + x^2 + \frac{1}{2} x^4 + \frac{1}{6} x^6\right) c_1 + O(x^8) \tag{2}$$

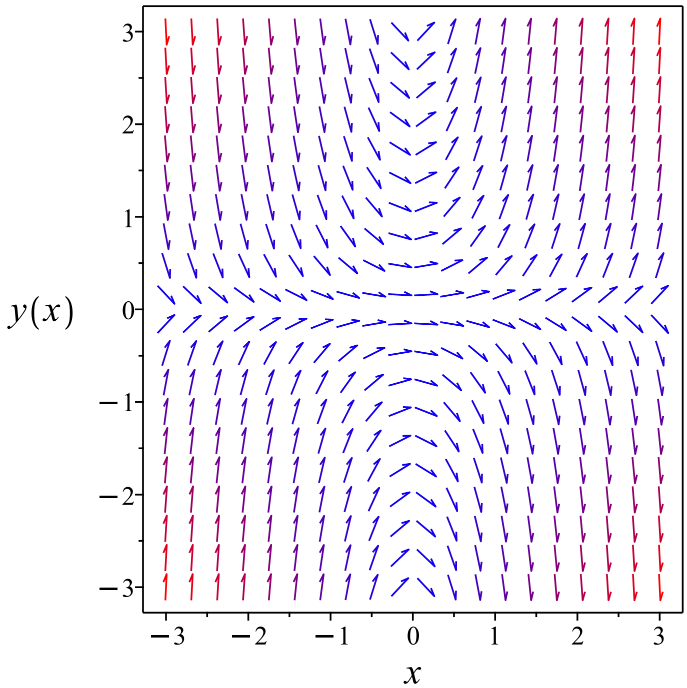

Figure 430: Slope field plot

Verification of solutions

$$y = \left(1 + x^2 + \frac{1}{2}x^4 + \frac{1}{6}x^6\right) y(0) + O(x^8)$$

Verified OK.

$$y = \left(1 + x^2 + \frac{1}{2}x^4 + \frac{1}{6}x^6\right) c_1 + O(x^8)$$

Verified OK.

17.1.2 Maple step by step solution

Let's solve

$y' - 2xy = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int 2x dx + c_1$

- Evaluate integral

  $\ln(y) = x^2 + c_1$

- Solve for y

  $y = \mathrm{e}^{x^2 + c_1}$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 1(a) solving directly.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y' - 2xy = 0}$$

17.2.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= 2xy \end{aligned}$$

Where $f(x) = 2x$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}\frac{1}{y}\,dy &= 2x\,dx\\ \int \frac{1}{y}\,dy &= \int 2x\,dx\\ \ln(y) &= x^2 + c_1\\ y &= \mathrm{e}^{x^2+c_1}\\ &= c_1\mathrm{e}^{x^2}\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{x^2} \tag{1}$$

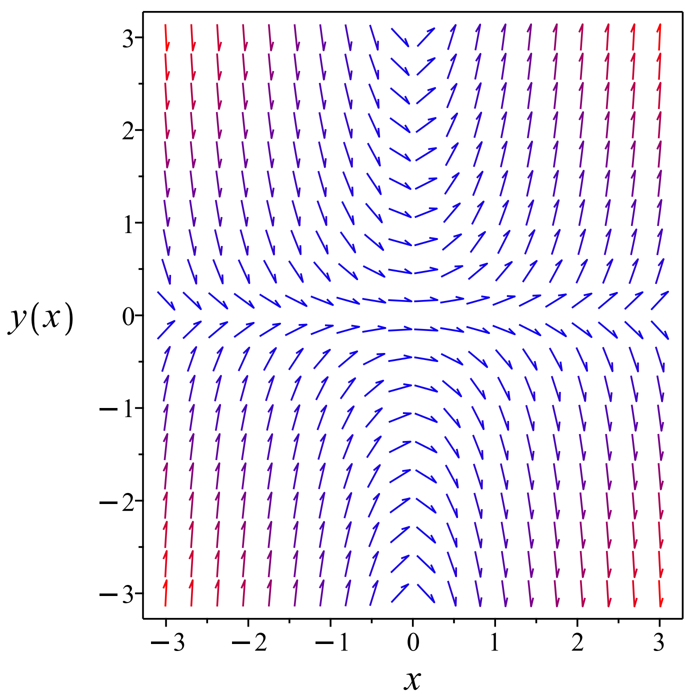

Figure 431: Slope field plot

Verification of solutions

$$y = c_1\mathrm{e}^{x^2}$$

Verified OK.

17.2.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -2x \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - 2xy = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -2x dx} \\ &= e^{-x^2} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}\mu y &= 0 \\ \frac{d}{dx}\left(e^{-x^2} y\right) &= 0 \end{aligned}$$

Integrating gives

$$e^{-x^2} y = c_1$$

Dividing both sides by the integrating factor $\mu = e^{-x^2}$ results in

$$y = c_1 e^{x^2}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{x^2} \tag{1}$$

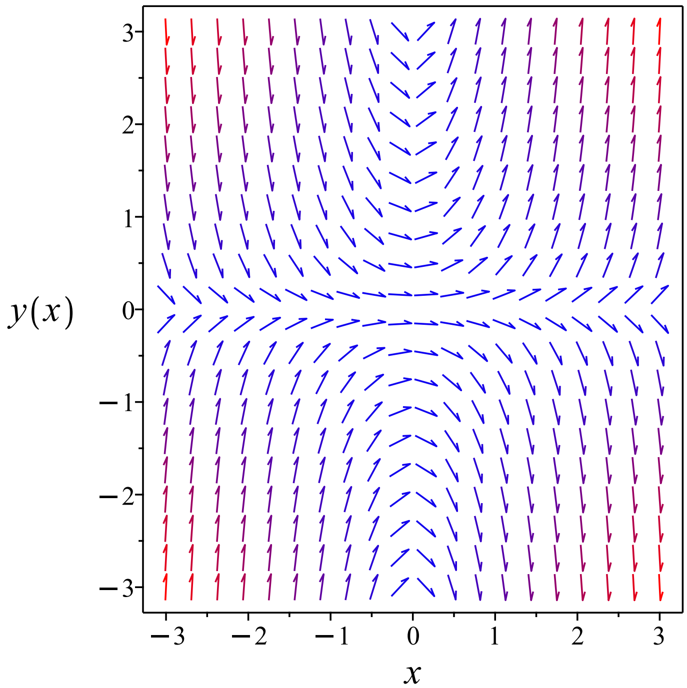

Figure 432: Slope field plot

Verification of solutions

$$y = c_1 e^{x^2}$$

Verified OK.

17.2.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$u'(x)\, x + u(x) - 2x^2 u(x) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x) g(u) \\
&= \frac{u(2x^2 - 1)}{x}
\end{aligned}$$

Where $f(x) = \frac{2x^2-1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= \frac{2x^2-1}{x}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{2x^2-1}{x}\, dx \\
\ln(u) &= x^2 - \ln(x) + c_2 \\
u &= \mathrm{e}^{x^2-\ln(x)+c_2} \\
&= c_2 \mathrm{e}^{x^2-\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = \frac{c_2 \mathrm{e}^{x^2}}{x}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= xu \\
&= c_2 \mathrm{e}^{x^2}
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_2 \mathrm{e}^{x^2} \tag{1}
$$

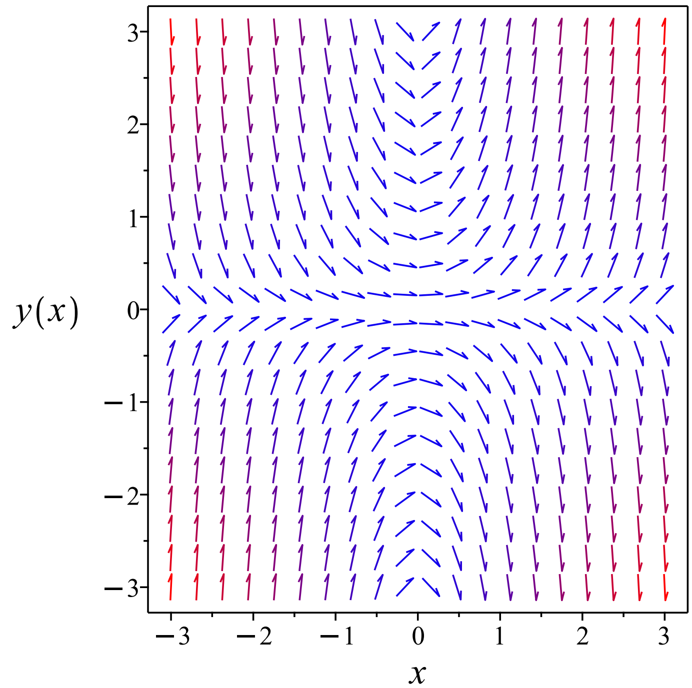

Figure 433: Slope field plot

Verification of solutions

$$y = c_2 \mathrm{e}^{x^2}$$

Verified OK.

17.2.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= 2xy \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 393: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= e^{x^2}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{x^2}} dy \end{aligned}$$

Which results in

$$S = e^{-x^2} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = 2xy$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -2x\, e^{-x^2} y \\ S_y &= e^{-x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{-x^2} y = c_1$$

Which simplifies to

$$e^{-x^2} y = c_1$$

Which gives

$$y = c_1 e^{x^2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = 2xy$ 	$R = x$ $S = e^{-x^2} y$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = c_1 e^{x^2} \tag{1}$$

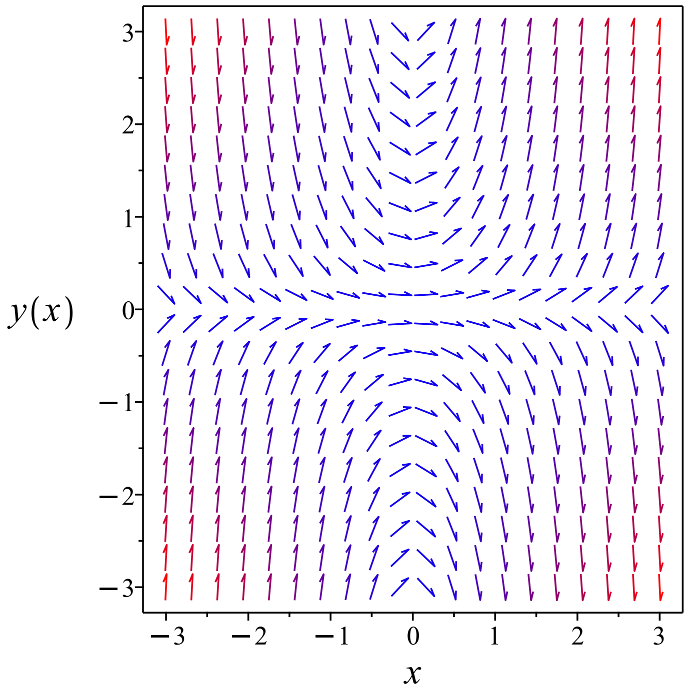

Figure 434: Slope field plot

Verification of solutions

$$y = c_1 e^{x^2}$$

Verified OK.

17.2.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{2y}\right)\mathrm{d}y = (x)\,\mathrm{d}x$$
$$(-x)\,\mathrm{d}x + \left(\frac{1}{2y}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = -x$$
$$N(x,y) = \frac{1}{2y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(-x)$$
$$= 0$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{2y}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -x\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\frac{x^2}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{2y}$. Therefore equation (4) becomes

$$
\frac{1}{2y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{2y}
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{2y}\right) \mathrm{d}y$$
$$f(y) = \frac{\ln(y)}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} + \frac{\ln(y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} + \frac{\ln(y)}{2}$$

The solution becomes

$$y = \mathrm{e}^{x^2+2c_1}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x^2+2c_1} \tag{1}$$

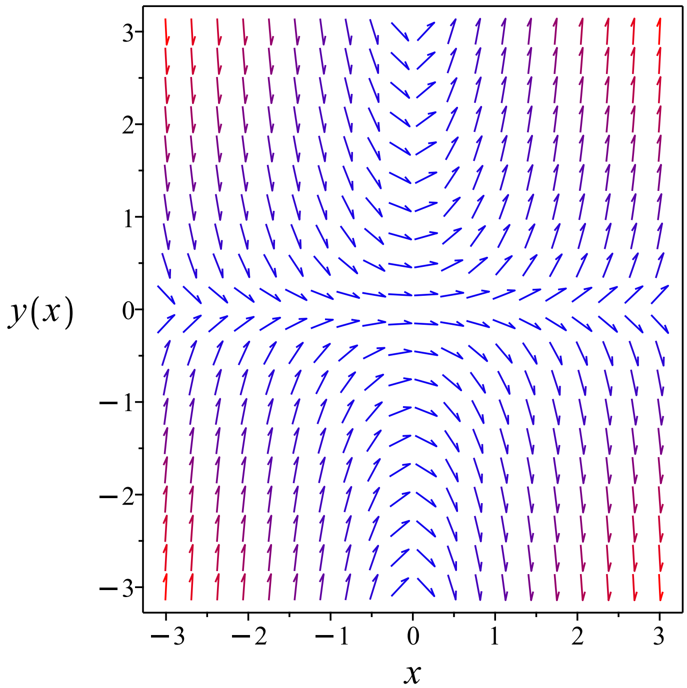

Figure 435: Slope field plot

Verification of solutions

$$y = e^{x^2+2c_1}$$

Verified OK.

17.2.6 Maple step by step solution

Let's solve

$y' - 2xy = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = 2x$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int 2x dx + c_1$

- Evaluate integral

$$\ln(y) = x^2 + c_1$$

- Solve for y

$$y = e^{x^2+c_1}$$

Problem number: 1(b) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{y + y' = 1}$$

With the expansion point for the power series method at $x = 0$.

17.3.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + x f + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}$$

For example, for $n = 1$ we see that

$$\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}$$

Which is (1). And when $n = 2$

$$\begin{aligned} F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= 1 - y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= y - 1 \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= 1 - y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= y - 1 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= 1 - y \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= y - 1 \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= 1 - y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= 1 - y(0) \\
F_1 &= y(0) - 1 \\
F_2 &= 1 - y(0) \\
F_3 &= y(0) - 1 \\
F_4 &= 1 - y(0) \\
F_5 &= y(0) - 1 \\
F_6 &= 1 - y(0)
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) y(0) \\
&+ x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)
\end{aligned}
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x) \\
y + y' &= 1
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= 1 \\
p(x) &= 1
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This

is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = 1 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = 1 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 1 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+1) a_{n+1} + a_n) x^n = 1 \tag{4}$$

For $n = 0$ the recurrence equation gives

$$(a_1 + a_0) 1 = 1$$
$$a_1 + a_0 = 1$$

Which after substituting the earlier terms found becomes

$$a_1 = 1 - a_0$$

For $n = 1$ the recurrence equation gives

$$(2a_2 + a_1) x = 0$$
$$2a_2 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = -\frac{1}{2} + \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$(3a_3 + a_2) x^2 = 0$$
$$3a_3 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{6} - \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$(4a_4 + a_3) x^3 = 0$$
$$4a_4 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{1}{24} + \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$(5a_5 + a_4) x^4 = 0$$
$$5a_5 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{120} - \frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(6a_6 + a_5)\, x^5 &= 0\\ 6a_6 + a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{1}{720} + \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(7a_7 + a_6)\, x^6 &= 0\\ 7a_7 + a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{5040} - \frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(8a_8 + a_7)\, x^7 &= 0\\ 8a_8 + a_7 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = -\frac{1}{40320} + \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n\\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + (1 - a_0)\,x + \left(-\frac{1}{2} + \frac{a_0}{2}\right)x^2 + \left(\frac{1}{6} - \frac{a_0}{6}\right)x^3 + \left(-\frac{1}{24} + \frac{a_0}{24}\right)x^4 + \left(\frac{1}{120} - \frac{a_0}{120}\right)x^5 + \left(-\frac{1}{720} + \frac{a_0}{720}\right)x^6 + \left(\frac{1}{5040} - \frac{a_0}{5040}\right)x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right)a_0 + x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8) \tag{3}$$

Summary

The solution(s) found are the following

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right)y(0) + x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8) \tag{1}$$

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right)c_1 + x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8) \tag{2}$$

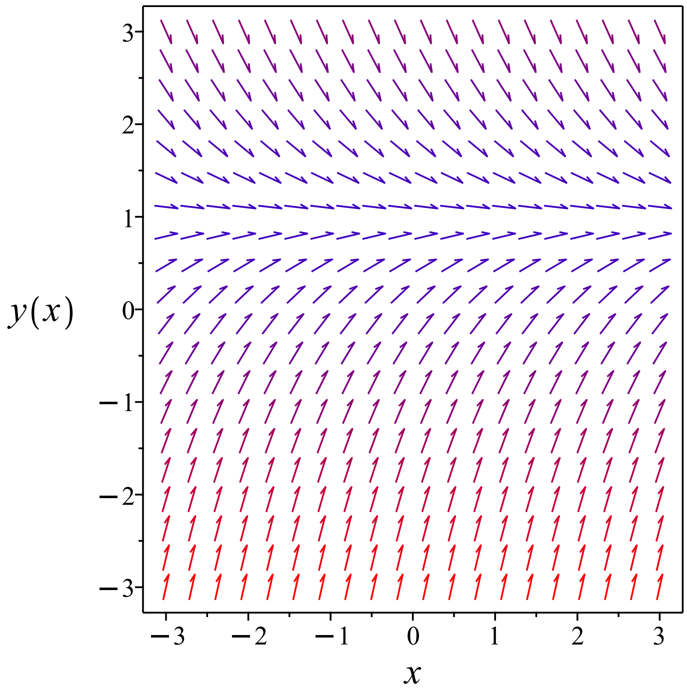

Figure 436: Slope field plot

Verification of solutions

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) y(0) + x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)$$

Verified OK.

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) c_1 + x - \frac{x^2}{2} + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} - \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)$$

Verified OK.

Problem number: 1(c) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - y = 2}$$

With the expansion point for the power series method at $x = 0$.

17.5.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + x f + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0, y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0, y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n=2$

$$\begin{aligned} F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right)f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)f \end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$\begin{aligned}
F_0 &= 2+y\\
F_1 &= \frac{dF_0}{dx}\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}F_0\\
&= 2+y\\
F_2 &= \frac{dF_1}{dx}\\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y}F_1\\
&= 2+y\\
F_3 &= \frac{dF_2}{dx}\\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y}F_2\\
&= 2+y\\
F_4 &= \frac{dF_3}{dx}\\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y}F_3\\
&= 2+y\\
F_5 &= \frac{dF_4}{dx}\\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y}F_4\\
&= 2+y\\
F_6 &= \frac{dF_5}{dx}\\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y}F_5\\
&= 2+y
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) + 2 \\
F_1 &= y(0) + 2 \\
F_2 &= y(0) + 2 \\
F_3 &= y(0) + 2 \\
F_4 &= y(0) + 2 \\
F_5 &= y(0) + 2 \\
F_6 &= y(0) + 2
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) \\
&+ 2x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8)
\end{aligned}
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x) \\
y' - y &= 2
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= -1 \\
p(x) &= 2
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This

is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = 2 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 2 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 2 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+1) a_{n+1} - a_n) x^n = 2 \tag{4}$$

For $n = 0$ the recurrence equation gives

$$(a_1 - a_0) 1 = 2$$
$$a_1 - a_0 = 2$$

Which after substituting the earlier terms found becomes

$$a_1 = 2 + a_0$$

For $n = 1$ the recurrence equation gives

$$(2a_2 - a_1) x = 0$$
$$2a_2 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = 1 + \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$(3a_3 - a_2) x^2 = 0$$
$$3a_3 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{3} + \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$(4a_4 - a_3) x^3 = 0$$
$$4a_4 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{12} + \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$(5a_5 - a_4) x^4 = 0$$
$$5a_5 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{60} + \frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(6a_6 - a_5) x^5 &= 0 \\ 6a_6 - a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1}{360} + \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(7a_7 - a_6) x^6 &= 0 \\ 7a_7 - a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{2520} + \frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(8a_8 - a_7) x^7 &= 0 \\ 8a_8 - a_7 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{20160} + \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + (2 + a_0)\, x + \left(1 + \frac{a_0}{2}\right) x^2 + \left(\frac{1}{3} + \frac{a_0}{6}\right) x^3 + \left(\frac{1}{12} + \frac{a_0}{24}\right) x^4 + \left(\frac{1}{60} + \frac{a_0}{120}\right) x^5 + \left(\frac{1}{360} + \frac{a_0}{720}\right) x^6 + \left(\frac{1}{2520} + \frac{a_0}{5040}\right) x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) a_0 + 2x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8) \tag{3}$$

Summary

The solution(s) found are the following

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + 2x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8) \tag{1}$$

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + 2x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8) \tag{2}$$

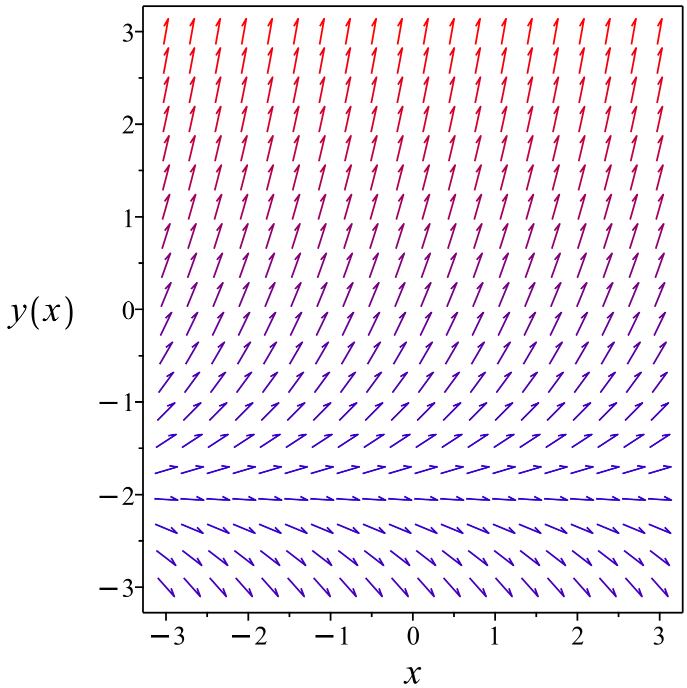

Figure 438: Slope field plot

Verification of solutions

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + 2x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8)$$

Verified OK.

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + 2x + x^2 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8)$$

Verified OK.

17.5.2 Maple step by step solution

Let's solve

$y' - y = 2$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{2+y} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{2+y}dx = \int 1dx + c_1$

- Evaluate integral

  $\ln(2+y) = x + c_1$

- Solve for y

  $y = \mathrm{e}^{x+c_1} - 2$

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y + y' = 0}$$

With the expansion point for the power series method at $x = 0$.

17.7.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n=1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y} \right) F_0 \\
&= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \right) + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \right) f \\
&= \frac{\partial}{\partial x} \left(\frac{df}{dx} \right) + \frac{\partial}{\partial y} \left(\frac{df}{dx} \right) f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n|_{x_0, y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= -y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= -y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= -y \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= -y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= y(0) \\
F_2 &= -y(0) \\
F_3 &= y(0) \\
F_4 &= -y(0) \\
F_5 &= y(0) \\
F_6 &= -y(0)
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) y(0) + O(x^8)
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x) \\
y + y' &= 0
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= 1 \\
p(x) &= 0
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$(n+1) a_{n+1} + a_n = 0 \tag{4}$$

Solving for a_{n+1}, gives

$$a_{n+1} = -\frac{a_n}{n+1} \tag{5}$$

For $n = 0$ the recurrence equation gives

$$a_1 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_1 = -a_0$$

For $n = 1$ the recurrence equation gives

$$2a_2 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$3a_3 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$4a_4 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$5a_5 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$6a_6 + a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$7a_7 + a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$8a_8 + a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 - a_0 x + \frac{1}{2} a_0 x^2 - \frac{1}{6} a_0 x^3 + \frac{1}{24} a_0 x^4 - \frac{1}{120} a_0 x^5 + \frac{1}{720} a_0 x^6 - \frac{1}{5040} a_0 x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) a_0 + O(x^8) \quad (3)$$

Summary

The solution(s) found are the following

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) y(0) + O(x^8) \quad (1)$$

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) c_1 + O(x^8) \quad (2)$$

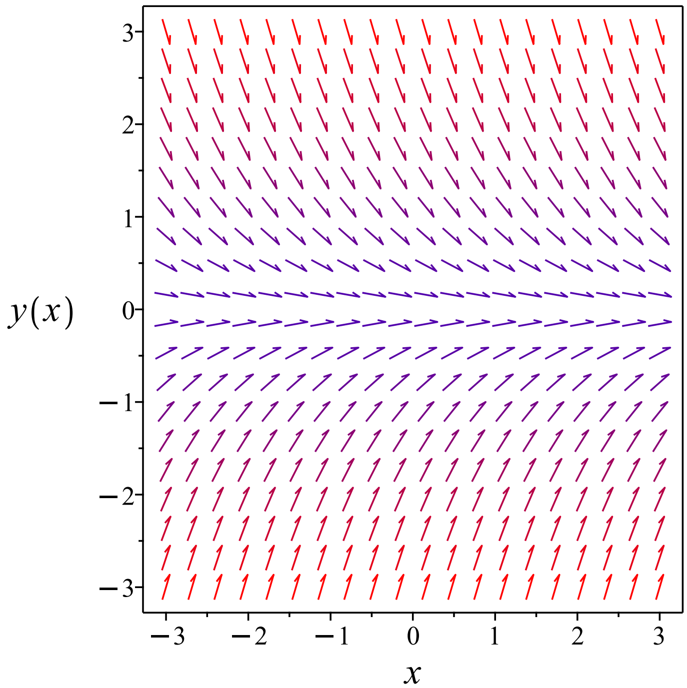

Figure 440: Slope field plot

Verification of solutions

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) y(0) + O(x^8)$$

Verified OK.

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) c_1 + O(x^8)$$

Verified OK.

17.7.2 Maple step by step solution

Let's solve

$y + y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = -1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int (-1) \, dx + c_1$

- Evaluate integral

  $\ln(y) = -x + c_1$

- Solve for y

  $y = e^{-x+c_1}$

17.9 problem 1(e) solving using series

Internal problem ID [6412]
Internal file name [`OUTPUT/5660_Sunday_June_05_2022_03_46_16_PM_73875935/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 1(e) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - y = 0}$$

With the expansion point for the power series method at $x = 0$.

17.9.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + x f + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0, y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0, y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$
\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}
$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$
y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n|_{x_0,y_0} \tag{6}
$$

Hence

$$\begin{aligned}
F_0 &= y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= y \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= y
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$\begin{aligned}
F_0 &= y(0) \\
F_1 &= y(0) \\
F_2 &= y(0) \\
F_3 &= y(0) \\
F_4 &= y(0) \\
F_5 &= y(0) \\
F_6 &= y(0)
\end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + O(x^8)$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\begin{aligned}
y' + q(x)y &= p(x) \\
y' - y &= 0
\end{aligned}$$

Where

$$\begin{aligned}
q(x) &= -1 \\
p(x) &= 0
\end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 0 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$(n+1) a_{n+1} - a_n = 0 \tag{4}$$

Solving for a_{n+1}, gives

$$a_{n+1} = \frac{a_n}{n+1} \tag{5}$$

For $n = 0$ the recurrence equation gives

$$a_1 - a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_1 = a_0$$

For $n = 1$ the recurrence equation gives

$$2a_2 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$3a_3 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$4a_4 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$5a_5 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$6a_6 - a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$7a_7 - a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$8a_8 - a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_0 x + \frac{1}{2} a_0 x^2 + \frac{1}{6} a_0 x^3 + \frac{1}{24} a_0 x^4 + \frac{1}{120} a_0 x^5 + \frac{1}{720} a_0 x^6 + \frac{1}{5040} a_0 x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) a_0 + O(x^8) \quad (3)$$

Summary

The solution(s) found are the following

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + O(x^8) \quad (1)$$

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + O(x^8) \quad (2)$$

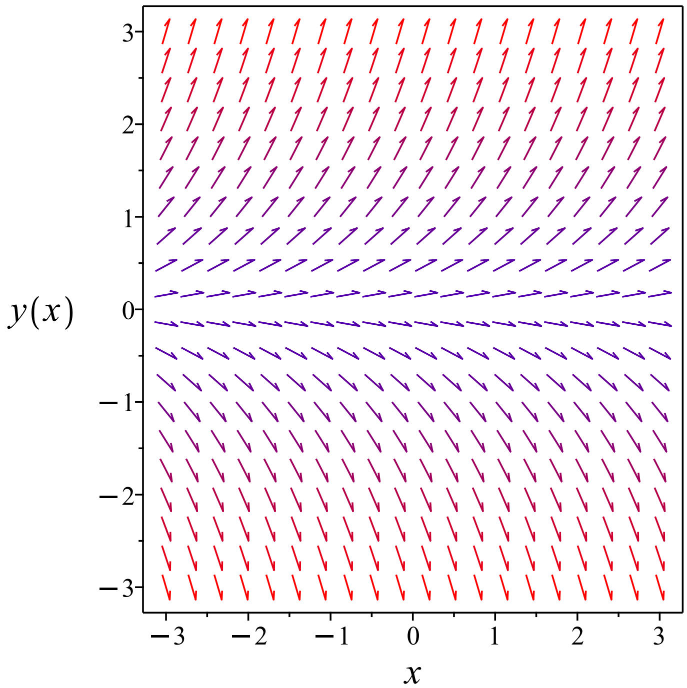

Figure 442: Slope field plot

Verification of solutions

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + O(x^8)$$

Verified OK.

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + O(x^8)$$

Verified OK.

17.10.2 Maple step by step solution

Let's solve

$y' - y = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{y} dx = \int 1 dx + c_1$

- Evaluate integral

$$\ln(y) = x + c_1$$

- Solve for y

$$y = e^{x+c_1}$$

Problem number: 1(f) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = x^2}$$

With the expansion point for the power series method at $x = 0$.

17.11.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\frac{df}{dx} = \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \tag{1}
$$

$$
\begin{aligned}
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned} \tag{2}
$$

$$
\begin{aligned}
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f
\end{aligned} \tag{3}
$$

$$
\vdots
$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$
F_0 = f(x, y) \tag{4}
$$

$$
\begin{aligned}
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0
\end{aligned} \tag{5}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n\big|_{x_0, y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= x^2 + y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= 2x + x^2 + y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= 2 + 2x + x^2 + y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= 2 + 2x + x^2 + y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= 2 + 2x + x^2 + y \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= 2 + 2x + x^2 + y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= 2 + 2x + x^2 + y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= y(0)\\
F_1 &= y(0)\\
F_2 &= y(0) + 2\\
F_3 &= y(0) + 2\\
F_4 &= y(0) + 2\\
F_5 &= y(0) + 2\\
F_6 &= y(0) + 2
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
\begin{aligned}
y = {} & \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0)\\
& + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O\left(x^8\right)
\end{aligned}
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x)\\
y' - y &= x^2
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= -1\\
p(x) &= x^2
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This

is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = x^2 \tag{1}$$

Expanding x^2 as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned} x^2 &= x^2 + \dots \\ &= x^2 \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = x^2 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} (-a_n x^n) = x^2 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = x^2 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+1)\, a_{n+1} - a_n)\, x^n = x^2 \tag{4}$$

For $n = 0$ the recurrence equation gives

$$\begin{aligned} (a_1 - a_0)\, 1 &= 0 \\ a_1 - a_0 &= 0 \end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_1 = a_0$$

For $n = 1$ the recurrence equation gives

$$\begin{aligned} (2a_2 - a_1)\, x &= 0 \\ 2a_2 - a_1 &= 0 \end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$\begin{aligned} (3a_3 - a_2)\, x^2 &= x^2 \\ 3a_3 - a_2 &= 1 \end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{3} + \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$\begin{aligned} (4a_4 - a_3)\, x^3 &= 0 \\ 4a_4 - a_3 &= 0 \end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{12} + \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(5a_5 - a_4)\, x^4 &= 0\\ 5a_5 - a_4 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{60} + \frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(6a_6 - a_5)\, x^5 &= 0\\ 6a_6 - a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1}{360} + \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(7a_7 - a_6)\, x^6 &= 0\\ 7a_7 - a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{2520} + \frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(8a_8 - a_7)\, x^7 &= 0\\ 8a_8 - a_7 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{20160} + \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_0 x + \frac{a_0 x^2}{2} + \left(\frac{1}{3} + \frac{a_0}{6}\right) x^3 + \left(\frac{1}{12} + \frac{a_0}{24}\right) x^4 \\ + \left(\frac{1}{60} + \frac{a_0}{120}\right) x^5 + \left(\frac{1}{360} + \frac{a_0}{720}\right) x^6 + \left(\frac{1}{2520} + \frac{a_0}{5040}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) a_0 \\ + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8) \end{aligned} \tag{3}$$

<u>Summary</u>

The solution(s) found are the following

$$\begin{aligned} y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) \\ + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8) \end{aligned} \tag{1}$$

$$\begin{aligned} y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 \\ + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8) \end{aligned} \tag{2}$$

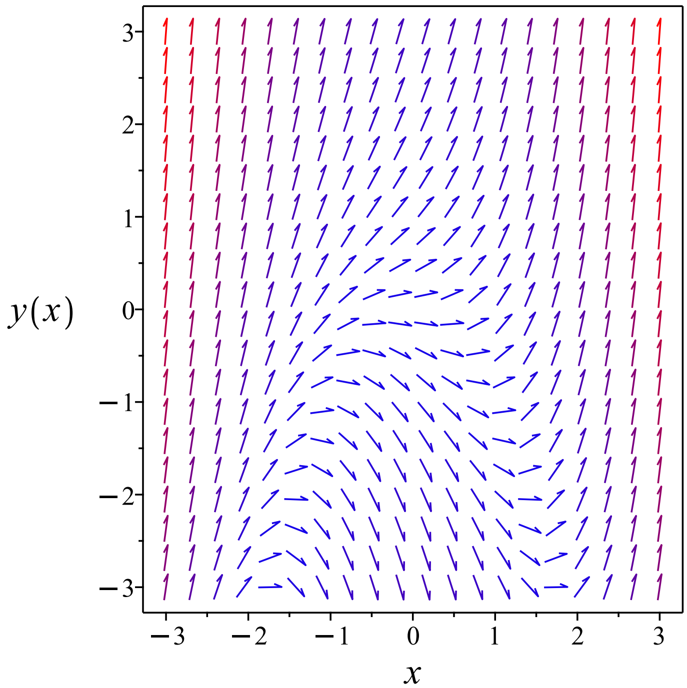

Figure 444: Slope field plot

Verification of solutions

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8)$$

Verified OK.

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + \frac{x^3}{3} + \frac{x^4}{12} + \frac{x^5}{60} + \frac{x^6}{360} + \frac{x^7}{2520} + O(x^8)$$

Verified OK.

17.11.2 Maple step by step solution

Let's solve

$y' - y = x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = x^2 + y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = x^2$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - y) = \mu(x)\,x^2$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' - y) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)$

- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{-x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,x^2 dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,x^2 dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x) x^2 dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \mathrm{e}^{-x}$

  $y = \frac{\int x^2 \mathrm{e}^{-x} dx + c_1}{\mathrm{e}^{-x}}$

- Evaluate the integrals on the rhs

  $y = \frac{-(x^2+2x+2)\,\mathrm{e}^{-x} + c_1}{\mathrm{e}^{-x}}$

- Simplify

  $y = c_1 \mathrm{e}^{x} - x^2 - 2x - 2$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y' - y = x^2}$$

17.12.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -1$$
$$q(x) = x^2$$

Hence the ode is

$$y' - y = x^2$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int (-1)dx} \\ &= e^{-x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(x^2\right) \\ \frac{d}{dx}\left(e^{-x}y\right) &= \left(e^{-x}\right)\left(x^2\right) \\ d\left(e^{-x}y\right) &= \left(x^2 e^{-x}\right)\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}e^{-x}y &= \int x^2 e^{-x}\, dx \\ e^{-x}y &= -\left(x^2+2x+2\right)e^{-x} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^{-x}$ results in

$$y = -e^{x}\left(x^2+2x+2\right)e^{-x} + c_1 e^{x}$$

which simplifies to

$$y = c_1 e^{x} - x^2 - 2x - 2$$

Summary

The solution(s) found are the following

$$y = c_1 e^{x} - x^2 - 2x - 2 \tag{1}$$

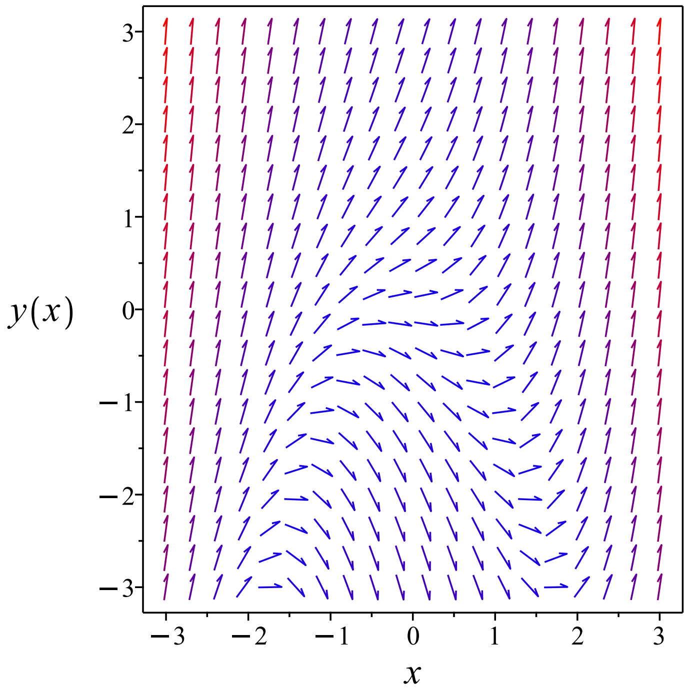

Figure 445: Slope field plot

Verification of solutions

$$y = c_1 e^{x} - x^2 - 2x - 2$$

Verified OK.

17.12.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = x^2 + y$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 405: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^x
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^x} dy \end{aligned}$$

Which results in

$$S = e^{-x} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = x^2 + y$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -e^{-x} y \\ S_y &= e^{-x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x^2 e^{-x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2 e^{-R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\left(R^2 + 2R + 2\right) \mathrm{e}^{-R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y\,\mathrm{e}^{-x} = -\left(x^2 + 2x + 2\right) \mathrm{e}^{-x} + c_1$$

Which simplifies to

$$\left(2 + 2x + x^2 + y\right) \mathrm{e}^{-x} - c_1 = 0$$

Which gives

$$y = -\left(x^2 \mathrm{e}^{-x} + 2x\,\mathrm{e}^{-x} + 2\,\mathrm{e}^{-x} - c_1\right) \mathrm{e}^{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = x^2 + y$ 	$R = x$ $S = \mathrm{e}^{-x} y$	$\frac{dS}{dR} = R^2 \mathrm{e}^{-R}$ 
Summary
The solution(s) found are the following

$$y = -\left(x^2 \mathrm{e}^{-x} + 2x\,\mathrm{e}^{-x} + 2\,\mathrm{e}^{-x} - c_1\right) \mathrm{e}^{x} \tag{1}$$

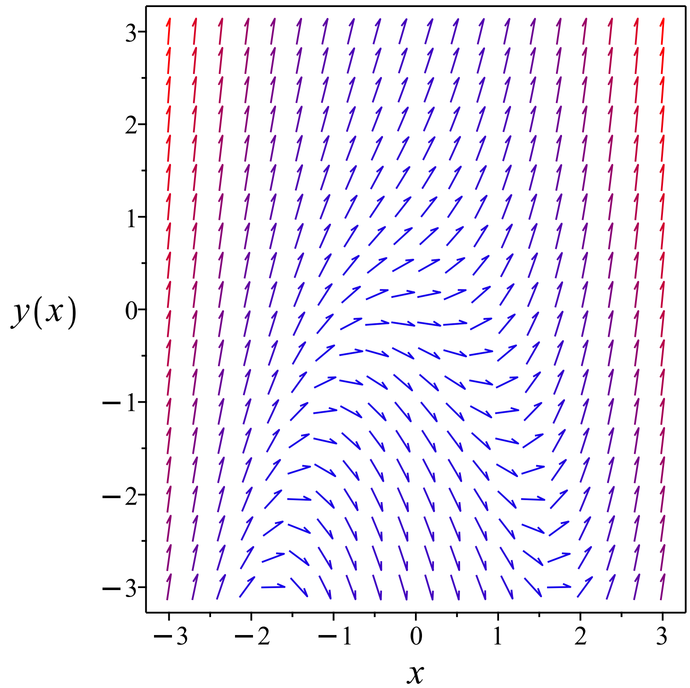

Figure 446: Slope field plot

Verification of solutions

$$y = -\left(x^2 e^{-x} + 2x\, e^{-x} + 2\, e^{-x} - c_1\right) e^{x}$$

Verified OK.

17.12.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\mathrm{d}y &= \left(x^2 + y\right) \mathrm{d}x \\
\left(-x^2 - y\right) \mathrm{d}x + \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -x^2 - y \\
N(x, y) &= 1
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2 - y\right) \\
&= -1
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= 1((-1) - (0)) \\ &= -1 \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int -1 \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-x} \\ &= \mathrm{e}^{-x} \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= \mathrm{e}^{-x}(-x^2 - y) \\ &= -\mathrm{e}^{-x}(x^2 + y) \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \mathrm{e}^{-x}(1) \\ &= \mathrm{e}^{-x} \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(-\mathrm{e}^{-x}(x^2 + y)\right) + \left(\mathrm{e}^{-x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int \overline{M} \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -\mathrm{e}^{-x}\left(x^2+y\right) \mathrm{d}x \\
\phi &= \left(x^2+2x+y+2\right) \mathrm{e}^{-x} + f(y) \qquad (3)
\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x} + f'(y) \qquad (4)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \mathrm{e}^{-x}$. Therefore equation (4) becomes

$$\mathrm{e}^{-x} = \mathrm{e}^{-x} + f'(y) \qquad (5)$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \left(x^2+2x+y+2\right) \mathrm{e}^{-x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \left(x^2+2x+y+2\right) \mathrm{e}^{-x}$$

The solution becomes

$$y = -\left(x^2 \mathrm{e}^{-x} + 2x\,\mathrm{e}^{-x} + 2\,\mathrm{e}^{-x} - c_1\right) \mathrm{e}^{x}$$

Summary

The solution(s) found are the following

$$y = -\left(x^2 e^{-x} + 2x\,e^{-x} + 2\,e^{-x} - c_1\right) e^{x} \tag{1}$$

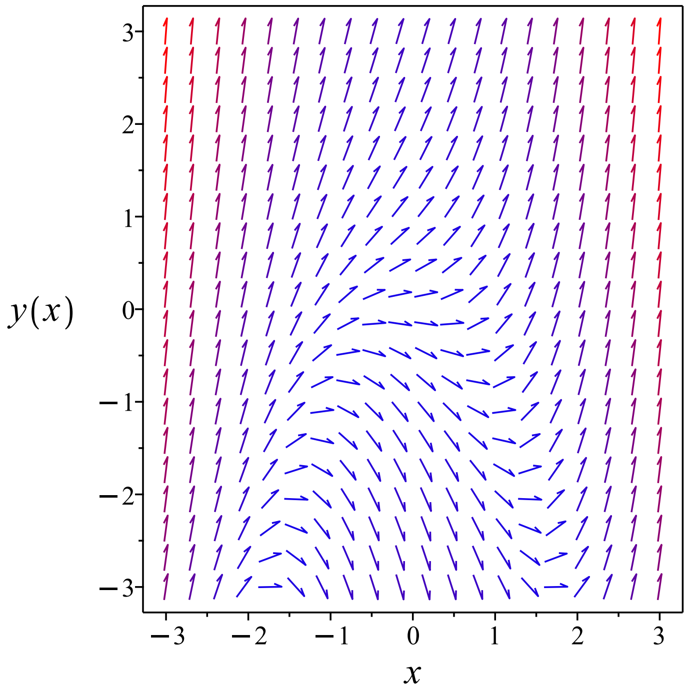

Figure 447: Slope field plot

Verification of solutions

$$y = -\left(x^2 e^{-x} + 2x\,e^{-x} + 2\,e^{-x} - c_1\right) e^{x}$$

Verified OK.

17.12.4 Maple step by step solution

Let's solve

$y' - y = x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = x^2 + y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - y = x^2$
- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y' - y) = \mu(x)\,x^2$
- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y' - y) = \mu'(x)\,y + \mu(x)\,y'$
- Isolate $\mu'(x)$

  $\mu'(x) = -\mu(x)$
- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{-x}$
- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,x^2 dx + c_1$
- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,x^2 dx + c_1$
- Solve for y

  $y = \frac{\int \mu(x)x^2 dx + c_1}{\mu(x)}$
- Substitute $\mu(x) = \mathrm{e}^{-x}$

  $y = \frac{\int x^2 \mathrm{e}^{-x} dx + c_1}{\mathrm{e}^{-x}}$
- Evaluate the integrals on the rhs

  $y = \frac{-(x^2+2x+2)\,\mathrm{e}^{-x} + c_1}{\mathrm{e}^{-x}}$
- Simplify

  $y = c_1 \mathrm{e}^{x} - x^2 - 2x - 2$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 2(a) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Regular singular point"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{-y + xy' = 0}$$

With the expansion point for the power series method at $x = 0$.

17.13.1 Solving as series ode

Writing the ODE as

$$y' + q(x)y = p(x)$$
$$y' - \frac{y}{x} = 0$$

Where

$$q(x) = -\frac{1}{x}$$
$$p(x) = 0$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not.

Since $x = 0$ is not an ordinary point, we now check to see if it is a regular singular point. $xq(x) = -1$ has a Taylor series around $x = 0$. Since $x = 0$ is regular singular point, then Frobenius power series is used. Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \frac{\sum_{n=0}^{\infty} a_n x^{n+r}}{x} = 0 \tag{1}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) - \frac{\sum_{n=0}^{\infty} a_n x^{n+r}}{x} = 0 \tag{1}$$

Expanding the second term in (1) gives

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + -1 \cdot \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) + \frac{1}{x} \cdot \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1} a_n\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2) this gives

$$(n+r)\, a_n x^{n+r-1} - x^{n+r-1} a_n = 0$$

When $n=0$ the above becomes

$$r a_0 x^{-1+r} - x^{-1+r} a_0 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(-1+r)\, x^{-1+r} = 0$$

Since the above is true for all x then the indicial equation simplifies to

$$-1+r = 0$$

Solving for r gives the root of the indicial equation as

$$r = 1$$

We start by finding y_h. Replacing $r=1$ found above results in

$$\left(\sum_{n=0}^{\infty} (n+1)\, a_n x^{n}\right) + \sum_{n=0}^{\infty} \left(-x^{n} a_n\right) = 0$$

From the above we see that there is no recurrence relation since there is only one summation term. Therefore all a_n terms are zero except for a_0. Hence

$$y_h = a_0 x^r$$

Therefore the homogeneous solution is

$$y_h(x) = a_0 \left(x + O\left(x^8\right)\right)$$

At $x = 0$ the solution above becomes

$$y = c_1 \left(x + O\left(x^8\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \left(x + O\left(x^8\right)\right) \tag{1}$$

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{-y + xy' = 0}$$

17.14.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= \frac{1}{x}\,dx \\
\int \frac{1}{y}\,dy &= \int \frac{1}{x}\,dx \\
\ln(y) &= \ln(x) + c_1 \\
y &= e^{\ln(x)+c_1} \\
&= c_1 x
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x \tag{1}$$

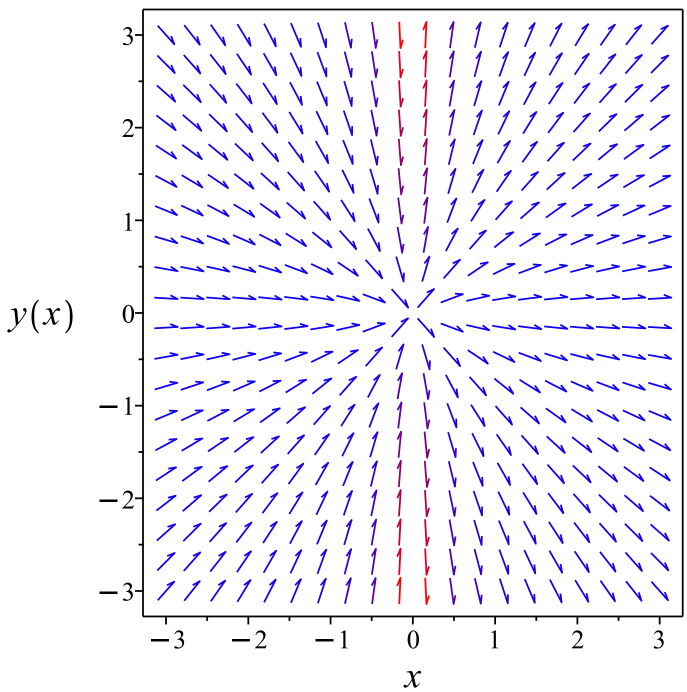

Figure 449: Slope field plot

Verification of solutions

$$y = c_1 x$$

Verified OK.

17.14.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{1}{x}\\ q(x) &= 0\end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = 0$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{1}{x}dx}\\ &= \frac{1}{x}\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}\mu y &= 0\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= 0\end{aligned}$$

Integrating gives

$$\frac{y}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = c_1 x$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 x \tag{1}$$

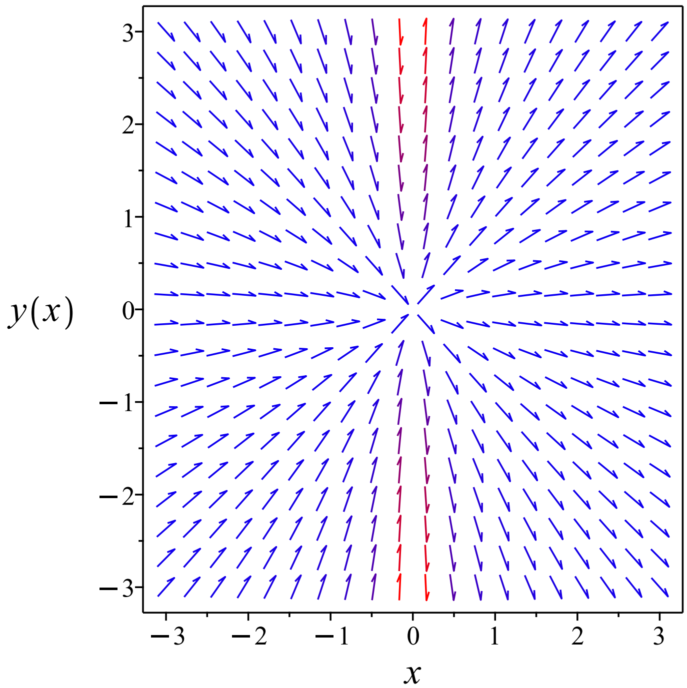

Figure 450: Slope field plot

Verification of solutions

$$y = c_1 x$$

Verified OK.

17.14.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$-u(x)\,x + x(u'(x)\,x + u(x)) = 0$$

Integrating both sides gives

$$\begin{aligned}u(x) &= \int 0\,\mathrm{d}x \\ &= c_2\end{aligned}$$

Therefore the solution y is

$$\begin{aligned}y &= ux \\ &= c_2 x\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 x \tag{1}$$

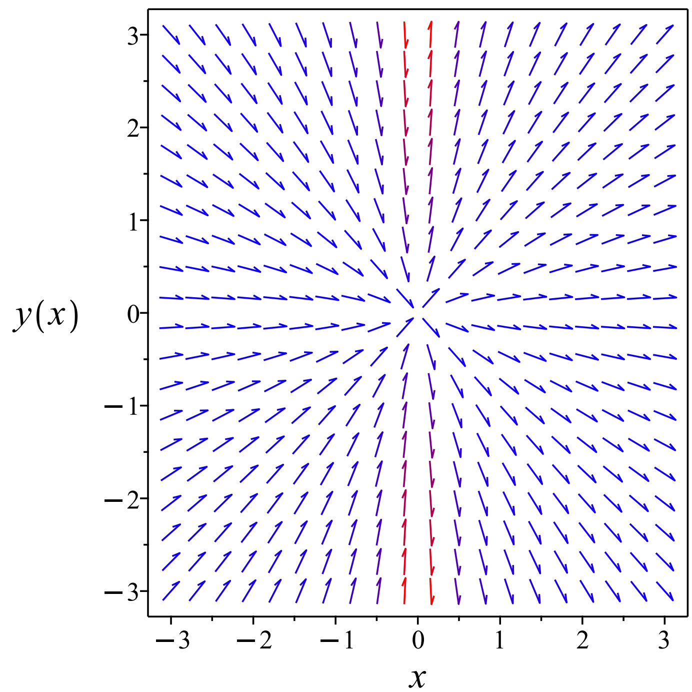

Figure 451: Slope field plot

Verification of solutions

$$y = c_2 x$$

Verified OK.

17.14.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 409: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= x
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = \frac{y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{x^2} \\ S_y &= \frac{1}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x} = c_1$$

Which simplifies to

$$\frac{y}{x} = c_1$$

Which gives

$$y = c_1 x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y}{x}$ 	$R = x$ $S = \frac{y}{x}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = c_1 x \tag{1}$$

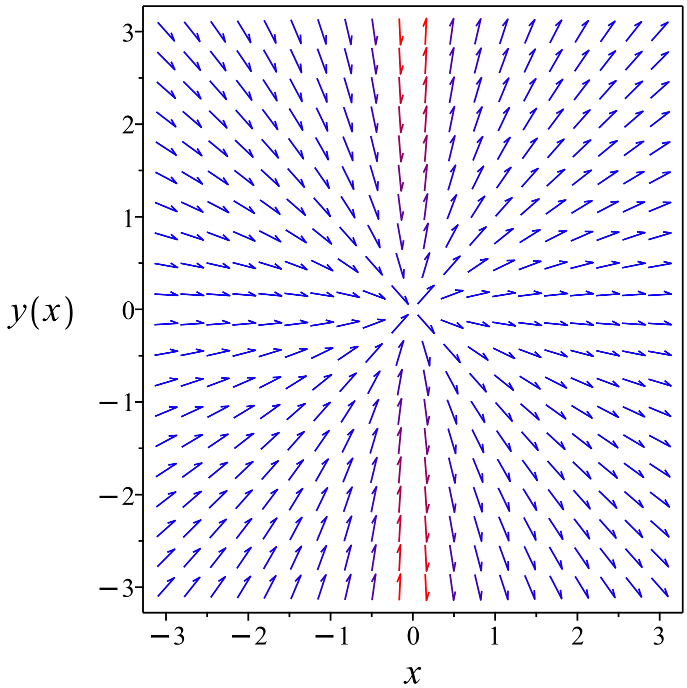

Figure 452: Slope field plot

Verification of solutions

$$y = c_1 x$$

Verified OK.

17.14.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{y}\right) \mathrm{d}y &= \left(\frac{1}{x}\right) \mathrm{d}x \\ \left(-\frac{1}{x}\right) \mathrm{d}x + \left(\frac{1}{y}\right) \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -\frac{1}{x} \\ N(x, y) &= \frac{1}{y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right) \\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -\frac{1}{x} \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\ln(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$
\frac{1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(\frac{1}{y}\right) \mathrm{d}y \\
f(y) &= \ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) + \ln(y)$$

The solution becomes

$$y = x\,e^{c_1}$$

Summary

The solution(s) found are the following

$$y = x\,e^{c_1} \tag{1}$$

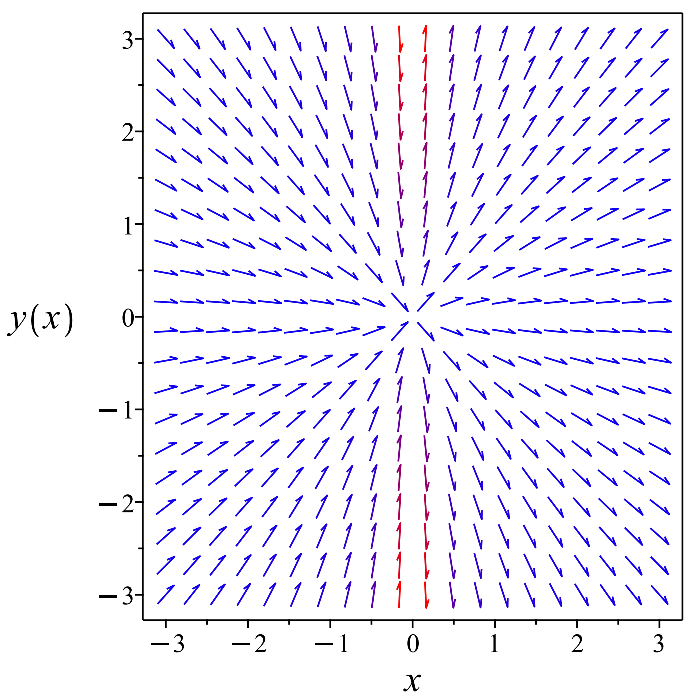

Figure 453: Slope field plot

Verification of solutions

$$y = x\,e^{c_1}$$

Verified OK.

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 2(b) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Irregular singular point"**

Maple gives the following as the ode type

`[_separable]`

Unable to solve or complete the solution.

$$\boxed{x^2y' - y = 0}$$

With the expansion point for the power series method at $x = 0$.

17.15.1 Solving as series ode

Writing the ODE as

$$y' + q(x)y = p(x)$$
$$y' - \frac{y}{x^2} = 0$$

Where

$$q(x) = -\frac{1}{x^2}$$
$$p(x) = 0$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not.

Since $x = 0$ is not an ordinary point, we now check to see if it is a regular singular point.

$$xq(x) = -\frac{1}{x}$$

does not have a Taylor series around $x = 0$.

Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 2(b) solving directly.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{x^2y' - y = 0}$$

17.16.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y}{x^2} \end{aligned}$$

Where $f(x) = \frac{1}{x^2}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\,dy &= \frac{1}{x^2}\,dx \\
\int \frac{1}{y}\,dy &= \int \frac{1}{x^2}\,dx \\
\ln(y) &= c_1 - \frac{1}{x} \\
y &= \mathrm{e}^{c_1 - \frac{1}{x}} \\
&= c_1 \mathrm{e}^{-\frac{1}{x}}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{1}{x}} \tag{1}$$

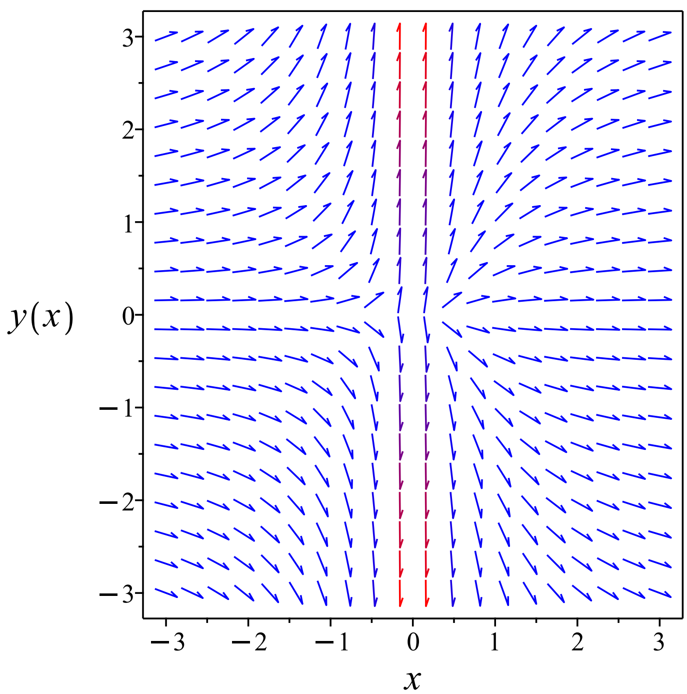

Figure 454: Slope field plot

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{1}{x}}$$

Verified OK.

17.16.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x^2} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x^2} = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{1}{x^2}dx} \\ &= \mathrm{e}^{\frac{1}{x}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}\mu y &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{1}{x}} y\right) &= 0 \end{aligned}$$

Integrating gives

$$\mathrm{e}^{\frac{1}{x}} y = c_1$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{1}{x}}$ results in

$$y = c_1 \mathrm{e}^{-\frac{1}{x}}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{1}{x}} \tag{1}$$

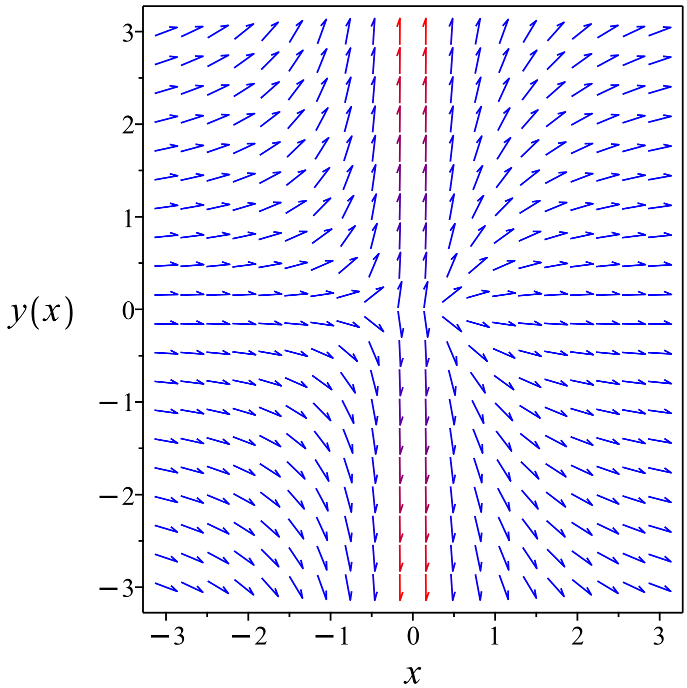

Figure 455: Slope field plot

Verification of solutions

$$y = c_1 e^{-\frac{1}{x}}$$

Verified OK.

17.16.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$x^2(u'(x)\,x + u(x)) - u(x)\,x = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u(x-1)}{x^2} \end{aligned}$$

Where $f(x) = -\frac{x-1}{x^2}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{x-1}{x^2}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{x-1}{x^2}\, dx \\
\ln(u) &= -\ln(x) - \frac{1}{x} + c_2 \\
u &= \mathrm{e}^{-\ln(x) - \frac{1}{x} + c_2} \\
&= c_2 \mathrm{e}^{-\ln(x) - \frac{1}{x}}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_2 \mathrm{e}^{-\frac{1}{x}}}{x}$$

Therefore the solution y is

$$\begin{aligned}
y &= ux \\
&= c_2 \mathrm{e}^{-\frac{1}{x}}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_2 \mathrm{e}^{-\frac{1}{x}} \tag{1}$$

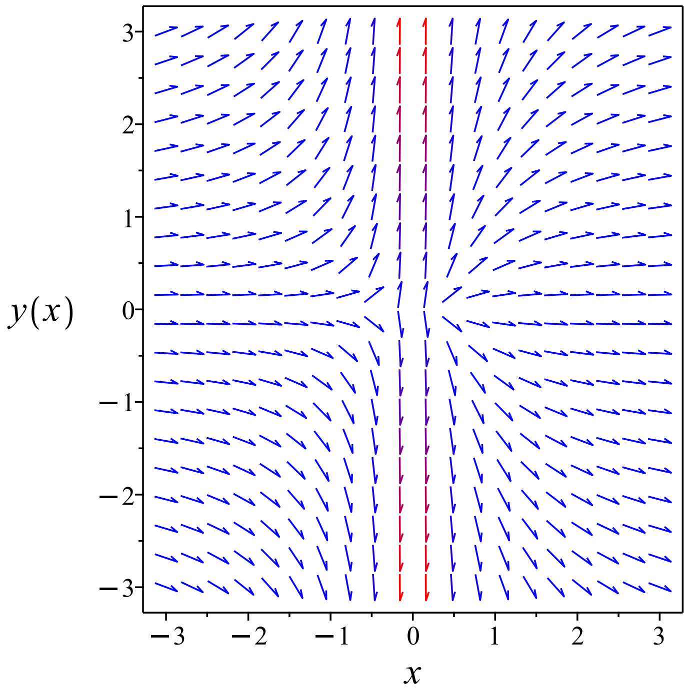

Figure 456: Slope field plot

Verification of solutions

$$y = c_2 e^{-\frac{1}{x}}$$

Verified OK.

17.16.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 413: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{-\frac{1}{x}} \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{e^{-\frac{1}{x}}} dy \end{aligned}$$

Which results in

$$S = e^{\frac{1}{x}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{e^{\frac{1}{x}} y}{x^2} \\ S_y &= e^{\frac{1}{x}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^{\frac{1}{x}} y = c_1$$

Which simplifies to

$$e^{\frac{1}{x}} y = c_1$$

Which gives

$$y = c_1 e^{-\frac{1}{x}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y}{x^2}$ 	$R = x$ $S = e^{\frac{1}{x}} y$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = c_1 e^{-\frac{1}{x}} \tag{1}$$

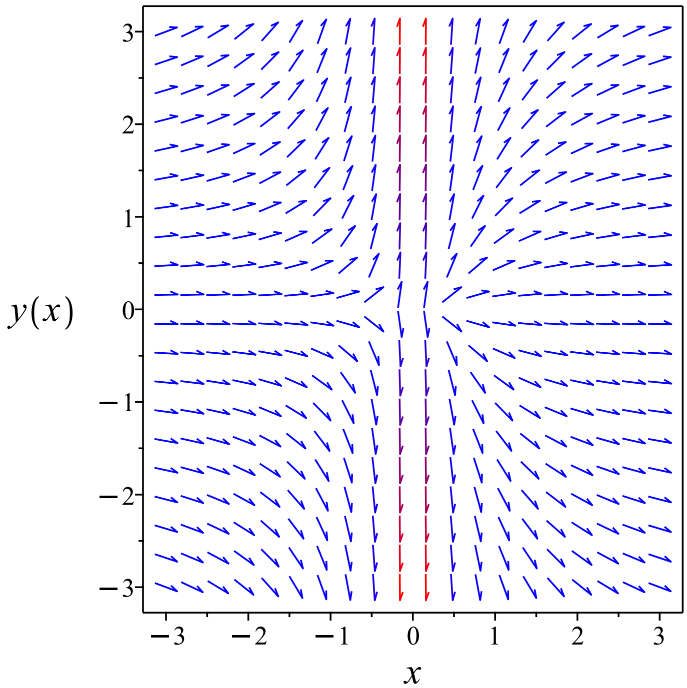

Figure 457: Slope field plot

Verification of solutions

$$y = c_1 e^{-\frac{1}{x}}$$

Verified OK.

17.16.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(\frac{1}{y}\right) \mathrm{d}y &= \left(\frac{1}{x^2}\right) \mathrm{d}x \\
\left(-\frac{1}{x^2}\right) \mathrm{d}x + \left(\frac{1}{y}\right) \mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{1}{x^2} \\
N(x, y) &= \frac{1}{y}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{1}{x^2} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{1}{x} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$
\frac{1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \, \mathrm{d}y &= \int \left(\frac{1}{y}\right) \mathrm{d}y \\
f(y) &= \ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{x} + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{x} + \ln(y)$$

The solution becomes

$$y = \mathrm{e}^{\frac{c_1 x - 1}{x}}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\frac{c_1 x - 1}{x}} \tag{1}$$

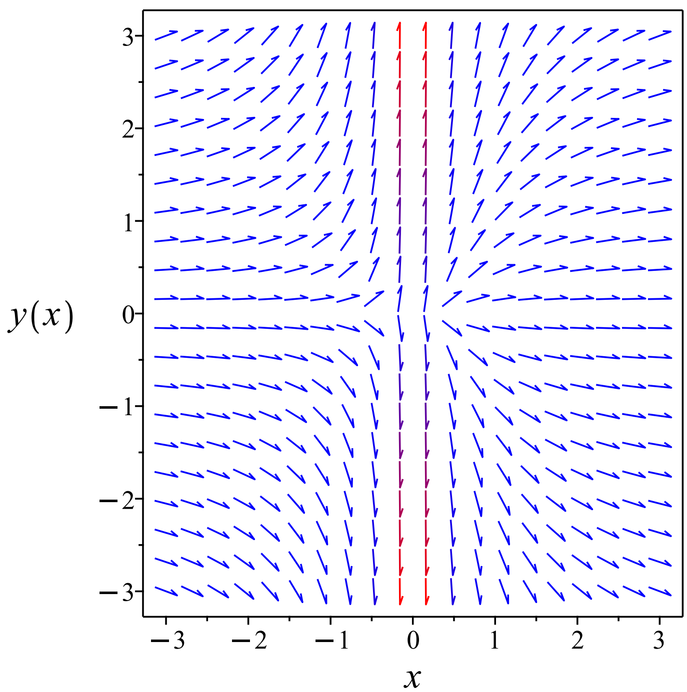

Figure 458: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{\frac{c_1 x - 1}{x}}$$

Verified OK.

17.17 problem 2(c) solving using series

Internal problem ID [6420]
Internal file name [`OUTPUT/5668_Sunday_June_05_2022_03_46_29_PM_78088919/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 2(c) solving using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Regular singular point"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - \frac{y}{x} = x^2}$$

With the expansion point for the power series method at $x = 0$.

17.17.1 Solving as series ode

Writing the ODE as

$$\begin{aligned} y' + q(x)y &= p(x) \\ y' - \frac{y}{x} &= x^2 \end{aligned}$$

Where

$$\begin{aligned} q(x) &= -\frac{1}{x} \\ p(x) &= x^2 \end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not.

Since $x = 0$ is not an ordinary point, we now check to see if it is a regular singular point. $xq(x) = -1$ has a Taylor series around $x = 0$. Since $x = 0$ is regular singular point, then Frobenius power series is used. Since this is an inhomogeneous, then let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ode $y' - \frac{y}{x} = 0$,and y_p is a particular solution to the inhomogeneous ode. First, we solve for y_h Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - \frac{\sum_{n=0}^{\infty} a_n x^{n+r}}{x} = 0 \tag{1}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) - \frac{\sum_{n=0}^{\infty} a_n x^{n+r}}{x} = 0 \tag{1}$$

Expanding the second term in (1) gives

$$\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + -1 \cdot \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) + \frac{1}{x} \cdot \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1} a_n\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2) this gives

$$(n+r)\, a_n x^{n+r-1} - x^{n+r-1} a_n = 0$$

When $n = 0$ the above becomes

$$r a_0 x^{-1+r} - x^{-1+r} a_0 = 0$$

The corresponding balance equation is found by replacing r by m and a by c to avoid confusing terms between particular solution and the homogeneous solution. Hence the balance equation is

$$\left(x^{-1+m} m - x^{-1+m}\right) c_0 = x^2$$

This equation will used later to find the particular solution.

Since $a_0 \neq 0$ then the indicial equation becomes

$$(-1+r)\, x^{-1+r} = 0$$

Since the above is true for all x then the indicial equation simplifies to

$$-1+r = 0$$

Solving for r gives the root of the indicial equation as

$$r = 1$$

We start by finding y_h. From the above we see that there is no recurrence relation since there is only one summation term. Therefore all a_n terms are zero except for a_0. Hence

$$y_h = a_0 x^r$$

Therefore the homogeneous solution is

$$y_h(x) = a_0\left(x + O\left(x^8\right)\right)$$

Now we determine the particular solution y_p by solving the balance equation

$$\left(x^{-1+m} m - x^{-1+m}\right) c_0 = x^2$$

For c_0 and x. This results in

$$\begin{aligned} c_0 &= \frac{1}{2} \\ m &= 3 \end{aligned}$$

The particular solution is therefore

$$\begin{aligned} y_p &= \sum_{n=0}^{\infty} c_n x^{n+m} \\ &= \sum_{n=0}^{\infty} c_n x^{n+3} \end{aligned}$$

Where in the above $c_0 = \frac{1}{2}$. The remaining c_n values are found using the same recurrence relation used to find the homogeneous solution but using c_0 in place of a_0 and using $m = 3$ in place of the root of the indicial equation used to find the homogeneous solution. The following are the values of a_n found in terms of the indicial root r. These will be now used to find find c_n by replacing $a_0 = \frac{1}{2}$ and $r = 3$. The following table gives the a_n values found and the corresponding c_n values which will be used to find the particular solution

n	a_n	c_n
0	$a_0 = 1$	$c_0 = \frac{1}{2}$

The particular solution is now found using

$$\begin{aligned} y_p &= x^m \sum_{n=0}^{\infty} c_n x^n \\ &= x^3 \sum_{n=0}^{\infty} c_n x^n \end{aligned}$$

Using the values found above for c_n into the above sum gives

$$y_p = x^3\left(\frac{1}{2}\right)$$

At $x = 0$ the solution above becomes

$$y = \frac{x^3}{2} + O(x^8) + c_1(x + O(x^8))$$

Summary

The solution(s) found are the following

$$y = \frac{x^3}{2} + O(x^8) + c_1(x + O(x^8)) \tag{1}$$

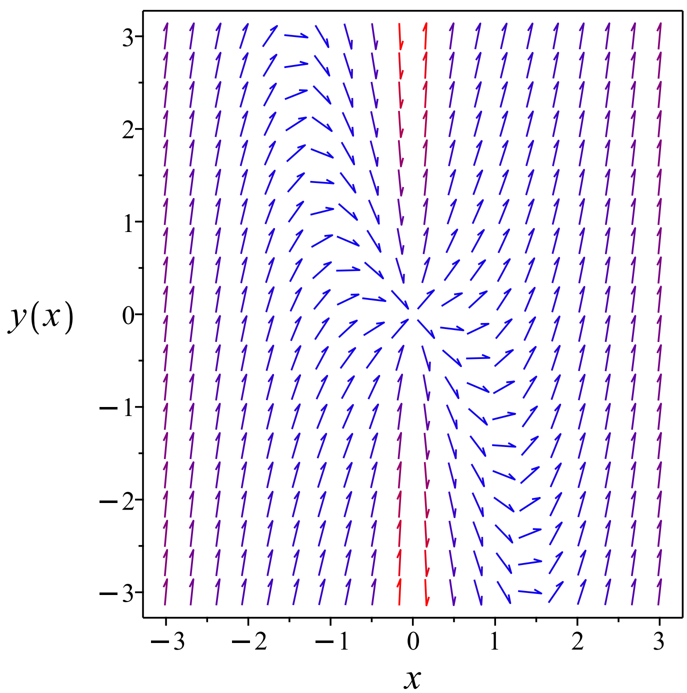

Figure 459: Slope field plot

Verification of solutions

$$y = \frac{x^3}{2} + O(x^8) + c_1(x + O(x^8))$$

Verified OK.

17.17.2 Maple step by step solution

Let's solve

$y' - \frac{y}{x} = x^2$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{y}{x} + x^2$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{y}{x} = x^2$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = \mu(x)\, x^2$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' - \frac{y}{x}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = \frac{1}{x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \mu(x)\, x^2 dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \mu(x)\, x^2 dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x) x^2 dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \frac{1}{x}$

  $y = x\left(\int x dx + c_1\right)$

- Evaluate the integrals on the rhs

  $y = x\left(\frac{x^2}{2} + c_1\right)$

- Simplify

$$y = \frac{x(x^2+2c_1)}{2}$$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 2(c) solving directly.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{y' - \frac{y}{x} = x^2}$$

17.18.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = x^2$$

Hence the ode is

$$y' - \frac{y}{x} = x^2$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x} dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(x^2\right)$$
$$\frac{d}{dx}\left(\frac{y}{x}\right) = \left(\frac{1}{x}\right)\left(x^2\right)$$
$$d\left(\frac{y}{x}\right) = x\,dx$$

Integrating gives

$$\frac{y}{x} = \int x\,dx$$
$$\frac{y}{x} = \frac{x^2}{2} + c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = \frac{1}{2}x^3 + c_1 x$$

Summary
The solution(s) found are the following

$$y = \frac{1}{2}x^3 + c_1 x \tag{1}$$

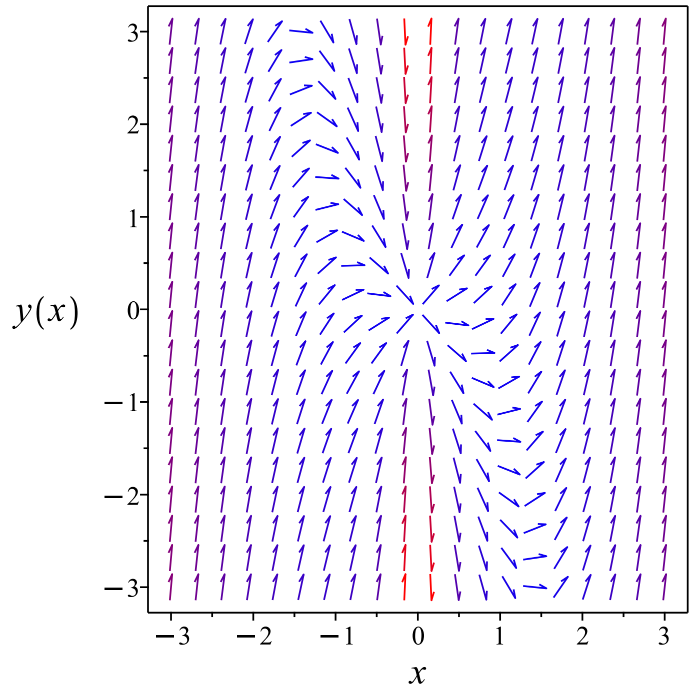

Figure 460: Slope field plot

Verification of solutions

$$y = \frac{1}{2}x^3 + c_1 x$$

Verified OK.

17.18.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u'(x)\,x = x^2$$

Integrating both sides gives

$$\begin{aligned} u(x) &= \int x \, dx \\ &= \frac{x^2}{2} + c_2 \end{aligned}$$

Therefore the solution y is

$$\begin{aligned} y &= xu \\ &= x\left(\frac{x^2}{2} + c_2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x\left(\frac{x^2}{2} + c_2\right) \tag{1}$$

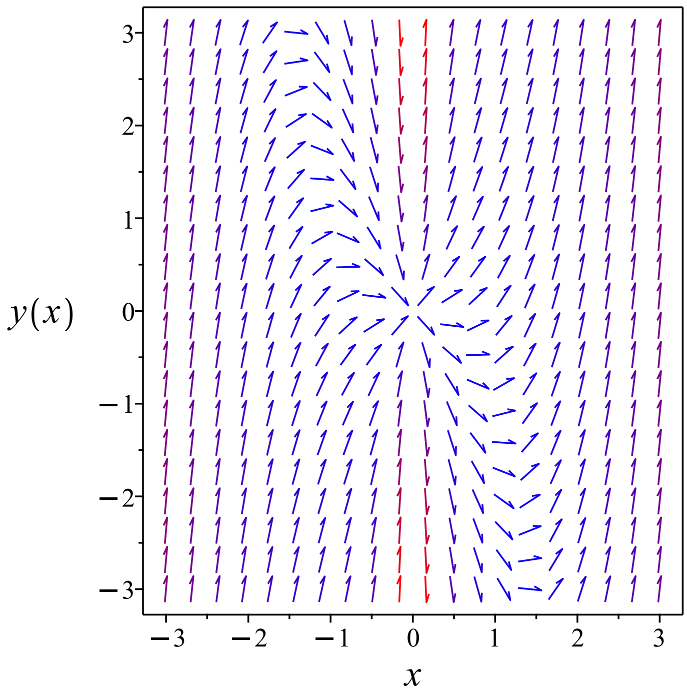

Figure 461: Slope field plot

Verification of solutions

$$y = x\left(\frac{x^2}{2} + c_2\right)$$

Verified OK.

17.18.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{x^3 + y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 417: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= x \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R=x$$

S is found from

$$\begin{aligned}S&=\int\frac{1}{\eta}dy\\&=\int\frac{1}{x}dy\end{aligned}$$

Which results in

$$S=\frac{y}{x}$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR}=\frac{S_x+\omega(x,y)S_y}{R_x+\omega(x,y)R_y} \tag{2}$$

Where in the above R_x,R_y,S_x,S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y)=\frac{x^3+y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x&=1\\R_y&=0\\S_x&=-\frac{y}{x^2}\\S_y&=\frac{1}{x}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR}=x \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x,y in terms of R,S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR}=R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x} = \frac{x^2}{2} + c_1$$

Which simplifies to

$$\frac{y}{x} = \frac{x^2}{2} + c_1$$

Which gives

$$y = \frac{x(x^2 + 2c_1)}{2}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{x^3+y}{x}$ 	$R = x$ $S = \frac{y}{x}$	$\frac{dS}{dR} = R$ 
Summary
The solution(s) found are the following

$$y = \frac{x(x^2 + 2c_1)}{2} \tag{1}$$

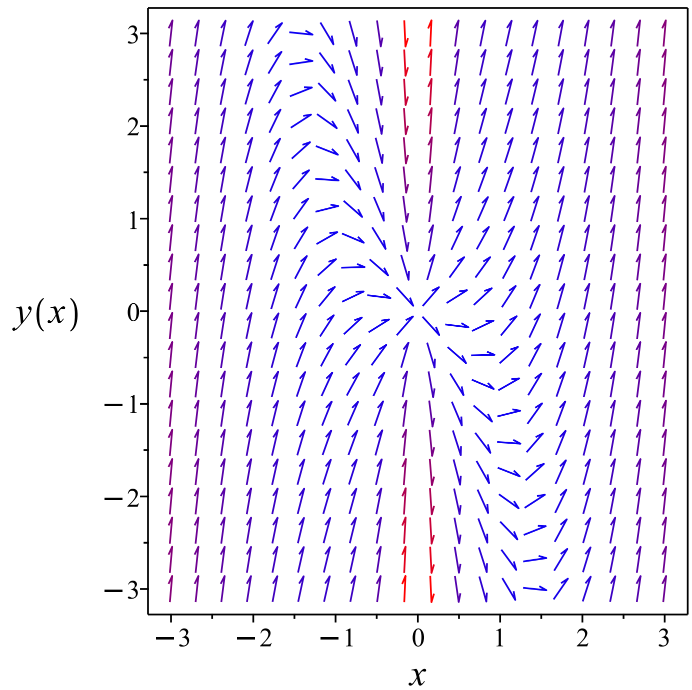

Figure 462: Slope field plot

Verification of solutions

$$y = \frac{x(x^2 + 2c_1)}{2}$$

Verified OK.

17.18.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y&=\left(\frac{y}{x}+x^2\right)\mathrm{d}x\\ \left(-\frac{y}{x}-x^2\right)\mathrm{d}x+\mathrm{d}y&=0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-\frac{y}{x}-x^2\\ N(x,y)&=1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-\frac{y}{x}-x^2\right)\\ &=-\frac{1}{x}\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= 1\left(\left(-\frac{1}{x}\right) - (0)\right) \\
&= -\frac{1}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\frac{1}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-\ln(x)} \\
&= \frac{1}{x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x}\left(-\frac{y}{x} - x^2\right) \\
&= \frac{-x^3 - y}{x^2}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x}(1) \\
&= \frac{1}{x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\frac{-x^3 - y}{x^2}\right) + \left(\frac{1}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{-x^3 - y}{x^2}\,\mathrm{d}x$$
$$\phi = \frac{-x^3 + 2y}{2x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{1}{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{x}$. Therefore equation (4) becomes

$$\frac{1}{x} = \frac{1}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{-x^3 + 2y}{2x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{-x^3 + 2y}{2x}$$

The solution becomes

$$y = \frac{x(x^2 + 2c_1)}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{x(x^2 + 2c_1)}{2} \tag{1}$$

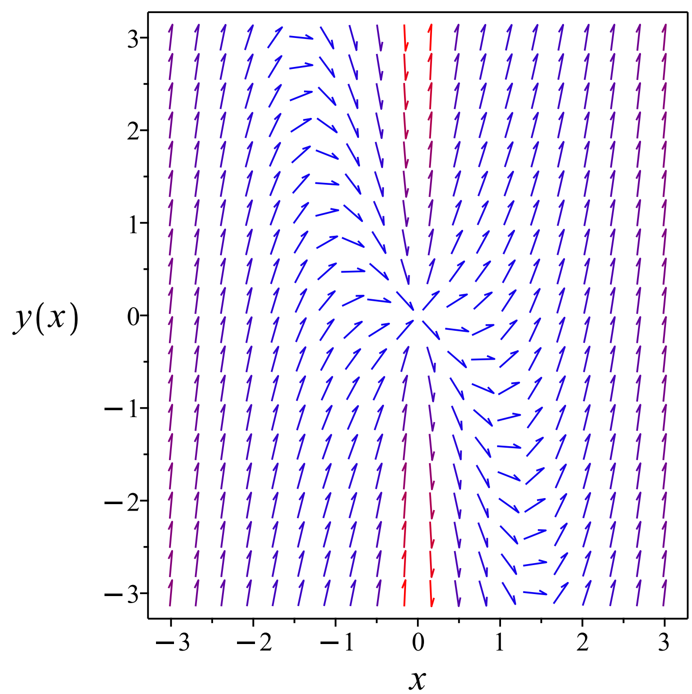

Figure 463: Slope field plot

Verification of solutions

$$y = \frac{x(x^2 + 2c_1)}{2}$$

Verified OK.

Maple gives the following as the ode type

```
[_linear]
```

$$\boxed{y' + \frac{y}{x} = x}$$

17.19.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{1}{x}$$
$$q(x) = x$$

Hence the ode is

$$y' + \frac{y}{x} = x$$

The integrating factor μ is

$$\mu = e^{\int \frac{1}{x}dx}$$
$$= x$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(x)$$
$$\frac{d}{dx}(xy) = (x)(x)$$
$$d(xy) = x^2\,dx$$

Integrating gives

$$xy = \int x^2\,dx$$
$$xy = \frac{x^3}{3} + c_1$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{x^2}{3} + \frac{c_1}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{x^2}{3} + \frac{c_1}{x} \tag{1}$$

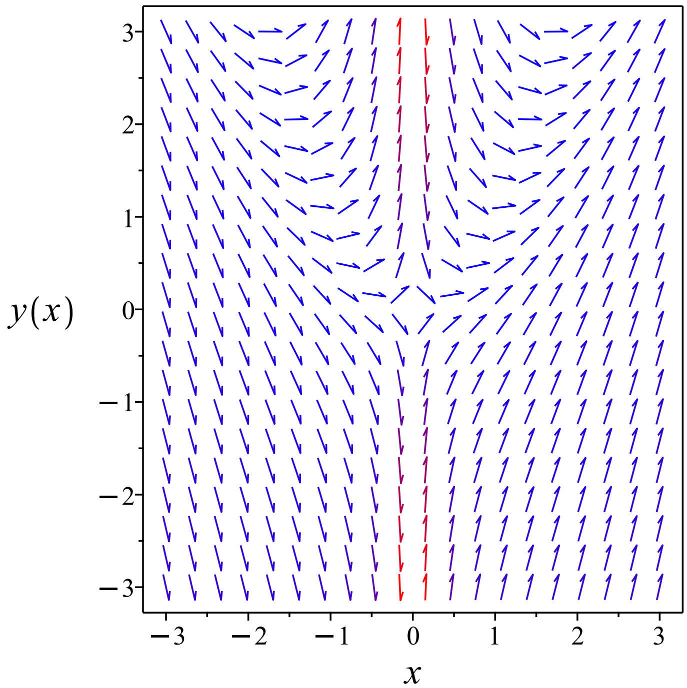

Figure 464: Slope field plot

Verification of solutions

$$y = \frac{x^2}{3} + \frac{c_1}{x}$$

Verified OK.

17.19.2 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{y}{x} + x \tag{1}$$

Which becomes

$$0 = (-x)\,dy + \left(x^2 - y\right) dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + \left(x^2 - y\right) dx = d\left(\frac{1}{3}x^3 - xy\right)$$

Hence (2) becomes

$$0 = d\left(\frac{1}{3}x^3 - xy\right)$$

Integrating both sides gives gives these solutions

$$y = \frac{x^3 + 3c_1}{3x} + c_1$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 + 3c_1}{3x} + c_1 \tag{1}$$

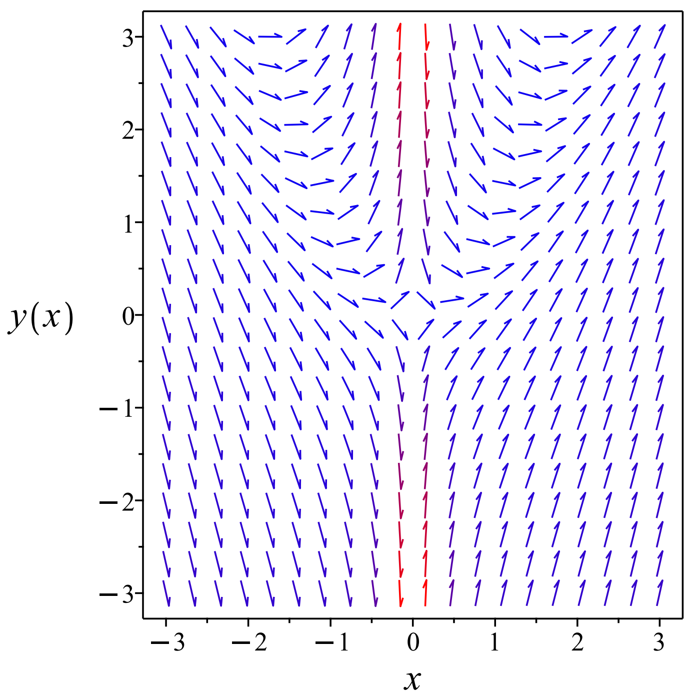

Figure 465: Slope field plot

Verification of solutions

$$y = \frac{x^3 + 3c_1}{3x} + c_1$$

Verified OK.

17.19.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-x^2+y}{x} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 420: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x,y) = 0$$
$$\eta(x,y) = \frac{1}{x} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = xy$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{-x^2 + y}{x}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= y \\
S_y &= x
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x^2 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R^2$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^3}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$xy = \frac{x^3}{3} + c_1$$

Which simplifies to

$$xy = \frac{x^3}{3} + c_1$$

Which gives

$$y = \frac{x^3 + 3c_1}{3x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{-x^2+y}{x}$ 	$R = x$ $S = xy$	$\frac{dS}{dR} = R^2$ 
Summary

The solution(s) found are the following

$$y = \frac{x^3 + 3c_1}{3x} \tag{1}$$

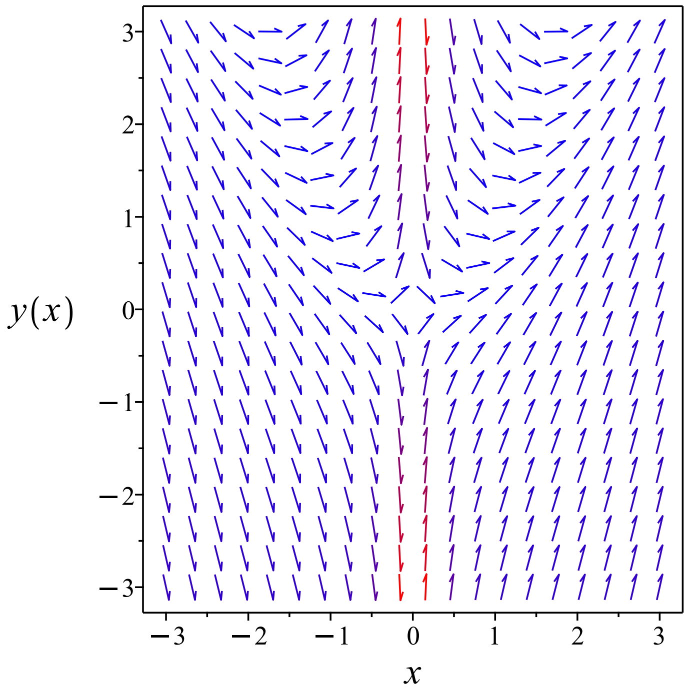

Figure 466: Slope field plot

Verification of solutions

$$y = \frac{x^3 + 3c_1}{3x}$$

Verified OK.

17.19.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(x)\,\mathrm{d}y &= \left(x^2 - y\right)\mathrm{d}x\\ \left(-x^2 + y\right)\mathrm{d}x + (x)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x, y) &= -x^2 + y \\ N(x, y) &= x \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-x^2 + y\right) \\ &= 1 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x) \\ &= 1 \end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -x^2 + y \, \mathrm{d}x$$
$$\phi = -\frac{1}{3}x^3 + xy + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x$. Therefore equation (4) becomes

$$x = x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{1}{3}x^3 + xy + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{1}{3}x^3 + xy$$

The solution becomes

$$y = \frac{x^3 + 3c_1}{3x}$$

Summary
The solution(s) found are the following

$$y = \frac{x^3 + 3c_1}{3x} \tag{1}$$

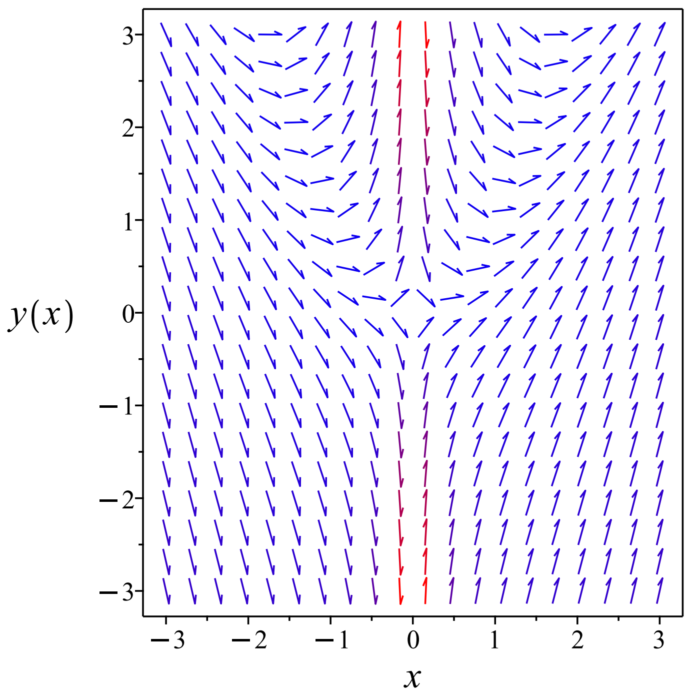

Figure 467: Slope field plot

Verification of solutions

$$y = \frac{x^3 + 3c_1}{3x}$$

Verified OK.

17.19.5 Maple step by step solution

Let's solve

$y' + \frac{y}{x} = x$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{y}{x} + x$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{y}{x} = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' + \frac{y}{x}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)}{x}$

- Solve to find the integrating factor

  $\mu(x) = x$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,x dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,x dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x) x dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = x$

  $y = \frac{\int x^2 dx + c_1}{x}$

- Evaluate the integrals on the rhs

  $y = \frac{\frac{x^3}{3} + c_1}{x}$

- Simplify

$$y = \frac{x^3+3c_1}{3x}$$

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[_quadrature]
```

$$\boxed{y' = \frac{1}{\sqrt{-x^2+1}}}$$

With the expansion point for the power series method at $x = 0$.

17.20.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \left.\frac{df}{dx}\right|_{x_0,y_0} + \frac{x^3}{3!} \left.\frac{d^2 f}{dx^2}\right|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) f \qquad (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y) \qquad (4)\\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned} F_2 &= \frac{d}{dx}(F_1) \\ &= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0 \\ &= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f\right) f \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n\big|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= \frac{1}{\sqrt{-x^2+1}} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= \frac{x}{(-x^2+1)^{\frac{3}{2}}} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= \frac{2x^2+1}{(-x^2+1)^{\frac{5}{2}}} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= \frac{6x^3+9x}{(-x^2+1)^{\frac{7}{2}}} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= \frac{24x^4+72x^2+9}{(-x^2+1)^{\frac{9}{2}}} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= \frac{120x\left(x^4+5x^2+\frac{15}{8}\right)}{(-x^2+1)^{\frac{11}{2}}} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= \frac{720x^6+5400x^4+4050x^2+225}{(-x^2+1)^{\frac{13}{2}}}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= 1 \\
F_1 &= 0 \\
F_2 &= 1 \\
F_3 &= 0 \\
F_4 &= 9 \\
F_5 &= 0 \\
F_6 &= 225
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
y = y(0) + x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + O(x^8)
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x) \\
y' &= \frac{1}{\sqrt{-x^2 + 1}}
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= 0 \\
p(x) &= \frac{1}{\sqrt{-x^2 + 1}}
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Now the ode is normalized by writing it as

$$
y'\sqrt{-x^2 + 1} = 1
$$

Let the solution be represented as power series of the form

$$y=\sum_{n=0}^{\infty}a_n x^n$$

Then

$$y'=\sum_{n=1}^{\infty}n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)\sqrt{-x^2+1}=1 \tag{1}$$

Expanding $\sqrt{-x^2+1}$ as Taylor series around $x=0$ and keeping only the first 8 terms gives

$$\begin{aligned}\sqrt{-x^2+1}&=1-\frac{1}{2}x^2-\frac{1}{8}x^4-\frac{1}{16}x^6-\frac{5}{128}x^8+\dots\\&=1-\frac{1}{2}x^2-\frac{1}{8}x^4-\frac{1}{16}x^6-\frac{5}{128}x^8\end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(1-\frac{1}{2}x^2-\frac{1}{8}x^4-\frac{1}{16}x^6-\frac{5}{128}x^8\right)\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)=1 \tag{1}$$

Expanding the first term in (1) gives

$$1\cdot\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)-\frac{x^2}{2}\cdot\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)-\frac{x^4}{8}\cdot\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)-\frac{x^6}{16}\cdot\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)-\frac{5x^8}{128}\cdot\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right) \tag{1}$$

Which simplifies to

$$\begin{aligned}&\left(\sum_{n=1}^{\infty}n a_n x^{n-1}\right)+\sum_{n=1}^{\infty}\left(-\frac{n\,x^{1+n}a_n}{2}\right)+\sum_{n=1}^{\infty}\left(-\frac{n\,x^{n+3}a_n}{8}\right)\\&+\sum_{n=1}^{\infty}\left(-\frac{n\,x^{n+5}a_n}{16}\right)+\sum_{n=1}^{\infty}\left(-\frac{5n\,x^{n+7}a_n}{128}\right)=1\end{aligned} \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n$$

$$\sum_{n=1}^{\infty} \left(-\frac{n\, x^{1+n} a_n}{2}\right) = \sum_{n=2}^{\infty} \left(-\frac{(n-1)\, a_{n-1} x^n}{2}\right)$$

$$\sum_{n=1}^{\infty} \left(-\frac{n\, x^{n+3} a_n}{8}\right) = \sum_{n=4}^{\infty} \left(-\frac{(n-3)\, a_{n-3} x^n}{8}\right)$$

$$\sum_{n=1}^{\infty} \left(-\frac{n\, x^{n+5} a_n}{16}\right) = \sum_{n=6}^{\infty} \left(-\frac{(n-5)\, a_{n-5} x^n}{16}\right)$$

$$\sum_{n=1}^{\infty} \left(-\frac{5n\, x^{n+7} a_n}{128}\right) = \sum_{n=8}^{\infty} \left(-\frac{5(n-7)\, a_{n-7} x^n}{128}\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n\right) + \sum_{n=2}^{\infty} \left(-\frac{(n-1)\, a_{n-1} x^n}{2}\right) + \sum_{n=4}^{\infty} \left(-\frac{(n-3)\, a_{n-3} x^n}{8}\right) + \sum_{n=6}^{\infty} \left(-\frac{(n-5)\, a_{n-5} x^n}{16}\right) + \sum_{n=8}^{\infty} \left(-\frac{5(n-7)\, a_{n-7} x^n}{128}\right) = 1 \tag{3}$$

$n = 0$ gives

$$(a_1)\, 1 = 1$$
$$a_1 = 1$$

Or

$$a_1 = 1$$

$n = 2$ gives

$$3a_3 - \frac{a_1}{2} = 0$$

Which after substituting earlier equations, simplifies to

$$3a_3 - \frac{1}{2} = 0$$

Or

$$a_3 = \frac{1}{6}$$

$n = 3$ gives

$$4a_4 - a_2 = 0$$

Which after substituting earlier equations, simplifies to

$$4a_4 = 0$$

Or

$$a_4 = 0$$

$n = 4$ gives

$$5a_5 - \frac{3a_3}{2} - \frac{a_1}{8} = 0$$

Which after substituting earlier equations, simplifies to

$$5a_5 - \frac{3}{8} = 0$$

Or

$$a_5 = \frac{3}{40}$$

$n = 5$ gives

$$6a_6 - 2a_4 - \frac{a_2}{4} = 0$$

Which after substituting earlier equations, simplifies to

$$6a_6 = 0$$

Or

$$a_6 = 0$$

$n = 6$ gives

$$7a_7 - \frac{5a_5}{2} - \frac{3a_3}{8} - \frac{a_1}{16} = 0$$

Which after substituting earlier equations, simplifies to

$$7a_7 - \frac{5}{16} = 0$$

Or

$$a_7 = \frac{5}{112}$$

$n = 7$ gives

$$8a_8 - 3a_6 - \frac{a_4}{2} - \frac{a_2}{8} = 0$$

Which after substituting earlier equations, simplifies to

$$8a_8 = 0$$

Or

$$a_8 = 0$$

For $8 \leq n$, the recurrence equation is

$$\left((1+n)\, a_{1+n} - \frac{(n-1)\, a_{n-1}}{2} - \frac{(n-3)\, a_{n-3}}{8} - \frac{(n-5)\, a_{n-5}}{16} - \frac{5(n-7)\, a_{n-7}}{128}\right) x^n = 1 \tag{4}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + x + \frac{1}{6}x^3 + \frac{3}{40}x^5 + \frac{5}{112}x^7 + \dots$$

Collecting terms, the solution becomes

$$y = a_0 + x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + O(x^8) \tag{3}$$

Summary

The solution(s) found are the following

$$y = y(0) + x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + O(x^8) \tag{1}$$

$$y = c_1 + x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + O(x^8) \tag{2}$$

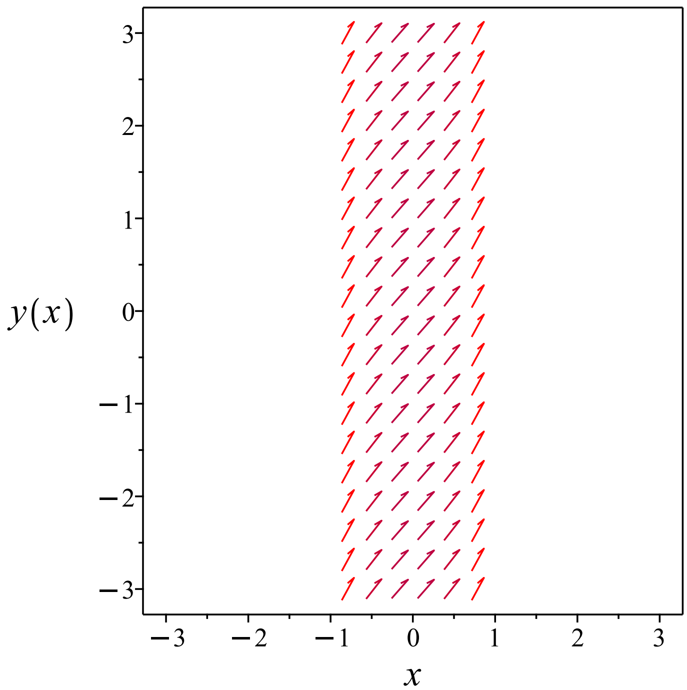

Figure 468: Slope field plot

Verification of solutions

$$y = y(0) + x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + O(x^8)$$

Verified OK.

$$y = c_1 + x + \frac{x^3}{6} + \frac{3x^5}{40} + \frac{5x^7}{112} + O(x^8)$$

Verified OK.

17.20.2 Maple step by step solution

Let's solve

$y'\sqrt{-x^2+1} = 1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $y' = \frac{1}{\sqrt{-x^2+1}}$

- Integrate both sides with respect to x

  $\int y' dx = \int \frac{1}{\sqrt{-x^2+1}} dx + c_1$

- Evaluate integral

  $y = \arcsin(x) + c_1$

- Solve for y

  $y = \arcsin(x) + c_1$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{y' - y = 1}$$

With the expansion point for the power series method at $x = 0$.

17.21.1 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor

series

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0,y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0,y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \qquad (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f \qquad (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f \qquad (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y) \qquad (4) \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n = 1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0) \\
&= \frac{\partial}{\partial x} F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0 \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n = 2$

$$\begin{aligned}
F_2 &= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y} \right) F_0 \\
&= \frac{\partial}{\partial x} \left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \right) + \frac{\partial}{\partial y} \left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f \right) f \\
&= \frac{\partial}{\partial x} \left(\frac{df}{dx} \right) + \frac{\partial}{\partial y} \left(\frac{df}{dx} \right) f
\end{aligned}$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} F_n|_{x_0,y_0} \tag{6}$$

Hence

$$
\begin{aligned}
F_0 &= 1 + y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= 1 + y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= 1 + y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= 1 + y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= 1 + y \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= 1 + y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= 1 + y
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = y(0)$ gives

$$
\begin{aligned}
F_0 &= 1 + y(0) \\
F_1 &= 1 + y(0) \\
F_2 &= 1 + y(0) \\
F_3 &= 1 + y(0) \\
F_4 &= 1 + y(0) \\
F_5 &= 1 + y(0) \\
F_6 &= 1 + y(0)
\end{aligned}
$$

Substituting all the above in (6) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) \\
&+ x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)
\end{aligned}
$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$
\begin{aligned}
y' + q(x)y &= p(x) \\
y' - y &= 1
\end{aligned}
$$

Where

$$
\begin{aligned}
q(x) &= -1 \\
p(x) &= 1
\end{aligned}
$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This

is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = 1 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 1 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 1 \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+1) a_{n+1} - a_n) x^n = 1 \tag{4}$$

For $n = 0$ the recurrence equation gives

$$(a_1 - a_0) 1 = 1$$
$$a_1 - a_0 = 1$$

Which after substituting the earlier terms found becomes

$$a_1 = 1 + a_0$$

For $n = 1$ the recurrence equation gives

$$(2a_2 - a_1)\, x = 0$$
$$2a_2 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{1}{2} + \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$(3a_3 - a_2)\, x^2 = 0$$
$$3a_3 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{6} + \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$(4a_4 - a_3)\, x^3 = 0$$
$$4a_4 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24} + \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$(5a_5 - a_4)\, x^4 = 0$$
$$5a_5 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{120} + \frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(6a_6 - a_5)\, x^5 &= 0 \\ 6a_6 - a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1}{720} + \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(7a_7 - a_6)\, x^6 &= 0 \\ 7a_7 - a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{5040} + \frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(8a_8 - a_7)\, x^7 &= 0 \\ 8a_8 - a_7 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{40320} + \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + (1 + a_0)\, x + \left(\frac{1}{2} + \frac{a_0}{2}\right) x^2 + \left(\frac{1}{6} + \frac{a_0}{6}\right) x^3 + \left(\frac{1}{24} + \frac{a_0}{24}\right) x^4 + \left(\frac{1}{120} + \frac{a_0}{120}\right) x^5 + \left(\frac{1}{720} + \frac{a_0}{720}\right) x^6 + \left(\frac{1}{5040} + \frac{a_0}{5040}\right) x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) a_0 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8) \tag{3}$$

Summary

The solution(s) found are the following

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8) \tag{1}$$

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8) \tag{2}$$

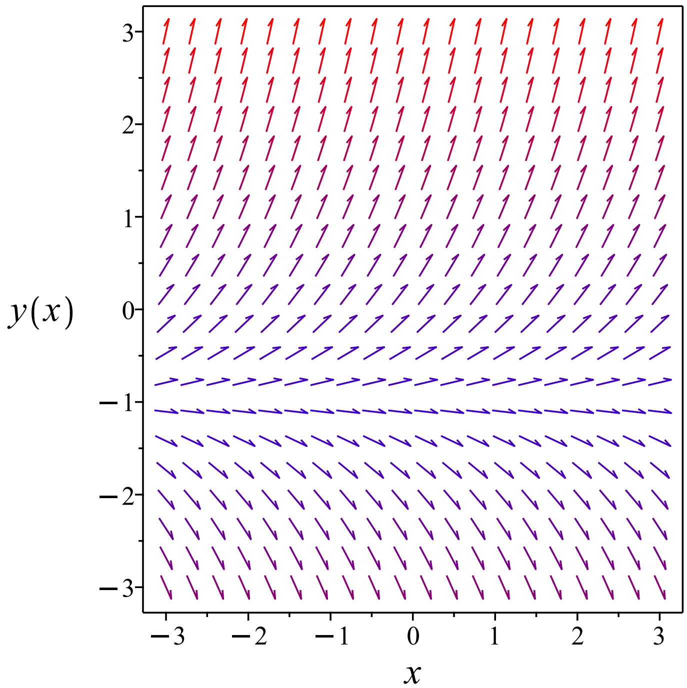

Figure 469: Slope field plot

Verification of solutions

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) y(0) + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)$$

Verified OK.

$$y = \left(1 + x + \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{720}x^6 + \frac{1}{5040}x^7\right) c_1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)$$

Verified OK.

17.21.2 Maple step by step solution

Let's solve

$y' - y = 1$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{1+y} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'}{1+y}dx = \int 1dx + c_1$

- Evaluate integral

  $\ln(1+y) = x + c_1$

- Solve for y

  $y = e^{x+c_1} - 1$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.2. Series Solutions of First-Order Differential Equations Page 162
Problem number: 5 solved using series.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup", "first order ode series method. Ordinary point", "first order ode series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + y' = x}$$

With initial conditions

$$[y(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

17.22.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = x$$

Hence the ode is

$$y + y' = x$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

17.22.2 Solving as series ode

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving first order ode. Let

$$y' = f(x, y)$$

Where $f(x, y)$ is analytic at expansion point x_0. We can always shift to $x_0 = 0$ if x_0 is not zero. So from now we assume $x_0 = 0$. Assume also that $y(x_0) = y_0$. Using Taylor series

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y''(x_0) + \cdots \\
&= y_0 + xf + \frac{x^2}{2} \frac{df}{dx}\bigg|_{x_0, y_0} + \frac{x^3}{3!} \frac{d^2 f}{dx^2}\bigg|_{x_0, y_0} + \cdots \\
&= y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f && (1) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y)$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y) \qquad (4)\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) F_0 \qquad (5)
\end{aligned}
$$

For example, for $n=1$ we see that

$$
\begin{aligned}
F_1 &= \frac{d}{dx}(F_0)\\
&= \frac{\partial}{\partial x}F_0 + \left(\frac{\partial F_0}{\partial y}\right) F_0\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} f
\end{aligned}
$$

Which is (1). And when $n=2$

$$
\begin{aligned}
F_2 &= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right) F_0\\
&= \frac{\partial}{\partial x}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) + \frac{\partial}{\partial y}\left(\frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}f\right) f\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) f
\end{aligned}
$$

Which is (2) and so on. Therefore (4,5) can be used from now on along with

$$
y(x) = y_0 + \sum_{n=0}^{\infty} \frac{x^{n+1}}{(n+1)!} F_n|_{x_0,y_0} \qquad (6)
$$

Hence

$$
\begin{aligned}
F_0 &= x - y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} F_0 \\
&= -x + y + 1 \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} F_1 \\
&= x - y - 1 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} F_2 \\
&= -x + y + 1 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} F_3 \\
&= x - y - 1 \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} F_4 \\
&= -x + y + 1 \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} F_5 \\
&= x - y - 1
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x(0) = 0$ and $y(0) = 0$ gives

$$\begin{aligned} F_0 &= 0 \\ F_1 &= 1 \\ F_2 &= -1 \\ F_3 &= 1 \\ F_4 &= -1 \\ F_5 &= 1 \\ F_6 &= -1 \end{aligned}$$

Substituting all the above in (6) and simplifying gives the solution as

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = y(0)$$

Therefore the solution becomes

$$y = \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7$$

Hence the solution can be written as

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

which simplifies to

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

Since $x = 0$ is also an ordinary point, then standard power series can also be used. Writing the ODE as

$$\begin{aligned} y' + q(x)y &= p(x) \\ y + y' &= x \end{aligned}$$

Where

$$\begin{aligned} q(x) &= 1 \\ p(x) &= x \end{aligned}$$

Next, the type of the expansion point $x = 0$ is determined. This point can be an ordinary point, a regular singular point (also called removable singularity), or irregular singular point (also called non-removable singularity or essential singularity). When $x = 0$ is an ordinary point, then the standard power series is used. If the point is a regular singular point, Frobenius series is used instead. Irregular singular point requires more advanced methods (asymptotic methods) and is not supported now. Hopefully this will be added in the future. $x = 0$ is called an ordinary point $q(x)$ has a Taylor series expansion around the point $x = 0$. $x = 0$ is called a regular singular point if $q(x)$ is not not analytic at $x = 0$ but $xq(x)$ has Taylor series expansion. And finally, $x = 0$ is an irregular singular point if the point is not ordinary and not regular singular. This is the most complicated case. Now the expansion point $x = 0$ is checked to see if it is an ordinary point or not. Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = x \tag{1}$$

Expanding x as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned} x &= x + \dots \\ &= x \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = x \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) = x \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+1) a_{n+1} + a_n) x^n = x \tag{4}$$

For $n = 0$ the recurrence equation gives

$$\begin{aligned}(a_1 + a_0) 1 &= 0 \\ a_1 + a_0 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_1 = -a_0$$

For $n = 1$ the recurrence equation gives

$$\begin{aligned}(2a_2 + a_1) x &= x \\ 2a_2 + a_1 &= 1\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_2 = \frac{1}{2} + \frac{a_0}{2}$$

For $n = 2$ the recurrence equation gives

$$\begin{aligned}(3a_3 + a_2) x^2 &= 0 \\ 3a_3 + a_2 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{1}{6} - \frac{a_0}{6}$$

For $n = 3$ the recurrence equation gives

$$\begin{aligned}(4a_4 + a_3)\, x^3 &= 0\\ 4a_4 + a_3 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24} + \frac{a_0}{24}$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(5a_5 + a_4)\, x^4 &= 0\\ 5a_5 + a_4 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{1}{120} - \frac{a_0}{120}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(6a_6 + a_5)\, x^5 &= 0\\ 6a_6 + a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1}{720} + \frac{a_0}{720}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(7a_7 + a_6)\, x^6 &= 0\\ 7a_7 + a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{1}{5040} - \frac{a_0}{5040}$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(8a_8 + a_7)\, x^7 &= 0\\ 8a_8 + a_7 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{40320} + \frac{a_0}{40320}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n\\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned}y = a_0 - a_0 x + \left(\frac{1}{2} + \frac{a_0}{2}\right) x^2 + \left(-\frac{1}{6} - \frac{a_0}{6}\right) x^3 + \left(\frac{1}{24} + \frac{a_0}{24}\right) x^4\\ + \left(-\frac{1}{120} - \frac{a_0}{120}\right) x^5 + \left(\frac{1}{720} + \frac{a_0}{720}\right) x^6 + \left(-\frac{1}{5040} - \frac{a_0}{5040}\right) x^7 + \dots\end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned}y = &\left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) a_0\\ &+ \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$y(0) = a_0$$

Therefore the solution in Eq(3) now can be written as

$$y = \left(1 - x + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7\right) y(0) \\ + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

Now we substitute the given initial conditions in the above to solve for $y(0)$. Solving for $y(0)$ from initial conditions gives

$$y(0) = 0$$

Therefore the solution becomes

$$y = \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{5040}x^7$$

Hence the solution can be written as

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

which simplifies to

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

Summary

The solution(s) found are the following

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8) \tag{1}$$

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8) \tag{2}$$

Verification of solutions

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

Verified OK.

$$y = \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)$$

Verified OK.

17.22.3 Maple step by step solution

Let's solve

$[y + y' = x, y(0) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = x - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y + y' = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\,(y + y') = \mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y + y') = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)$

- Solve to find the integrating factor

  $\mu(x) = e^x$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,x dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,x dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x) x dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = e^x$

  $y = \frac{\int x\, e^x dx + c_1}{e^x}$

- Evaluate the integrals on the rhs

  $y = \frac{(x-1) e^x + c_1}{e^x}$

- Simplify

  $y = x - 1 + c_1 e^{-x}$

- Use initial condition $y(0) = 0$

  $0 = -1 + c_1$
- Solve for c_1

  $c_1 = 1$
- Substitute $c_1 = 1$ into general solution and simplify

  $y = x - 1 + e^{-x}$
- Solution to the IVP

  $y = x - 1 + e^{-x}$

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{y + y' = x}$$

With initial conditions

$$[y(0) = 0]$$

17.23.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = 1$$
$$q(x) = x$$

Hence the ode is

$$y + y' = x$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

17.23.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int 1dx} \\ &= e^x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)(x) \\ \frac{d}{dx}(y\,e^x) &= (e^x)(x) \\ d(y\,e^x) &= (x\,e^x)\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}y\,e^x &= \int x\,e^x\,dx \\ y\,e^x &= (x-1)\,e^x + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = e^x$ results in

$$y = e^{-x}(x-1)\,e^x + c_1 e^{-x}$$

which simplifies to

$$y = x - 1 + c_1 e^{-x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -1 + c_1$$

$$c_1 = 1$$

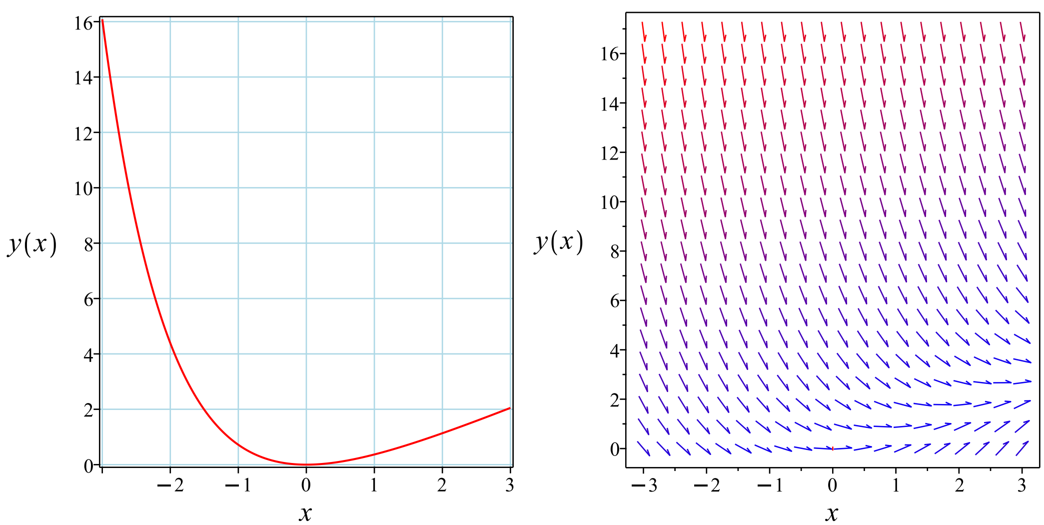
Substituting c_1 found above in the general solution gives

$$y = x - 1 + e^{-x}$$

Summary

The solution(s) found are the following

$$y = x - 1 + e^{-x} \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = x - 1 + e^{-x}$$

17.23.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= x - y \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 426: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \mathrm{e}^{-x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\mathrm{e}^{-x}} dy
\end{aligned}
$$

Which results in

$$
S = y\,\mathrm{e}^{x}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = x - y
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= y\,\mathrm{e}^{x} \\
S_y &= \mathrm{e}^{x}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = x\,\mathrm{e}^{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R\,\mathrm{e}^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = (R-1)\,\mathrm{e}^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{x} y = (x-1)\,\mathrm{e}^{x} + c_1$$

Which simplifies to

$$\mathrm{e}^{x} y = (x-1)\,\mathrm{e}^{x} + c_1$$

Which gives

$$y = \left(x\,\mathrm{e}^{x} - \mathrm{e}^{x} + c_1\right)\mathrm{e}^{-x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = x - y$ 	$R = x$ $S = y\,\mathrm{e}^{x}$	$\frac{dS}{dR} = R\,\mathrm{e}^{R}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -1 + c_1$$

$$c_1 = 1$$

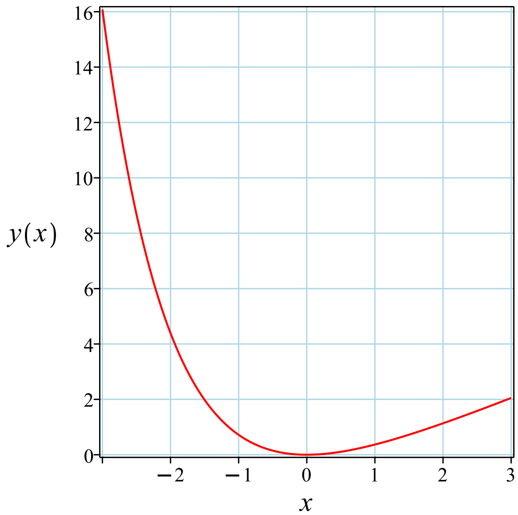
Substituting c_1 found above in the general solution gives

$$y = x - 1 + \mathrm{e}^{-x}$$

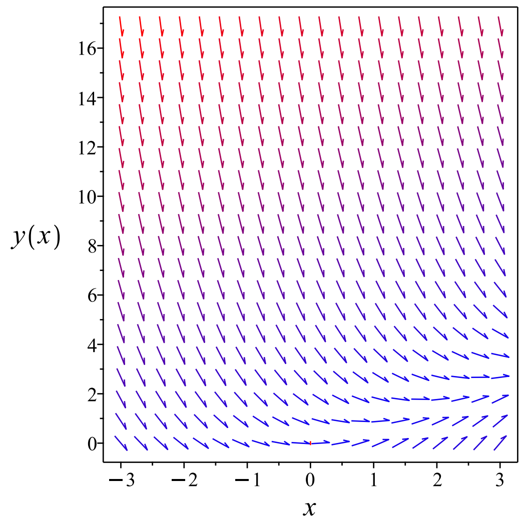
<u>Summary</u>

The solution(s) found are the following

$$y = x - 1 + \mathrm{e}^{-x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = x - 1 + \mathrm{e}^{-x}$$

Verified OK.

17.23.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\mathrm{d}y &= (x - y)\,\mathrm{d}x\\ (-x + y)\,\mathrm{d}x + \mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x + y\\ N(x, y) &= 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x + y)\\ &= 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(1)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= 1((1) - (0))\\ &= 1\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int 1 \, \mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{x} \\ &= \mathrm{e}^{x}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M \\ &= \mathrm{e}^{x}(-x+y) \\ &= -\mathrm{e}^{x}(x-y)\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N \\ &= \mathrm{e}^{x}(1) \\ &= \mathrm{e}^{x}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ \left(-\mathrm{e}^{x}(x-y)\right) + \left(\mathrm{e}^{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int \overline{M} \, \mathrm{d}x \\ \int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\mathrm{e}^{x}(x-y) \, \mathrm{d}x\end{aligned}$$

$$\phi = -(x-y-1)\,\mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial\phi}{\partial y} = e^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial\phi}{\partial y} = e^{x}$. Therefore equation (4) becomes

$$e^{x} = e^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -(x - y - 1)\, e^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -(x - y - 1)\, e^{x}$$

The solution becomes

$$y = (x\, e^{x} - e^{x} + c_1)\, e^{-x}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$0 = -1 + c_1$$

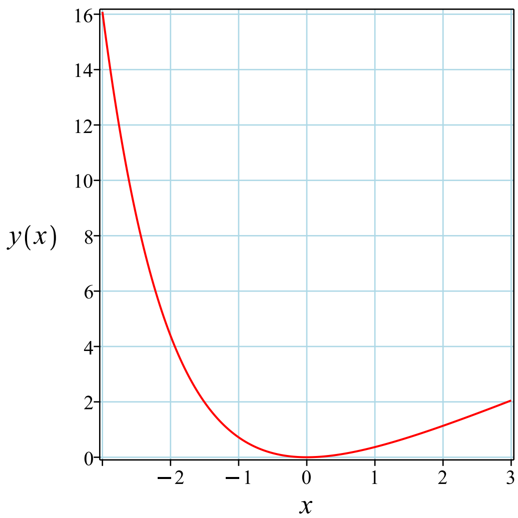
$$c_1 = 1$$

Substituting c_1 found above in the general solution gives

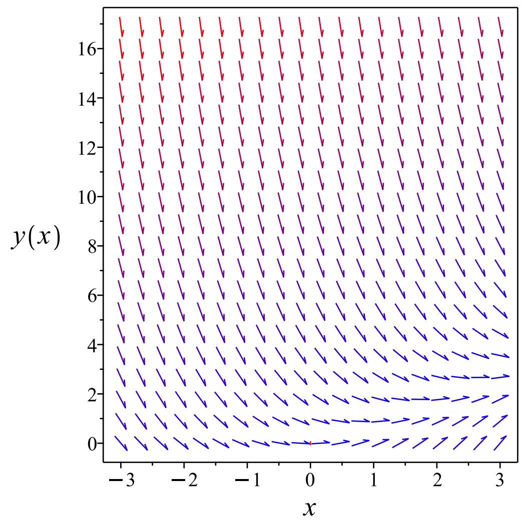
$$y = x - 1 + e^{-x}$$

Summary
The solution(s) found are the following

$$y = x - 1 + e^{-x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = x - 1 + e^{-x}$$

Verified OK.

17.23.5 Maple step by step solution

Let's solve

$[y + y' = x, y(0) = 0]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = x - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y + y' = x$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$\mu(x)\,(y+y') = \mu(x)\,x$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\,(y+y') = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \mu(x)$

- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int \mu(x)\,x dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int \mu(x)\,x dx + c_1$

- Solve for y

  $y = \frac{\int \mu(x)x dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \mathrm{e}^{x}$

  $y = \frac{\int x\,\mathrm{e}^{x} dx + c_1}{\mathrm{e}^{x}}$

- Evaluate the integrals on the rhs

  $y = \frac{(x-1)\mathrm{e}^{x} + c_1}{\mathrm{e}^{x}}$

- Simplify

  $y = x - 1 + c_1\mathrm{e}^{-x}$

- Use initial condition $y(0) = 0$

  $0 = -1 + c_1$

- Solve for c_1

  $c_1 = 1$

- Substitute $c_1 = 1$ into general solution and simplify

  $y = x - 1 + \mathrm{e}^{-x}$

- Solution to the IVP

  $y = x - 1 + \mathrm{e}^{-x}$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.3. Second-Order Linear Equations: Ordinary Points. Page 169
Problem number: 1(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' + xy' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left. \frac{d^n f}{dx^n} \right|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (647) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (648) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4) \\
F_1 &= \frac{df}{dx} \\
&= \frac{dF_0}{dx} \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5) \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\
&= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\
&\vdots \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -y - xy' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= x^2 y' + xy - 2y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -y' x^3 - y x^2 + 5xy' + 3y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 - 9x^2 + 8\right) y' + yx\left(x^2 - 7\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-x^5 + 14x^3 - 33x\right) y' - y\left(x^4 - 12x^2 + 15\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(x^6 - 20x^4 + 87x^2 - 48\right) y' + yx\left(x^4 - 18x^2 + 57\right) \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(-x^7 + 27x^5 - 185x^3 + 279x\right) y' - y\left(x^2 - 7\right) \left(x^4 - 18x^2 + 15\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -2y'(0) \\
F_2 &= 3y(0) \\
F_3 &= 8y'(0) \\
F_4 &= -15y(0) \\
F_5 &= -48y'(0) \\
F_6 &= 105y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6 + \frac{1}{384}x^8\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) y'(0) + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=0}^{\infty} a_n x^n\right) - x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n}{n+2} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{48}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{105}$$

For $n = 6$ the recurrence equation gives

$$56a_8 + 7a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{384}$$

For $n = 7$ the recurrence equation gives

$$72a_9 + 8a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{a_1}{945}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 - \frac{1}{3} a_1 x^3 + \frac{1}{8} a_0 x^4 + \frac{1}{15} a_1 x^5 - \frac{1}{48} a_0 x^6 - \frac{1}{105} a_1 x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) a_0 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) a_1 + O(x^8) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) c_2 + O(x^8)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6 + \frac{1}{384}x^8\right) y(0) \\ & + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) y'(0) + O(x^8) \end{aligned} \quad (1)$$

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) c_2 + O(x^8) \quad (2)$$

Verification of solutions

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6 + \frac{1}{384}x^8\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) y'(0) + O(x^8)$$

Verified OK.

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) c_2 + O(x^8)$$

Verified OK.

18.1.1 Maple step by step solution

Let's solve

$y'' = -y - xy'$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + xy' + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} (a_{k+2}(k+2)(k+1) + a_k(k+1))\, x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+1)(a_{k+2}(k+2) + a_k) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+2}\right]$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\ &= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y_0'} \end{aligned}$$

But

$$\begin{aligned} \frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (650) \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (651) \\ \frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\ \frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\ &= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\ &\vdots \end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= y' - xy \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= (1-x)\, y' - (1+x)\, y \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= (-1-2x)\, y' + y\left(x^2 - x - 1\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^2 - 3x - 4\right) y' + y\left(2x^2 + 3x - 1\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(3x^2 + 2x - 8\right) y' - y\left(x^3 - 3x^2 - 8x - 3\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(-x^3 + 6x^2 + 16x - 3\right) y' - 3\left(x^3 + \frac{5}{3}x^2 - \frac{14}{3}x - \frac{8}{3}\right) y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(-4x^3 - 2x^2 + 42x + 21\right) y' + y\left(x^4 - 6x^3 - 25x^2 - 7x + 14\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y'(0) \\
F_1 &= -y(0) + y'(0) \\
F_2 &= -y'(0) - y(0) \\
F_3 &= -4y'(0) - y(0) \\
F_4 &= -8y'(0) + 3y(0) \\
F_5 &= -3y'(0) + 8y(0) \\
F_6 &= 21y'(0) + 14y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{240}x^6 + \frac{1}{630}x^7 + \frac{1}{2880}x^8\right) y(0) \\
&+ \left(x + \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{30}x^5 - \frac{1}{90}x^6 - \frac{1}{1680}x^7 + \frac{1}{1920}x^8\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - x\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \sum_{n=1}^{\infty} \left(-n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n} a_n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n$$

$$\sum_{n=1}^{\infty} \left(-n a_n x^{n-1}\right) = \sum_{n=0}^{\infty} \left(-(1+n) a_{1+n} x^n\right)$$

$$\sum_{n=0}^{\infty} x^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n\right) + \sum_{n=0}^{\infty} \left(-(1+n) a_{1+n} x^n\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^n\right) = 0 \quad (3)$$

$n = 0$ gives

$$2a_2 - a_1 = 0$$

$$a_2 = \frac{a_1}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2) a_{n+2}(1+n) - (1+n) a_{1+n} + a_{n-1} = 0 \quad (4)$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{n a_{1+n} + a_{1+n} - a_{n-1}}{(n+2)(1+n)} \\ &= \frac{a_{1+n}}{n+2} - \frac{a_{n-1}}{(n+2)(1+n)} \end{aligned} \quad (5)$$

For $n = 1$ the recurrence equation gives

$$6a_3 - 2a_2 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{6} - \frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 - 3a_3 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_1}{24} - \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$20a_5 - 4a_4 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_1}{30} - \frac{a_0}{120}$$

For $n = 4$ the recurrence equation gives

$$30a_6 - 5a_5 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_1}{90} + \frac{a_0}{240}$$

For $n = 5$ the recurrence equation gives

$$42a_7 - 6a_6 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{1680} + \frac{a_0}{630}$$

For $n = 6$ the recurrence equation gives

$$56a_8 - 7a_7 + a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_1}{1920} + \frac{a_0}{2880}$$

For $n = 7$ the recurrence equation gives

$$72a_9 - 8a_8 + a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{11a_1}{51840} - \frac{a_0}{51840}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x + \frac{a_1 x^2}{2} + \left(\frac{a_1}{6} - \frac{a_0}{6}\right) x^3 + \left(-\frac{a_1}{24} - \frac{a_0}{24}\right) x^4 \\ + \left(-\frac{a_1}{30} - \frac{a_0}{120}\right) x^5 + \left(-\frac{a_1}{90} + \frac{a_0}{240}\right) x^6 + \left(-\frac{a_1}{1680} + \frac{a_0}{630}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = \left(1 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{240}x^6 + \frac{1}{630}x^7\right) a_0 \\ + \left(x + \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{30}x^5 - \frac{1}{90}x^6 - \frac{1}{1680}x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$\begin{aligned} y = \left(1 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{240}x^6 + \frac{1}{630}x^7\right) c_1 \\ + \left(x + \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{30}x^5 - \frac{1}{90}x^6 - \frac{1}{1680}x^7\right) c_2 + O(x^8) \end{aligned}$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = &\left(1-\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{120}x^{5}+\frac{1}{240}x^{6}+\frac{1}{630}x^{7}+\frac{1}{2880}x^{8}\right)y(0) \\
&+\left(x+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{30}x^{5}-\frac{1}{90}x^{6}-\frac{1}{1680}x^{7}+\frac{1}{1920}x^{8}\right)y'(0)+O(x^{8})
\end{aligned} \tag{1}
$$

$$
\begin{aligned}
y = &\left(1-\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{120}x^{5}+\frac{1}{240}x^{6}+\frac{1}{630}x^{7}\right)c_1 \\
&+\left(x+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{30}x^{5}-\frac{1}{90}x^{6}-\frac{1}{1680}x^{7}\right)c_2+O(x^{8})
\end{aligned} \tag{2}
$$

Verification of solutions

$$
\begin{aligned}
y = &\left(1-\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{120}x^{5}+\frac{1}{240}x^{6}+\frac{1}{630}x^{7}+\frac{1}{2880}x^{8}\right)y(0) \\
&+\left(x+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{30}x^{5}-\frac{1}{90}x^{6}-\frac{1}{1680}x^{7}+\frac{1}{1920}x^{8}\right)y'(0)+O(x^{8})
\end{aligned}
$$

Verified OK.

$$
\begin{aligned}
y = &\left(1-\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{120}x^{5}+\frac{1}{240}x^{6}+\frac{1}{630}x^{7}\right)c_1 \\
&+\left(x+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}-\frac{1}{30}x^{5}-\frac{1}{90}x^{6}-\frac{1}{1680}x^{7}\right)c_2+O(x^{8})
\end{aligned}
$$

Verified OK.

18.2.1 Maple step by step solution

Let's solve

$y'' = y' - xy$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - y' + xy = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- Convert $x \cdot y$ to series expansion

  $$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$$

- Shift index using $k->k-1$

  $$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^k$$

- Convert y' to series expansion

  $$y' = \sum_{k=1}^{\infty} a_k k \, x^{k-1}$$

- Shift index using $k->k+1$

  $$y' = \sum_{k=0}^{\infty} a_{k+1}(k+1) \, x^k$$

- Convert y'' to series expansion

  $$y'' = \sum_{k=2}^{\infty} a_k k(k-1) \, x^{k-2}$$

- Shift index using $k->k+2$

  $$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2) \, (k+1) \, x^k$$

  Rewrite ODE with series expansions

  $$2a_2 - a_1 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a_{k+1}(k+1) + a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

  $$2a_2 - a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$(k^2 + 3k + 2)\, a_{k+2} - a_{k+1} k + a_{k-1} - a_{k+1} = 0$$

- Shift index using $k->k+1$

  $$\left((k+1)^2 + 3k + 5\right) a_{k+3} - a_{k+2}(k+1) + a_k - a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = \frac{k a_{k+2} - a_k + 2a_{k+2}}{k^2 + 5k + 6}, 2a_2 - a_1 = 0\right]$$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.3. Second-Order Linear Equations: Ordinary Points. Page 169
Problem number: 1(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 2xy' - y = x}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\ &= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0} \end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (653)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (654)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{align*}
F_0 &= f(x,y,y') \tag{4}\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{5}\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \tag{6}
\end{align*}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -2xy' + y + x \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= 4x^2 y' - 2xy - 2x^2 - y' + 1 \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(-8x^3 + 8x\right) y' + 4x^3 + 4yx^2 - 5x - 3y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(16x^4 - 36x^2 + 5\right) y' + \left(-8x^3 + 16x\right) y - 8x^4 + 20x^2 - 5 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-32x^5 + 128x^3 - 66x\right) y' + \left(16x^4 - 60x^2 + 21\right) y + 16x^5 - 68x^3 + 45x \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(64x^6 - 400x^4 + 456x^2 - 45\right) y' + \left(-32x^5 + 192x^3 - 186x\right) y - 32x^6 + 208x^4 - 270x^2 + 45 \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(-128x^7 + 1152x^5 - 2320x^3 + 816x\right) y' + \left(64x^6 - 560x^4 + 1032x^2 - 231\right) y + 64x^7 - 592x^5 + 1288
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) \\
F_1 &= -y'(0) + 1 \\
F_2 &= -3y(0) \\
F_3 &= 5y'(0) - 5 \\
F_4 &= 21y(0) \\
F_5 &= -45y'(0) + 45 \\
F_6 &= -231y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 + \frac{1}{2}x^2 - \frac{1}{8}x^4 + \frac{7}{240}x^6 - \frac{11}{1920}x^8\right) y(0) \\
&+ \left(x - \frac{1}{6}x^3 + \frac{1}{24}x^5 - \frac{1}{112}x^7\right) y'(0) + \frac{x^3}{6} - \frac{x^5}{24} + \frac{x^7}{112} + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = -2x \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) + x \tag{1}
$$

Expanding x as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$
\begin{aligned}
x &= x + \dots \\
&= x
\end{aligned}
$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + 2x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) = x$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 2n\, x^n a_n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = x \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} 2n\, x^n a_n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = x \tag{3}$$

$n = 0$ gives

$$2a_2 - a_0 = 0$$

$$a_2 = \frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$((n+2)\, a_{n+2}(n+1) + 2n a_n - a_n)\, x^n = x \tag{4}$$

For $n = 1$ the recurrence equation gives

$$(6a_3 + a_1)\, x = x$$

$$6a_3 + a_1 = 1$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{6} - \frac{a_1}{6}$$

For $n = 2$ the recurrence equation gives

$$(12a_4 + 3a_2)\,x^2 = 0$$
$$12a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$(20a_5 + 5a_3)\,x^3 = 0$$
$$20a_5 + 5a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{1}{24} + \frac{a_1}{24}$$

For $n = 4$ the recurrence equation gives

$$(30a_6 + 7a_4)\,x^4 = 0$$
$$30a_6 + 7a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{7a_0}{240}$$

For $n = 5$ the recurrence equation gives

$$(42a_7 + 9a_5)\,x^5 = 0$$
$$42a_7 + 9a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{1}{112} - \frac{a_1}{112}$$

For $n = 6$ the recurrence equation gives

$$\left(56a_8 + 11a_6\right)x^6 = 0$$
$$56a_8 + 11a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = -\frac{11a_0}{1920}$$

For $n = 7$ the recurrence equation gives

$$\left(72a_9 + 13a_7\right)x^7 = 0$$
$$72a_9 + 13a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = -\frac{13}{8064} + \frac{13a_1}{8064}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x + \frac{a_0 x^2}{2} + \left(\frac{1}{6} - \frac{a_1}{6}\right) x^3 - \frac{a_0 x^4}{8} \\ + \left(-\frac{1}{24} + \frac{a_1}{24}\right) x^5 + \frac{7 a_0 x^6}{240} + \left(\frac{1}{112} - \frac{a_1}{112}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$y = \left(1+\frac{1}{2}x^{2}-\frac{1}{8}x^{4}+\frac{7}{240}x^{6}\right) a_{0} + \left(x-\frac{1}{6}x^{3}+\frac{1}{24}x^{5}-\frac{1}{112}x^{7}\right) a_{1}+\frac{x^{3}}{6}-\frac{x^{5}}{24}+\frac{x^{7}}{112}+O\left(x^{8}\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1+\frac{1}{2}x^{2}-\frac{1}{8}x^{4}+\frac{7}{240}x^{6}\right) c_{1}+\left(x-\frac{1}{6}x^{3}+\frac{1}{24}x^{5}-\frac{1}{112}x^{7}\right) c_{2}+\frac{x^{3}}{6}-\frac{x^{5}}{24}+\frac{x^{7}}{112}+O\left(x^{8}\right)$$

Summary

The solution(s) found are the following

$$y = \left(1+\frac{1}{2}x^{2}-\frac{1}{8}x^{4}+\frac{7}{240}x^{6}-\frac{11}{1920}x^{8}\right) y(0) + \left(x-\frac{1}{6}x^{3}+\frac{1}{24}x^{5}-\frac{1}{112}x^{7}\right) y'(0)+\frac{x^{3}}{6}-\frac{x^{5}}{24}+\frac{x^{7}}{112}+O\left(x^{8}\right) \tag{1}$$

$$y = \left(1+\frac{1}{2}x^{2}-\frac{1}{8}x^{4}+\frac{7}{240}x^{6}\right) c_{1} + \left(x-\frac{1}{6}x^{3}+\frac{1}{24}x^{5}-\frac{1}{112}x^{7}\right) c_{2}+\frac{x^{3}}{6}-\frac{x^{5}}{24}+\frac{x^{7}}{112}+O\left(x^{8}\right) \tag{2}$$

Verification of solutions

$$y = \left(1+\frac{1}{2}x^{2}-\frac{1}{8}x^{4}+\frac{7}{240}x^{6}-\frac{11}{1920}x^{8}\right) y(0) + \left(x-\frac{1}{6}x^{3}+\frac{1}{24}x^{5}-\frac{1}{112}x^{7}\right) y'(0)+\frac{x^{3}}{6}-\frac{x^{5}}{24}+\frac{x^{7}}{112}+O\left(x^{8}\right)$$

Verified OK.

$$y = \left(1+\frac{1}{2}x^{2}-\frac{1}{8}x^{4}+\frac{7}{240}x^{6}\right) c_{1}+\left(x-\frac{1}{6}x^{3}+\frac{1}{24}x^{5}-\frac{1}{112}x^{7}\right) c_{2}+\frac{x^{3}}{6}-\frac{x^{5}}{24}+\frac{x^{7}}{112}+O\left(x^{8}\right)$$

Verified OK.

Problem number: 1(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' - yx^2 = 1}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left. \frac{d^n f}{dx^n} \right|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (656)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (657)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -y' + yx^2 + 1 \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= y' - yx^2 - 1 + x^2 y' + 2xy \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(-2x^2 + 4x - 1\right) y' + \left(x^4 + x^2 - 2x + 2\right) y + x^2 + 1 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 + 3x^2 - 10x + 7\right) y' + \left(-2x^4 + 8x^3 - x^2 + 2x - 2\right) y - 2x^2 + 6x - 1 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-3x^4 + 12x^3 - 4x^2 + 18x - 19\right) y' + \left(x^6 + 3x^4 - 18x^3 + 31x^2 - 2x + 2\right) y + x^4 + 3x^2 - 14x + 13 \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(x^6 + 6x^4 - 42x^3 + 71x^2 - 28x + 39\right) y' + \left(-3x^6 + 18x^5 - 4x^4 + 30x^3 - 73x^2 + 62x - 2\right) y - 3x^4 + \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(-4x^6 + 24x^5 - 10x^4 + 96x^3 - 270x^2 + 232x - 69\right) y' + \left(x^8 + 6x^6 - 60x^5 + 161x^4 - 44x^3 + 129x^2
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y'(0) + 1 \\
F_1 &= y'(0) - 1 \\
F_2 &= -y'(0) + 2y(0) + 1 \\
F_3 &= 7y'(0) - 2y(0) - 1 \\
F_4 &= -19y'(0) + 2y(0) + 13 \\
F_5 &= 39y'(0) - 2y(0) - 33 \\
F_6 &= -69y'(0) + 62y(0) + 63
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 + \frac{1}{12}x^4 - \frac{1}{60}x^5 + \frac{1}{360}x^6 - \frac{1}{2520}x^7 + \frac{31}{20160}x^8\right) y(0) \\
&+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{7}{120}x^5 - \frac{19}{720}x^6 + \frac{13}{1680}x^7 - \frac{23}{13440}x^8\right) y'(0) \\
&+ \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{13x^6}{720} - \frac{11x^7}{1680} + \frac{x^8}{640} + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) x^2 + 1 \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n+2} a_n\right) = 1 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$
$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1) a_{n+1} x^n$$
$$\sum_{n=0}^{\infty} \left(-x^{n+2} a_n\right) = \sum_{n=2}^{\infty} \left(-a_{n-2} x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \left(\sum_{n=0}^{\infty} (n+1) a_{n+1} x^n\right) + \sum_{n=2}^{\infty} \left(-a_{n-2} x^n\right) = 1 \quad (3)$$

$n = 0$ gives

$$(2a_2 + a_1) x^0 = 1$$
$$2a_2 + a_1 = 1$$

$$a_2 = -\frac{a_1}{2} + \frac{1}{2}$$

$n = 1$ gives

$$6a_3 + 2a_2 = 0$$

Which after substituting earlier equations, simplifies to

$$6a_3 - a_1 + 1 = 0$$

Or

$$a_3 = \frac{a_1}{6} - \frac{1}{6}$$

For $2 \leq n$, the recurrence equation is

$$((n+2)\, a_{n+2}(n+1) + (n+1)\, a_{n+1} - a_{n-2})\, x^n = 1 \tag{4}$$

For $n = 2$ the recurrence equation gives

$$\begin{aligned}(12a_4 + 3a_3 - a_0)\, x^2 &= 0\\ 12a_4 + 3a_3 - a_0 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24} - \frac{a_1}{24} + \frac{a_0}{12}$$

For $n = 3$ the recurrence equation gives

$$\begin{aligned}(20a_5 + 4a_4 - a_1)\, x^3 &= 0\\ 20a_5 + 4a_4 - a_1 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{1}{120} + \frac{7a_1}{120} - \frac{a_0}{60}$$

For $n = 4$ the recurrence equation gives

$$\begin{aligned}(30a_6 + 5a_5 - a_2)\, x^4 &= 0\\ 30a_6 + 5a_5 - a_2 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{13}{720} - \frac{19a_1}{720} + \frac{a_0}{360}$$

For $n = 5$ the recurrence equation gives

$$\begin{aligned}(42a_7 + 6a_6 - a_3)\, x^5 &= 0\\ 42a_7 + 6a_6 - a_3 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{11}{1680} + \frac{13a_1}{1680} - \frac{a_0}{2520}$$

For $n = 6$ the recurrence equation gives

$$\begin{aligned}(56a_8 + 7a_7 - a_4)\, x^6 &= 0 \\ 56a_8 + 7a_7 - a_4 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{640} - \frac{23a_1}{13440} + \frac{31a_0}{20160}$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(72a_9 + 8a_8 - a_5)\, x^7 &= 0 \\ 72a_9 + 8a_8 - a_5 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_9 = -\frac{1}{3456} + \frac{121a_1}{120960} - \frac{73a_0}{181440}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned}y = a_0 + a_1 x + \left(-\frac{a_1}{2} + \frac{1}{2}\right) x^2 + \left(\frac{a_1}{6} - \frac{1}{6}\right) x^3 \\ + \left(\frac{1}{24} - \frac{a_1}{24} + \frac{a_0}{12}\right) x^4 + \left(-\frac{1}{120} + \frac{7a_1}{120} - \frac{a_0}{60}\right) x^5 \\ + \left(\frac{13}{720} - \frac{19a_1}{720} + \frac{a_0}{360}\right) x^6 + \left(-\frac{11}{1680} + \frac{13a_1}{1680} - \frac{a_0}{2520}\right) x^7 + \dots\end{aligned}$$

Collecting terms, the solution becomes

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{12}x^{4}-\frac{1}{60}x^{5}+\frac{1}{360}x^{6}-\frac{1}{2520}x^{7}\right) a_{0} \\
& +\left(x-\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}+\frac{7}{120}x^{5}-\frac{19}{720}x^{6}+\frac{13}{1680}x^{7}\right) a_{1} \\
& +\frac{x^{2}}{2}-\frac{x^{3}}{6}+\frac{x^{4}}{24}-\frac{x^{5}}{120}+\frac{13x^{6}}{720}-\frac{11x^{7}}{1680}+O\left(x^{8}\right)
\end{aligned} \tag{3}
$$

At $x = 0$ the solution above becomes

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{12}x^{4}-\frac{1}{60}x^{5}+\frac{1}{360}x^{6}-\frac{1}{2520}x^{7}\right) c_{1} \\
& +\left(x-\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}+\frac{7}{120}x^{5}-\frac{19}{720}x^{6}+\frac{13}{1680}x^{7}\right) c_{2} \\
& +\frac{x^{2}}{2}-\frac{x^{3}}{6}+\frac{x^{4}}{24}-\frac{x^{5}}{120}+\frac{13x^{6}}{720}-\frac{11x^{7}}{1680}+O\left(x^{8}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{12}x^{4}-\frac{1}{60}x^{5}+\frac{1}{360}x^{6}-\frac{1}{2520}x^{7}+\frac{31}{20160}x^{8}\right) y(0) \\
& +\left(x-\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}+\frac{7}{120}x^{5}-\frac{19}{720}x^{6}+\frac{13}{1680}x^{7}-\frac{23}{13440}x^{8}\right) y'(0) \\
& +\frac{x^{2}}{2}-\frac{x^{3}}{6}+\frac{x^{4}}{24}-\frac{x^{5}}{120}+\frac{13x^{6}}{720}-\frac{11x^{7}}{1680}+\frac{x^{8}}{640}+O\left(x^{8}\right)
\end{aligned} \tag{1}
$$

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{12}x^{4}-\frac{1}{60}x^{5}+\frac{1}{360}x^{6}-\frac{1}{2520}x^{7}\right) c_{1} \\
& +\left(x-\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}+\frac{7}{120}x^{5}-\frac{19}{720}x^{6}+\frac{13}{1680}x^{7}\right) c_{2} \\
& +\frac{x^{2}}{2}-\frac{x^{3}}{6}+\frac{x^{4}}{24}-\frac{x^{5}}{120}+\frac{13x^{6}}{720}-\frac{11x^{7}}{1680}+O\left(x^{8}\right)
\end{aligned} \tag{2}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{12}x^{4}-\frac{1}{60}x^{5}+\frac{1}{360}x^{6}-\frac{1}{2520}x^{7}+\frac{31}{20160}x^{8}\right) y(0) \\
& + \left(x-\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}+\frac{7}{120}x^{5}-\frac{19}{720}x^{6}+\frac{13}{1680}x^{7}-\frac{23}{13440}x^{8}\right) y'(0) \\
& + \frac{x^{2}}{2}-\frac{x^{3}}{6}+\frac{x^{4}}{24}-\frac{x^{5}}{120}+\frac{13x^{6}}{720}-\frac{11x^{7}}{1680}+\frac{x^{8}}{640}+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{12}x^{4}-\frac{1}{60}x^{5}+\frac{1}{360}x^{6}-\frac{1}{2520}x^{7}\right) c_{1} \\
& + \left(x-\frac{1}{2}x^{2}+\frac{1}{6}x^{3}-\frac{1}{24}x^{4}+\frac{7}{120}x^{5}-\frac{19}{720}x^{6}+\frac{13}{1680}x^{7}\right) c_{2} \\
& + \frac{x^{2}}{2}-\frac{x^{3}}{6}+\frac{x^{4}}{24}-\frac{x^{5}}{120}+\frac{13x^{6}}{720}-\frac{11x^{7}}{1680}+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.3. Second-Order Linear Equations: Ordinary Points. Page 169
Problem number: 1(e).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{(x^2+1)\,y''+xy'+y=0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2}\, f|_{x_0,y_0,y_0'} + \frac{x^3}{3!}\, f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (659) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (660) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{xy'+y}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{x^2 y' + 3xy - 2y'}{\left(x^2+1\right)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{-10yx^2 + 15xy' + 5y}{\left(x^2+1\right)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{\left(-10x^4 - 95x^2 + 20\right) y' + \left(40x^3 - 65x\right) y}{\left(x^2+1\right)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{\left(90x^5 + 600x^3 - 435x\right) y' + \left(-190x^4 + 670x^2 - 85\right) y}{\left(x^2+1\right)^5} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{\left(-730x^6 - 3870x^4 + 6735x^2 - 520\right) y' + 1050\left(x^4 - \frac{32}{5}x^2 + \frac{5}{2}\right) yx}{\left(x^2+1\right)^6} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \frac{\left(6160x^7 + 24780x^5 - 93660x^3 + 22855x\right) y' + \left(-6620x^6 + 69600x^4 - 55770x^2 + 3145\right) y}{\left(x^2+1\right)^7}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -2y'(0) \\
F_2 &= 5y(0) \\
F_3 &= 20y'(0) \\
F_4 &= -85y(0) \\
F_5 &= -520y'(0) \\
F_6 &= 3145y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{5}{24}x^4 - \frac{17}{144}x^6 + \frac{629}{8064}x^8\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{6}x^5 - \frac{13}{126}x^7\right) y'(0) + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(x^2 + 1)\, y'' + xy' + y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(x^2 + 1) \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

$n = 1$ gives

$$6a_3 + 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_1}{3}$$

For $2 \leq n$, the recurrence equation is

$$n a_n(n-1) + (n+2)\, a_{n+2}(n+1) + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n(n^2+1)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$5a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{5a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$10a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{6}$$

For $n = 4$ the recurrence equation gives

$$17a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{17a_0}{144}$$

For $n = 5$ the recurrence equation gives

$$26a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{13a_1}{126}$$

For $n = 6$ the recurrence equation gives

$$37a_6 + 56a_8 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{629a_0}{8064}$$

For $n = 7$ the recurrence equation gives

$$50a_7 + 72a_9 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{325a_1}{4536}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x - \frac{1}{2}a_0x^2 - \frac{1}{3}a_1x^3 + \frac{5}{24}a_0x^4 + \frac{1}{6}a_1x^5 - \frac{17}{144}a_0x^6 - \frac{13}{126}a_1x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{5}{24}x^4 - \frac{17}{144}x^6\right)a_0 + \left(x - \frac{1}{3}x^3 + \frac{1}{6}x^5 - \frac{13}{126}x^7\right)a_1 + O(x^8) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{5}{24}x^4 - \frac{17}{144}x^6\right)c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{6}x^5 - \frac{13}{126}x^7\right)c_2 + O(x^8)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \left(1 - \frac{1}{2}x^2 + \frac{5}{24}x^4 - \frac{17}{144}x^6 + \frac{629}{8064}x^8\right)y(0) \\ & + \left(x - \frac{1}{3}x^3 + \frac{1}{6}x^5 - \frac{13}{126}x^7\right)y'(0) + O(x^8) \end{aligned} \quad (1)$$

$$y = \left(1 - \frac{1}{2}x^2 + \frac{5}{24}x^4 - \frac{17}{144}x^6\right)c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{6}x^5 - \frac{13}{126}x^7\right)c_2 + O(x^8) \quad (2)$$

Verification of solutions

$$y = \left(1-\frac{1}{2}x^2+\frac{5}{24}x^4-\frac{17}{144}x^6+\frac{629}{8064}x^8\right)y(0)+\left(x-\frac{1}{3}x^3+\frac{1}{6}x^5-\frac{13}{126}x^7\right)y'(0)+O(x^8)$$

Verified OK.

$$y = \left(1-\frac{1}{2}x^2+\frac{5}{24}x^4-\frac{17}{144}x^6\right)c_1+\left(x-\frac{1}{3}x^3+\frac{1}{6}x^5-\frac{13}{126}x^7\right)c_2+O(x^8)$$

Verified OK.

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.3. Second-Order Linear Equations: Ordinary Points. Page 169
Problem number: 1(f).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + (1 + x)\, y' - y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \tag{662}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \tag{663}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \quad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \quad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \quad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \quad (7)$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -xy' - y' + y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= (1+x)\left((1+x)\, y' - y\right) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -(x+2)\left((1+x)\, y' - y\right) x \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= (1+x)\left((1+x)\, y' - y\right)\left(x^2 + 2x - 2\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= -\left((1+x)\, y' - y\right)\left(x^4 + 4x^3 - 8x - 2\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= (1+x)\left((1+x)\, y' - y\right)\left(x^4 + 4x^3 - 4x^2 - 16x + 6\right) \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= -\left(x^6 + 6x^5 - 40x^3 - 30x^2 + 36x + 16\right)\left((1+x)\, y' - y\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) - y'(0) \\
F_1 &= -y(0) + y'(0) \\
F_2 &= 0 \\
F_3 &= 2y(0) - 2y'(0) \\
F_4 &= 2y'(0) - 2y(0) \\
F_5 &= 6y'(0) - 6y(0) \\
F_6 &= -16y'(0) + 16y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1+\frac{1}{2}x^2-\frac{1}{6}x^3+\frac{1}{60}x^5-\frac{1}{360}x^6-\frac{1}{840}x^7+\frac{1}{2520}x^8\right)y(0) \\
&+\left(x-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{60}x^5+\frac{1}{360}x^6+\frac{1}{840}x^7-\frac{1}{2520}x^8\right)y'(0)+O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)-\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)+\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right)+\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)+\left(\sum_{n=1}^{\infty} n a_n x^{n}\right)+\sum_{n=0}^{\infty}(-a_n x^n) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1)\, a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=0}^{\infty} (n+1)\, a_{n+1} x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^n\right) + \sum_{n=0}^{\infty} (-a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_1 - a_0 = 0$$

$$a_2 = \frac{a_0}{2} - \frac{a_1}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) + (n+1)\, a_{n+1} + n a_n - a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n a_n + n a_{n+1} - a_n + a_{n+1}}{(n+2)\,(n+1)} \\ &= -\frac{(n-1)\, a_n}{(n+2)\,(n+1)} - \frac{a_{n+1}}{n+2} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_0}{6} + \frac{a_1}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_3 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = 0$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_4 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_0}{60} - \frac{a_1}{60}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_5 + 3a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{360} + \frac{a_1}{360}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_6 + 4a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_0}{840} + \frac{a_1}{840}$$

For $n = 6$ the recurrence equation gives

$$56a_8 + 7a_7 + 5a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{2520} - \frac{a_1}{2520}$$

For $n = 7$ the recurrence equation gives

$$72a_9 + 8a_8 + 6a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{a_0}{18144} - \frac{a_1}{18144}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x + \left(\frac{a_0}{2} - \frac{a_1}{2}\right) x^2 + \left(-\frac{a_0}{6} + \frac{a_1}{6}\right) x^3 + \left(\frac{a_0}{60} - \frac{a_1}{60}\right) x^5 \\ + \left(-\frac{a_0}{360} + \frac{a_1}{360}\right) x^6 + \left(-\frac{a_0}{840} + \frac{a_1}{840}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = &\left(1 + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{360}x^6 - \frac{1}{840}x^7\right) a_0 \\ &+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{60}x^5 + \frac{1}{360}x^6 + \frac{1}{840}x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$\begin{aligned} y = &\left(1 + \frac{1}{2}x^2 - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{360}x^6 - \frac{1}{840}x^7\right) c_1 \\ &+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{60}x^5 + \frac{1}{360}x^6 + \frac{1}{840}x^7\right) c_2 + O(x^8) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(1+\frac{1}{2}x^2-\frac{1}{6}x^3+\frac{1}{60}x^5-\frac{1}{360}x^6-\frac{1}{840}x^7+\frac{1}{2520}x^8\right)y(0) + \left(x-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{60}x^5+\frac{1}{360}x^6+\frac{1}{840}x^7-\frac{1}{2520}x^8\right)y'(0)+O(x^8) \tag{1}$$

$$y = \left(1+\frac{1}{2}x^2-\frac{1}{6}x^3+\frac{1}{60}x^5-\frac{1}{360}x^6-\frac{1}{840}x^7\right)c_1 + \left(x-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{60}x^5+\frac{1}{360}x^6+\frac{1}{840}x^7\right)c_2+O(x^8) \tag{2}$$

Verification of solutions

$$y = \left(1+\frac{1}{2}x^2-\frac{1}{6}x^3+\frac{1}{60}x^5-\frac{1}{360}x^6-\frac{1}{840}x^7+\frac{1}{2520}x^8\right)y(0) + \left(x-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{60}x^5+\frac{1}{360}x^6+\frac{1}{840}x^7-\frac{1}{2520}x^8\right)y'(0)+O(x^8)$$

Verified OK.

$$y = \left(1+\frac{1}{2}x^2-\frac{1}{6}x^3+\frac{1}{60}x^5-\frac{1}{360}x^6-\frac{1}{840}x^7\right)c_1 + \left(x-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{60}x^5+\frac{1}{360}x^6+\frac{1}{840}x^7\right)c_2+O(x^8)$$

Verified OK.

18.6.1 Maple step by step solution

Let's solve

$y'' = -xy' - y' + y$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (1+x)\,y' - y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $$x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k \, x^{k-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k + 1 - m) \, x^k$$

- Convert y'' to series expansion

  $$y'' = \sum_{k=2}^{\infty} a_k k(k - 1) \, x^{k-2}$$

- Shift index using $k- >k + 2$

  $$y'' = \sum_{k=0}^{\infty} a_{k+2}(k + 2) \, (k + 1) \, x^k$$

  Rewrite DE with series expansions

  $$\sum_{k=0}^{\infty} (a_{k+2}(k + 2) \, (k + 1) + a_{k+1}(k + 1) + a_k(k - 1)) \, x^k = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$k^2 a_{k+2} + (a_k + a_{k+1} + 3a_{k+2}) \, k - a_k + a_{k+1} + 2a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k k + a_{k+1} k - a_k + a_{k+1}}{k^2 + 3k + 2}\right]$$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\,y''+2xy'-2y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2}\, f\big|_{x_0, y_0, y_0'} + \frac{x^3}{3!}\, f'\big|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (665)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (666)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4) \\
F_1 &= \frac{df}{dx} \\
&= \frac{dF_0}{dx} \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5) \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\
&= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\
&\vdots \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{2(-y+xy')}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{8(-y+xy')\,x}{(x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -\frac{8(-y+xy')\,(5x^2-1)}{(x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{240(-y+xy')\left(x^2-\frac{3}{5}\right)x}{(x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= -\frac{48(-y+xy')\,(35x^4-42x^2+3)}{(x^2+1)^5} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{13440(-y+xy')\left(x^4-2x^2+\frac{3}{7}\right)x}{(x^2+1)^6} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= -\frac{5760(-y+xy')\,(21x^6-63x^4+27x^2-1)}{(x^2+1)^7}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 2y(0) \\
F_1 &= 0 \\
F_2 &= -8y(0) \\
F_3 &= 0 \\
F_4 &= 144y(0) \\
F_5 &= 0 \\
F_6 &= -5760y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 + x^2 - \frac{1}{3}x^4 + \frac{1}{5}x^6 - \frac{1}{7}x^8\right) y(0) + xy'(0) + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(x^2 + 1)\, y'' + 2xy' - 2y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(x^2 + 1)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + 2x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 2n a_n x^n\right) + \sum_{n=0}^{\infty} (-2a_n x^n) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} 2n a_n x^n\right) + \sum_{n=0}^{\infty} (-2a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - 2a_0 = 0$$

$$a_2 = a_0$$

For $2 \leq n$, the recurrence equation is

$$n a_n(n-1) + (n+2)\, a_{n+2}(n+1) + 2n a_n - 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{(n-1)\, a_n}{n+1} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$4a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{3}$$

For $n = 3$ the recurrence equation gives

$$10a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$18a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{5}$$

For $n = 5$ the recurrence equation gives

$$28a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

For $n = 6$ the recurrence equation gives

$$40a_6 + 56a_8 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = -\frac{a_0}{7}$$

For $n = 7$ the recurrence equation gives

$$54a_7 + 72a_9 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = 0$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x + a_0 x^2 - \frac{1}{3} a_0 x^4 + \frac{1}{5} a_0 x^6 + \dots
$$

Collecting terms, the solution becomes

$$
y = \left(1 + x^2 - \frac{1}{3} x^4 + \frac{1}{5} x^6\right) a_0 + a_1 x + O\left(x^8\right) \tag{3}
$$

At $x = 0$ the solution above becomes

$$
y = \left(1 + x^2 - \frac{1}{3} x^4 + \frac{1}{5} x^6\right) c_1 + c_2 x + O\left(x^8\right)
$$

Summary

The solution(s) found are the following

$$
y = \left(1 + x^2 - \frac{1}{3} x^4 + \frac{1}{5} x^6 - \frac{1}{7} x^8\right) y(0) + x y'(0) + O\left(x^8\right) \tag{1}
$$

$$
y = \left(1 + x^2 - \frac{1}{3} x^4 + \frac{1}{5} x^6\right) c_1 + c_2 x + O\left(x^8\right) \tag{2}
$$

Verification of solutions

$$
y = \left(1 + x^2 - \frac{1}{3} x^4 + \frac{1}{5} x^6 - \frac{1}{7} x^8\right) y(0) + x y'(0) + O\left(x^8\right)
$$

Verified OK.

$$
y = \left(1 + x^2 - \frac{1}{3} x^4 + \frac{1}{5} x^6\right) c_1 + c_2 x + O\left(x^8\right)
$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.3. Second-Order Linear Equations: Ordinary Points. Page 169
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' + xy' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (668) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (669) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y'_0} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -y - xy' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= x^2 y' + xy - 2y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -y' x^3 - yx^2 + 5xy' + 3y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 - 9x^2 + 8\right) y' + yx\left(x^2 - 7\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-x^5 + 14x^3 - 33x\right) y' - y\left(x^4 - 12x^2 + 15\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(x^6 - 20x^4 + 87x^2 - 48\right) y' + yx\left(x^4 - 18x^2 + 57\right) \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(-x^7 + 27x^5 - 185x^3 + 279x\right) y' - y\left(x^2 - 7\right)\left(x^4 - 18x^2 + 15\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -2y'(0) \\
F_2 &= 3y(0) \\
F_3 &= 8y'(0) \\
F_4 &= -15y(0) \\
F_5 &= -48y'(0) \\
F_6 &= 105y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6 + \frac{1}{384}x^8\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) y'(0) + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = -\left(\sum_{n=0}^{\infty} a_n x^n\right) - x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \left(\sum_{n=1}^{\infty} n x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2) a_{n+2}(n+1) + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n}{n+2} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{48}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{105}$$

For $n = 6$ the recurrence equation gives

$$56a_8 + 7a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{384}$$

For $n = 7$ the recurrence equation gives

$$72a_9 + 8a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{a_1}{945}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 - \frac{1}{3} a_1 x^3 + \frac{1}{8} a_0 x^4 + \frac{1}{15} a_1 x^5 - \frac{1}{48} a_0 x^6 - \frac{1}{105} a_1 x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) a_0 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) a_1 + O(x^8) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) c_2 + O(x^8)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6 + \frac{1}{384}x^8\right) y(0) \\ & + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) y'(0) + O(x^8) \end{aligned} \quad (1)$$

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) c_2 + O(x^8) \quad (2)$$

Verification of solutions

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6 + \frac{1}{384}x^8\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) y'(0) + O(x^8)$$

Verified OK.

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{8}x^4 - \frac{1}{48}x^6\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{15}x^5 - \frac{1}{105}x^7\right) c_2 + O(x^8)$$

Verified OK.

18.8.1 Maple step by step solution

Let's solve

$y'' = -y - xy'$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + xy' + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- >k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(k+1)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k+1)\,(a_{k+2}(k+2) + a_k) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{k+2}\right]$

Problem number: 4(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second__order__airy", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y' - xy = 0}$$

With initial conditions

$$[y(0) = 1, y'(0) = 0]$$

With the expansion point for the power series method at $x = 0$.

18.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -x \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + y' - xy = 0$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (671)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (672)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n \Big|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= xy - y' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= xy' + y - xy + y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= (1 - 2x)\, y' + y\left(x^2 + x - 1\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^2 + 3x - 4\right) y' + \left(-2x^2 + 3x + 1\right) y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(-3x^2 + 2x + 8\right) y' + y\left(x^3 + 3x^2 - 8x + 3\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(x^3 + 6x^2 - 16x - 3\right) y' - 3\left(x^3 - \frac{5}{3}x^2 - \frac{14}{3}x + \frac{8}{3}\right) y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(-4x^3 + 2x^2 + 42x - 21\right) y' + y\left(x^4 + 6x^3 - 25x^2 + 7x + 14\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = 1$ and

$y'(0) = 0$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= 1 \\
F_2 &= -1 \\
F_3 &= 1 \\
F_4 &= 3 \\
F_5 &= -8 \\
F_6 &= 14
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + \frac{x^8}{2880} + O(x^8)
$$

$$
y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + \frac{x^8}{2880} + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = x\left(\sum_{n=0}^{\infty} a_n x^n\right) - \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} &= \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n \\
\sum_{n=1}^{\infty} n a_n x^{n-1} &= \sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n \\
\sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) &= \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right)
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$
\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \left(\sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right) = 0 \tag{3}
$$

$n = 0$ gives

$$
2a_2 + a_1 = 0
$$

$$
a_2 = -\frac{a_1}{2}
$$

For $1 \leq n$, the recurrence equation is

$$
(n+2)\, a_{n+2}(1+n) + (1+n)\, a_{1+n} - a_{n-1} = 0 \tag{4}
$$

Solving for a_{n+2}, gives

$$
\begin{aligned}
a_{n+2} &= -\frac{n a_{1+n} + a_{1+n} - a_{n-1}}{(n+2)\,(1+n)} \\
&= -\frac{a_{1+n}}{n+2} + \frac{a_{n-1}}{(n+2)\,(1+n)}
\end{aligned} \tag{5}
$$

For $n = 1$ the recurrence equation gives

$$
6a_3 + 2a_2 - a_0 = 0
$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{6} + \frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_3 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_1}{24} - \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_4 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_1}{30} + \frac{a_0}{120}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_5 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_1}{90} + \frac{a_0}{240}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_6 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{1680} - \frac{a_0}{630}$$

For $n = 6$ the recurrence equation gives

$$56a_8 + 7a_7 - a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = -\frac{a_1}{1920} + \frac{a_0}{2880}$$

For $n = 7$ the recurrence equation gives

$$72a_9 + 8a_8 - a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{11a_1}{51840} + \frac{a_0}{51840}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x - \frac{a_1 x^2}{2} + \left(\frac{a_1}{6} + \frac{a_0}{6}\right) x^3 + \left(\frac{a_1}{24} - \frac{a_0}{24}\right) x^4 \\ + \left(-\frac{a_1}{30} + \frac{a_0}{120}\right) x^5 + \left(\frac{a_1}{90} + \frac{a_0}{240}\right) x^6 + \left(-\frac{a_1}{1680} - \frac{a_0}{630}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = &\left(1 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{240}x^6 - \frac{1}{630}x^7\right) a_0 \\ &+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{30}x^5 + \frac{1}{90}x^6 - \frac{1}{1680}x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$\begin{aligned} y = &\left(1 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{240}x^6 - \frac{1}{630}x^7\right) c_1 \\ &+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{30}x^5 + \frac{1}{90}x^6 - \frac{1}{1680}x^7\right) c_2 + O(x^8) \end{aligned}$$

$$y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + O(x^8)$$

Summary

The solution(s) found are the following

$$y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + \frac{x^8}{2880} + O(x^8) \tag{1}$$

$$y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + O(x^8) \tag{2}$$

Verification of solutions

$$y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + \frac{x^8}{2880} + O(x^8)$$

Verified OK.

$$y = 1 + \frac{x^3}{6} - \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{240} - \frac{x^7}{630} + O(x^8)$$

Verified OK.

18.9.2 Maple step by step solution

Let's solve

$$\left[y'' = xy - y', y(0) = 1, y'\Big|_{\{x=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' - xy = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x \cdot y$ to series expansion

    $x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$

  ◦ Shift index using $k- > k-1$

$$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^k$$

- Convert y' to series expansion

$$y' = \sum_{k=1}^{\infty} a_k k\, x^{k-1}$$

- Shift index using $k- >k+1$

$$y' = \sum_{k=0}^{\infty} a_{k+1}(k+1)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + a_1 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k+1}(k+1) - a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

$$2a_2 + a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$\left(k^2+3k+2\right) a_{k+2} + a_{k+1} k - a_{k-1} + a_{k+1} = 0$$

- Shift index using $k- >k+1$

$$\left((k+1)^2 + 3k + 5\right) a_{k+3} + a_{k+2}(k+1) - a_k + a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{k a_{k+2} - a_k + 2a_{k+2}}{k^2+5k+6}, 2a_2 + a_1 = 0\right]$$

$$\boxed{y'' + y' - xy = 0}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

With the expansion point for the power series method at $x = 0$.

18.10.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= 1 \\ q(x) &= -x \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + y' - xy = 0$$

The domain of $p(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y_0'}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{674}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{675}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx} \\
&= \frac{dF_0}{dx} \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right) \\
&= \frac{d}{dx}(F_1) \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0 \\
&\vdots \\
F_n &= \frac{d}{dx}(F_{n-1}) \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y'' \\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= xy - y' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= xy' + y - xy + y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= (1 - 2x)\, y' + y\big(x^2 + x - 1\big) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \big(x^2 + 3x - 4\big)\, y' + \big(-2x^2 + 3x + 1\big)\, y \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \big(-3x^2 + 2x + 8\big)\, y' + y\big(x^3 + 3x^2 - 8x + 3\big) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \big(x^3 + 6x^2 - 16x - 3\big)\, y' - 3\left(x^3 - \frac{5}{3}x^2 - \frac{14}{3}x + \frac{8}{3}\right) y \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \big(-4x^3 + 2x^2 + 42x - 21\big)\, y' + y\big(x^4 + 6x^3 - 25x^2 + 7x + 14\big)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = 0$ and

$y'(0) = 1$ gives

$$
\begin{aligned}
F_0 &= -1 \\
F_1 &= 1 \\
F_2 &= 1 \\
F_3 &= -4 \\
F_4 &= 8 \\
F_5 &= -3 \\
F_6 &= -21
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} - \frac{x^8}{1920} + O(x^8)
$$

$$
y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} - \frac{x^8}{1920} + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = x\left(\sum_{n=0}^{\infty} a_n x^n\right) - \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n$$

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n$$

$$\sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \left(\sum_{n=0}^{\infty} (1+n)\, a_{1+n} x^n\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right) = 0 \quad (3)$$

$n = 0$ gives

$$2a_2 + a_1 = 0$$

$$a_2 = -\frac{a_1}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(1+n) + (1+n)\, a_{1+n} - a_{n-1} = 0 \quad (4)$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n a_{1+n} + a_{1+n} - a_{n-1}}{(n+2)\,(1+n)} \\ &= -\frac{a_{1+n}}{n+2} + \frac{a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \quad (5)$$

For $n = 1$ the recurrence equation gives

$$6a_3 + 2a_2 - a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{6} + \frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + 3a_3 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_1}{24} - \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + 4a_4 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_1}{30} + \frac{a_0}{120}$$

For $n = 4$ the recurrence equation gives

$$30a_6 + 5a_5 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_1}{90} + \frac{a_0}{240}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + 6a_6 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{1680} - \frac{a_0}{630}$$

For $n = 6$ the recurrence equation gives

$$56a_8 + 7a_7 - a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = -\frac{a_1}{1920} + \frac{a_0}{2880}$$

For $n = 7$ the recurrence equation gives

$$72a_9 + 8a_8 - a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{11a_1}{51840} + \frac{a_0}{51840}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x - \frac{a_1 x^2}{2} + \left(\frac{a_1}{6} + \frac{a_0}{6}\right) x^3 + \left(\frac{a_1}{24} - \frac{a_0}{24}\right) x^4 \\ + \left(-\frac{a_1}{30} + \frac{a_0}{120}\right) x^5 + \left(\frac{a_1}{90} + \frac{a_0}{240}\right) x^6 + \left(-\frac{a_1}{1680} - \frac{a_0}{630}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = &\left(1 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{240}x^6 - \frac{1}{630}x^7\right) a_0 \\ &+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{30}x^5 + \frac{1}{90}x^6 - \frac{1}{1680}x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$\begin{aligned} y = &\left(1 + \frac{1}{6}x^3 - \frac{1}{24}x^4 + \frac{1}{120}x^5 + \frac{1}{240}x^6 - \frac{1}{630}x^7\right) c_1 \\ &+ \left(x - \frac{1}{2}x^2 + \frac{1}{6}x^3 + \frac{1}{24}x^4 - \frac{1}{30}x^5 + \frac{1}{90}x^6 - \frac{1}{1680}x^7\right) c_2 + O(x^8) \end{aligned}$$

$$y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} + O(x^8)$$

Summary

The solution(s) found are the following

$$y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} - \frac{x^8}{1920} + O(x^8) \tag{1}$$

$$y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} + O(x^8) \tag{2}$$

Verification of solutions

$$y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} - \frac{x^8}{1920} + O(x^8)$$

Verified OK.

$$y = x - \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{30} + \frac{x^6}{90} - \frac{x^7}{1680} + O(x^8)$$

Verified OK.

18.10.2 Maple step by step solution

Let's solve

$\left[y'' = xy - y', y(0) = 0, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' - xy = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

  ◦ Convert $x \cdot y$ to series expansion

    $x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$

  ◦ Shift index using $k- >k-1$

$$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k}$$

- Convert y' to series expansion

$$y' = \sum_{k=1}^{\infty} a_k k \, x^{k-1}$$

- Shift index using $k- >k+1$

$$y' = \sum_{k=0}^{\infty} a_{k+1}(k+1) \, x^{k}$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1) \, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2) \, (k+1) \, x^{k}$$

Rewrite ODE with series expansions

$$2a_2 + a_1 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2) \, (k+1) + a_{k+1}(k+1) - a_{k-1}\right) x^{k}\right) = 0$$

- Each term must be 0

$$2a_2 + a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2) \, a_{k+2} + a_{k+1} k - a_{k-1} + a_{k+1} = 0$$

- Shift index using $k- >k+1$

$$\left((k+1)^2 + 3k + 5\right) a_{k+3} + a_{k+2}(k+1) - a_k + a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k}, a_{k+3} = -\frac{k a_{k+2} - a_k + 2a_{k+2}}{k^2 + 5k + 6}, 2a_2 + a_1 = 0\right]$$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(p + \frac{1}{2} - \frac{x^2}{4}\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x-x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (677) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (678) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} F_n|_{x_0,y_0,y'_0} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{(-x^2+4p+2)\,y}{4} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(x^2-4p-2)\,y'}{4} + \frac{xy}{2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= xy' + \left(\frac{x^4}{16} + \left(-\frac{p}{2} - \frac{1}{4}\right) x^2 + p^2 + p + \frac{3}{4}\right) y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(x^4 + (-8p-4)\,x^2 + 16p^2 + 16p + 28)\,y'}{16} - 2y\left(p + \frac{1}{2} - \frac{x^2}{4}\right) x \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{3(x^3 + 2(-2p-1)\,x)\,y'}{4} - \left(-\frac{x^6}{64} + \frac{3\left(p+\frac{1}{2}\right) x^4}{16} + \frac{3\left(-\frac{11}{4} - p^2 - p\right) x^2}{4} + \left(p + \frac{1}{2}\right)\left(p^2 + p + \frac{15}{4}\right)\right. \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{(x^6 + (-12p-6)\,x^4 + (48p^2 + 48p + 276)\,x^2 - 64p^3 - 96p^2 - 464p - 216)\,y'}{64} + \frac{9yx\left(\frac{x^4}{16} + \left(-\frac{p}{2} - \frac{1}{4}\right.\right.}{2} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= 6\left(\frac{9}{4} + \frac{x^4}{16} + \frac{\left(-p-\frac{1}{2}\right) x^2}{2} + p^2 + p\right) xy' + y\left(\frac{105}{16} + \frac{x^8}{256} + \frac{\left(-p-\frac{1}{2}\right) x^6}{16} + \frac{3\left(p^2+p+\frac{27}{4}\right) x^4}{8} + \left(-\right.\right.
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -\frac{y(0)\,(2p+1)}{2} \\
F_1 &= -y'(0)\,p - \frac{y'(0)}{2} \\
F_2 &= y(0)\,p^2 + y(0)\,p + \frac{3y(0)}{4} \\
F_3 &= y'(0)\,p^2 + y'(0)\,p + \frac{7y'(0)}{4} \\
F_4 &= -y(0)\,p^3 - \frac{3y(0)\,p^2}{2} - \frac{17y(0)\,p}{4} - \frac{15y(0)}{8} \\
F_5 &= -y'(0)\,p^3 - \frac{3y'(0)\,p^2}{2} - \frac{29y'(0)\,p}{4} - \frac{27y'(0)}{8} \\
F_6 &= y(0)\,p^4 + 2y(0)\,p^3 + \frac{25y(0)\,p^2}{2} + \frac{23y(0)\,p}{2} + \frac{105y(0)}{16}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = {} & \left(1 - \frac{1}{2}x^2 p + \frac{1}{24}x^4 p^2 + \frac{1}{24}x^4 p - \frac{1}{720}x^6 p^3 - \frac{1}{480}x^6 p^2 - \frac{17}{2880}x^6 p + \frac{1}{40320}x^8 p^4 \right. \\
& \left. + \frac{1}{20160}x^8 p^3 + \frac{5}{16128}x^8 p^2 + \frac{23}{80640}x^8 p - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6 + \frac{1}{6144}x^8 \right) y(0) \\
& + \left(-\frac{1}{6}x^3 p + \frac{1}{120}x^5 p^2 + \frac{1}{120}x^5 p - \frac{1}{5040}x^7 p^3 - \frac{1}{3360}x^7 p^2 - \frac{29}{20160}x^7 p - \frac{1}{12}x^3 \right. \\
& \left. + \frac{7}{480}x^5 - \frac{3}{4480}x^7 + x \right) y'(0) + O\left(x^8\right)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\frac{(-x^2+4p+2)\left(\sum_{n=0}^{\infty} a_n x^n\right)}{4} \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+2} a_n}{4}\right) + \left(\sum_{n=0}^{\infty} \frac{a_n x^n (2p+1)}{2}\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+2} a_n}{4}\right) = \sum_{n=2}^{\infty} \left(-\frac{a_{n-2} x^n}{4}\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=2}^{\infty} \left(-\frac{a_{n-2} x^n}{4}\right) + \left(\sum_{n=0}^{\infty} \frac{a_n x^n (2p+1)}{2}\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + \frac{a_0(2p+1)}{2} = 0$$

$$a_2 = -\frac{1}{2} a_0 p - \frac{1}{4} a_0$$

$n = 1$ gives

$$6a_3 + \frac{a_1(2p+1)}{2} = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{1}{6}a_1 p - \frac{1}{12}a_1$$

For $2 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) - \frac{a_{n-2}}{4} + \frac{a_n(2p+1)}{2} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{4pa_n + 2a_n - a_{n-2}}{4\,(n+2)\,(n+1)} \\ &= -\frac{(4p+2)\, a_n}{4\,(n+2)\,(n+1)} + \frac{a_{n-2}}{4\,(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$12a_4 - \frac{a_0}{4} + \frac{a_2(2p+1)}{2} = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{32}a_0 + \frac{1}{24}a_0 p^2 + \frac{1}{24}a_0 p$$

For $n = 3$ the recurrence equation gives

$$20a_5 - \frac{a_1}{4} + \frac{a_3(2p+1)}{2} = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{7}{480}a_1 + \frac{1}{120}a_1 p^2 + \frac{1}{120}a_1 p$$

For $n = 4$ the recurrence equation gives

$$30a_6 - \frac{a_2}{4} + \frac{a_4(2p+1)}{2} = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{17}{2880}a_0 p - \frac{1}{384}a_0 - \frac{1}{720}a_0 p^3 - \frac{1}{480}a_0 p^2$$

For $n = 5$ the recurrence equation gives

$$42a_7 - \frac{a_3}{4} + \frac{a_5(2p+1)}{2} = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{29}{20160}a_1 p - \frac{3}{4480}a_1 - \frac{1}{5040}a_1 p^3 - \frac{1}{3360}a_1 p^2$$

For $n = 6$ the recurrence equation gives

$$56a_8 - \frac{a_4}{4} + \frac{a_6(2p+1)}{2} = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{6144}a_0 + \frac{5}{16128}a_0 p^2 + \frac{23}{80640}a_0 p + \frac{1}{40320}a_0 p^4 + \frac{1}{20160}a_0 p^3$$

For $n = 7$ the recurrence equation gives

$$72a_9 - \frac{a_5}{4} + \frac{a_7(2p+1)}{2} = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{107}{1935360}a_1 + \frac{37}{725760}a_1 p^2 + \frac{1}{20736}a_1 p + \frac{1}{362880}a_1 p^4 + \frac{1}{181440}a_1 p^3$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$
\begin{aligned}
y = a_0 + a_1 x + \left(-\frac{1}{2} a_0 p - \frac{1}{4} a_0\right) x^2 + \left(-\frac{1}{6} a_1 p - \frac{1}{12} a_1\right) x^3 + \left(\frac{1}{32} a_0 + \frac{1}{24} a_0 p^2 + \frac{1}{24} a_0 p\right) x^4 \\
+ \left(\frac{7}{480} a_1 + \frac{1}{120} a_1 p^2 + \frac{1}{120} a_1 p\right) x^5 + \left(-\frac{17}{2880} a_0 p - \frac{1}{384} a_0 - \frac{1}{720} a_0 p^3 - \frac{1}{480} a_0 p^2\right) x^6 \\
+ \left(-\frac{29}{20160} a_1 p - \frac{3}{4480} a_1 - \frac{1}{5040} a_1 p^3 - \frac{1}{3360} a_1 p^2\right) x^7 + \dots
\end{aligned}
$$

Collecting terms, the solution becomes

$$
\begin{aligned}
y = \Bigg(1 + \left(-\frac{p}{2} - \frac{1}{4}\right) x^2 + \left(\frac{1}{32} + \frac{1}{24} p^2 + \frac{1}{24} p\right) x^4 \\
+ \left(-\frac{17}{2880} p - \frac{1}{384} - \frac{1}{720} p^3 - \frac{1}{480} p^2\right) x^6\Bigg) a_0 \\
+ \Bigg(x + \left(-\frac{p}{6} - \frac{1}{12}\right) x^3 + \left(\frac{7}{480} + \frac{1}{120} p^2 + \frac{1}{120} p\right) x^5 \\
+ \left(-\frac{29}{20160} p - \frac{3}{4480} - \frac{1}{5040} p^3 - \frac{1}{3360} p^2\right) x^7\Bigg) a_1 + O\left(x^8\right)
\end{aligned}
\tag{3}
$$

At $x = 0$ the solution above becomes

$$
\begin{aligned}
y = \Bigg(1 + \left(-\frac{p}{2} - \frac{1}{4}\right) x^2 + \left(\frac{1}{32} + \frac{1}{24} p^2 + \frac{1}{24} p\right) x^4 \\
+ \left(-\frac{17}{2880} p - \frac{1}{384} - \frac{1}{720} p^3 - \frac{1}{480} p^2\right) x^6\Bigg) c_1 \\
+ \Bigg(x + \left(-\frac{p}{6} - \frac{1}{12}\right) x^3 + \left(\frac{7}{480} + \frac{1}{120} p^2 + \frac{1}{120} p\right) x^5 \\
+ \left(-\frac{29}{20160} p - \frac{3}{4480} - \frac{1}{5040} p^3 - \frac{1}{3360} p^2\right) x^7\Bigg) c_2 + O\left(x^8\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = \left(1-\frac{1}{2}x^{2}p+\frac{1}{24}x^{4}p^{2}+\frac{1}{24}x^{4}p-\frac{1}{720}x^{6}p^{3}-\frac{1}{480}x^{6}p^{2}-\frac{17}{2880}x^{6}p+\frac{1}{40320}x^{8}p^{4}+\frac{1}{20160}x^{8}p^{3}+\frac{5}{16128}x^{8}p^{2}+\frac{23}{80640}x^{8}p-\frac{1}{4}x^{2}+\frac{1}{32}x^{4}-\frac{1}{384}x^{6}+\frac{1}{6144}x^{8}\right)y(0)+\left(-\frac{1}{6}x^{3}p+\frac{1}{120}x^{5}p^{2}+\frac{1}{120}x^{5}p-\frac{1}{5040}x^{7}p^{3}-\frac{1}{3360}x^{7}p^{2}-\frac{29}{20160}x^{7}p-\frac{1}{12}x^{3}+\frac{7}{480}x^{5}-\frac{3}{4480}x^{7}+x\right)y'(0)+O\left(x^{8}\right) \tag{1}$$

$$y = \left(1+\left(-\frac{p}{2}-\frac{1}{4}\right)x^{2}+\left(\frac{1}{32}+\frac{1}{24}p^{2}+\frac{1}{24}p\right)x^{4}+\left(-\frac{17}{2880}p-\frac{1}{384}-\frac{1}{720}p^{3}-\frac{1}{480}p^{2}\right)x^{6}\right)c_{1}+\left(x+\left(-\frac{p}{6}-\frac{1}{12}\right)x^{3}+\left(\frac{7}{480}+\frac{1}{120}p^{2}+\frac{1}{120}p\right)x^{5}+\left(-\frac{29}{20160}p-\frac{3}{4480}-\frac{1}{5040}p^{3}-\frac{1}{3360}p^{2}\right)x^{7}\right)c_{2}+O\left(x^{8}\right) \tag{2}$$

Verification of solutions

$$
\begin{aligned}
y = {} & \left(1-\frac{1}{2}x^{2}p+\frac{1}{24}x^{4}p^{2}+\frac{1}{24}x^{4}p-\frac{1}{720}x^{6}p^{3}-\frac{1}{480}x^{6}p^{2}-\frac{17}{2880}x^{6}p+\frac{1}{40320}x^{8}p^{4}\right. \\
& \left.+\frac{1}{20160}x^{8}p^{3}+\frac{5}{16128}x^{8}p^{2}+\frac{23}{80640}x^{8}p-\frac{1}{4}x^{2}+\frac{1}{32}x^{4}-\frac{1}{384}x^{6}+\frac{1}{6144}x^{8}\right) y(0) \\
& +\left(-\frac{1}{6}x^{3}p+\frac{1}{120}x^{5}p^{2}+\frac{1}{120}x^{5}p-\frac{1}{5040}x^{7}p^{3}-\frac{1}{3360}x^{7}p^{2}-\frac{29}{20160}x^{7}p-\frac{1}{12}x^{3}\right. \\
& \left.+\frac{7}{480}x^{5}-\frac{3}{4480}x^{7}+x\right) y'(0)+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

$$
\begin{aligned}
y = {} & \left(1+\left(-\frac{p}{2}-\frac{1}{4}\right)x^{2}+\left(\frac{1}{32}+\frac{1}{24}p^{2}+\frac{1}{24}p\right)x^{4}\right. \\
& \left.+\left(-\frac{17}{2880}p-\frac{1}{384}-\frac{1}{720}p^{3}-\frac{1}{480}p^{2}\right)x^{6}\right)c_{1} \\
& +\left(x+\left(-\frac{p}{6}-\frac{1}{12}\right)x^{3}+\left(\frac{7}{480}+\frac{1}{120}p^{2}+\frac{1}{120}p\right)x^{5}\right. \\
& \left.+\left(-\frac{29}{20160}p-\frac{3}{4480}-\frac{1}{5040}p^{3}-\frac{1}{3360}p^{2}\right)x^{7}\right)c_{2}+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

18.11.1 Maple step by step solution

Let's solve

$y''=-\frac{(-x^{2}+4p+2)y}{4}$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\left(-p-\frac{1}{2}+\frac{x^{2}}{4}\right)y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\left(p+\frac{1}{2}-\frac{x^{2}}{4}\right)y=0$

- Multiply by denominators

  $4y''+(-x^{2}+4p+2)y=0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^k$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

$$x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$$

- Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$8a_2 + 2a_0(2p+1) + (24a_3 + 2a_1(2p+1))\, x + \left(\sum_{k=2}^{\infty} (4a_{k+2}(k+2)\,(k+1) + 2a_k(2p+1) - a_{k-2})\, x$$

- The coefficients of each power of x must be 0

$$[8a_2 + 2a_0(2p+1) = 0, 24a_3 + 2a_1(2p+1) = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{1}{2}a_0 p - \frac{1}{4}a_0, a_3 = -\frac{1}{6}a_1 p - \frac{1}{12}a_1\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$4(k^2+3k+2)\, a_{k+2} + 2a_k(2p+1) - a_{k-2} = 0$$

- Shift index using $k->k+2$

$$4\left((k+2)^2 + 3k + 8\right) a_{k+4} + 2a_{k+2}(2p+1) - a_k = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{4pa_{k+2} - a_k + 2a_{k+2}}{4(k^2+7k+12)}, a_2 = -\frac{1}{2}a_0 p - \frac{1}{4}a_0, a_3 = -\frac{1}{6}a_1 p - \frac{1}{12}a_1\right]$$

The type(s) of ODE detected by this program : **"second_order_airy", "second_order_bessel_ode", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{y'' + xy = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (680) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (681) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n\big|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$\begin{aligned}
F_0 &= -xy \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= -y - xy' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -2y' + yx^2 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= x(xy' + 4y) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= -yx^3 + 6xy' + 4y \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= -9yx^2 - y'x^3 + 10y' \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= -12x^2y' + xy\left(x^3 - 28\right)
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$\begin{aligned}
F_0 &= 0 \\
F_1 &= -y(0) \\
F_2 &= -2y'(0) \\
F_3 &= 0 \\
F_4 &= 4y(0) \\
F_5 &= 10y'(0) \\
F_6 &= 0
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1 - \frac{1}{6}x^3 + \frac{1}{180}x^6\right) y(0) + \left(x - \frac{1}{12}x^4 + \frac{1}{504}x^7\right) y'(0) + O(x^8)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -x\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=0}^{\infty} x^{1+n} a_n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n$$

$$\sum_{n=0}^{\infty} x^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^n\right) = 0 \tag{3}$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(1+n) + a_{n-1} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_{n-1}}{(n+2)\,(1+n)} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_3 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$20a_5 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$30a_6 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{180}$$

For $n = 5$ the recurrence equation gives

$$42a_7 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_1}{504}$$

For $n = 6$ the recurrence equation gives

$$56a_8 + a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = 0$$

For $n = 7$ the recurrence equation gives

$$72a_9 + a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = -\frac{a_0}{12960}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x - \frac{1}{6} a_0 x^3 - \frac{1}{12} a_1 x^4 + \frac{1}{180} a_0 x^6 + \frac{1}{504} a_1 x^7 + \dots
$$

Collecting terms, the solution becomes

$$
y = \left(1 - \frac{1}{6} x^3 + \frac{1}{180} x^6\right) a_0 + \left(x - \frac{1}{12} x^4 + \frac{1}{504} x^7\right) a_1 + O(x^8) \tag{3}
$$

At $x = 0$ the solution above becomes

$$
y = \left(1 - \frac{1}{6} x^3 + \frac{1}{180} x^6\right) c_1 + \left(x - \frac{1}{12} x^4 + \frac{1}{504} x^7\right) c_2 + O(x^8)
$$

Summary

The solution(s) found are the following

$$
y = \left(1 - \frac{1}{6} x^3 + \frac{1}{180} x^6\right) y(0) + \left(x - \frac{1}{12} x^4 + \frac{1}{504} x^7\right) y'(0) + O(x^8) \tag{1}
$$

$$
y = \left(1 - \frac{1}{6} x^3 + \frac{1}{180} x^6\right) c_1 + \left(x - \frac{1}{12} x^4 + \frac{1}{504} x^7\right) c_2 + O(x^8) \tag{2}
$$

Verification of solutions

$$
y = \left(1 - \frac{1}{6} x^3 + \frac{1}{180} x^6\right) y(0) + \left(x - \frac{1}{12} x^4 + \frac{1}{504} x^7\right) y'(0) + O(x^8)
$$

Verified OK.

$$
y = \left(1 - \frac{1}{6} x^3 + \frac{1}{180} x^6\right) c_1 + \left(x - \frac{1}{12} x^4 + \frac{1}{504} x^7\right) c_2 + O(x^8)
$$

Verified OK.

18.12.1 Maple step by step solution

Let's solve

$y'' = -xy$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + xy = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x \cdot y$ to series expansion

    $x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$

  - Shift index using $k- > k-1$

    $x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^k$

  - Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- > k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $2a_2 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k-1}\right) x^k\right) = 0$

- Each term must be 0

  $2a_2 = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} + a_{k-1} = 0$

- Shift index using $k- > k+1$

$$\left((k+1)^2+3k+5\right) a_{k+3}+a_k=0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+3}=-\frac{a_k}{k^2+5k+6}, 2a_2=0\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.3. Second-Order Linear Equations: Ordinary Points. Page 169
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[_Gegenbauer, [_2nd_order, _linear, `_with_symmetry_[0,F(x)]`]]
```

$$\boxed{\left(-x^2+1\right) y''-x y'+p^2 y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2}\, f|_{x_0, y_0, y_0'} + \frac{x^3}{3!}\, f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (683) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (684) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{p^2 y - x y'}{x^2 - 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{\left(\left(p^2+2\right) x^2 - p^2 + 1\right) y' - 3 y p^2 x}{\left(x^2-1\right)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{\left(-6p^2 x^3 + 6x\,p^2 - 6x^3 - 9x\right) y' + y\left(\left(p^2+11\right) x^2 - p^2 + 4\right) p^2}{\left(x^2-1\right)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{\left(\left(p^4 + 35p^2 + 24\right) x^4 + \left(-2p^4 - 25p^2 + 72\right) x^2 + p^4 - 10p^2 + 9\right) y' - 10 y x \left(\left(p^2+5\right) x^2 - p^2 + \frac{11}{2}\right) p^2}{\left(x^2-1\right)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(1+x)\left(-15\left(\left(p^4 + 15p^2 + 8\right) x^4 + \left(-2p^4 - 2p^2 + 40\right) x^2 + p^4 - 13p^2 + 15\right) x y' + y\left(\left(p^4 + 85p^2 + 274\right.\right.\right.}{\left(x^2-1\right)^6} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{(1+x)\left(\left(\left(\left(p^6 + 175p^4 + 1624p^2 + 720\right) x^6 + \left(-3p^6 - 315p^4 + 1218p^2 + 5400\right) x^4 + \left(3p^6 + 105p^4 - 25\right.\right.\right.\right.}{} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \frac{\left(-28\left(\frac{1575}{4} + \left(p^6 + 70p^4 + 469p^2 + 180\right) x^6 + 3\left(630 - p^6 - \frac{65}{2}p^4 + \frac{607}{2}p^2\right) x^4 + 3\left(p^6 - 5p^4 - \frac{667}{2}p^2 + \right.\right.\right.}{}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and $y'(0)=y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0)\,p^2 \\
F_1 &= -y'(0)\,p^2 + y'(0) \\
F_2 &= y(0)\,p^4 - 4y(0)\,p^2 \\
F_3 &= y'(0)\,p^4 - 10y'(0)\,p^2 + 9y'(0) \\
F_4 &= -y(0)\,p^6 + 20y(0)\,p^4 - 64y(0)\,p^2 \\
F_5 &= -y'(0)\,p^6 + 35y'(0)\,p^4 - 259y'(0)\,p^2 + 225y'(0) \\
F_6 &= y(0)\,p^8 - 56y(0)\,p^6 + 784y(0)\,p^4 - 2304y(0)\,p^2
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = \bigg(1 - \frac{1}{2}x^2p^2 + \frac{1}{24}p^4x^4 - \frac{1}{6}x^4p^2 - \frac{1}{720}p^6x^6 + \frac{1}{36}p^4x^6 - \frac{4}{45}x^6p^2 + \frac{1}{40320}x^8p^8 \\
- \frac{1}{720}x^8p^6 + \frac{7}{360}x^8p^4 - \frac{2}{35}x^8p^2\bigg) y(0) + \bigg(x - \frac{1}{6}p^2x^3 + \frac{1}{6}x^3 + \frac{1}{120}p^4x^5 - \frac{1}{12}x^5p^2 \\
+ \frac{3}{40}x^5 - \frac{1}{5040}x^7p^6 + \frac{1}{144}x^7p^4 - \frac{37}{720}x^7p^2 + \frac{5}{112}x^7\bigg) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x=0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(-x^2+1)\,y'' - xy' + p^2y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(-x^2+1)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) - x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + p^2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \quad (1)
$$

Which simplifies to

$$\sum_{n=2}^{\infty} \left(-x^n a_n n(n-1)\right)+\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right)+\sum_{n=1}^{\infty} \left(-n a_n x^n\right)+\left(\sum_{n=0}^{\infty} p^2 a_n x^n\right)=0 \quad (2)$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{aligned}\sum_{n=2}^{\infty} \left(-x^n a_n n(n-1)\right)+\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) \\ +\sum_{n=1}^{\infty} \left(-n a_n x^n\right)+\left(\sum_{n=0}^{\infty} p^2 a_n x^n\right)=0\end{aligned} \quad (3)$$

$n = 0$ gives

$$a_0 p^2 + 2a_2 = 0$$

$$a_2 = -\frac{a_0 p^2}{2}$$

$n = 1$ gives

$$a_1 p^2 - a_1 + 6a_3 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{1}{6} a_1 p^2 + \frac{1}{6} a_1$$

For $2 \leq n$, the recurrence equation is

$$-n a_n(n-1) + (n+2)\, a_{n+2}(n+1) - n a_n + a_n p^2 = 0 \quad (4)$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{a_n(n^2 - p^2)}{(n+2)(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$a_2p^2 - 4a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24}p^4a_0 - \frac{1}{6}a_0p^2$$

For $n = 3$ the recurrence equation gives

$$a_3p^2 - 9a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{120}p^4a_1 - \frac{1}{12}a_1p^2 + \frac{3}{40}a_1$$

For $n = 4$ the recurrence equation gives

$$a_4p^2 - 16a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{1}{720}p^6a_0 + \frac{1}{36}p^4a_0 - \frac{4}{45}a_0p^2$$

For $n = 5$ the recurrence equation gives

$$a_5p^2 - 25a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{1}{5040}p^6a_1 + \frac{1}{144}p^4a_1 - \frac{37}{720}a_1p^2 + \frac{5}{112}a_1$$

For $n = 6$ the recurrence equation gives

$$a_6 p^2 - 36a_6 + 56a_8 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{40320} p^8 a_0 - \frac{1}{720} p^6 a_0 + \frac{7}{360} p^4 a_0 - \frac{2}{35} a_0 p^2$$

For $n = 7$ the recurrence equation gives

$$a_7 p^2 - 49a_7 + 72a_9 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{1}{362880} p^8 a_1 - \frac{1}{4320} p^6 a_1 + \frac{47}{8640} p^4 a_1 - \frac{3229}{90720} a_1 p^2 + \frac{35}{1152} a_1$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x - \frac{a_0 p^2 x^2}{2} + \left(-\frac{1}{6} a_1 p^2 + \frac{1}{6} a_1\right) x^3 + \left(\frac{1}{24} p^4 a_0 - \frac{1}{6} a_0 p^2\right) x^4 \\ + \left(\frac{1}{120} p^4 a_1 - \frac{1}{12} a_1 p^2 + \frac{3}{40} a_1\right) x^5 + \left(-\frac{1}{720} p^6 a_0 + \frac{1}{36} p^4 a_0 - \frac{4}{45} a_0 p^2\right) x^6 \\ + \left(-\frac{1}{5040} p^6 a_1 + \frac{1}{144} p^4 a_1 - \frac{37}{720} a_1 p^2 + \frac{5}{112} a_1\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = \left(1 - \frac{x^2 p^2}{2} + \left(\frac{1}{24} p^4 - \frac{1}{6} p^2\right) x^4 + \left(-\frac{1}{720} p^6 + \frac{1}{36} p^4 - \frac{4}{45} p^2\right) x^6\right) a_0 \\ + \left(x + \left(-\frac{p^2}{6} + \frac{1}{6}\right) x^3 + \left(\frac{1}{120} p^4 - \frac{1}{12} p^2 + \frac{3}{40}\right) x^5 \right. \\ \left. + \left(-\frac{1}{5040} p^6 + \frac{1}{144} p^4 - \frac{37}{720} p^2 + \frac{5}{112}\right) x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{x^2 p^2}{2} + \left(\frac{1}{24} p^4 - \frac{1}{6} p^2\right) x^4 + \left(-\frac{1}{720} p^6 + \frac{1}{36} p^4 - \frac{4}{45} p^2\right) x^6\right) c_1 + \left(x + \left(-\frac{p^2}{6} + \frac{1}{6}\right) x^3 + \left(\frac{1}{120} p^4 - \frac{1}{12} p^2 + \frac{3}{40}\right) x^5 + \left(-\frac{1}{5040} p^6 + \frac{1}{144} p^4 - \frac{37}{720} p^2 + \frac{5}{112}\right) x^7\right) c_2 + O(x^8)$$

<u>Summary</u>

The solution(s) found are the following

$$y = \left(1 - \frac{1}{2} x^2 p^2 + \frac{1}{24} p^4 x^4 - \frac{1}{6} x^4 p^2 - \frac{1}{720} p^6 x^6 + \frac{1}{36} p^4 x^6 - \frac{4}{45} x^6 p^2 + \frac{1}{40320} x^8 p^8 - \frac{1}{720} x^8 p^6 + \frac{7}{360} x^8 p^4 - \frac{2}{35} x^8 p^2\right) y(0) + \left(x - \frac{1}{6} p^2 x^3 + \frac{1}{6} x^3 + \frac{1}{120} p^4 x^5 - \frac{1}{12} x^5 p^2 + \frac{3}{40} x^5 - \frac{1}{5040} x^7 p^6 + \frac{1}{144} x^7 p^4 - \frac{37}{720} x^7 p^2 + \frac{5}{112} x^7\right) y'(0) + O(x^8) \tag{1}$$

$$y = \left(1 - \frac{x^2 p^2}{2} + \left(\frac{1}{24} p^4 - \frac{1}{6} p^2\right) x^4 + \left(-\frac{1}{720} p^6 + \frac{1}{36} p^4 - \frac{4}{45} p^2\right) x^6\right) c_1 + \left(x + \left(-\frac{p^2}{6} + \frac{1}{6}\right) x^3 + \left(\frac{1}{120} p^4 - \frac{1}{12} p^2 + \frac{3}{40}\right) x^5 + \left(-\frac{1}{5040} p^6 + \frac{1}{144} p^4 - \frac{37}{720} p^2 + \frac{5}{112}\right) x^7\right) c_2 + O(x^8) \tag{2}$$

Verification of solutions

$$y = \left(1-\frac{1}{2}x^2p^2+\frac{1}{24}p^4x^4-\frac{1}{6}x^4p^2-\frac{1}{720}p^6x^6+\frac{1}{36}p^4x^6-\frac{4}{45}x^6p^2+\frac{1}{40320}x^8p^8-\frac{1}{720}x^8p^6+\frac{7}{360}x^8p^4-\frac{2}{35}x^8p^2\right)y(0)+\left(x-\frac{1}{6}p^2x^3+\frac{1}{6}x^3+\frac{1}{120}p^4x^5-\frac{1}{12}x^5p^2+\frac{3}{40}x^5-\frac{1}{5040}x^7p^6+\frac{1}{144}x^7p^4-\frac{37}{720}x^7p^2+\frac{5}{112}x^7\right)y'(0)+O(x^8)$$

Verified OK.

$$y = \left(1-\frac{x^2p^2}{2}+\left(\frac{1}{24}p^4-\frac{1}{6}p^2\right)x^4+\left(-\frac{1}{720}p^6+\frac{1}{36}p^4-\frac{4}{45}p^2\right)x^6\right)c_1+\left(x+\left(-\frac{p^2}{6}+\frac{1}{6}\right)x^3+\left(\frac{1}{120}p^4-\frac{1}{12}p^2+\frac{3}{40}\right)x^5+\left(-\frac{1}{5040}p^6+\frac{1}{144}p^4-\frac{37}{720}p^2+\frac{5}{112}\right)x^7\right)c_2+O(x^8)$$

Verified OK.

18.13.1 Maple step by step solution

Let's solve

$(-x^2+1)\,y''-xy'+p^2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{xy'}{x^2-1}+\frac{p^2y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{xy'}{x^2-1}-\frac{p^2y}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{x}{x^2-1}, P_3(x)=-\frac{p^2}{x^2-1}\right]$

  ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left.((1+x)\cdot P_2(x))\right|_{x=-1}=\frac{1}{2}$

  ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

$$\left((1+x)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $(x^2-1)\,y'' + xy' - p^2 y = 0$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^2 - 2u)\left(\frac{d^2}{du^2}y(u)\right) + (u-1)\left(\frac{d}{du}y(u)\right) - p^2 y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-a_0 r(-1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)(2k+1+2r) + a_k(k+p+r)(k-p+r)\right) u^{k+r}\right)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(-1+2r) = 0$

- Values of r that satisfy the indicial equation

$r \in \left\{0, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-2\left(k+\frac{1}{2}+r\right)\left(k+1+r\right) a_{k+1}+a_{k}\left(k+p+r\right)\left(k-p+r\right)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_{k}(k+p+r)(k-p+r)}{(2k+1+2r)(k+1+r)}$

- Recursion relation for $r=0$

  $a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}$

- Solution for $r=0$

  $\left[y(u)=\sum_{k=0}^{\infty} a_{k} u^{k}, a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}\right]$

- Revert the change of variables $u=1+x$

  $\left[y=\sum_{k=0}^{\infty} a_{k}(1+x)^{k}, a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}\right]$

- Recursion relation for $r=\frac{1}{2}$

  $a_{k+1}=\frac{a_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}$

- Solution for $r=\frac{1}{2}$

  $\left[y(u)=\sum_{k=0}^{\infty} a_{k} u^{k+\frac{1}{2}}, a_{k+1}=\frac{a_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$

- Revert the change of variables $u=1+x$

  $\left[y=\sum_{k=0}^{\infty} a_{k}(1+x)^{k+\frac{1}{2}}, a_{k+1}=\frac{a_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_{k}(1+x)^{k}\right)+\left(\sum_{k=0}^{\infty} b_{k}(1+x)^{k+\frac{1}{2}}\right), a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}, b_{k+1}=\frac{b_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$

Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - 2xy' + 2py = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{686}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{687}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y'_0} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= 2xy' - 2py \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \left(4x^2 - 2p + 2\right) y' - 4pxy \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(8x^3 - 8px + 12x\right) y' + 4py\left(-2x^2 + p - 2\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= 4\left(3 + p^2 + 2\left(-3x^2 - 2\right) p + 4x^4 + 12x^2\right) y' + 16yxp\left(-x^2 + p - \frac{5}{2}\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= 24x\left(p^2 + \left(-\frac{8x^2}{3} - 5\right) p + \frac{4x^4}{3} + \frac{20x^2}{3} + 5\right) y' - 8py\left(4x^4 - 6x^2p + p^2 + 18x^2 - 6p + 8\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(-8p^3 + \left(96x^2 + 72\right) p^2 + \left(-160x^4 - 576x^2 - 184\right) p + 64x^6 + 480x^4 + 720x^2 + 120\right) y' - 48y\left(p^2 +\right. \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= -64x\left(p^3 + \left(-5x^2 - \frac{21}{2}\right) p^2 + \left(6x^4 + 35x^2 + 32\right) p - 2x^6 - 21x^4 - \frac{105x^2}{2} - \frac{105}{4}\right) y' + 16y\left(p^3 + \left(\right.\right.
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -2y(0)\,p \\
F_1 &= -2y'(0)\,p + 2y'(0) \\
F_2 &= 4y(0)\,p^2 - 8y(0)\,p \\
F_3 &= 4y'(0)\,p^2 - 16y'(0)\,p + 12y'(0) \\
F_4 &= -8y(0)\,p^3 + 48y(0)\,p^2 - 64y(0)\,p \\
F_5 &= -8y'(0)\,p^3 + 72y'(0)\,p^2 - 184y'(0)\,p + 120y'(0) \\
F_6 &= 16y(0)\,p^4 - 192y(0)\,p^3 + 704y(0)\,p^2 - 768y(0)\,p
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = {} & \left(1 - x^2 p + \frac{1}{6} x^4 p^2 - \frac{1}{3} x^4 p - \frac{1}{90} x^6 p^3 + \frac{1}{15} x^6 p^2 - \frac{4}{45} x^6 p + \frac{1}{2520} x^8 p^4 - \frac{1}{210} x^8 p^3 \right. \\
& \left. + \frac{11}{630} x^8 p^2 - \frac{2}{105} x^8 p\right) y(0) + \left(x - \frac{1}{3} x^3 p + \frac{1}{3} x^3 + \frac{1}{30} x^5 p^2 - \frac{2}{15} x^5 p + \frac{1}{10} x^5 \right. \\
& \left. - \frac{1}{630} x^7 p^3 + \frac{1}{70} x^7 p^2 - \frac{23}{630} x^7 p + \frac{1}{42} x^7\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = 2x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - 2p\left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n\,=1}^{\infty} \left(-2n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} 2p a_n x^n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=1}^{\infty} (-2n\, x^n a_n) + \left(\sum_{n=0}^{\infty} 2p a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2pa_0 + 2a_2 = 0$$

$$a_2 = -pa_0$$

For $1 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(n+1) - 2na_n + 2pa_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{2a_n(n-p)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$2pa_1 - 2a_1 + 6a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{1}{3}pa_1 + \frac{1}{3}a_1$$

For $n = 2$ the recurrence equation gives

$$2pa_2 - 4a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{6}p^2 a_0 - \frac{1}{3}p a_0$$

For $n = 3$ the recurrence equation gives

$$2pa_3 - 6a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{30}p^2 a_1 - \frac{2}{15}p a_1 + \frac{1}{10}a_1$$

For $n = 4$ the recurrence equation gives

$$2pa_4 - 8a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{1}{90}p^3 a_0 + \frac{1}{15}p^2 a_0 - \frac{4}{45}p a_0$$

For $n = 5$ the recurrence equation gives

$$2pa_5 - 10a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{1}{630}p^3 a_1 + \frac{1}{70}p^2 a_1 - \frac{23}{630}p a_1 + \frac{1}{42}a_1$$

For $n = 6$ the recurrence equation gives

$$2pa_6 - 12a_6 + 56a_8 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{1}{2520}p^4 a_0 - \frac{1}{210}p^3 a_0 + \frac{11}{630}p^2 a_0 - \frac{2}{105}p a_0$$

For $n = 7$ the recurrence equation gives

$$2pa_7 - 14a_7 + 72a_9 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{1}{22680}p^4 a_1 - \frac{2}{2835}p^3 a_1 + \frac{43}{11340}p^2 a_1 - \frac{22}{2835}pa_1 + \frac{1}{216}a_1$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1x - pa_0x^2 &+ \left(-\frac{1}{3}pa_1 + \frac{1}{3}a_1\right)x^3 + \left(\frac{1}{6}p^2a_0 - \frac{1}{3}pa_0\right)x^4 \\ &+ \left(\frac{1}{30}p^2a_1 - \frac{2}{15}pa_1 + \frac{1}{10}a_1\right)x^5 + \left(-\frac{1}{90}p^3a_0 + \frac{1}{15}p^2a_0 - \frac{4}{45}pa_0\right)x^6 \\ &+ \left(-\frac{1}{630}p^3a_1 + \frac{1}{70}p^2a_1 - \frac{23}{630}pa_1 + \frac{1}{42}a_1\right)x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = \left(1 - x^2p + \left(\frac{1}{6}p^2 - \frac{1}{3}p\right)x^4 + \left(-\frac{1}{90}p^3 + \frac{1}{15}p^2 - \frac{4}{45}p\right)x^6\right)a_0 + \left(x + \left(-\frac{p}{3} + \frac{1}{3}\right)x^3 \right. \\ \left. + \left(\frac{1}{30}p^2 - \frac{2}{15}p + \frac{1}{10}\right)x^5 + \left(-\frac{1}{630}p^3 + \frac{1}{70}p^2 - \frac{23}{630}p + \frac{1}{42}\right)x^7\right)a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$\begin{aligned} y = \left(1 - x^2p + \left(\frac{1}{6}p^2 - \frac{1}{3}p\right)x^4 + \left(-\frac{1}{90}p^3 + \frac{1}{15}p^2 - \frac{4}{45}p\right)x^6\right)c_1 + \left(x + \left(-\frac{p}{3} + \frac{1}{3}\right)x^3 \right. \\ \left. + \left(\frac{1}{30}p^2 - \frac{2}{15}p + \frac{1}{10}\right)x^5 + \left(-\frac{1}{630}p^3 + \frac{1}{70}p^2 - \frac{23}{630}p + \frac{1}{42}\right)x^7\right)c_2 + O(x^8) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(1 - x^2 p + \frac{1}{6}x^4 p^2 - \frac{1}{3}x^4 p - \frac{1}{90}x^6 p^3 + \frac{1}{15}x^6 p^2 - \frac{4}{45}x^6 p + \frac{1}{2520}x^8 p^4 - \frac{1}{210}x^8 p^3 + \frac{11}{630}x^8 p^2 - \frac{2}{105}x^8 p\right) y(0) + \left(x - \frac{1}{3}x^3 p + \frac{1}{3}x^3 + \frac{1}{30}x^5 p^2 - \frac{2}{15}x^5 p + \frac{1}{10}x^5 - \frac{1}{630}x^7 p^3 + \frac{1}{70}x^7 p^2 - \frac{23}{630}x^7 p + \frac{1}{42}x^7\right) y'(0) + O(x^8) \tag{1}$$

$$y = \left(1 - x^2 p + \left(\frac{1}{6}p^2 - \frac{1}{3}p\right) x^4 + \left(-\frac{1}{90}p^3 + \frac{1}{15}p^2 - \frac{4}{45}p\right) x^6\right) c_1 + \left(x + \left(-\frac{p}{3} + \frac{1}{3}\right) x^3 + \left(\frac{1}{30}p^2 - \frac{2}{15}p + \frac{1}{10}\right) x^5 + \left(-\frac{1}{630}p^3 + \frac{1}{70}p^2 - \frac{23}{630}p + \frac{1}{42}\right) x^7\right) c_2 + O(x^8) \tag{2}$$

Verification of solutions

$$y = \left(1 - x^2 p + \frac{1}{6}x^4 p^2 - \frac{1}{3}x^4 p - \frac{1}{90}x^6 p^3 + \frac{1}{15}x^6 p^2 - \frac{4}{45}x^6 p + \frac{1}{2520}x^8 p^4 - \frac{1}{210}x^8 p^3 + \frac{11}{630}x^8 p^2 - \frac{2}{105}x^8 p\right) y(0) + \left(x - \frac{1}{3}x^3 p + \frac{1}{3}x^3 + \frac{1}{30}x^5 p^2 - \frac{2}{15}x^5 p + \frac{1}{10}x^5 - \frac{1}{630}x^7 p^3 + \frac{1}{70}x^7 p^2 - \frac{23}{630}x^7 p + \frac{1}{42}x^7\right) y'(0) + O(x^8)$$

Verified OK.

$$y = \left(1 - x^2 p + \left(\frac{1}{6}p^2 - \frac{1}{3}p\right) x^4 + \left(-\frac{1}{90}p^3 + \frac{1}{15}p^2 - \frac{4}{45}p\right) x^6\right) c_1 + \left(x + \left(-\frac{p}{3} + \frac{1}{3}\right) x^3 + \left(\frac{1}{30}p^2 - \frac{2}{15}p + \frac{1}{10}\right) x^5 + \left(-\frac{1}{630}p^3 + \frac{1}{70}p^2 - \frac{23}{630}p + \frac{1}{42}\right) x^7\right) c_2 + O(x^8)$$

Verified OK.

18.14.1 Maple step by step solution

Let's solve

$y'' = 2xy' - 2py$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - 2xy' + 2py = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite DE with series expansions

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  - Convert y'' to series expansion

    $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  - Shift index using $k- >k+2$

    $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - 2a_k(k-p)\right) x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k^2+3k+2)\, a_{k+2} - 2a_k(k-p) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{2a_k(k-p)}{k^2+3k+2}\right]$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 1(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Irregular singular point"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{x^3(x-1)\,y''-2(x-1)\,y'+3xy=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^4-x^3\right)y''+(-2x+2)\,y'+3xy=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{2}{x^3}$$
$$q(x)=\frac{3}{x^2\,(x-1)}$$

Table 439: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{2}{x^3}$	
singularity	type
$x = 0$	"irregular"

$q(x) = \frac{3}{x^2(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[1, \infty]$

Irregular singular points : $[0]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 1(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(x^2-1)\,y''-x(1-x)\,y'+2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^4-x^2)\,y''+(x^2-x)\,y'+2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{1}{x\,(1+x)}$$
$$q(x)=\frac{2}{x^2\,(x^2-1)}$$

Table 440: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x(1+x)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{2}{x^2(x^2-1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, 1, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x^2-1)\,y'' + (x^2-x)\,y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x^2-1)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) + (x^2-x)\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2 a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)(n+r-1) = \sum_{n=2}^{\infty} a_{n-2}(n+r-2)(n-3+r)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)(n-3+r)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2 a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$-x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + 2 a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$-x^r a_0 r(-1+r) - x^r a_0 r + 2 a_0 x^r = 0$$

Or

$$\left(-x^r r(-1+r) - x^r r + 2 x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$-\left(r^2-2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$-r^2+2 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= -\sqrt{2} \\ r_2 &= \sqrt{2} \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$-\left(r^2-2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = -2\sqrt{2}$ is not an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n-\sqrt{2}} \\ y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+\sqrt{2}} \end{aligned}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{r}{r^2+2r-1}$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} &a_{n-2}(n+r-2)(n-3+r) - a_n(n+r)(n+r-1) \\ &+ a_{n-1}(n+r-1) - a_n(n+r) + 2a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{n^2 a_{n-2} + 2nr a_{n-2} + r^2 a_{n-2} - 5n a_{n-2} + n a_{n-1} - 5r a_{n-2} + r a_{n-1} + 6a_{n-2} - a_{n-1}}{n^2 + 2nr + r^2 - 2} \tag{4}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_n = \frac{(-2n a_{n-2} + 5a_{n-2} - a_{n-1})\sqrt{2} + n^2 a_{n-2} + (-5a_{n-2} + a_{n-1})\, n + 8a_{n-2} - a_{n-1}}{n\left(-2\sqrt{2} + n\right)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -\sqrt{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{-1+2\sqrt{2}}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r(r^3 + r^2 - 2r + 2)}{(r^2 + 2r - 1)(r^2 + 4r + 2)}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_2 = \frac{\sqrt{2}}{-5 + 3\sqrt{2}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{-1+2\sqrt{2}}$
a_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{-5+3\sqrt{2}}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{2r(r^4 + 4r^3 + 3r^2 + 2)}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_3 = -\frac{2\sqrt{2}}{15 - 9\sqrt{2}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{-1+2\sqrt{2}}$
a_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{-5+3\sqrt{2}}$
a_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$-\frac{2\sqrt{2}}{15-9\sqrt{2}}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(r^7 + 10r^6 + 36r^5 + 58r^4 + 41r^3 + 20r^2 + 42r + 40)}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_4 = \frac{-69 + 49\sqrt{2}}{-1104 + 780\sqrt{2}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{-1+2\sqrt{2}}$
a_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{-5+3\sqrt{2}}$
a_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$-\frac{2\sqrt{2}}{15-9\sqrt{2}}$
a_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{-69+49\sqrt{2}}{-1104+780\sqrt{2}}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{r(3r^8 + 48r^7 + 306r^6 + 996r^5 + 1749r^4 + 1616r^3 + 866r^2 + 680r + 496)}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)(r^2 + 10r + 23)}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_5 = \frac{-414 + 293\sqrt{2}}{6108\sqrt{2} - 8640}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{-1+2\sqrt{2}}$
a_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{-5+3\sqrt{2}}$
a_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$-\frac{2\sqrt{2}}{15-9\sqrt{2}}$
a_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{-69+49\sqrt{2}}{-1104+780\sqrt{2}}$
a_5	$\frac{r(3r^8+48r^7+306r^6+996r^5+1749r^4+1616r^3+866r^2+680r+496)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)}$	$\frac{-414+293\sqrt{2}}{6108\sqrt{2}-8640}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{r(r^{11} + 27r^{10} + 314r^9 + 2064r^8 + 8439r^7 + 22209r^6 + 37650r^5 + 40744r^4 + 30972r^3 + 26532r^2 + 26}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)(r^2 + 10r + 23)(r^2 + 12r + 34}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_6 = \frac{3898 - 2757\sqrt{2}}{114408 - 80892\sqrt{2}}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{-1+2\sqrt{2}}$
a_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{-5+3\sqrt{2}}$
a_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$-\frac{2\sqrt{2}}{15-9\sqrt{2}}$
a_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{-69+49\sqrt{2}}{-1104+780\sqrt{2}}$
a_5	$\frac{r(3r^8+48r^7+306r^6+996r^5+1749r^4+1616r^3+866r^2+680r+496)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)}$	$\frac{-414+293\sqrt{2}}{6108\sqrt{2}-8640}$
a_6	$\frac{r(r^{11}+27r^{10}+314r^9+2064r^8+8439r^7+22209r^6+37650r^5+40744r^4+30972r^3+26532r^2+26728r+13520)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)(r^2+12r+34)}$	$\frac{3898-2757\sqrt{2}}{114408-80892\sqrt{2}}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{4r(r^{12} + 36r^{11} + 569r^{10} + 5196r^9 + 30327r^8 + 118064r^7 + 310235r^6 + 544884r^5 + 625540r^4 + 4761}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)(r^2 + 10r + 23)(r^2 + 12r +}$$

Which for the root $r = -\sqrt{2}$ becomes

$$a_7 = -\frac{\sqrt{2}\,(-77567 + 54843\sqrt{2})}{126\,(-1 + 2\sqrt{2})\,(\sqrt{2} - 1)\,(-3 + 2\sqrt{2})\,(-2 + \sqrt{2})\,(-5 + 2\sqrt{2})\,(-3 + \sqrt{2})\,(-7 + 2\sqrt{2})}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r-1}$	$\frac{\surd}{-1+}$
a_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\surd}{-5+}$
a_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$-\frac{}{15}$
a_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{-6}{-110}$
a_5	$\frac{r(3r^8+48r^7+306r^6+996r^5+1749r^4+1616r^3+866r^2+680r+496)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)}$	$\frac{-41}{6108}$
a_6	$\frac{r(r^{11}+27r^{10}+314r^9+2064r^8+8439r^7+22209r^6+37650r^5+40744r^4+30972r^3+26532r^2+26728r+13520)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)(r^2+12r+34)}$	$\frac{38}{1144}$
a_7	$\frac{4r(r^{12}+36r^{11}+569r^{10}+5196r^9+30327r^8+118064r^7+310235r^6+544884r^5+625540r^4+476164r^3+306608r^2+226776r+104600)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)(r^2+12r+34)(r^2+14r+47)}$	$-\frac{}{12}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{-\sqrt{2}}(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots) \\ &= x^{-\sqrt{2}}\left(1 + \frac{\sqrt{2}\,x}{-1 + 2\sqrt{2}} + \frac{\sqrt{2}\,x^2}{-5 + 3\sqrt{2}} - \frac{2\sqrt{2}\,x^3}{15 - 9\sqrt{2}} + \frac{(-69 + 49\sqrt{2})\,x^4}{-1104 + 780\sqrt{2}} + \frac{(-414 + 293\sqrt{2})\,x^5}{6108\sqrt{2} - 8640} + \right. \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = \frac{r}{r^2 + 2r - 1}$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} b_{n-2}(n + r - 2)\,(n - 3 + r) - b_n(n + r)\,(n + r - 1) \\ + b_{n-1}(n + r - 1) - b_n(n + r) + 2b_n = 0 \end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{n^2 b_{n-2} + 2nr b_{n-2} + r^2 b_{n-2} - 5n b_{n-2} + n b_{n-1} - 5r b_{n-2} + r b_{n-1} + 6 b_{n-2} - b_{n-1}}{n^2 + 2nr + r^2 - 2} \tag{4}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_n = \frac{(2n b_{n-2} - 5 b_{n-2} + b_{n-1}) \sqrt{2} + n^2 b_{n-2} + (-5 b_{n-2} + b_{n-1}) n + 8 b_{n-2} - b_{n-1}}{n (2\sqrt{2} + n)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \sqrt{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{1+2\sqrt{2}}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r(r^3 + r^2 - 2r + 2)}{(r^2 + 2r - 1)(r^2 + 4r + 2)}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_2 = \frac{\sqrt{2}}{5 + 3\sqrt{2}}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{1+2\sqrt{2}}$
b_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{5+3\sqrt{2}}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{2r(r^4 + 4r^3 + 3r^2 + 2)}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_3 = \frac{2\sqrt{2}}{15 + 9\sqrt{2}}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{1+2\sqrt{2}}$
b_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{5+3\sqrt{2}}$
b_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$\frac{2\sqrt{2}}{15+9\sqrt{2}}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r(r^7 + 10r^6 + 36r^5 + 58r^4 + 41r^3 + 20r^2 + 42r + 40)}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_4 = \frac{69 + 49\sqrt{2}}{1104 + 780\sqrt{2}}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{1+2\sqrt{2}}$
b_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{5+3\sqrt{2}}$
b_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$\frac{2\sqrt{2}}{15+9\sqrt{2}}$
b_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{69+49\sqrt{2}}{1104+780\sqrt{2}}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{r(3r^8 + 48r^7 + 306r^6 + 996r^5 + 1749r^4 + 1616r^3 + 866r^2 + 680r + 496)}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)(r^2 + 10r + 23)}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_5 = \frac{414 + 293\sqrt{2}}{6108\sqrt{2} + 8640}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{1+2\sqrt{2}}$
b_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{5+3\sqrt{2}}$
b_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$\frac{2\sqrt{2}}{15+9\sqrt{2}}$
b_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{69+49\sqrt{2}}{1104+780\sqrt{2}}$
b_5	$\frac{r(3r^8+48r^7+306r^6+996r^5+1749r^4+1616r^3+866r^2+680r+496)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)}$	$\frac{414+293\sqrt{2}}{6108\sqrt{2}+8640}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{r(r^{11} + 27r^{10} + 314r^9 + 2064r^8 + 8439r^7 + 22209r^6 + 37650r^5 + 40744r^4 + 30972r^3 + 26532r^2 + 26}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)(r^2 + 10r + 23)(r^2 + 12r + 34}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_6 = \frac{3898 + 2757\sqrt{2}}{114408 + 80892\sqrt{2}}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}}{1+2\sqrt{2}}$
b_2	$\frac{r(r^3+r^2-2r+2)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}}{5+3\sqrt{2}}$
b_3	$\frac{2r(r^4+4r^3+3r^2+2)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$\frac{2\sqrt{2}}{15+9\sqrt{2}}$
b_4	$\frac{r(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{69+49\sqrt{2}}{1104+780\sqrt{2}}$
b_5	$\frac{r(3r^8+48r^7+306r^6+996r^5+1749r^4+1616r^3+866r^2+680r+496)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)}$	$\frac{414+293\sqrt{2}}{6108\sqrt{2}+8640}$
b_6	$\frac{r(r^{11}+27r^{10}+314r^9+2064r^8+8439r^7+22209r^6+37650r^5+40744r^4+30972r^3+26532r^2+26728r+13520)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)(r^2+12r+34)}$	$\frac{3898+2757\sqrt{2}}{114408+80892\sqrt{2}}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{4r(r^{12} + 36r^{11} + 569r^{10} + 5196r^9 + 30327r^8 + 118064r^7 + 310235r^6 + 544884r^5 + 625540r^4 + 4761\cdots}{(r^2 + 2r - 1)(r^2 + 4r + 2)(r^2 + 6r + 7)(r^2 + 8r + 14)(r^2 + 10r + 23)(r^2 + 12r + \cdots}$$

Which for the root $r = \sqrt{2}$ becomes

$$b_7 = \frac{\sqrt{2}\left(77567 + 54843\sqrt{2}\right)}{126\left(1 + 2\sqrt{2}\right)\left(1 + \sqrt{2}\right)\left(3 + 2\sqrt{2}\right)\left(2 + \sqrt{2}\right)\left(5 + 2\sqrt{2}\right)\left(3 + \sqrt{2}\right)\left(7 + 2\sqrt{2}\right)}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+2r-1}$	$\frac{\sqrt{2}\cdots}{1+2\sqrt{\cdots}}$
b_2	$\frac{r\left(r^3+r^2-2r+2\right)}{(r^2+2r-1)(r^2+4r+2)}$	$\frac{\sqrt{2}\cdots}{5+3\sqrt{\cdots}}$
b_3	$\frac{2r\left(r^4+4r^3+3r^2+2\right)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)}$	$\frac{2\sqrt{\cdots}}{15+9\cdots}$
b_4	$\frac{r\left(r^7+10r^6+36r^5+58r^4+41r^3+20r^2+42r+40\right)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)}$	$\frac{69+\cdots}{1104\cdots}$
b_5	$\frac{r\left(3r^8+48r^7+306r^6+996r^5+1749r^4+1616r^3+866r^2+680r+496\right)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)}$	$\frac{414\cdots}{6108\cdots}$
b_6	$\frac{r\left(r^{11}+27r^{10}+314r^9+2064r^8+8439r^7+22209r^6+37650r^5+40744r^4+30972r^3+26532r^2+26728r+13520\right)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)(r^2+12r+34)}$	$\frac{389\cdots}{1144\cdots}$
b_7	$\frac{4r\left(r^{12}+36r^{11}+569r^{10}+5196r^9+30327r^8+118064r^7+310235r^6+544884r^5+625540r^4+476164r^3+306608r^2+226776r+104600\right)}{(r^2+2r-1)(r^2+4r+2)(r^2+6r+7)(r^2+8r+14)(r^2+10r+23)(r^2+12r+34)(r^2+14r+47)}$	$\frac{\cdots}{126\left(\cdots\right.}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^{-\sqrt{2}}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots\right) \\ &= x^{\sqrt{2}}\left(1 + \frac{\sqrt{2}\,x}{1 + 2\sqrt{2}} + \frac{\sqrt{2}\,x^2}{5 + 3\sqrt{2}} + \frac{2\sqrt{2}\,x^3}{15 + 9\sqrt{2}} + \frac{\left(69 + 49\sqrt{2}\right)x^4}{1104 + 780\sqrt{2}} + \frac{\left(414 + 293\sqrt{2}\right)x^5}{6108\sqrt{2} + 8640} + \frac{\left(3898 + 2\cdots\right.}{114408 + \cdots} \right. \end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1 y_1(x) + c_2 y_2(x)$$

$$
\begin{aligned}
&= c_1 x^{-\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{-1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{-5+3\sqrt{2}} - \frac{2\sqrt{2}\, x^3}{15-9\sqrt{2}} + \frac{\left(-69+49\sqrt{2}\right) x^4}{-1104+780\sqrt{2}} \right.\\
&\quad + \frac{\left(-414+293\sqrt{2}\right) x^5}{6108\sqrt{2}-8640} + \frac{\left(3898-2757\sqrt{2}\right) x^6}{114408-80892\sqrt{2}}\\
&\quad - \frac{\sqrt{2}\left(-77567+54843\sqrt{2}\right) x^7}{126\left(-1+2\sqrt{2}\right)\left(\sqrt{2}-1\right)\left(-3+2\sqrt{2}\right)\left(-2+\sqrt{2}\right)\left(-5+2\sqrt{2}\right)\left(-3+\sqrt{2}\right)\left(-7+2\sqrt{2}\right)}\\
&\quad \left. + O\left(x^8\right)\right) + c_2 x^{\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{5+3\sqrt{2}} + \frac{2\sqrt{2}\, x^3}{15+9\sqrt{2}} + \frac{\left(69+49\sqrt{2}\right) x^4}{1104+780\sqrt{2}} \right.\\
&\quad + \frac{\left(414+293\sqrt{2}\right) x^5}{6108\sqrt{2}+8640} + \frac{\left(3898+2757\sqrt{2}\right) x^6}{114408+80892\sqrt{2}}\\
&\quad + \frac{\sqrt{2}\left(77567+54843\sqrt{2}\right) x^7}{126\left(1+2\sqrt{2}\right)\left(1+\sqrt{2}\right)\left(3+2\sqrt{2}\right)\left(2+\sqrt{2}\right)\left(5+2\sqrt{2}\right)\left(3+\sqrt{2}\right)\left(7+2\sqrt{2}\right)}\\
&\quad \left. + O\left(x^8\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h\\
&= c_1 x^{-\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{-1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{-5+3\sqrt{2}} - \frac{2\sqrt{2}\, x^3}{15-9\sqrt{2}} + \frac{\left(-69+49\sqrt{2}\right) x^4}{-1104+780\sqrt{2}} \right.\\
&\quad + \frac{\left(-414+293\sqrt{2}\right) x^5}{6108\sqrt{2}-8640} + \frac{\left(3898-2757\sqrt{2}\right) x^6}{114408-80892\sqrt{2}}\\
&\quad - \frac{\sqrt{2}\left(-77567+54843\sqrt{2}\right) x^7}{126\left(-1+2\sqrt{2}\right)\left(\sqrt{2}-1\right)\left(-3+2\sqrt{2}\right)\left(-2+\sqrt{2}\right)\left(-5+2\sqrt{2}\right)\left(-3+\sqrt{2}\right)\left(-7+2\sqrt{2}\right)}\\
&\quad \left. + O\left(x^8\right)\right) + c_2 x^{\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{5+3\sqrt{2}} + \frac{2\sqrt{2}\, x^3}{15+9\sqrt{2}} + \frac{\left(69+49\sqrt{2}\right) x^4}{1104+780\sqrt{2}} \right.\\
&\quad + \frac{\left(414+293\sqrt{2}\right) x^5}{6108\sqrt{2}+8640} + \frac{\left(3898+2757\sqrt{2}\right) x^6}{114408+80892\sqrt{2}}\\
&\quad + \frac{\sqrt{2}\left(77567+54843\sqrt{2}\right) x^7}{126\left(1+2\sqrt{2}\right)\left(1+\sqrt{2}\right)\left(3+2\sqrt{2}\right)\left(2+\sqrt{2}\right)\left(5+2\sqrt{2}\right)\left(3+\sqrt{2}\right)\left(7+2\sqrt{2}\right)}\\
&\quad \left. + O\left(x^8\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^{-\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{-1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{-5+3\sqrt{2}} - \frac{2\sqrt{2}\, x^3}{15-9\sqrt{2}} + \frac{\left(-69+49\sqrt{2}\right) x^4}{-1104+780\sqrt{2}} \right. \\
& + \frac{\left(-414+293\sqrt{2}\right) x^5}{6108\sqrt{2}-8640} + \frac{\left(3898-2757\sqrt{2}\right) x^6}{114408-80892\sqrt{2}} \\
& - \frac{\sqrt{2}\left(-77567+54843\sqrt{2}\right) x^7}{126\left(-1+2\sqrt{2}\right)\left(\sqrt{2}-1\right)\left(-3+2\sqrt{2}\right)\left(-2+\sqrt{2}\right)\left(-5+2\sqrt{2}\right)\left(-3+\sqrt{2}\right)\left(-7+2\sqrt{2}\right)} \\
& \left. + O\left(x^8\right)\right) + c_2 x^{\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{5+3\sqrt{2}} + \frac{2\sqrt{2}\, x^3}{15+9\sqrt{2}} + \frac{\left(69+49\sqrt{2}\right) x^4}{1104+780\sqrt{2}} \right. \\
& + \frac{\left(414+293\sqrt{2}\right) x^5}{6108\sqrt{2}+8640} + \frac{\left(3898+2757\sqrt{2}\right) x^6}{114408+80892\sqrt{2}} \\
& + \frac{\sqrt{2}\left(77567+54843\sqrt{2}\right) x^7}{126\left(1+2\sqrt{2}\right)\left(1+\sqrt{2}\right)\left(3+2\sqrt{2}\right)\left(2+\sqrt{2}\right)\left(5+2\sqrt{2}\right)\left(3+\sqrt{2}\right)\left(7+2\sqrt{2}\right)} \\
& \left. + O\left(x^8\right)\right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 x^{-\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{-1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{-5+3\sqrt{2}} - \frac{2\sqrt{2}\, x^3}{15-9\sqrt{2}} + \frac{\left(-69+49\sqrt{2}\right) x^4}{-1104+780\sqrt{2}} \right. \\
& + \frac{\left(-414+293\sqrt{2}\right) x^5}{6108\sqrt{2}-8640} + \frac{\left(3898-2757\sqrt{2}\right) x^6}{114408-80892\sqrt{2}} \\
& - \frac{\sqrt{2}\left(-77567+54843\sqrt{2}\right) x^7}{126\left(-1+2\sqrt{2}\right)\left(\sqrt{2}-1\right)\left(-3+2\sqrt{2}\right)\left(-2+\sqrt{2}\right)\left(-5+2\sqrt{2}\right)\left(-3+\sqrt{2}\right)\left(-7+2\sqrt{2}\right)} \\
& \left. + O\left(x^8\right)\right) + c_2 x^{\sqrt{2}} \left(1 + \frac{\sqrt{2}\, x}{1+2\sqrt{2}} + \frac{\sqrt{2}\, x^2}{5+3\sqrt{2}} + \frac{2\sqrt{2}\, x^3}{15+9\sqrt{2}} + \frac{\left(69+49\sqrt{2}\right) x^4}{1104+780\sqrt{2}} \right. \\
& + \frac{\left(414+293\sqrt{2}\right) x^5}{6108\sqrt{2}+8640} + \frac{\left(3898+2757\sqrt{2}\right) x^6}{114408+80892\sqrt{2}} \\
& + \frac{\sqrt{2}\left(77567+54843\sqrt{2}\right) x^7}{126\left(1+2\sqrt{2}\right)\left(1+\sqrt{2}\right)\left(3+2\sqrt{2}\right)\left(2+\sqrt{2}\right)\left(5+2\sqrt{2}\right)\left(3+\sqrt{2}\right)\left(7+2\sqrt{2}\right)} \\
& \left. + O\left(x^8\right)\right)
\end{aligned}
$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 1(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y", "second order series method. Irregular singular point"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

Unable to solve or complete the solution.

$$\boxed{x^2y'' + (2 - x)\,y' = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + (2 - x)\,y' = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{-2 + x}{x^2}$$
$$q(x) = 0$$

Table 441: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{-2+x}{x^2}$	
singularity	type
$x = 0$	"irregular"

$q(x) = 0$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[\infty]$

Irregular singular points : $[0]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 1(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(3x+1)\,xy''-(1+x)\,y'+2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(3x^2+x)\,y''+(-1-x)\,y'+2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=-\frac{1+x}{(3x+1)\,x}$$
$$q(x)=\frac{2}{(3x+1)\,x}$$

Table 442: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1+x}{(3x+1)x}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{1}{3}$	"regular"

$q(x) = \frac{2}{(3x+1)x}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{1}{3}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, -\frac{1}{3}, \infty\right]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$(3x+1)\, x y'' + (-1-x)\, y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\, (n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$(3x+1)\, x \left(\sum_{n=0}^{\infty} (n+r)\, (n+r-1)\, a_n x^{n+r-2}\right) + (-1-x) \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 3x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 3x^{n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} 3a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} 2a_n x^{n+r} = \sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty} 3a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) - (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) - r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) - r\,x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\,x^{-1+r}(-2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^2\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} &3a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) \\ &- a_{n-1}(n+r-1) - a_n(n+r) + 2a_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(3n^2 + 6nr + 3r^2 - 10n - 10r + 9)}{n^2 + 2nr + r^2 - 2n - 2r} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = -\frac{a_{n-1}(3n^2 + 2n + 1)}{n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-3r^2 + 4r - 2}{r^2 - 1}$$

Which for the root $r = 2$ becomes

$$a_1 = -2$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9r^4 - 6r^3 + r^2 + 2}{(r^2 - 1)\, r\, (r+2)}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{17}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2
a_2	$\frac{9r^4-6r^3+r^2+2}{(r^2-1)r(r+2)}$	$\frac{17}{4}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-27r^6 - 54r^5 - 9r^4 + 28r^3 - 12r^2 - 16r - 12}{r(-1+r)(r+2)(r+1)^2(r+3)}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{289}{30}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2
a_2	$\frac{9r^4-6r^3+r^2+2}{(r^2-1)r(r+2)}$	$\frac{17}{4}$
a_3	$\frac{-27r^6-54r^5-9r^4+28r^3-12r^2-16r-12}{r(-1+r)(r+2)(r+1)^2(r+3)}$	$-\frac{289}{30}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81r^8 + 540r^7 + 1242r^6 + 960r^5 - 203r^4 - 260r^3 + 464r^2 + 440r + 204}{r(-1+r)(r+2)^2(r+1)^2(r+3)(r+4)}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{5491}{240}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2
a_2	$\frac{9r^4-6r^3+r^2+2}{(r^2-1)r(r+2)}$	$\frac{17}{4}$
a_3	$\frac{-27r^6-54r^5-9r^4+28r^3-12r^2-16r-12}{r(-1+r)(r+2)(r+1)^2(r+3)}$	$-\frac{289}{30}$
a_4	$\frac{81r^8+540r^7+1242r^6+960r^5-203r^4-260r^3+464r^2+440r+204}{r(-1+r)(r+2)^2(r+1)^2(r+3)(r+4)}$	$\frac{5491}{240}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-243r^{10} - 3240r^9 - 17280r^8 - 46080r^7 - 60819r^6 - 27800r^5 + 10710r^4 - 1760r^3 - 25188r^2 - 1904}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)(r+5)}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{236113}{4200}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2
a_2	$\frac{9r^4-6r^3+r^2+2}{(r^2-1)r(r+2)}$	$\frac{17}{4}$
a_3	$\frac{-27r^6-54r^5-9r^4+28r^3-12r^2-16r-12}{r(-1+r)(r+2)(r+1)^2(r+3)}$	$-\frac{289}{30}$
a_4	$\frac{81r^8+540r^7+1242r^6+960r^5-203r^4-260r^3+464r^2+440r+204}{r(-1+r)(r+2)^2(r+1)^2(r+3)(r+4)}$	$\frac{5491}{240}$
a_5	$\frac{-243r^{10}-3240r^9-17280r^8-46080r^7-60819r^6-27800r^5+10710r^4-1760r^3-25188r^2-19040r-6936}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)(r+5)}$	$-\frac{236113}{4200}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{(3r^2+26r+57)(3r^2-4r+2)(3r^2+8r+6)(3r^2+2r+1)(3r^2+14r+17)(3r^2+20r+34)}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)^2(r+5)(r+6)}$$

Which for the root $r = 2$ becomes

$$a_6 = \frac{28569673}{201600}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2
a_2	$\frac{9r^4-6r^3+r^2+2}{(r^2-1)r(r+2)}$	$\frac{17}{4}$
a_3	$\frac{-27r^6-54r^5-9r^4+28r^3-12r^2-16r-12}{r(-1+r)(r+2)(r+1)^2(r+3)}$	$-\frac{289}{30}$
a_4	$\frac{81r^8+540r^7+1242r^6+960r^5-203r^4-260r^3+464r^2+440r+204}{r(-1+r)(r+2)^2(r+1)^2(r+3)(r+4)}$	$\frac{5491}{240}$
a_5	$\frac{-243r^{10}-3240r^9-17280r^8-46080r^7-60819r^6-27800r^5+10710r^4-1760r^3-25188r^2-19040r-6936}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)(r+5)}$	$-\frac{236113}{4200}$
a_6	$\frac{(3r^2+26r+57)(3r^2-4r+2)(3r^2+8r+6)(3r^2+2r+1)(3r^2+14r+17)(3r^2+20r+34)}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)^2(r+5)(r+6)}$	$\frac{28569673}{201600}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{(3r^2+26r+57)(3r^2-4r+2)(3r^2+8r+6)(3r^2+2r+1)(3r^2+14r+17)(3r^2+20r+34)(3r}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)^2(r+5)^2(r+6)(r+7)}$$

Which for the root $r = 2$ becomes

$$a_7 = -\frac{28569673}{78400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3r^2+4r-2}{r^2-1}$	-2
a_2	$\frac{9r^4-6r^3+r^2+2}{(r^2-1)r(r+2)}$	$\frac{17}{4}$
a_3	$\frac{-27r^6-54r^5-9r^4+28r^3-12r^2-16r-12}{r(-1+r)(r+2)(r+1)^2(r+3)}$	$-\frac{289}{30}$
a_4	$\frac{81r^8+540r^7+1242r^6+960r^5-203r^4-260r^3+464r^2+440r+204}{r(-1+r)(r+2)^2(r+1)^2(r+3)(r+4)}$	$\frac{5491}{240}$
a_5	$\frac{-243r^{10}-3240r^9-17280r^8-46080r^7-60819r^6-27800r^5+10710r^4-1760r^3-25188r^2-19040r-6936}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)(r+5)}$	$-\frac{236113}{4200}$
a_6	$\frac{(3r^2+26r+57)(3r^2-4r+2)(3r^2+8r+6)(3r^2+2r+1)(3r^2+14r+17)(3r^2+20r+34)}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)^2(r+5)(r+6)}$	$\frac{28569673}{201600}$
a_7	$-\frac{(3r^2+26r+57)(3r^2-4r+2)(3r^2+8r+6)(3r^2+2r+1)(3r^2+14r+17)(3r^2+20r+34)(3r^2+32r+86)}{r(-1+r)(r+2)^2(r+1)^2(r+3)^2(r+4)^2(r+5)^2(r+6)(r+7)}$	$-\frac{28569673}{78400}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^2\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots\right) \\
&= x^2\left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\rightarrow r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_2 \\
&= \frac{9r^4 - 6r^3 + r^2 + 2}{(r^2 - 1)\, r\, (r + 2)}
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r\rightarrow r_2} \frac{9r^4 - 6r^3 + r^2 + 2}{(r^2 - 1)\, r\, (r + 2)} &= \lim_{r\rightarrow 0} \frac{9r^4 - 6r^3 + r^2 + 2}{(r^2 - 1)\, r\, (r + 2)} \\
&= \textit{undefined}
\end{aligned}
$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$
y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)
$$

Therefore

$$
\begin{aligned}
\frac{d}{dx} y_2(x) &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n + r_2)}{x}\right) \\
&= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n + r_2)\right) \\
\frac{d^2}{dx^2} y_2(x) &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n + r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n + r_2)}{x^2}\right) \\
&= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n + r_2) (-1 + n + r_2)\right)
\end{aligned}
$$

Substituting these back into the given ode $(3x+1)\,x y''+(-1-x)\,y'+2y = 0$ gives

$$(3x+1)\,x\left(C y_1''(x)\ln\left(x\right)+\frac{2C y_1'(x)}{x}-\frac{C y_1(x)}{x^{2}}+\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}\left(n+r_2\right)^{2}}{x^{2}}-\frac{b_n x^{n+r_2}\left(n+r_2\right)}{x^{2}}\right)\right)+\left(-1-x\right)\left(C y_1'(x)\ln\left(x\right)+\frac{C y_1(x)}{x}+\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}\left(n+r_2\right)}{x}\right)\right)+2C y_1(x)\ln\left(x\right)+2\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0$$

Which can be written as

$$\left(\left(\left(3x+1\right)x y_1''(x)+\left(-1-x\right)y_1'(x)+2y_1(x)\right)\ln\left(x\right)+\left(3x+1\right)x\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^{2}}\right)+\frac{\left(-1-x\right)y_1(x)}{x}\right)C+\left(3x+1\right)x\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}\left(n+r_2\right)^{2}}{x^{2}}-\frac{b_n x^{n+r_2}\left(n+r_2\right)}{x^{2}}\right)\right)+\left(-1-x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}\left(n+r_2\right)}{x}\right)+2\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$\left(3x+1\right)x y_1''(x)+\left(-1-x\right)y_1'(x)+2y_1(x)=0$$

Eq (7) simplifes to

$$\left(\left(3x+1\right)x\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^{2}}\right)+\frac{\left(-1-x\right)y_1(x)}{x}\right)C+\left(3x+1\right)x\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}\left(n+r_2\right)^{2}}{x^{2}}-\frac{b_n x^{n+r_2}\left(n+r_2\right)}{x^{2}}\right)\right)+\left(-1-x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}\left(n+r_2\right)}{x}\right)+2\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$
\begin{aligned}
&\frac{\left(6x\left(x+\frac{1}{3}\right)\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right) + 2(-1-2x)\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right) C}{x} \\
&+ \frac{(3x^3+x^2)\left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) + (-x^2-x)\left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) + 2\left(\sum_{n=0}^{\infty} b_n x\right.}{x} \\
&= 0
\end{aligned} \tag{9}
$$

Since $r_1 = 2$ and $r_2 = 0$ then the above becomes

$$
\begin{aligned}
&\frac{\left(6x\left(x+\frac{1}{3}\right)\left(\sum_{n=0}^{\infty} x^{1+n} a_n (n+2)\right) + 2(-1-2x)\left(\sum_{n=0}^{\infty} a_n x^{n+2}\right)\right) C}{x} \\
&+ \frac{(3x^3+x^2)\left(\sum_{n=0}^{\infty} x^{-2+n} b_n n(n-1)\right) + (-x^2-x)\left(\sum_{n=0}^{\infty} x^{n-1} b_n n\right) + 2\left(\sum_{n=0}^{\infty} b_n x^n\right) x}{x} = 0
\end{aligned} \tag{10}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 6C\, x^{n+2} a_n (n+2)\right) + \left(\sum_{n=0}^{\infty} 2C\, x^{1+n} a_n (n+2)\right) + \sum_{n\,=0}^{\infty} \left(-2C\, x^{1+n} a_n\right) \\
&+ \sum_{n\,=0}^{\infty} \left(-4C\, x^{n+2} a_n\right) + \left(\sum_{n=0}^{\infty} 3x^n b_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} n\, x^{n-1} b_n (n-1)\right) \\
&+ \sum_{n\,=0}^{\infty} \left(-x^n b_n n\right) + \sum_{n\,=0}^{\infty} \left(-x^{n-1} b_n n\right) + \left(\sum_{n=0}^{\infty} 2 b_n x^n\right) = 0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-1} and adjusting the power and the corresponding index gives

$$
\sum_{n\,=0}^{\infty} 6C\, x^{n+2} a_n (n+2) = \sum_{n=3}^{\infty} 6C a_{n-3} (n-1)\, x^{n-1}
$$

$$
\sum_{n\,=0}^{\infty} 2C\, x^{1+n} a_n (n+2) = \sum_{n=2}^{\infty} 2C a_{-2+n} n\, x^{n-1}
$$

$$\sum_{n=0}^{\infty} \left(-2C\, x^{1+n} a_{n}\right) = \sum_{n=2}^{\infty} \left(-2C a_{-2+n} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} \left(-4C\, x^{n+2} a_{n}\right) = \sum_{n=3}^{\infty} \left(-4C a_{n-3} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} 3x^{n} b_{n} n(n-1) = \sum_{n=1}^{\infty} 3(n-1)\, b_{n-1} (-2+n)\, x^{n-1}$$

$$\sum_{n=0}^{\infty} \left(-x^{n} b_{n} n\right) = \sum_{n=1}^{\infty} \left(-(n-1)\, b_{n-1} x^{n-1}\right)$$

$$\sum_{n=0}^{\infty} 2b_{n} x^{n} = \sum_{n=1}^{\infty} 2b_{n-1} x^{n-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-1$.

$$\begin{aligned}
&\left(\sum_{n=3}^{\infty} 6C a_{n-3} (n-1)\, x^{n-1}\right) + \left(\sum_{n=2}^{\infty} 2C a_{-2+n} n\, x^{n-1}\right) \\
&+ \sum_{n=2}^{\infty} \left(-2C a_{-2+n} x^{n-1}\right) + \sum_{n=3}^{\infty} \left(-4C a_{n-3} x^{n-1}\right) \\
&\quad + \left(\sum_{n=1}^{\infty} 3(n-1)\, b_{n-1} (-2+n)\, x^{n-1}\right) + \left(\sum_{n=0}^{\infty} n\, x^{n-1} b_{n} (n-1)\right) \\
&\quad + \sum_{n=1}^{\infty} \left(-(n-1)\, b_{n-1} x^{n-1}\right) + \sum_{n=0}^{\infty} \left(-x^{n-1} b_{n} n\right) + \left(\sum_{n=1}^{\infty} 2b_{n-1} x^{n-1}\right) = 0
\end{aligned} \tag{2B}$$

For $n = 0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n = 1$, Eq (2B) gives

$$-b_1 + 2b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-b_1 + 2 = 0$$

Solving the above for b_1 gives

$$b_1 = 2$$

For $n = N$, where $N = 2$ which is the difference between the two roots, we are free to choose $b_2 = 0$. Hence for $n = 2$, Eq (2B) gives

$$2C + 2 = 0$$

Which is solved for C. Solving for C gives

$$C = -1$$

For $n = 3$, Eq (2B) gives

$$(8a_0 + 4a_1) C + 6b_2 + 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$3b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = 0$$

For $n = 4$, Eq (2B) gives

$$(14a_1 + 6a_2) C + 17b_3 + 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{5}{2} + 8b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = -\frac{5}{16}$$

For $n = 5$, Eq (2B) gives

$$(20a_2 + 8a_3) C + 34b_4 + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{2227}{120} + 15b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = \frac{2227}{1800}$$

For $n = 6$, Eq (2B) gives

$$(26a_3 + 10a_4) C + 57b_5 + 24b_6 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{27659}{300}+24b_6 = 0$$

Solving the above for b_6 gives

$$b_6 = -\frac{27659}{7200}$$

For $n = 7$, Eq (2B) gives

$$(32a_4+12a_5)\,C+86b_6+35b_7 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{9774983}{25200}+35b_7 = 0$$

Solving the above for b_7 gives

$$b_7 = \frac{9774983}{882000}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x)+\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -1$ and all b_n, then the second solution becomes

$$y_2(x) = (-1)\left(x^2\left(1-2x+\frac{17x^2}{4}-\frac{289x^3}{30}+\frac{5491x^4}{240}-\frac{236113x^5}{4200}+\frac{28569673x^6}{201600}-\frac{28569673x^7}{78400}+O(x^8)\right)\right)\ln(x)+1+2x-\frac{5x^4}{16}+\frac{2227x^5}{1800}-\frac{27659x^6}{7200}+\frac{9774983x^7}{882000}+O(x^8)$$

Therefore the homogeneous solution is

$$\begin{aligned}y_h(x) &= c_1y_1(x)+c_2y_2(x)\\ &= c_1x^2\left(1-2x+\frac{17x^2}{4}-\frac{289x^3}{30}+\frac{5491x^4}{240}-\frac{236113x^5}{4200}+\frac{28569673x^6}{201600}-\frac{28569673x^7}{78400}+O(x^8)\right)\\ &\quad+c_2\left((-1)\left(x^2\left(1-2x+\frac{17x^2}{4}-\frac{289x^3}{30}+\frac{5491x^4}{240}-\frac{236113x^5}{4200}+\frac{28569673x^6}{201600}-\frac{28569673x^7}{78400}+O(x^8)\right)\right)\ln(x)\right.\\ &\quad\left.+1+2x-\frac{5x^4}{16}+\frac{2227x^5}{1800}-\frac{27659x^6}{7200}+\frac{9774983x^7}{882000}+O(x^8)\right)\end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2 \left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right) \\
&\quad + c_2 \left(-x^2 \left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right) \ln(x) + 1 + 2x - \frac{5x^4}{16} + \frac{2227x^5}{1800} - \frac{27659x^6}{7200} + \frac{9774983x^7}{882000} + O(x^8)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^2 \left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right) + c_2 \left(-x^2 \left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right) \ln(x) + 1 + 2x - \frac{5x^4}{16} + \frac{2227x^5}{1800} - \frac{27659x^6}{7200} + \frac{9774983x^7}{882000} + O(x^8)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2 \left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right) + c_2 \left(-x^2 \left(1 - 2x + \frac{17x^2}{4} - \frac{289x^3}{30} + \frac{5491x^4}{240} - \frac{236113x^5}{4200} + \frac{28569673x^6}{201600} - \frac{28569673x^7}{78400} + O(x^8)\right) \ln(x) + 1 + 2x - \frac{5x^4}{16} + \frac{2227x^5}{1800} - \frac{27659x^6}{7200} + \frac{9774983x^7}{882000} + O(x^8)\right)
$$

Verified OK.

19.4.1 Maple step by step solution

Let's solve

$(3x+1)\,xy''+(-1-x)\,y'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{2y}{(3x+1)x}+\frac{(1+x)y'}{(3x+1)x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(1+x)y'}{(3x+1)x}+\frac{2y}{(3x+1)x}=0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=-\frac{1+x}{(3x+1)x}, P_3(x)=\frac{2}{(3x+1)x}\right]$

- ○ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-1$

- ○ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=0$

- ○ $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $(3x+1)\,xy''+(-1-x)\,y'+2y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m\cdot y'$ to series expansion for $m=0..1$

  $x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- > k+1-m$

  $$x^{m}\cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^{m}\cdot y''$ to series expansion for $m = 1..2$

  $$x^{m}\cdot y'' = \sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

  $$x^{m}\cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_{0}r(-2+r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r-1) + a_{k}(3k^{2}+6kr+3r^{2}-4k-4r+2)\right) x^{k}\right.$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{0, 2\}$$

- Each term in the series must be 0, giving the recursion relation

  $$(3k^{2}+(6r-4)\,k+3r^{2}-4r+2)\, a_{k} + a_{k+1}(k+1+r)\,(k+r-1) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = -\frac{(3k^{2}+6kr+3r^{2}-4k-4r+2)\, a_{k}}{(k+1+r)\,(k+r-1)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = -\frac{(3k^{2}-4k+2)\, a_{k}}{(k+1)\,(k-1)}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 1$

  $$a_{k+1} = -\frac{(3k^{2}-4k+2)\, a_{k}}{(k+1)\,(k-1)}$$

- Recursion relation for $r = 2$

  $$a_{k+1} = -\frac{(3k^{2}+8k+6)\, a_{k}}{(k+3)\,(k+1)}$$

- Solution for $r = 2$

  $$\left[y = \sum_{k=0}^{\infty} a_{k}x^{k+2}, a_{k+1} = -\frac{(3k^{2}+8k+6)\, a_{k}}{(k+3)\,(k+1)}\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 2(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \sin(x)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{691}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{692}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\sin(x)\, y \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= -\sin(x)\, y' - y\cos(x) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -2\cos(x)\, y' + \sin(x)\, y(1+\sin(x)) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(\sin(x)^2 + 3\sin(x)\right) y' + 4\cos(x)\, y\left(\sin(x) + \frac{1}{4}\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= (6\sin(x)+4)\cos(x)\, y' + y\left((\sin(x)+11)\cos(x)^2 - 2\sin(x) - 7\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left((\sin(x)+23)\cos(x)^2 - 6\sin(x) - 13\right) y' + 9\cos(x)\, y\left(\cos(x)^2 - \frac{26\sin(x)}{9} - \frac{10}{9}\right) \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(12\cos(x)^3 + (-72\sin(x) - 18)\cos(x)\right) y' + y\left(\cos(x)^4 + (-50\sin(x) - 59)\cos(x)^2 + 23\sin(x) + \right.
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= -y(0) \\
F_2 &= -2y'(0) \\
F_3 &= y(0) \\
F_4 &= 4y(0) + 4y'(0) \\
F_5 &= -y(0) + 10y'(0) \\
F_6 &= -26y(0) - 6y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 - \frac{1}{6}x^3 + \frac{1}{120}x^5 + \frac{1}{180}x^6 - \frac{1}{5040}x^7 - \frac{13}{20160}x^8\right) y(0) \\
&+ \left(x - \frac{1}{12}x^4 + \frac{1}{180}x^6 + \frac{1}{504}x^7 - \frac{1}{6720}x^8\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\sin(x) \left(\sum_{n=0}^{\infty} a_n x^n\right) \tag{1}
$$

Expanding $\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$
\begin{aligned}
\sin(x) &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + \dots \\
&= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9
\end{aligned}
$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right)+\left(x-\frac{1}{6}x^{3}+\frac{1}{120}x^{5}-\frac{1}{5040}x^{7}+\frac{1}{362880}x^{9}\right)\left(\sum_{n=0}^{\infty} a_n x^{n}\right)=0$$

Expanding the second term in (1) gives

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right)+x\cdot\left(\sum_{n=0}^{\infty} a_n x^{n}\right)-\frac{x^{3}}{6}\cdot\left(\sum_{n=0}^{\infty} a_n x^{n}\right)+\frac{x^{5}}{120}\cdot\left(\sum_{n=0}^{\infty} a_n x^{n}\right)-\frac{x^{7}}{5040}\cdot\left(\sum_{n=0}^{\infty} a_n x^{n}\right)+\frac{x^{9}}{362880}\cdot\left(\sum_{n=0}^{\infty} a_n x^{n}\right)=0$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right)+\left(\sum_{n=0}^{\infty} x^{1+n} a_n\right)+\sum_{n=0}^{\infty}\left(-\frac{x^{n+3} a_n}{6}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+5} a_n}{120}\right)+\sum_{n=0}^{\infty}\left(-\frac{x^{n+7} a_n}{5040}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+9} a_n}{362880}\right)=0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}=\sum_{n=0}^{\infty}(n+2)\, a_{n+2}(1+n)\, x^{n}$$

$$\sum_{n=0}^{\infty} x^{1+n} a_n=\sum_{n=1}^{\infty} a_{n-1} x^{n}$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+3} a_n}{6}\right)=\sum_{n=3}^{\infty}\left(-\frac{a_{n-3} x^{n}}{6}\right)$$

$$\sum_{n=0}^{\infty}\frac{x^{n+5} a_n}{120}=\sum_{n=5}^{\infty}\frac{a_{n-5} x^{n}}{120}$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+7} a_n}{5040}\right)=\sum_{n=7}^{\infty}\left(-\frac{a_{n-7} x^{n}}{5040}\right)$$

$$\sum_{n=0}^{\infty}\frac{x^{n+9} a_n}{362880}=\sum_{n=9}^{\infty}\frac{a_{n-9} x^{n}}{362880}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^{n}\right)+\left(\sum_{n=1}^{\infty} a_{n-1} x^{n}\right)+\sum_{n =3}^{\infty} \left(-\frac{a_{n-3} x^{n}}{6}\right) \\ +\left(\sum_{n=5}^{\infty} \frac{a_{n-5} x^{n}}{120}\right)+\sum_{n =7}^{\infty} \left(-\frac{a_{n-7} x^{n}}{5040}\right)+\left(\sum_{n=9}^{\infty} \frac{a_{n-9} x^{n}}{362880}\right) = 0 \tag{3}$$

$n = 1$ gives

$$6a_{3}+a_{0} = 0$$

Which after substituting earlier equations, simplifies to

$$a_{3} = -\frac{a_{0}}{6}$$

$n = 2$ gives

$$12a_{4}+a_{1} = 0$$

Which after substituting earlier equations, simplifies to

$$a_{4} = -\frac{a_{1}}{12}$$

$n = 3$ gives

$$20a_{5}+a_{2}-\frac{a_{0}}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_{5} = \frac{a_{0}}{120}$$

$n = 4$ gives

$$30a_{6}+a_{3}-\frac{a_{1}}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_{6} = \frac{a_{0}}{180}+\frac{a_{1}}{180}$$

$n = 5$ gives

$$42a_7 + a_4 - \frac{a_2}{6} + \frac{a_0}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_7 = -\frac{a_0}{5040} + \frac{a_1}{504}$$

$n = 6$ gives

$$56a_8 + a_5 - \frac{a_3}{6} + \frac{a_1}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_8 = -\frac{13a_0}{20160} - \frac{a_1}{6720}$$

$n = 7$ gives

$$72a_9 + a_6 - \frac{a_4}{6} + \frac{a_2}{120} - \frac{a_0}{5040} = 0$$

Which after substituting earlier equations, simplifies to

$$a_9 = -\frac{a_0}{13440} - \frac{7a_1}{25920}$$

For $9 \leq n$, the recurrence equation is

$$(n+2)\, a_{n+2}(1+n) + a_{n-1} - \frac{a_{n-3}}{6} + \frac{a_{n-5}}{120} - \frac{a_{n-7}}{5040} + \frac{a_{n-9}}{362880} = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{362880a_{n-1} - 60480a_{n-3} + 3024a_{n-5} - 72a_{n-7} + a_{n-9}}{362880\,(n+2)\,(1+n)} \\ &= -\frac{a_{n-9}}{362880\,(n+2)\,(1+n)} + \frac{a_{n-7}}{5040\,(n+2)\,(1+n)} \\ &\quad - \frac{a_{n-5}}{120\,(n+2)\,(1+n)} + \frac{a_{n-3}}{6\,(n+2)\,(1+n)} - \frac{a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \tag{5}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{a_0 x^3}{6} - \frac{a_1 x^4}{12} + \frac{a_0 x^5}{120} + \left(\frac{a_0}{180} + \frac{a_1}{180}\right) x^6 + \left(-\frac{a_0}{5040} + \frac{a_1}{504}\right) x^7 + \dots$$

Collecting terms, the solution becomes

$$\begin{aligned} y = {} & \left(1 - \frac{1}{6} x^3 + \frac{1}{120} x^5 + \frac{1}{180} x^6 - \frac{1}{5040} x^7\right) a_0 \\ & + \left(x - \frac{1}{12} x^4 + \frac{1}{180} x^6 + \frac{1}{504} x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{6} x^3 + \frac{1}{120} x^5 + \frac{1}{180} x^6 - \frac{1}{5040} x^7\right) c_1 + \left(x - \frac{1}{12} x^4 + \frac{1}{180} x^6 + \frac{1}{504} x^7\right) c_2 + O(x^8)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \left(1 - \frac{1}{6} x^3 + \frac{1}{120} x^5 + \frac{1}{180} x^6 - \frac{1}{5040} x^7 - \frac{13}{20160} x^8\right) y(0) \\ & + \left(x - \frac{1}{12} x^4 + \frac{1}{180} x^6 + \frac{1}{504} x^7 - \frac{1}{6720} x^8\right) y'(0) + O(x^8) \end{aligned} \tag{1}$$

$$\begin{aligned} y = {} & \left(1 - \frac{1}{6} x^3 + \frac{1}{120} x^5 + \frac{1}{180} x^6 - \frac{1}{5040} x^7\right) c_1 \\ & + \left(x - \frac{1}{12} x^4 + \frac{1}{180} x^6 + \frac{1}{504} x^7\right) c_2 + O(x^8) \end{aligned} \tag{2}$$

Verification of solutions

$$y = \left(1 - \frac{1}{6}x^3 + \frac{1}{120}x^5 + \frac{1}{180}x^6 - \frac{1}{5040}x^7 - \frac{13}{20160}x^8\right) y(0) + \left(x - \frac{1}{12}x^4 + \frac{1}{180}x^6 + \frac{1}{504}x^7 - \frac{1}{6720}x^8\right) y'(0) + O(x^8)$$

Verified OK.

$$y = \left(1 - \frac{1}{6}x^3 + \frac{1}{120}x^5 + \frac{1}{180}x^6 - \frac{1}{5040}x^7\right) c_1 + \left(x - \frac{1}{12}x^4 + \frac{1}{180}x^6 + \frac{1}{504}x^7\right) c_2 + O(x^8)$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' + \sin(x)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (694)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (695)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{\sin(x)\, y}{x} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{-y' \sin(x)\, x - y(\cos(x)\, x - \sin(x))}{x^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-2\cos(x)\, x^2 + 2\sin(x)\, x)\, y' + y\left(\sin(x)^2 x + (x^2-2)\sin(x) + 2\cos(x)\, x\right)}{x^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{\left(\sin(x)^2 x^2 + (3x^3-6x)\sin(x) + 6\cos(x)\, x^2\right) y' + y\left(-4\sin(x)^2 x + (4\cos(x)\, x^2 - 3x^2 + 6)\sin(x)\right.}{x^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{2\left(-3\sin(x)^2 x^2 + 3(\cos(x)\, x^3 - 2x^3 + 4x)\sin(x) + 2x^2\cos(x)\,(x^2-6)\right) y' - y\left(x^2\sin(x)^3 + 3(x^3 -\right.}{x^5} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{-5\left(-\frac{23x^2\left(x+\frac{\sin(x)}{23}\right)\cos(x)^2}{5} + \left(4x^3 + \frac{46x^2\sin(x)}{5} - 24x\right)\cos(x) - \frac{36\sin(x)^2 x}{5} + \left(x^4 - \frac{59}{5}x^2 + 24\right)\sin(x) + \right.}{} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \frac{-6\left(-2x^3\cos(x)^3 + (36x^3 + 2x^2\sin(x))\cos(x)^2 + ((12x^3-56x)\sin(x) + x^4 - 18x^2 + 120)\, x\cos(x\right.}{}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= -y'(0) \\
F_2 &= \frac{4y(0)}{3} \\
F_3 &= 2y'(0) \\
F_4 &= -\frac{53y(0)}{15} \\
F_5 &= -\frac{19y'(0)}{3} \\
F_6 &= \frac{467y(0)}{35}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6 + \frac{467}{1411200}x^8\right) y(0) \\
&+ \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
xy'' + \sin(x) y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) x + \sin(x) \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}
$$

Expanding $\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned}\sin(x) &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + \dots \\ &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9\end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) x + \left(x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9\right) \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0$$

Expanding the second term in (1) gives

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) x + x \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^3}{6} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) + \frac{x^5}{120} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) - \frac{x^7}{5040} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) + \frac{x^9}{362880} \cdot \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\, x^{n-1} a_n (n-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n} a_n\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+3} a_n}{6}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+5} a_n}{120}\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+7} a_n}{5040}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+9} a_n}{362880}\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\, x^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, x^n$$

$$\sum_{n=0}^{\infty} x^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} x^n$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+3} a_n}{6}\right) = \sum_{n=3}^{\infty} \left(-\frac{a_{n-3} x^n}{6}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+5} a_n}{120} = \sum_{n=5}^{\infty} \frac{a_{n-5} x^n}{120}$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+7} a_n}{5040}\right) = \sum_{n=7}^{\infty} \left(-\frac{a_{n-7} x^n}{5040}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+9} a_n}{362880} = \sum_{n=9}^{\infty} \frac{a_{n-9} x^n}{362880}$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (1+n) a_{1+n} n x^n\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^n\right) + \sum_{n=3}^{\infty} \left(-\frac{a_{n-3} x^n}{6}\right) + \left(\sum_{n=5}^{\infty} \frac{a_{n-5} x^n}{120}\right) + \sum_{n=7}^{\infty} \left(-\frac{a_{n-7} x^n}{5040}\right) + \left(\sum_{n=9}^{\infty} \frac{a_{n-9} x^n}{362880}\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

$n = 1$ gives

$$6a_3 + a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_1}{6}$$

$n = 2$ gives

$$12a_4 + a_2 - \frac{a_0}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_4 = \frac{a_0}{18}$$

$n = 3$ gives

$$20a_5 + a_3 - \frac{a_1}{6} = 0$$

Which after substituting earlier equations, simplifies to

$$a_5 = \frac{a_1}{60}$$

$n = 4$ gives

$$30a_6 + a_4 - \frac{a_2}{6} + \frac{a_0}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_6 = -\frac{53a_0}{10800}$$

$n = 5$ gives

$$42a_7 + a_5 - \frac{a_3}{6} + \frac{a_1}{120} = 0$$

Which after substituting earlier equations, simplifies to

$$a_7 = -\frac{19a_1}{15120}$$

$n = 6$ gives

$$56a_8 + a_6 - \frac{a_4}{6} + \frac{a_2}{120} - \frac{a_0}{5040} = 0$$

Which after substituting earlier equations, simplifies to

$$a_8 = \frac{467a_0}{1411200}$$

For $9 \leq n$, the recurrence equation is

$$(1+n)\, a_{1+n} n + a_{n-1} - \frac{a_{n-3}}{6} + \frac{a_{n-5}}{120} - \frac{a_{n-7}}{5040} + \frac{a_{n-9}}{362880} = 0 \tag{4}$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 - \frac{1}{6} a_1 x^3 + \frac{1}{18} a_0 x^4 + \frac{1}{60} a_1 x^5 - \frac{53}{10800} a_0 x^6 - \frac{19}{15120} a_1 x^7 + \dots
$$

Collecting terms, the solution becomes

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6\right) a_0 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) a_1 + O(x^8) \quad (3)
$$

At $x = 0$ the solution above becomes

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6\right) c_1 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) c_2 + O(x^8)
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6 + \frac{467}{1411200}x^8\right) y(0) \\
& + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) y'(0) + O(x^8)
\end{aligned} \quad (1)
$$

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6\right) c_1 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) c_2 + O(x^8) \quad (2)
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6 + \frac{467}{1411200}x^8\right) y(0) \\
& + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) y'(0) + O(x^8)
\end{aligned}
$$

Verified OK.

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{18}x^4 - \frac{53}{10800}x^6\right) c_1 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{19}{15120}x^7\right) c_2 + O(x^8)
$$

Verified OK.

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 2(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \sin(x)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + \sin(x)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 0$$
$$q(x) = \frac{\sin(x)}{x^2}$$

Table 444: Table $p(x), q(x)$ singularites.

$p(x) = 0$	
singularity	type

$q(x) = \frac{\sin(x)}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + \sin(x)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \sin(x) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Expanding $\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned}\sin(x) &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + \dots \\ &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9\end{aligned}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+r+3} a_n}{6}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+r+5} a_n}{120}\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+r+7} a_n}{5040}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+r+9} a_n}{362880}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+r+3} a_n}{6}\right) = \sum_{n=3}^{\infty} \left(-\frac{a_{n-3} x^{n+r}}{6}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+5} a_n}{120} = \sum_{n=5}^{\infty} \frac{a_{n-5} x^{n+r}}{120}$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+r+7} a_n}{5040}\right) = \sum_{n=7}^{\infty} \left(-\frac{a_{n-7} x^{n+r}}{5040}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+9} a_n}{362880} = \sum_{n=9}^{\infty} \frac{a_{n-9} x^{n+r}}{362880}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right) + \sum_{n=3}^{\infty} \left(-\frac{a_{n-3} x^{n+r}}{6}\right) + \left(\sum_{n=5}^{\infty} \frac{a_{n-5} x^{n+r}}{120}\right) + \sum_{n=7}^{\infty} \left(-\frac{a_{n-7} x^{n+r}}{5040}\right) + \left(\sum_{n=9}^{\infty} \frac{a_{n-9} x^{n+r}}{362880}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) = 0$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) = 0$$

Or

$$x^r a_0 r(-1+r) = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^r r(-1+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-1+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^r r(-1+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = -\frac{1}{r(1+r)}$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = \frac{1}{r(1+r)^2(2+r)}$$

Substituting $n = 3$ in Eq. (2B) gives

$$a_3 = \frac{r^4 + 4r^3 + 5r^2 + 2r - 6}{6r(1+r)^2(2+r)^2(3+r)}$$

Substituting $n = 4$ in Eq. (2B) gives

$$a_4 = \frac{-r^4 - 6r^3 - 14r^2 - 15r - 3}{3r(1+r)^2(2+r)^2(3+r)^2(4+r)}$$

Substituting $n = 5$ in Eq. (2B) gives

$$a_5 = \frac{-r^8 - 16r^7 - 106r^6 - 376r^5 - 709r^4 - 424r^3 + 1056r^2 + 2496r + 1560}{120r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)}$$

Substituting $n = 6$ in Eq. (2B) gives

$$a_6 = \frac{2r^8 + 40r^7 + 337r^6 + 1555r^5 + 4258r^4 + 6955r^3 + 6113r^2 + 1440r - 1305}{45r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)^2(6+r)}$$

Substituting $n = 7$ in Eq. (2B) gives

$$a_7 = \frac{r^{12} + 36r^{11} + 575r^{10} + 5370r^9 + 31977r^8 + 120744r^7 + 245517r^6 - 40230r^5 - 1838278r^4 - 5602080}{5040r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)^2(6+r)^2(7+r}$$

Substituting $n = 8$ in Eq. (2B) gives

$$a_8 = \frac{-r^{12} - 42r^{11} - 785r^{10} - 8610r^9 - 61461r^8 - 298830r^7 - 1003386r^6 - 2292885r^5 - 3351683r^4 - 24}{315r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)^2(6+r)^2(7+r)^2}$$

For $9 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_{n-1} - \frac{a_{n-3}}{6} + \frac{a_{n-5}}{120} - \frac{a_{n-7}}{5040} + \frac{a_{n-9}}{362880} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{362880a_{n-1} - 60480a_{n-3} + 3024a_{n-5} - 72a_{n-7} + a_{n-9}}{362880\,(n+r)\,(n+r-1)} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{-362880a_{n-1} + 60480a_{n-3} - 3024a_{n-5} + 72a_{n-7} - a_{n-9}}{362880\,(1+n)\,n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$
a_0	1
a_1	$-\frac{1}{r(1+r)}$
a_2	$\frac{1}{r(1+r)^2(2+r)}$
a_3	$\frac{r^4+4r^3+5r^2+2r-6}{6r(1+r)^2(2+r)^2(3+r)}$
a_4	$\frac{-r^4-6r^3-14r^2-15r-3}{3r(1+r)^2(2+r)^2(3+r)^2(4+r)}$
a_5	$\frac{-r^8-16r^7-106r^6-376r^5-709r^4-424r^3+1056r^2+2496r+1560}{120r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)}$
a_6	$\frac{2r^8+40r^7+337r^6+1555r^5+4258r^4+6955r^3+6113r^2+1440r-1305}{45r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)^2(6+r)}$
a_7	$\frac{r^{12}+36r^{11}+575r^{10}+5370r^9+31977r^8+120744r^7+245517r^6-40230r^5-1838278r^4-5602080r^3-8696192r^2-7058640r-2172240}{5040r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)^2(6+r)^2(7+r)}$
a_8	$\frac{-r^{12}-42r^{11}-785r^{10}-8610r^9-61461r^8-298830r^7-1003386r^6-2292885r^5-3351683r^4-2497173r^3+466901r^2+2574075r+1562715}{315r(1+r)^2(2+r)^2(3+r)^2(4+r)^2(5+r)^2(6+r)^2(7+r)^2(8+r)}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots\right) \\ &= x\left(1 - \frac{x}{2} + \frac{x^2}{12} + \frac{x^3}{144} - \frac{13x^4}{2880} + \frac{29x^5}{86400} + \frac{431x^6}{3628800} - \frac{4961x^7}{203212800} - \frac{5197x^8}{4877107200} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if

C is zero or not. This is done by finding $\lim_{r\rightarrow r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_1 \\
&= -\frac{1}{r\,(1+r)}
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\rightarrow r_2} -\frac{1}{r\,(1+r)} &= \lim_{r\rightarrow 0} -\frac{1}{r\,(1+r)} \\
&= \textit{undefined}
\end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned}
\frac{d}{dx} y_2(x) &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) \\
\frac{d^2}{dx^2} y_2(x) &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right)
\end{aligned}$$

Substituting these back into the given ode $x^2 y'' + \sin(x)\, y = 0$ gives

$$\begin{aligned}
&x^2 \left(C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \right. \\
&\left. + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) \\
&+ \sin(x) \left(C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right) = 0
\end{aligned}$$

Which can be written as

$$\left(\left(y_1''(x)\,x^2+\sin(x)\,y_1(x)\right)\ln(x)+x^2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)\right)C \\ +x^2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) \\ +\sin(x)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x)\,x^2+\sin(x)\,y_1(x)=0$$

Eq (7) simplifes to

$$x^2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)C+x^2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) \\ +\sin(x)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\left(2\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)x-\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C \\ +\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)(-1+n+r_2)\right)x^2+\sin(x)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{9}$$

Since $r_1=1$ and $r_2=0$ then the above becomes

$$\left(2\left(\sum_{n=0}^{\infty}x^n a_n(1+n)\right)x-\left(\sum_{n=0}^{\infty}a_n x^{1+n}\right)\right)C \\ +\left(\sum_{n=0}^{\infty}x^{-2+n}b_n n(n-1)\right)x^2+\sin(x)\left(\sum_{n=0}^{\infty}b_n x^n\right)=0 \tag{10}$$

Expanding $\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned}\sin(x) &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + \dots \\ &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9\end{aligned}$$

Which simplifies to

$$\begin{aligned}&\left(\sum_{n=0}^{\infty} 2C\,x^{1+n} a_n (1+n)\right) + \sum_{n=0}^{\infty} \left(-C a_n x^{1+n}\right) + \left(\sum_{n=0}^{\infty} n\,x^n b_n (n-1)\right) \\ &+ \left(\sum_{n=0}^{\infty} x^{1+n} b_n\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+3} b_n}{6}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+5} b_n}{120}\right) \\ &+ \sum_{n=0}^{\infty} \left(-\frac{x^{n+7} b_n}{5040}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+9} b_n}{362880}\right) = 0\end{aligned} \tag{2A}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\,x^{1+n} a_n (1+n) = \sum_{n=1}^{\infty} 2C a_{n-1} n\,x^n$$

$$\sum_{n=0}^{\infty} \left(-C a_n x^{1+n}\right) = \sum_{n=1}^{\infty} \left(-C a_{n-1} x^n\right)$$

$$\sum_{n=0}^{\infty} x^{1+n} b_n = \sum_{n=1}^{\infty} b_{n-1} x^n$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+3} b_n}{6}\right) = \sum_{n=3}^{\infty} \left(-\frac{b_{n-3} x^n}{6}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+5} b_n}{120} = \sum_{n=5}^{\infty} \frac{b_{n-5} x^n}{120}$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+7} b_n}{5040}\right) = \sum_{n=7}^{\infty} \left(-\frac{b_{n-7} x^n}{5040}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+9} b_n}{362880} = \sum_{n=9}^{\infty} \frac{b_{n-9} x^n}{362880}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{aligned}\left(\sum_{n=1}^{\infty} 2C a_{n-1} n\, x^{n}\right)+\sum_{n\,=1}^{\infty}\left(-C a_{n-1} x^{n}\right)+\left(\sum_{n=0}^{\infty} n\, x^{n} b_{n}(n-1)\right)\\ +\left(\sum_{n=1}^{\infty} b_{n-1} x^{n}\right)+\sum_{n\,=3}^{\infty}\left(-\frac{b_{n-3} x^{n}}{6}\right)+\left(\sum_{n=5}^{\infty} \frac{b_{n-5} x^{n}}{120}\right)\\ +\sum_{n\,=7}^{\infty}\left(-\frac{b_{n-7} x^{n}}{5040}\right)+\left(\sum_{n=9}^{\infty} \frac{b_{n-9} x^{n}}{362880}\right)=0\end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=N$, where $N=1$ which is the difference between the two roots, we are free to choose $b_1=0$. Hence for $n=1$, Eq (2B) gives

$$C+1=0$$

Which is solved for C. Solving for C gives

$$C=-1$$

For $n=2$, Eq (2B) gives

$$3C a_1+b_1+2b_2=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$2b_2+\frac{3}{2}=0$$

Solving the above for b_2 gives

$$b_2=-\frac{3}{4}$$

For $n=3$, Eq (2B) gives

$$5C a_2+b_2+6b_3-\frac{b_0}{6}=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{4}{3}+6b_3=0$$

Solving the above for b_3 gives

$$b_3=\frac{2}{9}$$

For $n=4$, Eq (2B) gives

$$7C a_3+b_3+12b_4-\frac{b_1}{6}=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{25}{144} + 12b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = -\frac{25}{1728}$$

For $n = 5$, Eq (2B) gives

$$9Ca_4 + b_4 + 20b_5 - \frac{b_2}{6} + \frac{b_0}{120} = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$\frac{689}{4320} + 20b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = -\frac{689}{86400}$$

For $n = 6$, Eq (2B) gives

$$11Ca_5 + b_5 + 30b_6 - \frac{b_3}{6} + \frac{b_1}{120} = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{263}{5400} + 30b_6 = 0$$

Solving the above for b_6 gives

$$b_6 = \frac{263}{162000}$$

For $n = 7$, Eq (2B) gives

$$13Ca_6 + b_6 + 42b_7 - \frac{b_4}{6} + \frac{b_2}{120} - \frac{b_0}{5040} = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{71809}{18144000} + 42b_7 = 0$$

Solving the above for b_7 gives

$$b_7 = \frac{71809}{762048000}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -1$ and all b_n, then the second solution becomes

$$y_2(x) = (-1)\left(x\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800}-\frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200} + O(x^8)\right)\right)\ln(x) + 1 - \frac{3x^2}{4} + \frac{2x^3}{9} - \frac{25x^4}{1728} - \frac{689x^5}{86400} + \frac{263x^6}{162000} + \frac{71809x^7}{762048000} + O(x^8)$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800}-\frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200} + O(x^8)\right) \\ &+ c_2\left((-1)\left(x\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800}-\frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200}+O(x^8)\right)\right) \\ &+ 1 - \frac{3x^2}{4} + \frac{2x^3}{9} - \frac{25x^4}{1728} - \frac{689x^5}{86400} + \frac{263x^6}{162000} + \frac{71809x^7}{762048000} + O(x^8)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800}-\frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200}+O(x^8)\right) \\ &+ c_2\left(-x\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800}-\frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200} \right.\right. \\ &\left.\left. + O(x^8)\right)\ln(x)+1-\frac{3x^2}{4}+\frac{2x^3}{9}-\frac{25x^4}{1728}-\frac{689x^5}{86400}+\frac{263x^6}{162000}+\frac{71809x^7}{762048000}+O(x^8)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$\begin{aligned} y = c_1 x&\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800}-\frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200} \right. \\ &\left. + O(x^8)\right) + c_2\left(-x\left(1-\frac{x}{2}+\frac{x^2}{12}+\frac{x^3}{144}-\frac{13x^4}{2880}+\frac{29x^5}{86400}+\frac{431x^6}{3628800} \right.\right. \\ &\left. - \frac{4961x^7}{203212800}-\frac{5197x^8}{4877107200}+O(x^8)\right)\ln(x)+1-\frac{3x^2}{4}+\frac{2x^3}{9}-\frac{25x^4}{1728} \\ &\left. -\frac{689x^5}{86400}+\frac{263x^6}{162000}+\frac{71809x^7}{762048000}+O(x^8)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 x \left(1 - \frac{x}{2} + \frac{x^2}{12} + \frac{x^3}{144} - \frac{13x^4}{2880} + \frac{29x^5}{86400} + \frac{431x^6}{3628800} - \frac{4961x^7}{203212800} - \frac{5197x^8}{4877107200} + O(x^8)\right)$$
$$+ c_2 \left(-x \left(1 - \frac{x}{2} + \frac{x^2}{12} + \frac{x^3}{144} - \frac{13x^4}{2880} + \frac{29x^5}{86400} + \frac{431x^6}{3628800} - \frac{4961x^7}{203212800} - \frac{5197x^8}{4877107200} + O(x^8)\right) \ln(x) + 1 - \frac{3x^2}{4} + \frac{2x^3}{9} - \frac{25x^4}{1728} - \frac{689x^5}{86400} + \frac{263x^6}{162000} + \frac{71809x^7}{762048000} + O(x^8)\right)$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 2(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^3 y'' + \sin(x) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^3 y'' + \sin(x) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 0$$
$$q(x) = \frac{\sin(x)}{x^3}$$

Table 445: Table $p(x), q(x)$ singularites.

$p(x) = 0$	
singularity	type

$q(x) = \frac{\sin(x)}{x^3}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^3 y'' + \sin(x)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^3 + \sin(x) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Expanding $\sin(x)$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned}
\sin(x) &= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9 + \dots \\
&= x - \frac{1}{6}x^3 + \frac{1}{120}x^5 - \frac{1}{5040}x^7 + \frac{1}{362880}x^9
\end{aligned}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+r+3} a_n}{6}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+r+5} a_n}{120}\right) + \sum_{n=0}^{\infty} \left(-\frac{x^{n+r+7} a_n}{5040}\right) + \left(\sum_{n=0}^{\infty} \frac{x^{n+r+9} a_n}{362880}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $1+n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{1+n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+r+3} a_n}{6}\right) = \sum_{n=2}^{\infty} \left(-\frac{a_{n-2} x^{1+n+r}}{6}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+5} a_n}{120} = \sum_{n=4}^{\infty} \frac{a_{n-4} x^{1+n+r}}{120}$$

$$\sum_{n=0}^{\infty} \left(-\frac{x^{n+r+7} a_n}{5040}\right) = \sum_{n=6}^{\infty} \left(-\frac{a_{n-6} x^{1+n+r}}{5040}\right)$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+9} a_n}{362880} = \sum_{n=8}^{\infty} \frac{a_{n-8} x^{1+n+r}}{362880}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $1+n+r$.

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \sum_{n=2}^{\infty} \left(-\frac{a_{n-2} x^{1+n+r}}{6}\right) + \left(\sum_{n=4}^{\infty} \frac{a_{n-4} x^{1+n+r}}{120}\right) + \sum_{n=6}^{\infty} \left(-\frac{a_{n-6} x^{1+n+r}}{5040}\right) + \left(\sum_{n=8}^{\infty} \frac{a_{n-8} x^{1+n+r}}{362880}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$x^{1+n+r} a_n (n+r)(n+r-1) + x^{1+n+r} a_n = 0$$

When $n = 0$ the above becomes

$$x^{1+r} a_0 r(-1+r) + x^{1+r} a_0 = 0$$

Or

$$\left(x^{1+r} r(-1+r)+x^{1+r}\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2-r+1\right) x^{1+r}=0$$

Since the above is true for all x then the indicial equation becomes

$$r^2-r+1=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= \frac{1}{2}+\frac{i\sqrt{3}}{2} \\ r_2 &= \frac{1}{2}-\frac{i\sqrt{3}}{2} \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2-r+1\right) x^{1+r}=0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$\begin{aligned} y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}+\frac{i\sqrt{3}}{2}} \\ y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}-\frac{i\sqrt{3}}{2}} \end{aligned}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. Substituting $n=1$ in Eq. (2B) gives

$$a_1=0$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = \frac{1}{6r^2 + 18r + 18}$$

Substituting $n = 3$ in Eq. (2B) gives

$$a_3 = 0$$

Substituting $n = 4$ in Eq. (2B) gives

$$a_4 = \frac{-3r^2 - 9r + 1}{360\,(r^2 + 3r + 3)\,(r^2 + 7r + 13)}$$

Substituting $n = 5$ in Eq. (2B) gives

$$a_5 = 0$$

Substituting $n = 6$ in Eq. (2B) gives

$$a_6 = \frac{3r^4 + 30r^3 + 69r^2 - 30r - 149}{15120\,(r^2 + 3r + 3)\,(r^2 + 7r + 13)\,(r^2 + 11r + 31)}$$

Substituting $n = 7$ in Eq. (2B) gives

$$a_7 = 0$$

For $8 \leq n$ the recursive equation is

$$a_n(n + r)\,(n + r - 1) + a_n - \frac{a_{n-2}}{6} + \frac{a_{n-4}}{120} - \frac{a_{n-6}}{5040} + \frac{a_{n-8}}{362880} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{-60480a_{n-2} + 3024a_{n-4} - 72a_{n-6} + a_{n-8}}{362880\,(n^2 + 2nr + r^2 - n - r + 1)} \tag{4}$$

Which for the root $r = \frac{1}{2} + \frac{i\sqrt{3}}{2}$ becomes

$$a_n = \frac{60480a_{n-2} - 3024a_{n-4} + 72a_{n-6} - a_{n-8}}{362880n\,\left(i\sqrt{3} + n\right)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2} + \frac{i\sqrt{3}}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{1}{6r^2+18r+18}$	$\frac{1}{12i\sqrt{3}+24}$
a_3	0	0
a_4	$\frac{-3r^2-9r+1}{360(r^2+3r+3)(r^2+7r+13)}$	$\frac{-3i\sqrt{3}-1}{1440\left(i\sqrt{3}+2\right)\left(i\sqrt{3}+4\right)}$
a_5	0	0
a_6	$\frac{3r^4+30r^3+69r^2-30r-149}{15120(r^2+3r+3)(r^2+7r+13)(r^2+11r+31)}$	$\frac{9i\sqrt{3}-115}{362880\left(i\sqrt{3}+2\right)\left(i\sqrt{3}+4\right)\left(i\sqrt{3}+6\right)}$
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}}\left(1 + \frac{x^2}{12i\sqrt{3}+24} + \frac{\left(-3i\sqrt{3}-1\right)x^4}{1440\left(i\sqrt{3}+2\right)\left(i\sqrt{3}+4\right)} \right. \\
&\quad \left. + \frac{\left(9i\sqrt{3}-115\right)x^6}{362880\left(i\sqrt{3}+2\right)\left(i\sqrt{3}+4\right)\left(i\sqrt{3}+6\right)} + O\left(x^8\right)\right)
\end{aligned}
$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$
\begin{aligned}
y_2(x) = x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}}&\left(1 + \frac{x^2}{-12i\sqrt{3}+24} + \frac{\left(3i\sqrt{3}-1\right)x^4}{1440\left(2-i\sqrt{3}\right)\left(-i\sqrt{3}+4\right)} \right. \\
&\left. + \frac{\left(-9i\sqrt{3}-115\right)x^6}{362880\left(2-i\sqrt{3}\right)\left(-i\sqrt{3}+4\right)\left(-i\sqrt{3}+6\right)} + O\left(x^8\right)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
y_h(x) = c_1 y_1(x) + c_2 y_2(x)
$$

$$
\begin{aligned}
&= c_1 x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}} \left(1+\frac{x^2}{12 i\sqrt{3}+24}+\frac{\left(-3 i\sqrt{3}-1\right) x^4}{1440 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right)}\right. \\
&\qquad \left. + \frac{\left(9 i\sqrt{3}-115\right) x^6}{362880 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right) \left(i\sqrt{3}+6\right)}+O\left(x^8\right)\right) \\
&\quad + c_2 x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}} \left(1+\frac{x^2}{-12 i\sqrt{3}+24}+\frac{\left(3 i\sqrt{3}-1\right) x^4}{1440 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right)}\right. \\
&\qquad \left. + \frac{\left(-9 i\sqrt{3}-115\right) x^6}{362880 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right) \left(-i\sqrt{3}+6\right)}+O\left(x^8\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}} \left(1+\frac{x^2}{12 i\sqrt{3}+24}+\frac{\left(-3 i\sqrt{3}-1\right) x^4}{1440 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right)}\right. \\
&\qquad \left. + \frac{\left(9 i\sqrt{3}-115\right) x^6}{362880 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right) \left(i\sqrt{3}+6\right)}+O\left(x^8\right)\right) \\
&\quad + c_2 x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}} \left(1+\frac{x^2}{-12 i\sqrt{3}+24}+\frac{\left(3 i\sqrt{3}-1\right) x^4}{1440 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right)}\right. \\
&\qquad \left. + \frac{\left(-9 i\sqrt{3}-115\right) x^6}{362880 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right) \left(-i\sqrt{3}+6\right)}+O\left(x^8\right)\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}} \left(1+\frac{x^2}{12 i\sqrt{3}+24}+\frac{\left(-3 i\sqrt{3}-1\right) x^4}{1440 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right)}\right. \\
&\qquad \left. + \frac{\left(9 i\sqrt{3}-115\right) x^6}{362880 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right) \left(i\sqrt{3}+6\right)}+O\left(x^8\right)\right) \\
&\quad + c_2 x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}} \left(1+\frac{x^2}{-12 i\sqrt{3}+24}+\frac{\left(3 i\sqrt{3}-1\right) x^4}{1440 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right)}\right. \\
&\qquad \left. + \frac{\left(-9 i\sqrt{3}-115\right) x^6}{362880 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right) \left(-i\sqrt{3}+6\right)}+O\left(x^8\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1 x^{\frac{1}{2}+\frac{i\sqrt{3}}{2}} \left(1 + \frac{x^2}{12i\sqrt{3}+24} + \frac{\left(-3i\sqrt{3}-1\right) x^4}{1440 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right)} + \frac{\left(9i\sqrt{3}-115\right) x^6}{362880 \left(i\sqrt{3}+2\right) \left(i\sqrt{3}+4\right) \left(i\sqrt{3}+6\right)} + O\left(x^8\right)\right) + c_2 x^{\frac{1}{2}-\frac{i\sqrt{3}}{2}} \left(1 + \frac{x^2}{-12i\sqrt{3}+24} + \frac{\left(3i\sqrt{3}-1\right) x^4}{1440 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right)} + \frac{\left(-9i\sqrt{3}-115\right) x^6}{362880 \left(2-i\sqrt{3}\right) \left(-i\sqrt{3}+4\right) \left(-i\sqrt{3}+6\right)} + O\left(x^8\right)\right)$$

Verified OK.

19.8.1 Maple step by step solution

Let's solve

$y''x^3 + \sin(x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{\sin(x) y}{x^3}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{\sin(x) y}{x^3} = 0$

- Multiply by denominators of the ODE

  $y''x^3 + \sin(x)\, y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt} y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt} y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

$$y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x)\left(\frac{d}{dt}y(t)\right)$$

- Compute derivative

$$y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$$

Substitute the change of variables back into the ODE

$$\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) x^3 + \sin(x)\, y(t) = 0$$

- Simplify

$$x\left(\frac{d^2}{dt^2}y(t) - \frac{d}{dt}y(t)\right) + \sin(x)\, y(t) = 0$$

- Isolate 2nd derivative

$$\frac{d^2}{dt^2}y(t) = -\frac{\sin(x)y(t)}{x} + \frac{d}{dt}y(t)$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^2}{dt^2}y(t) + \frac{\sin(x)y(t)}{x} - \frac{d}{dt}y(t) = 0$$

- Characteristic polynomial of ODE

$$r^2 + \frac{\sin(x)}{x} - r = 0$$

- Factor the characteristic polynomial

$$\frac{r^2x - rx + \sin(x)}{x} = 0$$

- Roots of the characteristic polynomial

$$r = \left(\frac{x+\sqrt{x^2-4\sin(x)x}}{2x}, -\frac{-x+\sqrt{x^2-4\sin(x)x}}{2x}\right)$$

- 1st solution of the ODE

$$y_1(t) = e^{\frac{\left(x+\sqrt{x^2-4\sin(x)x}\right)t}{2x}}$$

- 2nd solution of the ODE

$$y_2(t) = e^{-\frac{\left(-x+\sqrt{x^2-4\sin(x)x}\right)t}{2x}}$$

- General solution of the ODE

$$y(t) = c_1y_1(t) + c_2y_2(t)$$

- Substitute in solutions

$$y(t) = c_1 e^{\frac{\left(x+\sqrt{x^2-4\sin(x)x}\right)t}{2x}} + c_2 e^{-\frac{\left(-x+\sqrt{x^2-4\sin(x)x}\right)t}{2x}}$$

- Change variables back using $t = \ln(x)$

$$y = c_1 \mathrm{e}^{\frac{\left(x+\sqrt{x^2-4\sin(x)x}\right)\ln(x)}{2x}} + c_2 \mathrm{e}^{-\frac{\left(-x+\sqrt{x^2-4\sin(x)x}\right)\ln(x)}{2x}}$$

- Simplify

$$y = x^{\frac{x+\sqrt{x(-4\sin(x)+x)}}{2x}} c_1 + c_2 x^{-\frac{-x+\sqrt{x(-4\sin(x)+x)}}{2x}}$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 2(e).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Irregular singular point"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{x^4 y'' + \sin(x)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^4 y'' + \sin(x)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 0$$
$$q(x) = \frac{\sin(x)}{x^4}$$

Table 447: Table $p(x), q(x)$ singularites.

$p(x) = 0$	
singularity	type

$q(x) = \frac{\sin(x)}{x^4}$	
singularity	type
$x = 0$	"irregular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : []

Irregular singular points : $[0, \infty]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 3(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^3y'' + (-1 + \cos(2x))\, y' + 2xy = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^3y'' + (-1 + \cos(2x))\, y' + 2xy = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= \frac{-1 + \cos(2x)}{x^3} \\ q(x) &= \frac{2}{x^2} \end{aligned}$$

Table 448: Table $p(x), q(x)$ singularites.

$p(x) = \frac{-1+\cos(2x)}{x^3}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^3y'' + (-1 + \cos(2x))\, y' + 2xy = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}\right) x^3 + (-1 + \cos(2x)) \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}\right) + 2x \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Expanding $-1+\cos(2x)$ as Taylor series around $x=0$ and keeping only the first 8 terms gives

$$\begin{aligned}
-1+\cos(2x) &= -2x^2+\frac{2}{3}x^4-\frac{4}{45}x^6+\frac{2}{315}x^8+\dots \\
&= -2x^2+\frac{2}{3}x^4-\frac{4}{45}x^6+\frac{2}{315}x^8
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{1+n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}\frac{2x^{n+r+7}a_n(n+r)}{315}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{4x^{n+r+5}a_n(n+r)}{45}\right)+\left(\sum_{n=0}^{\infty}\frac{2x^{n+r+3}a_n(n+r)}{3}\right) \\
&+\sum_{n=0}^{\infty}\left(-2x^{1+n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}2x^{1+n+r}a_n\right)=0
\end{aligned} \tag{2A}$$

The next step is to make all powers of x be $1+n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{1+n+r} and adjusting the power and the corresponding index gives

$$\begin{aligned}
\sum_{n=0}^{\infty}\frac{2x^{n+r+7}a_n(n+r)}{315} &= \sum_{n=6}^{\infty}\frac{2a_{n-6}(-6+n+r)\,x^{1+n+r}}{315} \\
\sum_{n=0}^{\infty}\left(-\frac{4x^{n+r+5}a_n(n+r)}{45}\right) &= \sum_{n=4}^{\infty}\left(-\frac{4a_{n-4}(-4+n+r)\,x^{1+n+r}}{45}\right) \\
\sum_{n=0}^{\infty}\frac{2x^{n+r+3}a_n(n+r)}{3} &= \sum_{n=2}^{\infty}\frac{2a_{n-2}(n+r-2)\,x^{1+n+r}}{3}
\end{aligned}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $1+n+r$.

$$\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{1+n+r}a_n(n+r)(n+r-1)\right)+\left(\sum_{n=6}^{\infty}\frac{2a_{n-6}(-6+n+r)\,x^{1+n+r}}{315}\right) \\
&+\sum_{n=4}^{\infty}\left(-\frac{4a_{n-4}(-4+n+r)\,x^{1+n+r}}{45}\right)+\left(\sum_{n=2}^{\infty}\frac{2a_{n-2}(n+r-2)\,x^{1+n+r}}{3}\right) \\
&+\sum_{n=0}^{\infty}\left(-2x^{1+n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}2x^{1+n+r}a_n\right)=0
\end{aligned} \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{1+n+r}a_n(n+r)(n+r-1)-2x^{1+n+r}a_n(n+r)+2x^{1+n+r}a_n=0$$

When $n=0$ the above becomes

$$x^{1+r}a_0r(-1+r)-2x^{1+r}a_0r+2x^{1+r}a_0=0$$

Or

$$\left(x^{1+r}r(-1+r)-2x^{1+r}r+2x^{1+r}\right)a_0=0$$

Since $a_0\neq 0$ then the above simplifies to

$$\left(r^2-3r+2\right)x^{1+r}=0$$

Since the above is true for all x then the indicial equation becomes

$$r^2-3r+2=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned}r_1&=2\\r_2&=1\end{aligned}$$

Since $a_0\neq 0$ then the indicial equation becomes

$$\left(r^2-3r+2\right)x^{1+r}=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=1$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned}y_1(x)&=x^{r_1}\left(\sum_{n=0}^{\infty}a_nx^n\right)\\y_2(x)&=Cy_1(x)\ln(x)+x^{r_2}\left(\sum_{n=0}^{\infty}b_nx^n\right)\end{aligned}$$

Or

$$\begin{aligned}y_1(x)&=x^2\left(\sum_{n=0}^{\infty}a_nx^n\right)\\y_2(x)&=Cy_1(x)\ln(x)+x\left(\sum_{n=0}^{\infty}b_nx^n\right)\end{aligned}$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+2} \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{1+n}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = -\frac{2}{3r+3}$$

Substituting $n = 3$ in Eq. (2B) gives

$$a_3 = 0$$

Substituting $n = 4$ in Eq. (2B) gives

$$a_4 = \frac{\frac{4}{45}r^2 + \frac{8}{15}r + \frac{8}{9}}{(1+r)(3+r)(2+r)}$$

Substituting $n = 5$ in Eq. (2B) gives

$$a_5 = 0$$

For $6 \leq n$ the recursive equation is

$$
\begin{aligned}
&a_n(n+r)(n+r-1) + \frac{2a_{n-6}(-6+n+r)}{315} - \frac{4a_{n-4}(-4+n+r)}{45} \\
&+ \frac{2a_{n-2}(n+r-2)}{3} - 2a_n(n+r) + 2a_n = 0
\end{aligned} \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2(na_{n-6} - 14na_{n-4} + 105na_{n-2} + ra_{n-6} - 14ra_{n-4} + 105ra_{n-2} - 6a_{n-6} + 56a_{n-4} - 210a_{n-2})}{315(n^2 + 2nr + r^2 - 3n - 3r + 2)} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{(-2a_{n-6} + 28a_{n-4} - 210a_{n-2})\, n + 8a_{n-6} - 56a_{n-4}}{315n\,(1+n)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{3r+3}$	$-\frac{2}{9}$
a_3	0	0
a_4	$\frac{\frac{4}{45}r^2+\frac{8}{15}r+\frac{8}{9}}{(1+r)(3+r)(2+r)}$	$\frac{26}{675}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{-\frac{2}{315}r^4 - \frac{148}{945}r^3 - \frac{1018}{945}r^2 - \frac{2836}{945}r - \frac{416}{135}}{(1+r)\,(3+r)\,(2+r)\,(5+r)\,(4+r)}$$

Which for the root $r = 2$ becomes

$$a_6 = -\frac{1742}{297675}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{3r+3}$	$-\frac{2}{9}$
a_3	0	0
a_4	$\frac{\frac{4}{45}r^2+\frac{8}{15}r+\frac{8}{9}}{(1+r)(3+r)(2+r)}$	$\frac{26}{675}$
a_5	0	0
a_6	$\frac{-\frac{2}{315}r^4-\frac{148}{945}r^3-\frac{1018}{945}r^2-\frac{2836}{945}r-\frac{416}{135}}{(1+r)(3+r)(2+r)(5+r)(4+r)}$	$-\frac{1742}{297675}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{2}{3r+3}$	$-\frac{2}{9}$
a_3	0	0
a_4	$\frac{\frac{4}{45}r^2+\frac{8}{15}r+\frac{8}{9}}{(1+r)(3+r)(2+r)}$	$\frac{26}{675}$
a_5	0	0
a_6	$\frac{-\frac{2}{315}r^4-\frac{148}{945}r^3-\frac{1018}{945}r^2-\frac{2836}{945}r-\frac{416}{135}}{(1+r)(3+r)(2+r)(5+r)(4+r)}$	$-\frac{1742}{297675}$
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= x^2\left(1 - \frac{2x^2}{9} + \frac{26x^4}{675} - \frac{1742x^6}{297675} + O(x^8)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_1 \\
&= 0
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} 0 &= \lim_{r\to 1} 0 \\
&= 0
\end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{1+n}
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

Substituting $n = 2$ in Eq(3) gives

$$b_2 = -\frac{2}{3(1+r)}$$

Substituting $n = 3$ in Eq(3) gives

$$b_3 = 0$$

Substituting $n = 4$ in Eq(3) gives

$$b_4 = \frac{\frac{4}{45}r^2 + \frac{8}{15}r + \frac{8}{9}}{(1+r)(r^2+5r+6)}$$

Substituting $n = 5$ in Eq(3) gives

$$b_5 = 0$$

For $6 \leq n$ the recursive equation is

$$
\begin{aligned}
& b_n(n+r)(n+r-1) + \frac{2b_{n-6}(-6+n+r)}{315} - \frac{4b_{n-4}(-4+n+r)}{45} \\
& + \frac{2b_{n-2}(n+r-2)}{3} - 2b_n(n+r) + 2b_n = 0
\end{aligned} \tag{4}
$$

Which for for the root $r = 1$ becomes

$$b_n(1+n)n + \frac{2b_{n-6}(-5+n)}{315} - \frac{4b_{n-4}(-3+n)}{45} + \frac{2b_{n-2}(n-1)}{3} - 2b_n(1+n) + 2b_n = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{2(nb_{n-6} - 14nb_{n-4} + 105nb_{n-2} + rb_{n-6} - 14rb_{n-4} + 105rb_{n-2} - 6b_{n-6} + 56b_{n-4} - 210b_{n-2})}{315(n^2+2nr+r^2-3n-3r+2)} \tag{5}$$

Which for the root $r = 1$ becomes

$$b_n = -\frac{2(n b_{n-6} - 14 n b_{n-4} + 105 n b_{n-2} - 5 b_{n-6} + 42 b_{n-4} - 105 b_{n-2})}{315 \left(n^2 - n\right)} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{3r+3}$	$-\frac{1}{3}$
b_3	0	0
b_4	$\frac{\frac{4}{45}r^2+\frac{8}{15}r+\frac{8}{9}}{(1+r)(3+r)(2+r)}$	$\frac{17}{270}$
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = -\frac{2(3r^4 + 74r^3 + 509r^2 + 1418r + 1456)}{945 \left(1 + r\right) \left(r^2 + 5r + 6\right) \left(r^2 + 9r + 20\right)}$$

Which for the root $r = 1$ becomes

$$b_6 = -\frac{173}{17010}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{3r+3}$	$-\frac{1}{3}$
b_3	0	0
b_4	$\frac{\frac{4}{45}r^2+\frac{8}{15}r+\frac{8}{9}}{(1+r)(3+r)(2+r)}$	$\frac{17}{270}$
b_5	0	0
b_6	$\frac{-\frac{2}{315}r^4-\frac{148}{945}r^3-\frac{1018}{945}r^2-\frac{2836}{945}r-\frac{416}{135}}{(1+r)(r^2+5r+6)(r^2+9r+20)}$	$-\frac{173}{17010}$

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{2}{3r+3}$	$-\frac{1}{3}$
b_3	0	0
b_4	$\frac{\frac{4}{45}r^2+\frac{8}{15}r+\frac{8}{9}}{(1+r)(3+r)(2+r)}$	$\frac{17}{270}$
b_5	0	0
b_6	$\frac{-\frac{2}{315}r^4-\frac{148}{945}r^3-\frac{1018}{945}r^2-\frac{2836}{945}r-\frac{416}{135}}{(1+r)(r^2+5r+6)(r^2+9r+20)}$	$-\frac{173}{17010}$
b_7	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^2\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots\right) \\ &= x\left(1 - \frac{x^2}{3} + \frac{17x^4}{270} - \frac{173x^6}{17010} + O(x^8)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2\left(1 - \frac{2x^2}{9} + \frac{26x^4}{675} - \frac{1742x^6}{297675} + O(x^8)\right) + c_2 x\left(1 - \frac{x^2}{3} + \frac{17x^4}{270} - \frac{173x^6}{17010} + O(x^8)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x^2\left(1 - \frac{2x^2}{9} + \frac{26x^4}{675} - \frac{1742x^6}{297675} + O(x^8)\right) + c_2 x\left(1 - \frac{x^2}{3} + \frac{17x^4}{270} - \frac{173x^6}{17010} + O(x^8)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^2 \left(1-\frac{2x^2}{9}+\frac{26x^4}{675}-\frac{1742x^6}{297675}+O\left(x^8\right)\right) \\
+ c_2 x \left(1-\frac{x^2}{3}+\frac{17x^4}{270}-\frac{173x^6}{17010}+O\left(x^8\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2 \left(1-\frac{2x^2}{9}+\frac{26x^4}{675}-\frac{1742x^6}{297675}+O\left(x^8\right)\right) + c_2 x \left(1-\frac{x^2}{3}+\frac{17x^4}{270}-\frac{173x^6}{17010}+O\left(x^8\right)\right)
$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 3(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2y'' + \left(2x^4 - 5x\right)y' + \left(3x^2 + 2\right)y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4x^2y'' + \left(2x^4 - 5x\right)y' + \left(3x^2 + 2\right)y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{2x^3 - 5}{4x}$$
$$q(x) = \frac{3x^2 + 2}{4x^2}$$

Table 449: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2x^3-5}{4x}$	
singularity	type
$x = 0$	"regular"
$x = \infty$	"regular"
$x = -\infty$	"regular"

$q(x) = \frac{3x^2+2}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2y'' + \left(2x^4 - 5x\right)y' + \left(3x^2 + 2\right)y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4x^2 \left(\sum_{n=0}^{\infty} (n + r)\,(n + r - 1)\, a_n x^{n+r-2}\right) + \left(2x^4 - 5x\right)\left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}\right) + \left(3x^2 + 2\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r+3} a_n (n+r)\right) \\ + \sum_{n=0}^{\infty} \left(-5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 3x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2x^{n+r+3} a_n (n+r) = \sum_{n=3}^{\infty} 2a_{n-3}(n-3+r)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} 3x^{n+r+2} a_n = \sum_{n=2}^{\infty} 3a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=3}^{\infty} 2a_{n-3}(n-3+r)\, x^{n+r}\right) \\ + \sum_{n=0}^{\infty} \left(-5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} 3a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r} a_n (n+r)(n+r-1) - 5x^{n+r} a_n (n+r) + 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$4x^r a_0 r(-1+r) - 5x^r a_0 r + 2a_0 x^r = 0$$

Or

$$\left(4x^r r(-1+r) - 5x^r r + 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 - 9r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - 9r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = \frac{1}{4}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 - 9r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{7}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{4}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = -\frac{3}{r(4r + 7)}$$

For $3 \leq n$ the recursive equation is

$$4a_n(n + r)(n + r - 1) + 2a_{n-3}(n - 3 + r) - 5a_n(n + r) + 3a_{n-2} + 2a_n = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2na_{n-3} + 2ra_{n-3} - 6a_{n-3} + 3a_{n-2}}{4n^2 + 8nr + 4r^2 - 9n - 9r + 2} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{-2na_{n-3} + 2a_{n-3} - 3a_{n-2}}{n(4n+7)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{3}{r(4r+7)}$	$-\frac{1}{10}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{2r}{4r^2 + 15r + 11}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{4}{57}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{3}{r(4r+7)}$	$-\frac{1}{10}$
a_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{4}{57}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{9}{r(4r+7)(4r^2+23r+30)}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{3}{920}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{3}{r(4r+7)}$	$-\frac{1}{10}$
a_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{4}{57}$
a_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{3}{920}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{48r^3 + 180r^2 + 246r + 132}{(4r + 7)\, r\, (4r^2 + 15r + 11)\, (4r^2 + 31r + 57)}$$

Which for the root $r = 2$ becomes

$$a_5 = \frac{32}{4275}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{3}{r(4r+7)}$	$-\frac{1}{10}$
a_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{4}{57}$
a_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{3}{920}$
a_5	$\frac{48r^3+180r^2+246r+132}{(4r+7)r(4r^2+15r+11)(4r^2+31r+57)}$	$\frac{32}{4275}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{64r^6 + 672r^5 + 2564r^4 + 4212r^3 + 2412r^2 - 405r - 297}{(4r^2 + 15r + 11)\, r\, (4r + 7)\, (4r^2 + 23r + 30)\, (4r^2 + 39r + 92)}$$

Which for the root $r = 2$ becomes

$$a_6 = \frac{36287}{9753840}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{3}{r(4r+7)}$	$-\frac{1}{10}$
a_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{4}{57}$
a_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{3}{920}$
a_5	$\frac{48r^3+180r^2+246r+132}{(4r+7)r(4r^2+15r+11)(4r^2+31r+57)}$	$\frac{32}{4275}$
a_6	$\frac{64r^6+672r^5+2564r^4+4212r^3+2412r^2-405r-297}{(4r^2+15r+11)r(4r+7)(4r^2+23r+30)(4r^2+39r+92)}$	$\frac{36287}{9753840}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{18(48r^5 + 552r^4 + 2567r^3 + 6075r^2 + 7147r + 3168)}{(4r + 7)(4r^2 + 23r + 30)\, r\, (4r^2 + 15r + 11)(4r^2 + 31r + 57)(4r^2 + 47r + 135)}$$

Which for the root $r = 2$ becomes

$$a_7 = -\frac{4037}{16059750}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{3}{r(4r+7)}$	$-\frac{1}{10}$
a_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{4}{57}$
a_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{3}{920}$
a_5	$\frac{48r^3+180r^2+246r+132}{(4r+7)r(4r^2+15r+11)(4r^2+31r+57)}$	$\frac{32}{4275}$
a_6	$\frac{64r^6+672r^5+2564r^4+4212r^3+2412r^2-405r-297}{(4r^2+15r+11)r(4r+7)(4r^2+23r+30)(4r^2+39r+92)}$	$\frac{36287}{9753840}$
a_7	$-\frac{18(48r^5+552r^4+2567r^3+6075r^2+7147r+3168)}{(4r+7)(4r^2+23r+30)r(4r^2+15r+11)(4r^2+31r+57)(4r^2+47r+135)}$	$-\frac{4037}{16059750}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= x^2\left(1 - \frac{x^2}{10} - \frac{4x^3}{57} + \frac{3x^4}{920} + \frac{32x^5}{4275} + \frac{36287x^6}{9753840} - \frac{4037x^7}{16059750} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = 0$$

Substituting $n = 2$ in Eq. (2B) gives

$$b_2 = -\frac{3}{r(4r+7)}$$

For $3 \leq n$ the recursive equation is

$$4b_n(n+r)(n+r-1) + 2b_{n-3}(n-3+r) - 5b_n(n+r) + 3b_{n-2} + 2b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{2nb_{n-3} + 2rb_{n-3} - 6b_{n-3} + 3b_{n-2}}{4n^2 + 8nr + 4r^2 - 9n - 9r + 2} \tag{4}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_n = \frac{-4nb_{n-3} + 11b_{n-3} - 6b_{n-2}}{8n^2 - 14n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{1}{4}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{3}{r(4r+7)}$	$-\frac{3}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{2r}{4r^2 + 15r + 11}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_3 = -\frac{1}{30}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{3}{r(4r+7)}$	$-\frac{3}{2}$
b_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{1}{30}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{9}{r\,(4r+7)\,(4r^2+23r+30)}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_4 = \frac{1}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{3}{r(4r+7)}$	$-\frac{3}{2}$
b_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{1}{30}$
b_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{1}{8}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{48r^3+180r^2+246r+132}{(4r+7)\,r\,(4r^2+15r+11)\,(4r^2+31r+57)}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_5 = \frac{137}{1300}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{3}{r(4r+7)}$	$-\frac{3}{2}$
b_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{1}{30}$
b_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{1}{8}$
b_5	$\frac{48r^3+180r^2+246r+132}{(4r+7)r(4r^2+15r+11)(4r^2+31r+57)}$	$\frac{137}{1300}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{64r^6 + 672r^5 + 2564r^4 + 4212r^3 + 2412r^2 - 405r - 297}{(4r^2 + 15r + 11)\, r\, (4r + 7)\, (4r^2 + 23r + 30)\, (4r^2 + 39r + 92)}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_6 = -\frac{19}{12240}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{3}{r(4r+7)}$	$-\frac{3}{2}$
b_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{1}{30}$
b_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{1}{8}$
b_5	$\frac{48r^3+180r^2+246r+132}{(4r+7)r(4r^2+15r+11)(4r^2+31r+57)}$	$\frac{137}{1300}$
b_6	$\frac{64r^6+672r^5+2564r^4+4212r^3+2412r^2-405r-297}{(4r^2+15r+11)r(4r+7)(4r^2+23r+30)(4r^2+39r+92)}$	$-\frac{19}{12240}$

For $n = 7$, using the above recursive equation gives

$$b_7 = -\frac{18(48r^5 + 552r^4 + 2567r^3 + 6075r^2 + 7147r + 3168)}{(4r + 7)\, (4r^2 + 23r + 30)\, r\, (4r^2 + 15r + 11)\, (4r^2 + 31r + 57)\, (4r^2 + 47r + 135)}$$

Which for the root $r = \frac{1}{4}$ becomes

$$b_7 = -\frac{7169}{764400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{3}{r(4r+7)}$	$-\frac{3}{2}$
b_3	$-\frac{2r}{4r^2+15r+11}$	$-\frac{1}{30}$
b_4	$\frac{9}{r(4r+7)(4r^2+23r+30)}$	$\frac{1}{8}$
b_5	$\frac{48r^3+180r^2+246r+132}{(4r+7)r(4r^2+15r+11)(4r^2+31r+57)}$	$\frac{137}{1300}$
b_6	$\frac{64r^6+672r^5+2564r^4+4212r^3+2412r^2-405r-297}{(4r^2+15r+11)r(4r+7)(4r^2+23r+30)(4r^2+39r+92)}$	$-\frac{19}{12240}$
b_7	$-\frac{18(48r^5+552r^4+2567r^3+6075r^2+7147r+3168)}{(4r+7)(4r^2+23r+30)r(4r^2+15r+11)(4r^2+31r+57)(4r^2+47r+135)}$	$-\frac{7169}{764400}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= x^2(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots) \\
&= x^{\frac{1}{4}}\left(1 - \frac{3x^2}{2} - \frac{x^3}{30} + \frac{x^4}{8} + \frac{137x^5}{1300} - \frac{19x^6}{12240} - \frac{7169x^7}{764400} + O(x^8)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2\left(1 - \frac{x^2}{10} - \frac{4x^3}{57} + \frac{3x^4}{920} + \frac{32x^5}{4275} + \frac{36287x^6}{9753840} - \frac{4037x^7}{16059750} + O(x^8)\right) \\
&\quad + c_2 x^{\frac{1}{4}}\left(1 - \frac{3x^2}{2} - \frac{x^3}{30} + \frac{x^4}{8} + \frac{137x^5}{1300} - \frac{19x^6}{12240} - \frac{7169x^7}{764400} + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2\left(1 - \frac{x^2}{10} - \frac{4x^3}{57} + \frac{3x^4}{920} + \frac{32x^5}{4275} + \frac{36287x^6}{9753840} - \frac{4037x^7}{16059750} + O(x^8)\right) \\
&\quad + c_2 x^{\frac{1}{4}}\left(1 - \frac{3x^2}{2} - \frac{x^3}{30} + \frac{x^4}{8} + \frac{137x^5}{1300} - \frac{19x^6}{12240} - \frac{7169x^7}{764400} + O(x^8)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = c_1x^2\left(1-\frac{x^2}{10}-\frac{4x^3}{57}+\frac{3x^4}{920}+\frac{32x^5}{4275}+\frac{36287x^6}{9753840}-\frac{4037x^7}{16059750}+O\left(x^8\right)\right) \\
+ c_2x^{\frac{1}{4}}\left(1-\frac{3x^2}{2}-\frac{x^3}{30}+\frac{x^4}{8}+\frac{137x^5}{1300}-\frac{19x^6}{12240}-\frac{7169x^7}{764400}+O\left(x^8\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1x^2\left(1-\frac{x^2}{10}-\frac{4x^3}{57}+\frac{3x^4}{920}+\frac{32x^5}{4275}+\frac{36287x^6}{9753840}-\frac{4037x^7}{16059750}+O\left(x^8\right)\right) \\
+ c_2x^{\frac{1}{4}}\left(1-\frac{3x^2}{2}-\frac{x^3}{30}+\frac{x^4}{8}+\frac{137x^5}{1300}-\frac{19x^6}{12240}-\frac{7169x^7}{764400}+O\left(x^8\right)\right)
\end{aligned}
$$

Verified OK.

19.11.1 Maple step by step solution

Let's solve

$4x^2y''+\left(2x^4-5x\right)y'+\left(3x^2+2\right)y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(3x^2+2)y}{4x^2}-\frac{(2x^3-5)y'}{4x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(2x^3-5)y'}{4x}+\frac{(3x^2+2)y}{4x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{2x^3-5}{4x}, P_3(x)=\frac{3x^2+2}{4x^2}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=-\frac{5}{4}$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=\frac{1}{2}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2 y'' + x(2x^3 - 5) y' + (3x^2 + 2) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..4$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r) x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k + 1 - m + r) x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)(k + r - 1) x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1 + 4r)(-2 + r) x^r + a_1(3 + 4r)(-1 + r) x^{1+r} + (a_2(7 + 4r) r + 3a_0) x^{2+r} + \left(\sum_{k=3}^{\infty} (a_k(4k +\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1 + 4r)(-2 + r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{2, \frac{1}{4}\right\}$

- The coefficients of each power of x must be 0

$[a_1(3+4r)(-1+r)=0, a_2(7+4r)r+3a_0=0]$

- Solve for the dependent coefficient(s)

$\left\{a_1=0, a_2=-\frac{3a_0}{r(7+4r)}\right\}$

- Each term in the series must be 0, giving the recursion relation

$a_k(4k+4r-1)(k+r-2)+3a_{k-2}+2a_{k-3}(k-3+r)=0$

- Shift index using $k->k+3$

$a_{k+3}(4k+11+4r)(k+1+r)+3a_{k+1}+2a_k(k+r)=0$

- Recursion relation that defines series solution to ODE

$a_{k+3}=-\frac{2ka_k+2ra_k+3a_{k+1}}{(4k+11+4r)(k+1+r)}$

- Recursion relation for $r=2$

$a_{k+3}=-\frac{2ka_k+4a_k+3a_{k+1}}{(4k+19)(k+3)}$

- Solution for $r=2$

$\left[y=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+3}=-\frac{2ka_k+4a_k+3a_{k+1}}{(4k+19)(k+3)}, a_1=0, a_2=-\frac{a_0}{10}\right]$

- Recursion relation for $r=\frac{1}{4}$

$a_{k+3}=-\frac{2ka_k+\frac{1}{2}a_k+3a_{k+1}}{(4k+12)(k+\frac{5}{4})}$

- Solution for $r=\frac{1}{4}$

$\left[y=\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{4}}, a_{k+3}=-\frac{2ka_k+\frac{1}{2}a_k+3a_{k+1}}{(4k+12)(k+\frac{5}{4})}, a_1=0, a_2=-\frac{3a_0}{2}\right]$

- Combine solutions and rename parameters

$\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k+2}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{4}}\right), a_{k+3}=-\frac{2ka_k+4a_k+3a_{k+1}}{(4k+19)(k+3)}, a_1=0, a_2=-\frac{a_0}{10}, b_{k+3}=-\frac{2kb_k+\frac{1}{2}b}{(4k+12}\right.$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 3(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + 3xy' + 4xy = 0}$$

With the expansion point for the power series method at $x = 0$.

The ODE is

$$x^2y'' + 3xy' + 4xy = 0$$

Or

$$x(y''x + 4y + 3y') = 0$$

For $x \neq 0$ the above simplifies to

$$y''x + 4y + 3y' = 0$$

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + 3xy' + 4xy = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$
\begin{aligned}
p(x) &= \frac{3}{x} \\
q(x) &= \frac{4}{x}
\end{aligned}
$$

Table 451: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{4}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$
x^2y'' + 3xy' + 4xy = 0
$$

Let the solution be represented as Frobenius power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^{n+r}
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1} \\
y'' &= \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$x^2\left(\sum_{n=0}^{\infty}(n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) \\ +3x\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+4x\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)\,(n+r-1)\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}4x^{1+n+r}a_n\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}4x^{1+n+r}a_n=\sum_{n=1}^{\infty}4a_{n-1}x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)\,(n+r-1)\right)+\left(\sum_{n=0}^{\infty}3x^{n+r}a_n(n+r)\right)+\left(\sum_{n=1}^{\infty}4a_{n-1}x^{n+r}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r}a_n(n+r)\,(n+r-1)+3x^{n+r}a_n(n+r)=0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r)+3x^r a_0 r=0$$

Or

$$(x^r r(-1+r)+3x^r r)\,a_0=0$$

Since $a_0\neq 0$ then the above simplifies to

$$x^r r(2+r)=0$$

Since the above is true for all x then the indicial equation becomes

$$r(2+r)=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned}r_1&=0\\r_2&=-2\end{aligned}$$

Since $a_0\neq 0$ then the indicial equation becomes

$$x^r r(2+r)=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=2$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned}y_1(x)&=x^{r_1}\left(\sum_{n=0}^{\infty}a_n x^n\right)\\y_2(x)&=Cy_1(x)\ln(x)+x^{r_2}\left(\sum_{n=0}^{\infty}b_n x^n\right)\end{aligned}$$

Or

$$\begin{aligned}y_1(x)&=\sum_{n=0}^{\infty}a_n x^n\\y_2(x)&=Cy_1(x)\ln(x)+\frac{\sum_{n=0}^{\infty}b_n x^n}{x^2}\end{aligned}$$

Or

$$\begin{aligned}y_1(x)&=\sum_{n=0}^{\infty}a_n x^n\\y_2(x)&=Cy_1(x)\ln(x)+\left(\sum_{n=0}^{\infty}b_n x^{n-2}\right)\end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. For $1\leq n$ the recursive equation is

$$a_n(n+r)(n+r-1)+3a_n(n+r)+4a_{n-1}=0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4a_{n-1}}{n^2 + 2nr + r^2 + 2n + 2r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{4a_{n-1}}{n\,(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{4}{r^2 + 4r + 3}$$

Which for the root $r = 0$ becomes

$$a_1 = -\frac{4}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{16}{(r^2 + 4r + 3)\,(r^2 + 6r + 8)}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{2}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$
a_2	$\frac{16}{(r^2+4r+3)(r^2+6r+8)}$	$\frac{2}{3}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{64}{(r+3)^2 (r+1) (r+4) (2+r) (r+5)}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{8}{45}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$
a_2	$\frac{16}{(r^2+4r+3)(r^2+6r+8)}$	$\frac{2}{3}$
a_3	$-\frac{64}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{8}{45}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{256}{(r+3)^2 (r+1) (r+4)^2 (2+r) (r+5) (r+6)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{4}{135}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$
a_2	$\frac{16}{(r^2+4r+3)(r^2+6r+8)}$	$\frac{2}{3}$
a_3	$-\frac{64}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{8}{45}$
a_4	$\frac{256}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{4}{135}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1024}{(r+3)^2 (r+1) (r+4)^2 (2+r) (r+5)^2 (r+6) (r+7)}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{16}{4725}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$
a_2	$\frac{16}{(r^2+4r+3)(r^2+6r+8)}$	$\frac{2}{3}$
a_3	$-\frac{64}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{8}{45}$
a_4	$\frac{256}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{4}{135}$
a_5	$-\frac{1024}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)(r+7)}$	$-\frac{16}{4725}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{4096}{(r+3)^2 (r+1) (r+4)^2 (2+r) (r+5)^2 (r+6)^2 (r+7) (r+8)}$$

Which for the root $r = 0$ becomes

$$a_6 = \frac{4}{14175}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$
a_2	$\frac{16}{(r^2+4r+3)(r^2+6r+8)}$	$\frac{2}{3}$
a_3	$-\frac{64}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{8}{45}$
a_4	$\frac{256}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{4}{135}$
a_5	$-\frac{1024}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)(r+7)}$	$-\frac{16}{4725}$
a_6	$\frac{4096}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)^2(r+7)(r+8)}$	$\frac{4}{14175}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{16384}{(r+3)^2 (r+1) (r+4)^2 (2+r) (r+5)^2 (r+6)^2 (r+7)^2 (r+8) (r+9)}$$

Which for the root $r = 0$ becomes

$$a_7 = -\frac{16}{893025}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{r^2+4r+3}$	$-\frac{4}{3}$
a_2	$\frac{16}{(r^2+4r+3)(r^2+6r+8)}$	$\frac{2}{3}$
a_3	$-\frac{64}{(r+3)^2(r+1)(r+4)(2+r)(r+5)}$	$-\frac{8}{45}$
a_4	$\frac{256}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)(r+6)}$	$\frac{4}{135}$
a_5	$-\frac{1024}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)(r+7)}$	$-\frac{16}{4725}$
a_6	$\frac{4096}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)^2(r+7)(r+8)}$	$\frac{4}{14175}$
a_7	$-\frac{16384}{(r+3)^2(r+1)(r+4)^2(2+r)(r+5)^2(r+6)^2(r+7)^2(r+8)(r+9)}$	$-\frac{16}{893025}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots \\
&= 1 - \frac{4x}{3} + \frac{2x^2}{3} - \frac{8x^3}{45} + \frac{4x^4}{135} - \frac{16x^5}{4725} + \frac{4x^6}{14175} - \frac{16x^7}{893025} + O(x^8)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_2 \\
&= \frac{16}{(r^2 + 4r + 3)(r^2 + 6r + 8)}
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} \frac{16}{(r^2 + 4r + 3)(r^2 + 6r + 8)} &= \lim_{r\to -2} \frac{16}{(r^2 + 4r + 3)(r^2 + 6r + 8)} \\
&= \textit{undefined}
\end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned}
\frac{d}{dx}y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\
&= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) \\
\frac{d^2}{dx^2}y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\
&\quad + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\
&= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)
\end{aligned}$$

Substituting these back into the given ode $x^2y'' + 3xy' + 4xy = 0$ gives

$$\begin{aligned}
&x^2\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2}\right. \\
&\left.+ \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) \\
&+ 3x\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) \\
&+ 4x\left(Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right) = 0
\end{aligned}$$

Which can be written as

$$\left(\left(\left(y_1''(x)\,x^2+4y_1(x)\,x+3y_1'(x)\,x\right)\ln\left(x\right)+x^2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+3y_1(x)\right)C \\ +x^2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) \\ +3x\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+4x\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$y_1''(x)\,x^2+4y_1(x)\,x+3y_1'(x)\,x=0$$

Eq (7) simplifes to

$$\left(x^2\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+3y_1(x)\right)C \\ +x^2\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) \\ +3x\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+4x\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\left(2\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)x+2\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C \\ +\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)\left(-1+n+r_2\right)\right)x^2 \\ +3\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)x+4x\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0 \tag{9}$$

Since $r_1=0$ and $r_2=-2$ then the above becomes

$$\left(2\left(\sum_{n=0}^{\infty}x^{n-1}a_n n\right)x+2\left(\sum_{n=0}^{\infty}a_n x^n\right)\right)C+\left(\sum_{n=0}^{\infty}x^{-4+n}b_n(n-2)\left(-3+n\right)\right)x^2 \\ +3\left(\sum_{n=0}^{\infty}x^{-3+n}b_n(n-2)\right)x+4x\left(\sum_{n=0}^{\infty}b_n x^{n-2}\right)=0 \tag{10}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2Cn\, x^{n} a_{n}\right)+\left(\sum_{n=0}^{\infty} 2C a_{n} x^{n}\right)+\left(\sum_{n=0}^{\infty} x^{n-2} b_{n} \left(n^{2}-5n+6\right)\right) + \left(\sum_{n=0}^{\infty} 3x^{n-2} b_{n} (n-2)\right)+\left(\sum_{n=0}^{\infty} 4x^{n-1} b_{n}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n-2$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-2} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2Cn\, x^{n} a_{n} = \sum_{n=2}^{\infty} 2C(n-2)\, a_{n-2} x^{n-2}$$

$$\sum_{n=0}^{\infty} 2C a_{n} x^{n} = \sum_{n=2}^{\infty} 2C a_{n-2} x^{n-2}$$

$$\sum_{n=0}^{\infty} 4x^{n-1} b_{n} = \sum_{n=1}^{\infty} 4 b_{n-1} x^{n-2}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-2$.

$$\left(\sum_{n=2}^{\infty} 2C(n-2)\, a_{n-2} x^{n-2}\right)+\left(\sum_{n=2}^{\infty} 2C a_{n-2} x^{n-2}\right) + \left(\sum_{n=0}^{\infty} x^{n-2} b_{n} \left(n^{2}-5n+6\right)\right)+\left(\sum_{n=0}^{\infty} 3x^{n-2} b_{n} (n-2)\right)+\left(\sum_{n=1}^{\infty} 4 b_{n-1} x^{n-2}\right) = 0 \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-b_1 + 4b_0 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-b_1 + 4 = 0$$

Solving the above for b_1 gives

$$b_1 = 4$$

For $n = N$, where $N = 2$ which is the difference between the two roots, we are free to choose $b_2 = 0$. Hence for $n = 2$, Eq (2B) gives

$$2C + 16 = 0$$

Which is solved for C. Solving for C gives

$$C = -8$$

For $n = 3$, Eq (2B) gives

$$4Ca_1 + 4b_2 + 3b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$3b_3 + \frac{128}{3} = 0$$

Solving the above for b_3 gives

$$b_3 = -\frac{128}{9}$$

For $n = 4$, Eq (2B) gives

$$6Ca_2 + 4b_3 + 8b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8b_4 - \frac{800}{9} = 0$$

Solving the above for b_4 gives

$$b_4 = \frac{100}{9}$$

For $n = 5$, Eq (2B) gives

$$8Ca_3 + 4b_4 + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$15b_5 + \frac{2512}{45} = 0$$

Solving the above for b_5 gives

$$b_5 = -\frac{2512}{675}$$

For $n = 6$, Eq (2B) gives

$$10Ca_4 + 4b_5 + 24b_6 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$24b_6 - \frac{11648}{675} = 0$$

Solving the above for b_6 gives

$$b_6 = \frac{1456}{2025}$$

For $n = 7$, Eq (2B) gives

$$12Ca_5 + 4b_6 + 35b_7 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$35b_7 + \frac{45376}{14175} = 0$$

Solving the above for b_7 gives

$$b_7 = -\frac{45376}{496125}$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -8$ and all b_n, then the second solution becomes

$$y_2(x) = (-8)\left(1 - \frac{4x}{3} + \frac{2x^2}{3} - \frac{8x^3}{45} + \frac{4x^4}{135} - \frac{16x^5}{4725} + \frac{4x^6}{14175} - \frac{16x^7}{893025} + O(x^8)\right)\ln(x) + \frac{1 + 4x - \frac{128x^3}{9} + \frac{100x^4}{9} - \frac{2512x^5}{675} + \frac{1456x^6}{2025} - \frac{45376x^7}{496125} + O(x^8)}{x^2}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1y_1(x) + c_2y_2(x) \\ &= c_1\left(1 - \frac{4x}{3} + \frac{2x^2}{3} - \frac{8x^3}{45} + \frac{4x^4}{135} - \frac{16x^5}{4725} + \frac{4x^6}{14175} - \frac{16x^7}{893025} + O(x^8)\right) \\ &\quad + c_2\left((-8)\left(1 - \frac{4x}{3} + \frac{2x^2}{3} - \frac{8x^3}{45} + \frac{4x^4}{135} - \frac{16x^5}{4725} + \frac{4x^6}{14175} - \frac{16x^7}{893025} + O(x^8)\right)\ln(x) \right. \\ &\quad \left. + \frac{1 + 4x - \frac{128x^3}{9} + \frac{100x^4}{9} - \frac{2512x^5}{675} + \frac{1456x^6}{2025} - \frac{45376x^7}{496125} + O(x^8)}{x^2}\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\left(1-\frac{4x}{3}+\frac{2x^2}{3}-\frac{8x^3}{45}+\frac{4x^4}{135}-\frac{16x^5}{4725}+\frac{4x^6}{14175}-\frac{16x^7}{893025}+O(x^8)\right) \\
&\quad + c_2\left(\left(-8+\frac{32x}{3}-\frac{16x^2}{3}+\frac{64x^3}{45}-\frac{32x^4}{135}+\frac{128x^5}{4725}-\frac{32x^6}{14175}+\frac{128x^7}{893025}-8O(x^8)\right)\ln(x) \right. \\
&\quad \left. + \frac{1+4x-\frac{128x^3}{9}+\frac{100x^4}{9}-\frac{2512x^5}{675}+\frac{1456x^6}{2025}-\frac{45376x^7}{496125}+O(x^8)}{x^2}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1\left(1-\frac{4x}{3}+\frac{2x^2}{3}-\frac{8x^3}{45}+\frac{4x^4}{135}-\frac{16x^5}{4725}+\frac{4x^6}{14175}-\frac{16x^7}{893025}+O(x^8)\right) \\
&\quad + c_2\left(\left(-8+\frac{32x}{3}-\frac{16x^2}{3}+\frac{64x^3}{45}-\frac{32x^4}{135}+\frac{128x^5}{4725}-\frac{32x^6}{14175}+\frac{128x^7}{893025} \right.\right. \\
&\quad \left.\left. -8O(x^8)\right)\ln(x) + \frac{1+4x-\frac{128x^3}{9}+\frac{100x^4}{9}-\frac{2512x^5}{675}+\frac{1456x^6}{2025}-\frac{45376x^7}{496125}+O(x^8)}{x^2}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1\left(1-\frac{4x}{3}+\frac{2x^2}{3}-\frac{8x^3}{45}+\frac{4x^4}{135}-\frac{16x^5}{4725}+\frac{4x^6}{14175}-\frac{16x^7}{893025}+O(x^8)\right) \\
&\quad + c_2\left(\left(-8+\frac{32x}{3}-\frac{16x^2}{3}+\frac{64x^3}{45}-\frac{32x^4}{135}+\frac{128x^5}{4725}-\frac{32x^6}{14175}+\frac{128x^7}{893025}-8O(x^8)\right)\ln(x) \right. \\
&\quad \left. + \frac{1+4x-\frac{128x^3}{9}+\frac{100x^4}{9}-\frac{2512x^5}{675}+\frac{1456x^6}{2025}-\frac{45376x^7}{496125}+O(x^8)}{x^2}\right)
\end{aligned}
$$

Verified OK.

19.12.1 Maple step by step solution

Let's solve

$x^2y'' + 3xy' + 4xy = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4y}{x} - \frac{3y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{3y'}{x} + \frac{4y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{3}{x}, P_3(x) = \frac{4}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 3$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + 4y + 3y' = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

  $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  ◦ Shift index using $k- > k+1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(2+r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+3+r) + 4a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-2, 0\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(k+3+r) + 4a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{4a_k}{(k+1+r)(k+3+r)}$$

- Recursion relation for $r = -2$

$$a_{k+1} = -\frac{4a_k}{(k-1)(k+1)}$$

- Series not valid for $r = -2$, division by 0 in the recursion relation at $k = 1$

$$a_{k+1} = -\frac{4a_k}{(k-1)(k+1)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{4a_k}{(k+1)(k+3)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{4a_k}{(k+1)(k+3)}\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 3(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^3y'' - 4x^2y' + 3xy = 0}$$

With the expansion point for the power series method at $x = 0$.

The ODE is

$$x^3y'' - 4x^2y' + 3xy = 0$$

Or

$$x\left(x^2y'' - 4xy' + 3y\right) = 0$$

For $x \neq 0$ the above simplifies to

$$x^2y'' - 4xy' + 3y = 0$$

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^3y'' - 4x^2y' + 3xy = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = \frac{3}{x^2}$$

Table 453: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{4}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{3}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^3y'' - 4x^2y' + 3xy = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty}(n+r)\,(n+r-1)\,a_n x^{n+r-2}\right)x^3 \\ -4x^2\left(\sum_{n=0}^{\infty}(n+r)\,a_n x^{n+r-1}\right)+3x\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}x^{1+n+r}a_n(n+r)\,(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-4x^{1+n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}3x^{1+n+r}a_n\right)=0 \tag{2A}$$

The next step is to make all powers of x be $1+n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{1+n+r} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $1+n+r$.

$$\left(\sum_{n=0}^{\infty}x^{1+n+r}a_n(n+r)\,(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-4x^{1+n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}3x^{1+n+r}a_n\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{1+n+r}a_n(n+r)\,(n+r-1)-4x^{1+n+r}a_n(n+r)+3x^{1+n+r}a_n=0$$

When $n=0$ the above becomes

$$x^{1+r}a_0r(-1+r)-4x^{1+r}a_0r+3x^{1+r}a_0=0$$

Or

$$\left(x^{1+r}r(-1+r)-4x^{1+r}r+3x^{1+r}\right)a_0=0$$

Since $a_0\neq 0$ then the above simplifies to

$$\left(r^2-5r+3\right)x^{1+r}=0$$

Since the above is true for all x then the indicial equation becomes

$$r^2-5r+3=0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{5}{2}+\frac{\sqrt{13}}{2}$$
$$r_2 = \frac{5}{2}-\frac{\sqrt{13}}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2-5r+3\right) x^{1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \sqrt{13}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{5}{2}+\frac{\sqrt{13}}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{5}{2}-\frac{\sqrt{13}}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. For $0 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - 4a_n(n+r) + 3a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = 0 \tag{4}$$

Which for the root $r = \frac{5}{2}+\frac{\sqrt{13}}{2}$ becomes

$$a_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{5}{2}+\frac{\sqrt{13}}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0
a_6	0	0

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0
a_6	0	0
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{5}{2}+\frac{\sqrt{13}}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= x^{\frac{5}{2}+\frac{\sqrt{13}}{2}}\left(1 + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $0 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - 4b_n(n+r) + 3b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = 0 \tag{4}$$

Which for the root $r = \frac{5}{2} - \frac{\sqrt{13}}{2}$ becomes

$$b_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{5}{2} - \frac{\sqrt{13}}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0
b_6	0	0

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0
b_6	0	0
b_7	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^{\frac{5}{2}+\frac{\sqrt{13}}{2}}\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + b_8x^8 \dots\right) \\ &= x^{\frac{5}{2}-\frac{\sqrt{13}}{2}}\left(1 + O(x^8)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1y_1(x) + c_2y_2(x) \\ &= c_1x^{\frac{5}{2}+\frac{\sqrt{13}}{2}}\left(1 + O(x^8)\right) + c_2x^{\frac{5}{2}-\frac{\sqrt{13}}{2}}\left(1 + O(x^8)\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{5}{2}+\frac{\sqrt{13}}{2}} \left(1+O(x^8)\right) + c_2 x^{\frac{5}{2}-\frac{\sqrt{13}}{2}} \left(1+O(x^8)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 x^{\frac{5}{2}+\frac{\sqrt{13}}{2}} \left(1+O(x^8)\right) + c_2 x^{\frac{5}{2}-\frac{\sqrt{13}}{2}} \left(1+O(x^8)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{5}{2}+\frac{\sqrt{13}}{2}} \left(1+O(x^8)\right) + c_2 x^{\frac{5}{2}-\frac{\sqrt{13}}{2}} \left(1+O(x^8)\right)
$$

Verified OK.

19.13.1 Maple step by step solution

Let's solve

$y''x^3 - 4x^2y' + 3xy = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4y'}{x} - \frac{3y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{x} + \frac{3y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'' - 4xy' + 3y = 0$

- Make a change of variables

  $t = \ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  ◦ Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

- Calculate the 2nd derivative of y with respect to x , using the chain rule

  $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

- Compute derivative

  $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) - 4\frac{d}{dt}y(t) + 3y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 5\frac{d}{dt}y(t) + 3y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 5r + 3 = 0$

- Use quadratic formula to solve for r

  $r = \frac{5\pm\left(\sqrt{13}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(\frac{5}{2} - \frac{\sqrt{13}}{2}, \frac{5}{2} + \frac{\sqrt{13}}{2}\right)$

- 1st solution of the ODE

  $y_1(t) = e^{\left(\frac{5}{2}-\frac{\sqrt{13}}{2}\right)t}$

- 2nd solution of the ODE

  $y_2(t) = e^{\left(\frac{5}{2}+\frac{\sqrt{13}}{2}\right)t}$

- General solution of the ODE

  $y(t) = c_1y_1(t) + c_2y_2(t)$

- Substitute in solutions

  $y(t) = c_1e^{\left(\frac{5}{2}-\frac{\sqrt{13}}{2}\right)t} + c_2e^{\left(\frac{5}{2}+\frac{\sqrt{13}}{2}\right)t}$

- Change variables back using $t = \ln(x)$

  $y = c_1e^{\left(\frac{5}{2}-\frac{\sqrt{13}}{2}\right)\ln(x)} + c_2e^{\left(\frac{5}{2}+\frac{\sqrt{13}}{2}\right)\ln(x)}$

- Simplify

  $y = x^{\frac{5}{2}}\left(x^{\frac{\sqrt{13}}{2}}c_2 + x^{-\frac{\sqrt{13}}{2}}c_1\right)$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 4(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{4y''x + 3y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4y''x + 3y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{3}{4x}$$
$$q(x) = \frac{1}{4x}$$

Table 455: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3}{4x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{4x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4y''x + 3y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + 3\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 4x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 4x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r-1} a_n (n+r)(n+r-1) + 3(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$4x^{-1+r} a_0 r(-1+r) + 3r a_0 x^{-1+r} = 0$$

Or

$$\left(4x^{-1+r} r(-1+r) + 3r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-1+4r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{4}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-1+4r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{4}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{4}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$4a_n(n+r)(n+r-1) + 3a_n(n+r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{4n^2 + 8nr + 4r^2 - n - r} \tag{4}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_n = -\frac{a_{n-1}}{4n^2 + n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{4}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{4r^2 + 7r + 3}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_1 = -\frac{1}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{16r^4 + 88r^3 + 173r^2 + 143r + 42}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_2 = \frac{1}{90}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{5}$
a_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{90}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{64r^6 + 720r^5 + 3244r^4 + 7455r^3 + 9166r^2 + 5685r + 1386}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_3 = -\frac{1}{3510}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{5}$
a_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{90}$
a_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{3510}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_4 = \frac{1}{238680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{5}$
a_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{90}$
a_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{3510}$
a_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$	$\frac{1}{238680}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160)\,(4}$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_5 = -\frac{1}{25061400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{5}$
a_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{90}$
a_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{3510}$
a_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$	$\frac{1}{238680}$
a_5	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)}$	$-\frac{1}{25061400}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{1}{(256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160)(4r^2$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_6 = \frac{1}{3759210000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{5}$
a_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{90}$
a_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{3510}$
a_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$	$\frac{1}{238680}$
a_5	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)}$	$-\frac{1}{25061400}$
a_6	$\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)(4r^2+47r+138)}$	$\frac{1}{3759210000}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{1}{(256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160)(4$$

Which for the root $r = \frac{1}{4}$ becomes

$$a_7 = -\frac{1}{763119630000}$$

And the table now becomes

n	$a_{n,r}$
a_0	1
a_1	$-\frac{1}{4r^2+7r+3}$
a_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$
a_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$
a_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$
a_5	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)}$
a_6	$\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)(4r^2+47r+138)}$
a_7	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)(4r^2+47r+138)(4r^2+55r+189)}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{1}{4}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= x^{\frac{1}{4}}\left(1 - \frac{x}{5} + \frac{x^2}{90} - \frac{x^3}{3510} + \frac{x^4}{238680} - \frac{x^5}{25061400} + \frac{x^6}{3759210000} - \frac{x^7}{763119630000} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$4b_n(n+r)(n+r-1) + 3(n+r)b_n + b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}}{4n^2 + 8nr + 4r^2 - n - r} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{b_{n-1}}{n(4n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -\frac{1}{4r^2 + 7r + 3}$$

Which for the root $r = 0$ becomes

$$b_1 = -\frac{1}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{16r^4 + 88r^3 + 173r^2 + 143r + 42}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{42}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{3}$
b_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{42}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{1}{64r^6 + 720r^5 + 3244r^4 + 7455r^3 + 9166r^2 + 5685r + 1386}$$

Which for the root $r = 0$ becomes

$$b_3 = -\frac{1}{1386}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{3}$
b_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{42}$
b_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{1386}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{1}{83160}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{3}$
b_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{42}$
b_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{1386}$
b_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$	$\frac{1}{83160}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{1}{(256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160)\,(4}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{1}{7900200}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{3}$
b_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{42}$
b_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{1386}$
b_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$	$\frac{1}{83160}$
b_5	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)}$	$-\frac{1}{7900200}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{1}{(256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160)\,(4r^2}$$

Which for the root $r = 0$ becomes

$$b_6 = \frac{1}{1090227600}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$-\frac{1}{4r^2+7r+3}$	$-\frac{1}{3}$
b_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$	$\frac{1}{42}$
b_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$	$-\frac{1}{1386}$
b_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$	$\frac{1}{83160}$
b_5	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)}$	$-\frac{1}{7900200}$
b_6	$\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)(4r^2+47r+138)}$	$\frac{1}{1090227600}$

For $n = 7$, using the above recursive equation gives

$$b_7 = -\frac{1}{(256r^8 + 4864r^7 + 39136r^6 + 173584r^5 + 462409r^4 + 754186r^3 + 731739r^2 + 384066r + 83160)\,(4}$$

Which for the root $r = 0$ becomes

$$b_7 = -\frac{1}{206053016400}$$

And the table now becomes

n	$b_{n,r}$
b_0	1
b_1	$-\frac{1}{4r^2+7r+3}$
b_2	$\frac{1}{16r^4+88r^3+173r^2+143r+42}$
b_3	$-\frac{1}{64r^6+720r^5+3244r^4+7455r^3+9166r^2+5685r+1386}$
b_4	$\frac{1}{256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160}$
b_5	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)}$
b_6	$\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)(4r^2+47r+138)}$
b_7	$-\frac{1}{(256r^8+4864r^7+39136r^6+173584r^5+462409r^4+754186r^3+731739r^2+384066r+83160)(4r^2+39r+95)(4r^2+47r+138)(4r^2+55r+189)}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= 1 - \frac{x}{3} + \frac{x^2}{42} - \frac{x^3}{1386} + \frac{x^4}{83160} - \frac{x^5}{7900200} + \frac{x^6}{1090227600} - \frac{x^7}{206053016400} + O(x^8)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{1}{4}} \left(1 - \frac{x}{5} + \frac{x^2}{90} - \frac{x^3}{3510} + \frac{x^4}{238680} - \frac{x^5}{25061400} + \frac{x^6}{3759210000} - \frac{x^7}{763119630000} \right. \\
&\quad \left. + O(x^8)\right) + c_2 \left(1 - \frac{x}{3} + \frac{x^2}{42} - \frac{x^3}{1386} + \frac{x^4}{83160} - \frac{x^5}{7900200} + \frac{x^6}{1090227600} \right. \\
&\quad \left. - \frac{x^7}{206053016400} + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{1}{4}} \left(1 - \frac{x}{5} + \frac{x^2}{90} - \frac{x^3}{3510} + \frac{x^4}{238680} - \frac{x^5}{25061400} + \frac{x^6}{3759210000} - \frac{x^7}{763119630000} + O(x^8)\right) \\
&\quad + c_2 \left(1 - \frac{x}{3} + \frac{x^2}{42} - \frac{x^3}{1386} + \frac{x^4}{83160} - \frac{x^5}{7900200} + \frac{x^6}{1090227600} - \frac{x^7}{206053016400} + O(x^8)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = c_1 x^{\frac{1}{4}} \left(1-\frac{x}{5}+\frac{x^2}{90}-\frac{x^3}{3510}+\frac{x^4}{238680}-\frac{x^5}{25061400}+\frac{x^6}{3759210000}-\frac{x^7}{763119630000} \right. \\
\left. +O\left(x^8\right)\right)+c_2\left(1-\frac{x}{3}+\frac{x^2}{42}-\frac{x^3}{1386}+\frac{x^4}{83160}-\frac{x^5}{7900200}+\frac{x^6}{1090227600} \right. \\
\left. -\frac{x^7}{206053016400}+O\left(x^8\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1 x^{\frac{1}{4}} \left(1-\frac{x}{5}+\frac{x^2}{90}-\frac{x^3}{3510}+\frac{x^4}{238680}-\frac{x^5}{25061400}+\frac{x^6}{3759210000}-\frac{x^7}{763119630000} \right. \\
\left. +O\left(x^8\right)\right) \\
+c_2\left(1-\frac{x}{3}+\frac{x^2}{42}-\frac{x^3}{1386}+\frac{x^4}{83160}-\frac{x^5}{7900200}+\frac{x^6}{1090227600}-\frac{x^7}{206053016400}+O\left(x^8\right)\right)
\end{aligned}
$$

Verified OK.

19.14.1 Maple step by step solution

Let's solve

$4y''x+3y'+y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y}{4x}-\frac{3y'}{4x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{3y'}{4x}+\frac{y}{4x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{3}{4x}, P_3(x)=\frac{1}{4x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x=0$

    $\left.(x \cdot P_2(x))\right|_{x=0}=\frac{3}{4}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4y''x + 3y' + y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert y' to series expansion

    $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  - Shift index using $k->k+1$

    $y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$

  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

  - Shift index using $k->k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-1+4r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(4k+3+4r) + a_k\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+4r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{4}\right\}$

- Each term in the series must be 0, giving the recursion relation

$$4\left(k+\frac{3}{4}+r\right)(k+1+r)\, a_{k+1}+a_{k}=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{a_{k}}{(4k+3+4r)(k+1+r)}$$

- Recursion relation for $r=0$

$$a_{k+1}=-\frac{a_{k}}{(4k+3)(k+1)}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty} a_{k} x^{k}, a_{k+1}=-\frac{a_{k}}{(4k+3)(k+1)}\right]$$

- Recursion relation for $r=\frac{1}{4}$

$$a_{k+1}=-\frac{a_{k}}{(4k+4)\left(k+\frac{5}{4}\right)}$$

- Solution for $r=\frac{1}{4}$

$$\left[y=\sum_{k=0}^{\infty} a_{k} x^{k+\frac{1}{4}}, a_{k+1}=-\frac{a_{k}}{(4k+4)\left(k+\frac{5}{4}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_{k} x^{k}\right)+\left(\sum_{k=0}^{\infty} b_{k} x^{k+\frac{1}{4}}\right), a_{k+1}=-\frac{a_{k}}{(4k+3)(k+1)}, b_{k+1}=-\frac{b_{k}}{(4k+4)\left(k+\frac{5}{4}\right)}\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 4(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{2y''x + (-x+3)\,y' - y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2y''x + (-x+3)\,y' - y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x-3}{2x}$$
$$q(x) = -\frac{1}{2x}$$

Table 457: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-3}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2y''x + (-x+3)\,y' - y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) x + (-x+3)\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) \\ + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r-1}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right) \\ + \left(\sum_{n=0}^{\infty} 3(n+r) a_n x^{n+r-1}\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + 3(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + 3r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) + 3r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 + r\right) x^{-1+r} = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 + r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -\frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 + r\right) x^{-1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + 3a_n(n+r) - a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{2n+1+2r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{a_{n-1}}{2n+1} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{3+2r}$$

Which for the root $r = 0$ becomes

$$a_1 = \frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^2 + 16r + 15}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{15}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{15}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{8r^3 + 60r^2 + 142r + 105}$$

Which for the root $r = 0$ becomes

$$a_3 = \frac{1}{105}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{15}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{105}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16r^4 + 192r^3 + 824r^2 + 1488r + 945}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{945}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{15}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{105}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{945}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{32r^5 + 560r^4 + 3760r^3 + 12040r^2 + 18258r + 10395}$$

Which for the root $r = 0$ becomes

$$a_5 = \frac{1}{10395}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{15}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{105}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{945}$
a_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{10395}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{1}{64r^6 + 1536r^5 + 14800r^4 + 72960r^3 + 193036r^2 + 258144r + 135135}$$

Which for the root $r = 0$ becomes

$$a_6 = \frac{1}{135135}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{15}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{105}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{945}$
a_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{10395}$
a_6	$\frac{1}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	$\frac{1}{135135}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{1}{128r^7 + 4032r^6 + 52640r^5 + 367920r^4 + 1480472r^3 + 3411828r^2 + 4142430r + 2027025}$$

Which for the root $r = 0$ becomes

$$a_7 = \frac{1}{2027025}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{3+2r}$	$\frac{1}{3}$
a_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{15}$
a_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{105}$
a_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{945}$
a_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{10395}$
a_6	$\frac{1}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	$\frac{1}{135135}$
a_7	$\frac{1}{128r^7+4032r^6+52640r^5+367920r^4+1480472r^3+3411828r^2+4142430r+2027025}$	$\frac{1}{2027025}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots \\ &= 1 + \frac{x}{3} + \frac{x^2}{15} + \frac{x^3}{105} + \frac{x^4}{945} + \frac{x^5}{10395} + \frac{x^6}{135135} + \frac{x^7}{2027025} + O(x^8) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + 3(n+r)b_n - b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}}{2n+1+2r} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = \frac{b_{n-1}}{2n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{1}{3 + 2r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_1 = \frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{4r^2 + 16r + 15}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = \frac{1}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{1}{8r^3 + 60r^2 + 142r + 105}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_3 = \frac{1}{48}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16r^4 + 192r^3 + 824r^2 + 1488r + 945}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{1}{384}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{1}{32r^5 + 560r^4 + 3760r^3 + 12040r^2 + 18258r + 10395}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_5 = \frac{1}{3840}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$
b_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{3840}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{1}{64r^6 + 1536r^5 + 14800r^4 + 72960r^3 + 193036r^2 + 258144r + 135135}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_6 = \frac{1}{46080}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$
b_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{3840}$
b_6	$\frac{1}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	$\frac{1}{46080}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{1}{128r^7 + 4032r^6 + 52640r^5 + 367920r^4 + 1480472r^3 + 3411828r^2 + 4142430r + 2027025}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_7 = \frac{1}{645120}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{3+2r}$	$\frac{1}{2}$
b_2	$\frac{1}{4r^2+16r+15}$	$\frac{1}{8}$
b_3	$\frac{1}{8r^3+60r^2+142r+105}$	$\frac{1}{48}$
b_4	$\frac{1}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{1}{384}$
b_5	$\frac{1}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{1}{3840}$
b_6	$\frac{1}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	$\frac{1}{46080}$
b_7	$\frac{1}{128r^7+4032r^6+52640r^5+367920r^4+1480472r^3+3411828r^2+4142430r+2027025}$	$\frac{1}{645120}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= 1\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + b_8x^8 \dots\right) \\
&= \frac{1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + \frac{x^6}{46080} + \frac{x^7}{645120} + O(x^8)}{\sqrt{x}}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1\left(1 + \frac{x}{3} + \frac{x^2}{15} + \frac{x^3}{105} + \frac{x^4}{945} + \frac{x^5}{10395} + \frac{x^6}{135135} + \frac{x^7}{2027025} + O(x^8)\right) \\
&\quad + \frac{c_2\left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + \frac{x^6}{46080} + \frac{x^7}{645120} + O(x^8)\right)}{\sqrt{x}}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\left(1 + \frac{x}{3} + \frac{x^2}{15} + \frac{x^3}{105} + \frac{x^4}{945} + \frac{x^5}{10395} + \frac{x^6}{135135} + \frac{x^7}{2027025} + O(x^8)\right) \\
&\quad + \frac{c_2\left(1 + \frac{x}{2} + \frac{x^2}{8} + \frac{x^3}{48} + \frac{x^4}{384} + \frac{x^5}{3840} + \frac{x^6}{46080} + \frac{x^7}{645120} + O(x^8)\right)}{\sqrt{x}}
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \left(1+\frac{x}{3}+\frac{x^2}{15}+\frac{x^3}{105}+\frac{x^4}{945}+\frac{x^5}{10395}+\frac{x^6}{135135}+\frac{x^7}{2027025}+O\left(x^8\right)\right) + \frac{c_2 \left(1+\frac{x}{2}+\frac{x^2}{8}+\frac{x^3}{48}+\frac{x^4}{384}+\frac{x^5}{3840}+\frac{x^6}{46080}+\frac{x^7}{645120}+O\left(x^8\right)\right)}{\sqrt{x}} \tag{1}
$$

Verification of solutions

$$
y = c_1 \left(1+\frac{x}{3}+\frac{x^2}{15}+\frac{x^3}{105}+\frac{x^4}{945}+\frac{x^5}{10395}+\frac{x^6}{135135}+\frac{x^7}{2027025}+O\left(x^8\right)\right) + \frac{c_2 \left(1+\frac{x}{2}+\frac{x^2}{8}+\frac{x^3}{48}+\frac{x^4}{384}+\frac{x^5}{3840}+\frac{x^6}{46080}+\frac{x^7}{645120}+O\left(x^8\right)\right)}{\sqrt{x}}
$$

Verified OK.

19.15.1 Maple step by step solution

Let's solve

$2y''x+(-x+3)\,y'-y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{y}{2x}+\frac{(x-3)y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(x-3)y'}{2x}-\frac{y}{2x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{x-3}{2x}, P_3(x)=-\frac{1}{2x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\Big|_{x=0}=\frac{3}{2}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$

- ∘ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x + (-x+3)\,y' - y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ∘ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- ∘ Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$

- ∘ Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$

- ∘ Shift index using $k- >k+1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(2k+3+2r) - a_k(k+1+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, -\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2(k+1+r)\left(\left(k+r+\frac{3}{2}\right) a_{k+1} - \frac{a_k}{2}\right) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{2k+3+2r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{2k+3}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{a_k}{2k+3}\right]$
- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+1} = \frac{a_k}{2k+2}$
- Solution for $r = -\frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k}{2k+2}\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-\frac{1}{2}}\right), a_{k+1} = \frac{a_k}{2k+3}, b_{k+1} = \frac{b_k}{2k+2}\right]$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 4(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2y''x + (1 + x)\, y' + 3y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2y''x + (1 + x)\, y' + 3y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1 + x}{2x}$$
$$q(x) = \frac{3}{2x}$$

Table 459: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1+x}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{3}{2x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2y''x + (1 + x) y' + 3y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) x + (1 + x) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + 3\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 3a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1) x^{n+r-1}$$

$$\sum_{n=0}^{\infty} 3a_n x^{n+r} = \sum_{n=1}^{\infty} 3a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1) x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 3a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) + r\,x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\,x^{-1+r}(-1+2r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-1 + 2r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n + r)(n + r - 1) + a_{n-1}(n + r - 1) + a_n(n + r) + 3a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}(n + r + 2)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = \frac{-2na_{n-1} - 5a_{n-1}}{4n^2 + 2n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-3 - r}{2r^2 + 3r + 1}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -\frac{7}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{(4 + r)(3 + r)}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = \frac{21}{40}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$
a_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{21}{40}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{(4 + r)(5 + r)}{8r^5 + 60r^4 + 170r^3 + 225r^2 + 137r + 30}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -\frac{11}{80}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$
a_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{21}{40}$
a_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{11}{80}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(5+r)(6+r)}{16r^6 + 176r^5 + 760r^4 + 1640r^3 + 1849r^2 + 1019r + 210}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{143}{5760}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$
a_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{21}{40}$
a_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{11}{80}$
a_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{143}{5760}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{(6+r)(7+r)}{32r^7 + 496r^6 + 3104r^5 + 10120r^4 + 18458r^3 + 18679r^2 + 9591r + 1890}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -\frac{13}{3840}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$
a_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{21}{40}$
a_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{11}{80}$
a_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{143}{5760}$
a_5	$-\frac{(6+r)(7+r)}{32r^7+496r^6+3104r^5+10120r^4+18458r^3+18679r^2+9591r+1890}$	$-\frac{13}{3840}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{(8+r)(7+r)}{64r^8+1344r^7+11664r^6+54384r^5+148236r^4+240396r^3+224651r^2+109281r+20790}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = \frac{17}{46080}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$
a_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{21}{40}$
a_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{11}{80}$
a_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{143}{5760}$
a_5	$-\frac{(6+r)(7+r)}{32r^7+496r^6+3104r^5+10120r^4+18458r^3+18679r^2+9591r+1890}$	$-\frac{13}{3840}$
a_6	$\frac{(8+r)(7+r)}{64r^8+1344r^7+11664r^6+54384r^5+148236r^4+240396r^3+224651r^2+109281r+20790}$	$\frac{17}{46080}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{(9+r)(8+r)}{128r^9+3520r^8+40800r^7+260400r^6+1003464r^5+2407860r^4+3574450r^3+3139025r^2+1462}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_7 = -\frac{323}{9676800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-3-r}{2r^2+3r+1}$	$-\frac{7}{6}$
a_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{21}{40}$
a_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{11}{80}$
a_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{143}{5760}$
a_5	$-\frac{(6+r)(7+r)}{32r^7+496r^6+3104r^5+10120r^4+18458r^3+18679r^2+9591r+1890}$	$-\frac{13}{3840}$
a_6	$\frac{(8+r)(7+r)}{64r^8+1344r^7+11664r^6+54384r^5+148236r^4+240396r^3+224651r^2+109281r+20790}$	$\frac{17}{46080}$
a_7	$-\frac{(9+r)(8+r)}{128r^9+3520r^8+40800r^7+260400r^6+1003464r^5+2407860r^4+3574450r^3+3139025r^2+1462233r+270270}$	$-\frac{323}{9676800}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \sqrt{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= \sqrt{x}\left(1 - \frac{7x}{6} + \frac{21x^2}{40} - \frac{11x^3}{80} + \frac{143x^4}{5760} - \frac{13x^5}{3840} + \frac{17x^6}{46080} - \frac{323x^7}{9676800} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) + b_{n-1}(n+r-1) + (n+r)b_n + 3b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{b_{n-1}(n+r+2)}{2n^2+4nr+2r^2-n-r} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{b_{n-1}(n+2)}{n(2n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-3 - r}{2r^2 + 3r + 1}$$

Which for the root $r = 0$ becomes

$$b_1 = -3$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{(4 + r)(3 + r)}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = 0$ becomes

$$b_2 = 2$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3
b_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	2

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{(4 + r)(5 + r)}{8r^5 + 60r^4 + 170r^3 + 225r^2 + 137r + 30}$$

Which for the root $r = 0$ becomes

$$b_3 = -\frac{2}{3}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3
b_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	2
b_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{2}{3}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(5+r)(6+r)}{16r^6 + 176r^5 + 760r^4 + 1640r^3 + 1849r^2 + 1019r + 210}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{1}{7}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3
b_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	2
b_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{2}{3}$
b_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{1}{7}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{(6+r)(7+r)}{32r^7 + 496r^6 + 3104r^5 + 10120r^4 + 18458r^3 + 18679r^2 + 9591r + 1890}$$

Which for the root $r = 0$ becomes

$$b_5 = -\frac{1}{45}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3
b_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	2
b_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{2}{3}$
b_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{1}{7}$
b_5	$-\frac{(6+r)(7+r)}{32r^7+496r^6+3104r^5+10120r^4+18458r^3+18679r^2+9591r+1890}$	$-\frac{1}{45}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{(8+r)(7+r)}{64r^8 + 1344r^7 + 11664r^6 + 54384r^5 + 148236r^4 + 240396r^3 + 224651r^2 + 109281r + 20790}$$

Which for the root $r = 0$ becomes

$$b_6 = \frac{4}{1485}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3
b_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	2
b_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{2}{3}$
b_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{1}{7}$
b_5	$-\frac{(6+r)(7+r)}{32r^7+496r^6+3104r^5+10120r^4+18458r^3+18679r^2+9591r+1890}$	$-\frac{1}{45}$
b_6	$\frac{(8+r)(7+r)}{64r^8+1344r^7+11664r^6+54384r^5+148236r^4+240396r^3+224651r^2+109281r+20790}$	$\frac{4}{1485}$

For $n = 7$, using the above recursive equation gives

$$b_7 = -\frac{(9+r)(8+r)}{128r^9 + 3520r^8 + 40800r^7 + 260400r^6 + 1003464r^5 + 2407860r^4 + 3574450r^3 + 3139025r^2 + 1462}$$

Which for the root $r = 0$ becomes

$$b_7 = -\frac{4}{15015}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-3-r}{2r^2+3r+1}$	-3
b_2	$\frac{(4+r)(3+r)}{4r^4+20r^3+35r^2+25r+6}$	2
b_3	$-\frac{(4+r)(5+r)}{8r^5+60r^4+170r^3+225r^2+137r+30}$	$-\frac{2}{3}$
b_4	$\frac{(5+r)(6+r)}{16r^6+176r^5+760r^4+1640r^3+1849r^2+1019r+210}$	$\frac{1}{7}$
b_5	$-\frac{(6+r)(7+r)}{32r^7+496r^6+3104r^5+10120r^4+18458r^3+18679r^2+9591r+1890}$	$-\frac{1}{45}$
b_6	$\frac{(8+r)(7+r)}{64r^8+1344r^7+11664r^6+54384r^5+148236r^4+240396r^3+224651r^2+109281r+20790}$	$\frac{4}{1485}$
b_7	$-\frac{(9+r)(8+r)}{128r^9+3520r^8+40800r^7+260400r^6+1003464r^5+2407860r^4+3574450r^3+3139025r^2+1462233r+270270}$	$-\frac{4}{15015}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= 1 - 3x + 2x^2 - \frac{2x^3}{3} + \frac{x^4}{7} - \frac{x^5}{45} + \frac{4x^6}{1485} - \frac{4x^7}{15015} + O(x^8)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \sqrt{x}\left(1 - \frac{7x}{6} + \frac{21x^2}{40} - \frac{11x^3}{80} + \frac{143x^4}{5760} - \frac{13x^5}{3840} + \frac{17x^6}{46080} - \frac{323x^7}{9676800} + O(x^8)\right) \\
&\quad + c_2\left(1 - 3x + 2x^2 - \frac{2x^3}{3} + \frac{x^4}{7} - \frac{x^5}{45} + \frac{4x^6}{1485} - \frac{4x^7}{15015} + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 \sqrt{x}\left(1 - \frac{7x}{6} + \frac{21x^2}{40} - \frac{11x^3}{80} + \frac{143x^4}{5760} - \frac{13x^5}{3840} + \frac{17x^6}{46080} - \frac{323x^7}{9676800} + O(x^8)\right) \\
&\quad + c_2\left(1 - 3x + 2x^2 - \frac{2x^3}{3} + \frac{x^4}{7} - \frac{x^5}{45} + \frac{4x^6}{1485} - \frac{4x^7}{15015} + O(x^8)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1\sqrt{x}\left(1-\frac{7x}{6}+\frac{21x^2}{40}-\frac{11x^3}{80}+\frac{143x^4}{5760}-\frac{13x^5}{3840}+\frac{17x^6}{46080}-\frac{323x^7}{9676800}+O\left(x^8\right)\right) \\
& + c_2\left(1-3x+2x^2-\frac{2x^3}{3}+\frac{x^4}{7}-\frac{x^5}{45}+\frac{4x^6}{1485}-\frac{4x^7}{15015}+O\left(x^8\right)\right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1\sqrt{x}\left(1-\frac{7x}{6}+\frac{21x^2}{40}-\frac{11x^3}{80}+\frac{143x^4}{5760}-\frac{13x^5}{3840}+\frac{17x^6}{46080}-\frac{323x^7}{9676800}+O\left(x^8\right)\right) \\
& + c_2\left(1-3x+2x^2-\frac{2x^3}{3}+\frac{x^4}{7}-\frac{x^5}{45}+\frac{4x^6}{1485}-\frac{4x^7}{15015}+O\left(x^8\right)\right)
\end{aligned}
$$

Verified OK.

19.16.1 Maple step by step solution

Let's solve

$2y''x+(1+x)\,y'+3y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(1+x)y'}{2x}-\frac{3y}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(1+x)y'}{2x}+\frac{3y}{2x}=0$

☐ Check to see if $x_0=0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x)=\frac{1+x}{2x}, P_3(x)=\frac{3}{2x}\right]$

- ○ $x\cdot P_2(x)$ is analytic at $x=0$

  $\left.\left(x\cdot P_2(x)\right)\right|_{x=0}=\frac{1}{2}$

- ○ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $\left.\left(x^2\cdot P_3(x)\right)\right|_{x=0}=0$

- ○ $x=0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$2y''x + (1+x)\,y' + 3y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  - Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

  - Shift index using $k- >k+1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

Rewrite ODE with series expansions

$$a_0 r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} (a_{k+1}(k+1+r)\,(2k+1+2r) + a_k(k+r+3))\, x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-1+2r) = 0$

- Values of r that satisfy the indicial equation

$r \in \left\{0, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

$2\left(k+\frac{1}{2}+r\right)(k+1+r)\, a_{k+1} + a_k(k+r+3) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = -\frac{a_k(k+r+3)}{(2k+1+2r)(k+1+r)}$

- Recursion relation for $r = 0$

$a_{k+1} = -\frac{a_k(k+3)}{(2k+1)(k+1)}$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{a_k(k+3)}{(2k+1)(k+1)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$a_{k+1} = -\frac{a_k\left(k+\frac{7}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k\left(k+\frac{7}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+1} = -\frac{a_k(k+3)}{(2k+1)(k+1)}, b_{k+1} = -\frac{b_k\left(k+\frac{7}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 4(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2x^2y'' + xy' - (1+x)\,y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2x^2y'' + xy' + (-1-x)\,y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{2x}$$
$$q(x) = -\frac{1+x}{2x^2}$$

Table 461: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = -\frac{1+x}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2x^2y'' + xy' + (-1 - x)\,y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) + x\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) + (-1-x)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\ + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n\right) = \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\ + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$2x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0$$

Or

$$(2x^r r(-1+r) + x^r r - x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(2r^2 - r - 1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -\frac{1}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(2r^2 - r - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n+r)(n+r-1) + a_n(n+r) - a_n - a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}}{2n^2 + 4nr + 2r^2 - n - r - 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{a_{n-1}}{n(2n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{1}{r(2r+3)}$$

Which for the root $r = 1$ becomes

$$a_1 = \frac{1}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{4r^4 + 20r^3 + 31r^2 + 15r}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{1}{70}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$\frac{1}{70}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{1}{8r^6 + 84r^5 + 338r^4 + 651r^3 + 599r^2 + 210r}$$

Which for the root $r = 1$ becomes

$$a_3 = \frac{1}{1890}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$\frac{1}{70}$
a_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$\frac{1}{1890}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{16r^8 + 288r^7 + 2152r^6 + 8640r^5 + 20089r^4 + 26982r^3 + 19323r^2 + 5670r}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{83160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$\frac{1}{70}$
a_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$\frac{1}{1890}$
a_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$\frac{1}{83160}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{1}{32r^{10} + 880r^9 + 10480r^8 + 70840r^7 + 299026r^6 + 815815r^5 + 1435220r^4 + 1565685r^3 + 957942r^2 +}$$

Which for the root $r = 1$ becomes

$$a_5 = \frac{1}{5405400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$\frac{1}{70}$
a_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$\frac{1}{1890}$
a_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$\frac{1}{83160}$
a_5	$\frac{1}{32r^{10}+880r^9+10480r^8+70840r^7+299026r^6+815815r^5+1435220r^4+1565685r^3+957942r^2+249480r}$	$\frac{1}{5405400}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{1}{r\left(32r^9 + 880r^8 + 10480r^7 + 70840r^6 + 299026r^5 + 815815r^4 + 1435220r^3 + 1565685r^2 + 957942r + \right.}$$

Which for the root $r = 1$ becomes

$$a_6 = \frac{1}{486486000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$\frac{1}{70}$
a_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$\frac{1}{1890}$
a_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$\frac{1}{83160}$
a_5	$\frac{1}{32r^{10}+880r^9+10480r^8+70840r^7+299026r^6+815815r^5+1435220r^4+1565685r^3+957942r^2+249480r}$	$\frac{1}{5405400}$
a_6	$\frac{1}{r(32r^9+880r^8+10480r^7+70840r^6+299026r^5+815815r^4+1435220r^3+1565685r^2+957942r+249480)(2r^2+23r+65)}$	$\frac{1}{486486000}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{1}{r\left(32r^9 + 880r^8 + 10480r^7 + 70840r^6 + 299026r^5 + 815815r^4 + 1435220r^3 + 1565685r^2 + 957942r + \right.}$$

Which for the root $r = 1$ becomes

$$a_7 = \frac{1}{57891834000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{1}{r(2r+3)}$	$\frac{1}{5}$
a_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$\frac{1}{70}$
a_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$\frac{1}{189}$
a_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	831
a_5	$\frac{1}{32r^{10}+880r^9+10480r^8+70840r^7+299026r^6+815815r^5+1435220r^4+1565685r^3+957942r^2+249480r}$	540
a_6	$\frac{1}{r(32r^9+880r^8+10480r^7+70840r^6+299026r^5+815815r^4+1435220r^3+1565685r^2+957942r+249480)(2r^2+23r+65)}$	486
a_7	$\frac{1}{r(32r^9+880r^8+10480r^7+70840r^6+299026r^5+815815r^4+1435220r^3+1565685r^2+957942r+249480)(2r^2+23r+65)(2r^2+27r+90)}$	578

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= x\left(1 + \frac{x}{5} + \frac{x^2}{70} + \frac{x^3}{1890} + \frac{x^4}{83160} + \frac{x^5}{5405400} + \frac{x^6}{486486000} + \frac{x^7}{57891834000} + O\left(x^8\right)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
2b_n(n+r)(n+r-1) + b_n(n+r) - b_n - b_{n-1} = 0 \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{b_{n-1}}{2n^2 + 4nr + 2r^2 - n - r - 1} \tag{4}
$$

Which for the root $r = -\frac{1}{2}$ becomes

$$
b_n = \frac{b_{n-1}}{n(2n-3)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{1}{r(2r+3)}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_1 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{1}{4r^4 + 20r^3 + 31r^2 + 15r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{1}{8r^6 + 84r^5 + 338r^4 + 651r^3 + 599r^2 + 210r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_3 = -\frac{1}{18}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$-\frac{1}{2}$
b_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$-\frac{1}{18}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{16r^8 + 288r^7 + 2152r^6 + 8640r^5 + 20089r^4 + 26982r^3 + 19323r^2 + 5670r}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = -\frac{1}{360}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$-\frac{1}{2}$
b_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$-\frac{1}{18}$
b_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$-\frac{1}{360}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{1}{32r^{10} + 880r^9 + 10480r^8 + 70840r^7 + 299026r^6 + 815815r^5 + 1435220r^4 + 1565685r^3 + 957942r^2 +}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_5 = -\frac{1}{12600}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$-\frac{1}{2}$
b_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$-\frac{1}{18}$
b_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$-\frac{1}{360}$
b_5	$\frac{1}{32r^{10}+880r^9+10480r^8+70840r^7+299026r^6+815815r^5+1435220r^4+1565685r^3+957942r^2+249480r}$	$-\frac{1}{12600}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{1}{r\left(32r^9 + 880r^8 + 10480r^7 + 70840r^6 + 299026r^5 + 815815r^4 + 1435220r^3 + 1565685r^2 + 957942r + \right.}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_6 = -\frac{1}{680400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$-\frac{1}{2}$
b_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$-\frac{1}{18}$
b_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$-\frac{1}{360}$
b_5	$\frac{1}{32r^{10}+880r^9+10480r^8+70840r^7+299026r^6+815815r^5+1435220r^4+1565685r^3+957942r^2+249480r}$	$-\frac{1}{12600}$
b_6	$\frac{1}{r(32r^9+880r^8+10480r^7+70840r^6+299026r^5+815815r^4+1435220r^3+1565685r^2+957942r+249480)(2r^2+23r+65)}$	$-\frac{1}{680400}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{1}{r\left(32r^9 + 880r^8 + 10480r^7 + 70840r^6 + 299026r^5 + 815815r^4 + 1435220r^3 + 1565685r^2 + 957942r + \right.}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_7 = -\frac{1}{52390800}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{1}{r(2r+3)}$	-1
b_2	$\frac{1}{4r^4+20r^3+31r^2+15r}$	$-$
b_3	$\frac{1}{8r^6+84r^5+338r^4+651r^3+599r^2+210r}$	$-$
b_4	$\frac{1}{16r^8+288r^7+2152r^6+8640r^5+20089r^4+26982r^3+19323r^2+5670r}$	$-$
b_5	$\frac{1}{32r^{10}+880r^9+10480r^8+70840r^7+299026r^6+815815r^5+1435220r^4+1565685r^3+957942r^2+249480r}$	$-$
b_6	$\frac{1}{r(32r^9+880r^8+10480r^7+70840r^6+299026r^5+815815r^4+1435220r^3+1565685r^2+957942r+249480)(2r^2+23r+65)}$	$-$
b_7	$\frac{1}{r(32r^9+880r^8+10480r^7+70840r^6+299026r^5+815815r^4+1435220r^3+1565685r^2+957942r+249480)(2r^2+23r+65)(2r^2+27r+90)}$	$-$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots\right) \\ &= \frac{1 - x - \frac{x^2}{2} - \frac{x^3}{18} - \frac{x^4}{360} - \frac{x^5}{12600} - \frac{x^6}{680400} - \frac{x^7}{52390800} + O(x^8)}{\sqrt{x}} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{70} + \frac{x^3}{1890} + \frac{x^4}{83160} + \frac{x^5}{5405400} + \frac{x^6}{486486000} + \frac{x^7}{57891834000} + O(x^8)\right) \\ &+ \frac{c_2 \left(1 - x - \frac{x^2}{2} - \frac{x^3}{18} - \frac{x^4}{360} - \frac{x^5}{12600} - \frac{x^6}{680400} - \frac{x^7}{52390800} + O(x^8)\right)}{\sqrt{x}} \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x \left(1 + \frac{x}{5} + \frac{x^2}{70} + \frac{x^3}{1890} + \frac{x^4}{83160} + \frac{x^5}{5405400} + \frac{x^6}{486486000} + \frac{x^7}{57891834000} + O(x^8)\right) \\ &+ \frac{c_2 \left(1 - x - \frac{x^2}{2} - \frac{x^3}{18} - \frac{x^4}{360} - \frac{x^5}{12600} - \frac{x^6}{680400} - \frac{x^7}{52390800} + O(x^8)\right)}{\sqrt{x}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x \left(1+\frac{x}{5}+\frac{x^2}{70}+\frac{x^3}{1890}+\frac{x^4}{83160}+\frac{x^5}{5405400}+\frac{x^6}{486486000}+\frac{x^7}{57891834000}+O(x^8)\right)+\frac{c_2\left(1-x-\frac{x^2}{2}-\frac{x^3}{18}-\frac{x^4}{360}-\frac{x^5}{12600}-\frac{x^6}{680400}-\frac{x^7}{52390800}+O(x^8)\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = c_1 x \left(1+\frac{x}{5}+\frac{x^2}{70}+\frac{x^3}{1890}+\frac{x^4}{83160}+\frac{x^5}{5405400}+\frac{x^6}{486486000}+\frac{x^7}{57891834000}+O(x^8)\right)+\frac{c_2\left(1-x-\frac{x^2}{2}-\frac{x^3}{18}-\frac{x^4}{360}-\frac{x^5}{12600}-\frac{x^6}{680400}-\frac{x^7}{52390800}+O(x^8)\right)}{\sqrt{x}}$$

Verified OK.

19.17.1 Maple step by step solution

Let's solve

$2x^2y''+xy'+(-1-x)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y'}{2x}+\frac{(1+x)y}{2x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{y'}{2x}-\frac{(1+x)y}{2x^2}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{1}{2x}, P_3(x)=-\frac{1+x}{2x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=\frac{1}{2}$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=-\frac{1}{2}$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $2x^2y''+xy'+(-1-x)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y$ to series expansion for $m=0..1$

  $x^m\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x\cdot y'$ to series expansion

  $x\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r}$

- Convert $x^2\cdot y''$ to series expansion

  $x^2\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)\,(-1+r)\,x^r+\left(\sum_{k=1}^{\infty} \left(a_k(2k+2r+1)\,(k+r-1)-a_{k-1}\right) x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)\,(-1+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{1,-\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $2(k+r-1)\left(k+\frac{1}{2}+r\right)a_k-a_{k-1}=0$

- Shift index using $k->k+1$

  $2(k+r)\left(k+\frac{3}{2}+r\right)a_{k+1}-a_k=0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = \frac{a_k}{(k+r)(2k+3+2r)}$

- Recursion relation for $r = 1$

$a_{k+1} = \frac{a_k}{(k+1)(2k+5)}$

- Solution for $r = 1$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = \frac{a_k}{(k+1)(2k+5)}\right]$

- Recursion relation for $r = -\frac{1}{2}$

$a_{k+1} = \frac{a_k}{\left(k-\frac{1}{2}\right)(2k+2)}$

- Solution for $r = -\frac{1}{2}$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.4. REGULAR SINGULAR POINTS. Page 175
Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[_Lienard]`

$$\boxed{x^2y'' + xy' + yx^2 = 0}$$

With the expansion point for the power series method at $x = 0$.

The ODE is

$$x^2y'' + xy' + yx^2 = 0$$

Or

$$x(y''x + y' + xy) = 0$$

For $x \neq 0$ the above simplifies to

$$y''x + y' + xy = 0$$

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + xy' + yx^2 = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = 1$$

Table 463: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = 1$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + xy' + yx^2 = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + x \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x^2 = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{2+n+r} a_n\right) = 0 \quad \text{(2A)}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{2+n+r} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) = 0 \quad \text{(2B)}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r = 0$$

Or

$$\left(x^r r(-1+r) + x^r r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^r r^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^r r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + a_{n-2} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{a_{n-2}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{(r+2)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = -\frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(r+2)^2 (r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{64}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{1}{(r+2)^2(r+4)^2}$	$\frac{1}{64}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{1}{(r+2)^2(r+4)^2}$	$\frac{1}{64}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{1}{(r+2)^2 (r+4)^2 (r+6)^2}$$

Which for the root $r = 0$ becomes

$$a_6 = -\frac{1}{2304}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{1}{(r+2)^2(r+4)^2}$	$\frac{1}{64}$
a_5	0	0
a_6	$-\frac{1}{(r+2)^2(r+4)^2(r+6)^2}$	$-\frac{1}{2304}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$
a_3	0	0
a_4	$\frac{1}{(r+2)^2(r+4)^2}$	$\frac{1}{64}$
a_5	0	0
a_6	$-\frac{1}{(r+2)^2(r+4)^2(r+6)^2}$	$-\frac{1}{2304}$
a_7	0	0

Using the above table, then the first solution $y_1(x)$ becomes

$$\begin{aligned}
y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots \\
&= 1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + O(x^8)
\end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr} a_{n,r}$	$b_n(r = 0)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	0	0	0	0
b_2	$-\frac{1}{(r+2)^2}$	$-\frac{1}{4}$	$\frac{2}{(r+2)^3}$	$\frac{1}{4}$
b_3	0	0	0	0
b_4	$\frac{1}{(r+2)^2(r+4)^2}$	$\frac{1}{64}$	$\frac{-4r-12}{(r+2)^3(r+4)^3}$	$-\frac{3}{128}$
b_5	0	0	0	0
b_6	$-\frac{1}{(r+2)^2(r+4)^2(r+6)^2}$	$-\frac{1}{2304}$	$\frac{6r^2+48r+88}{(r+2)^3(r+4)^3(r+6)^3}$	$\frac{11}{13824}$
b_7	0	0	0	0

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned}
y_2(x) &= y_1(x) \ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= \left(1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + O(x^8)\right) \ln(x) + \frac{x^2}{4} - \frac{3x^4}{128} + \frac{11x^6}{13824} + O(x^8)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + O(x^8)\right) \\
&\quad + c_2 \left(\left(1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + O(x^8)\right) \ln(x) + \frac{x^2}{4} - \frac{3x^4}{128} + \frac{11x^6}{13824} + O(x^8)\right)
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1 \left(1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + O(x^8)\right) \\
&\quad + c_2 \left(\left(1 - \frac{x^2}{4} + \frac{x^4}{64} - \frac{x^6}{2304} + O(x^8)\right) \ln(x) + \frac{x^2}{4} - \frac{3x^4}{128} + \frac{11x^6}{13824} + O(x^8)\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = c_1 \left(1-\frac{x^2}{4}+\frac{x^4}{64}-\frac{x^6}{2304}+O(x^8)\right) \\
+ c_2 \left(\left(1-\frac{x^2}{4}+\frac{x^4}{64}-\frac{x^6}{2304}+O(x^8)\right)\ln(x)+\frac{x^2}{4}-\frac{3x^4}{128}+\frac{11x^6}{13824}+O(x^8)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1 \left(1-\frac{x^2}{4}+\frac{x^4}{64}-\frac{x^6}{2304}+O(x^8)\right) \\
+ c_2 \left(\left(1-\frac{x^2}{4}+\frac{x^4}{64}-\frac{x^6}{2304}+O(x^8)\right)\ln(x)+\frac{x^2}{4}-\frac{3x^4}{128}+\frac{11x^6}{13824}+O(x^8)\right)
\end{aligned}
$$

Verified OK.

19.18.1 Maple step by step solution

Let's solve

$x^2y''+xy'+yx^2=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y'}{x}-y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{y'}{x}+y=0$

☐ Check to see if $x_0=0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=\frac{1}{x}, P_3(x)=1\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=1$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=0$

- ◦ $x=0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$y'' x + y' + xy = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x \cdot y$ to series expansion

  $x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$

  ◦ Shift index using $k- > k-1$

  $x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

  ◦ Convert y' to series expansion

  $y' = \sum_{k=0}^{\infty} a_k (k+r) x^{k+r-1}$

  ◦ Shift index using $k- > k+1$

  $y' = \sum_{k=-1}^{\infty} a_{k+1} (k+r+1) x^{k+r}$

  ◦ Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r) (k+r-1) x^{k+r-1}$

  ◦ Shift index using $k- > k+1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+r+1) (k+r) x^{k+r}$

Rewrite ODE with series expansions

$a_0 r^2 x^{-1+r} + a_1 (1+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1} (k+r+1)^2 + a_{k-1}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r^2 = 0$

- Values of r that satisfy the indicial equation

$r = 0$

- Each term must be 0

  $a_1(1+r)^2 = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1)^2 + a_{k-1} = 0$
- Shift index using $k->k+1$

  $a_{k+2}(k+2)^2 + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k}{(k+2)^2}$
- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{a_k}{(k+2)^2}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{(k+2)^2}, a_1 = 0\right]$

Problem number: 8.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Irregular singular point"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

Unable to solve or complete the solution.

$$\boxed{x^2y'' + (3x-1)\,y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + (3x-1)\,y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{3x-1}{x^2}$$
$$q(x) = \frac{1}{x^2}$$

Table 466: Table $p(x), q(x)$ singularites.

$p(x) = \frac{3x-1}{x^2}$	
singularity	type
$x = 0$	"irregular"

$q(x) = \frac{1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[\infty]$

Irregular singular points : $[0]$

Since $x = 0$ is not an ordinary point, then we will now check if it is a regular singular point. Unable to solve since $x = 0$ is not regular singular point. Terminating.

Verification of solutions N/A

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 3xy' + (4x + 4)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - 3xy' + (4x + 4)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{4x + 4}{x^2}$$

Table 467: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{3}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{4x+4}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' - 3xy' + (4x + 4)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2} \right) - 3x \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1} \right) + (4x+4) \left(\sum_{n=0}^{\infty} a_n x^{n+r} \right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n(n+r)\right) + \left(\sum_{n=0}^{\infty} 4x^{1+n+r} a_n\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 4x^{1+n+r} a_n = \sum_{n=1}^{\infty} 4a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-3x^{n+r} a_n(n+r)\right) + \left(\sum_{n=1}^{\infty} 4a_{n-1} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 4a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1) - 3x^{n+r} a_n(n+r) + 4a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - 3x^r a_0 r + 4a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - 3x^r r + 4x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(r-2)^2 x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(r-2)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r-2)^2 x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 2$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+2}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - 3a_n(n+r) + 4a_{n-1} + 4a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4a_{n-1}}{n^2 + 2nr + r^2 - 4n - 4r + 4} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = -\frac{4a_{n-1}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{4}{(-1+r)^2}$$

Which for the root $r = 2$ becomes

$$a_1 = -4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{16}{(-1+r)^2 r^2}$$

Which for the root $r = 2$ becomes

$$a_2 = 4$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{64}{(-1+r)^2 r^2 (r+1)^2}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{16}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{256}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2}$$

Which for the root $r = 2$ becomes

$$a_4 = \frac{4}{9}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$
a_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2}$	$\frac{4}{9}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{16}{225}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$
a_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2}$	$\frac{4}{9}$
a_5	$-\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2}$	$-\frac{16}{225}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{4096}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2}$$

Which for the root $r = 2$ becomes

$$a_6 = \frac{16}{2025}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$
a_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2}$	$\frac{4}{9}$
a_5	$-\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2}$	$-\frac{16}{225}$
a_6	$\frac{4096}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2}$	$\frac{16}{2025}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{16384}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2}$$

Which for the root $r = 2$ becomes

$$a_7 = -\frac{64}{99225}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{4}{(-1+r)^2}$	-4
a_2	$\frac{16}{(-1+r)^2 r^2}$	4
a_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$
a_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2}$	$\frac{4}{9}$
a_5	$-\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2}$	$-\frac{16}{225}$
a_6	$\frac{4096}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2}$	$\frac{16}{2025}$
a_7	$-\frac{16384}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2}$	$-\frac{64}{99225}$

Using the above table, then the first solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2 \left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= x^2 \left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + \frac{16x^6}{2025} - \frac{64x^7}{99225} + O(x^8)\right) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 2$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$
b_0	1	1	N/A since b_n starts from 1
b_1	$-\frac{4}{(-1+r)^2}$	-4	$\frac{8}{(-1+r)^3}$
b_2	$\frac{16}{(-1+r)^2 r^2}$	4	$\frac{-64r+32}{(-1+r)^3 r^3}$
b_3	$-\frac{64}{(-1+r)^2 r^2 (r+1)^2}$	$-\frac{16}{9}$	$\frac{384r^2-128}{(-1+r)^3 r^3 (r+1)^3}$
b_4	$\frac{256}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2}$	$\frac{4}{9}$	$\frac{-2048r^3-3072r^2+1024r+1024}{(-1+r)^3 r^3 (r+1)^3 (r+2)^3}$
b_5	$-\frac{1024}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2}$	$-\frac{16}{225}$	$\frac{10240r^4+40960r^3+30720r^2-20480r-12288}{(-1+r)^3 r^3 (r+1)^3 (r+2)^3 (r+3)^3}$
b_6	$\frac{4096}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2}$	$\frac{16}{2025}$	$-\frac{49152\left(r^4+6r^3+\frac{23}{3}r^2-4r-\frac{8}{3}\right)\left(\frac{3}{2}+r\right)}{(-1+r)^3 r^3 (r+1)^3 (r+2)^3 (r+3)^3 (r+4)^3}$
b_7	$-\frac{16384}{(-1+r)^2 r^2 (r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2}$	$-\frac{64}{99225}$	$\frac{229376r^6+2752512r^5+11468800r^4+18350080r^3+4816896r^2-10092544}{(-1+r)^3 r^3 (r+1)^3 (r+2)^3 (r+3)^3 (r+4)^3 (r+5)^3}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + b_8x^8 \ldots \\
&= x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + \frac{16x^6}{2025} - \frac{64x^7}{99225} + O\left(x^8\right)\right)\ln(x) \\
&\quad + x^2\left(-12x^2 + 8x + \frac{176x^3}{27} - \frac{50x^4}{27} + \frac{1096x^5}{3375} - \frac{392x^6}{10125} + \frac{3872x^7}{1157625} + O\left(x^8\right)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + \frac{16x^6}{2025} - \frac{64x^7}{99225} + O\left(x^8\right)\right) \\
&\quad + c_2\left(x^2\left(4x^2 - 4x + 1 - \frac{16x^3}{9} + \frac{4x^4}{9} - \frac{16x^5}{225} + \frac{16x^6}{2025} - \frac{64x^7}{99225} + O\left(x^8\right)\right)\ln(x)\right. \\
&\quad \left. + x^2\left(-12x^2 + 8x + \frac{176x^3}{27} - \frac{50x^4}{27} + \frac{1096x^5}{3375} - \frac{392x^6}{10125} + \frac{3872x^7}{1157625} + O\left(x^8\right)\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
y = y_h
$$

$$
\begin{aligned}
&= c_1x^2\left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+\frac{16x^6}{2025}-\frac{64x^7}{99225}+O(x^8)\right) \\
&\quad + c_2\left(x^2\left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+\frac{16x^6}{2025}-\frac{64x^7}{99225}+O(x^8)\right)\ln(x)\right. \\
&\quad \left. + x^2\left(-12x^2+8x+\frac{176x^3}{27}-\frac{50x^4}{27}+\frac{1096x^5}{3375}-\frac{392x^6}{10125}+\frac{3872x^7}{1157625}+O(x^8)\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1x^2\left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+\frac{16x^6}{2025}-\frac{64x^7}{99225}+O(x^8)\right) \\
&\quad + c_2\left(x^2\left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+\frac{16x^6}{2025}-\frac{64x^7}{99225}+O(x^8)\right)\ln(x)\right. \\
&\quad \left. + x^2\left(-12x^2+8x+\frac{176x^3}{27}-\frac{50x^4}{27}+\frac{1096x^5}{3375}-\frac{392x^6}{10125}+\frac{3872x^7}{1157625}+O(x^8)\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1x^2\left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+\frac{16x^6}{2025}-\frac{64x^7}{99225}+O(x^8)\right) \\
&\quad + c_2\left(x^2\left(4x^2-4x+1-\frac{16x^3}{9}+\frac{4x^4}{9}-\frac{16x^5}{225}+\frac{16x^6}{2025}-\frac{64x^7}{99225}+O(x^8)\right)\ln(x)\right. \\
&\quad \left. + x^2\left(-12x^2+8x+\frac{176x^3}{27}-\frac{50x^4}{27}+\frac{1096x^5}{3375}-\frac{392x^6}{10125}+\frac{3872x^7}{1157625}+O(x^8)\right)\right)
\end{aligned}
$$

Verified OK.

20.1.1 Maple step by step solution

Let's solve

$x^2y''-3xy'+(4x+4)y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{3y'}{x}-\frac{4(1+x)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{3y'}{x}+\frac{4(1+x)y}{x^2}=0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{3}{x}, P_3(x) = \frac{4(1+x)}{x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -3$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 4$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $x^2y'' - 3xy' + (4x + 4)\, y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- > k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$
  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r}$

    Rewrite ODE with series expansions

$$a_0(-2+r)^2 x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-2)^2 + 4a_{k-1}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-2+r)^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 2$
- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-2)^2 + 4a_{k-1} = 0$
- Shift index using $k- >k+1$

  $a_{k+1}(k+r-1)^2 + 4a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{4a_k}{(k+r-1)^2}$
- Recursion relation for $r = 2$

  $a_{k+1} = -\frac{4a_k}{(k+1)^2}$
- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = -\frac{4a_k}{(k+1)^2}\right]$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.5. More on Regular Singular Points. Page 183
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2y'' - 8x^2y' + (4x^2 + 1) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4x^2y'' - 8x^2y' + (4x^2 + 1) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$\begin{aligned} p(x) &= -2 \\ q(x) &= \frac{4x^2 + 1}{4x^2} \end{aligned}$$

Table 469: Table $p(x), q(x)$ singularites.

$p(x) = -2$	
singularity	type

$q(x) = \frac{4x^2+1}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2y'' - 8x^2y' + (4x^2 + 1)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4x^2 \left(\sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2} \right) - 8x^2 \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1} \right) + (4x^2 + 1) \left(\sum_{n=0}^{\infty} a_n x^{n+r} \right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-8x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 4x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-8x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-8a_{n-1}(n+r-1)\, x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} 4x^{n+r+2} a_n = \sum_{n=2}^{\infty} 4a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-8a_{n-1}(n+r-1)\, x^{n+r}\right) + \left(\sum_{n=2}^{\infty} 4a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r} a_n (n+r)(n+r-1) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$4x^r a_0 r(-1+r) + a_0 x^r = 0$$

Or

$$\left(4x^r r(-1+r) + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^r (2r-1)^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$(2r-1)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= \frac{1}{2} \\ r_2 &= \frac{1}{2} \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^r (2r-1)^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = \frac{1}{2}$, Eqs (1A,1B) become

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}} \\ y_2(x) &= y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+\frac{1}{2}}\right) \end{aligned}$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{8r}{(2r+1)^2}$$

For $2 \leq n$ the recursive equation is

$$4a_n(n+r)(n+r-1) - 8a_{n-1}(n+r-1) + 4a_{n-2} + a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{8na_{n-1} + 8ra_{n-1} - 4a_{n-2} - 8a_{n-1}}{4n^2 + 8nr + 4r^2 - 4n - 4r + 1} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = \frac{(2n-1)\, a_{n-1} - a_{n-2}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{48r^2 + 48r - 4}{(3+2r)^2 (2r+1)^2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = \frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1
a_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{256r^3 + 768r^2 + 448r - 64}{(3+2r)^2 (5+2r)^2 (2r+1)^2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = \frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1
a_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$
a_3	$\frac{256r^3+768r^2+448r-64}{(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{6}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1280r^4 + 7680r^3 + 13440r^2 + 5760r - 1136}{(3+2r)^2 (5+2r)^2 (2r+1)^2 (7+2r)^2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1
a_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$
a_3	$\frac{256r^3+768r^2+448r-64}{(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{6}$
a_4	$\frac{1280r^4+7680r^3+13440r^2+5760r-1136}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{6144(2+r)\left(r^4 + 8r^3 + \frac{109}{6}r^2 + \frac{26}{3}r - \frac{31}{16}\right)}{(3+2r)^2 (5+2r)^2 (2r+1)^2 (7+2r)^2 (9+2r)^2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1
a_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$
a_3	$\frac{256r^3+768r^2+448r-64}{(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{6}$
a_4	$\frac{1280r^4+7680r^3+13440r^2+5760r-1136}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2}$	$\frac{1}{24}$
a_5	$\frac{6144(2+r)\left(r^4+8r^3+\frac{109}{6}r^2+\frac{26}{3}r-\frac{31}{16}\right)}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2(9+2r)^2}$	$\frac{1}{120}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{28672r^6 + 430080r^5 + 2401280r^4 + 6092800r^3 + 6650112r^2 + 1890560r - 584256}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = \frac{1}{720}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1
a_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$
a_3	$\frac{256r^3+768r^2+448r-64}{(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{6}$
a_4	$\frac{1280r^4+7680r^3+13440r^2+5760r-1136}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2}$	$\frac{1}{24}$
a_5	$\frac{6144(2+r)\left(r^4+8r^3+\frac{109}{6}r^2+\frac{26}{3}r-\frac{31}{16}\right)}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2(9+2r)^2}$	$\frac{1}{120}$
a_6	$\frac{28672r^6+430080r^5+2401280r^4+6092800r^3+6650112r^2+1890560r-584256}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{720}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{131072\left(r^6+18r^5+\frac{477}{4}r^4+351r^3+\frac{6819}{16}r^2+\frac{1017}{8}r-\frac{2689}{64}\right)(r+3)}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2(13+2r)^2}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_7 = \frac{1}{5040}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{8r}{(2r+1)^2}$	1
a_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$
a_3	$\frac{256r^3+768r^2+448r-64}{(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{6}$
a_4	$\frac{1280r^4+7680r^3+13440r^2+5760r-1136}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2}$	$\frac{1}{24}$
a_5	$\frac{6144(2+r)\left(r^4+8r^3+\frac{109}{6}r^2+\frac{26}{3}r-\frac{31}{16}\right)}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2(9+2r)^2}$	$\frac{1}{120}$
a_6	$\frac{28672r^6+430080r^5+2401280r^4+6092800r^3+6650112r^2+1890560r-584256}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{720}$
a_7	$\frac{131072\left(r^6+18r^5+\frac{477}{4}r^4+351r^3+\frac{6819}{16}r^2+\frac{1017}{8}r-\frac{2689}{64}\right)(r+3)}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2(13+2r)^2}$	$\frac{1}{5040}$

Using the above table, then the first solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \sqrt{x}\left(a_0+a_1x+a_2x^2+a_3x^3+a_4x^4+a_5x^5+a_6x^6+a_7x^7+a_8x^8\dots\right) \\ &= \sqrt{x}\left(1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+\frac{x^6}{720}+\frac{x^7}{5040}+O(x^8)\right) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr}a_{n,r}$$

And the above is then evaluated at $r = \frac{1}{2}$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$
b_0	1	1	N/A since b_n starts from 1
b_1	$\frac{8r}{(2r+1)^2}$	1	$\frac{-16r+8}{(2r+1)^3}$
b_2	$\frac{48r^2+48r-4}{(3+2r)^2(2r+1)^2}$	$\frac{1}{2}$	$\frac{-384r^3-576r^2-32r+208}{(3+2r)^3(2r+1)^3}$
b_3	$\frac{256r^3+768r^2+448r-64}{(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{6}$	$-\frac{6144\left(r^4+6r^3+13r^2+12r+\frac{197}{48}\right)\left(r-\frac{1}{2}\right)}{(3+2r)^3(5+2r)^3(2r+1)^3}$
b_4	$\frac{1280r^4+7680r^3+13440r^2+5760r-1136}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2}$	$\frac{1}{24}$	$-\frac{81920\left(r-\frac{1}{2}\right)\left(r^6+12r^5+\frac{231}{4}r^4+142r^3+\frac{15003}{80} \cdots\right.}{(3+2r)^3(5+2r)^3(2r+1)^3(7+2r \cdots}$
b_5	$\frac{6144(2+r)\left(r^4+8r^3+\frac{109}{6}r^2+\frac{26}{3}r-\frac{31}{16}\right)}{(3+2r)^2(5+2r)^2(2r+1)^2(7+2r)^2(9+2r)^2}$	$\frac{1}{120}$	$-\frac{983040\left(r-\frac{1}{2}\right)\left(r^8+20r^7+\frac{508}{3}r^6+790r^5+\frac{17705}{8} \cdots\right.}{(9+2r)^3(7+2r)^3(3+2r) \cdots}$
b_6	$\frac{28672r^6+430080r^5+2401280r^4+6092800r^3+6650112r^2+1890560r-584256}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2}$	$\frac{1}{720}$	$-\frac{11010048\left(r-\frac{1}{2}\right)\left(r^{10}+30r^9+\frac{1575}{4}r^8+2970r^7+ \cdots\right.}{(9+2r) \cdots}$
b_7	$\frac{131072\left(r^6+18r^5+\frac{477}{4}r^4+351r^3+\frac{6819}{16}r^2+\frac{1017}{8}r-\frac{2689}{64}\right)(r+3)}{(9+2r)^2(7+2r)^2(11+2r)^2(3+2r)^2(5+2r)^2(2r+1)^2(13+2r)^2}$	$\frac{1}{5040}$	$-\frac{117440512\left(r^{12}+42r^{11}+789r^{10}+8750r^9+\frac{1018 \cdots}{1 \cdots} \cdots\right.}{\cdots}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + b_8x^8 \dots \\
&= \sqrt{x}\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)\right)\ln(x) + \sqrt{x}\,O(x^8)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1\sqrt{x}\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)\right) \\
&\quad + c_2\left(\sqrt{x}\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)\right)\ln(x) + \sqrt{x}\,O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\sqrt{x}\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)\right) \\
&\quad + c_2\left(\sqrt{x}\left(1 + x + \frac{x^2}{2} + \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{120} + \frac{x^6}{720} + \frac{x^7}{5040} + O(x^8)\right)\ln(x) + \sqrt{x}\,O(x^8)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1\sqrt{x}\left(1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+\frac{x^6}{720}+\frac{x^7}{5040}+O\left(x^8\right)\right) \\
+ c_2\left(\sqrt{x}\left(1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+\frac{x^6}{720}+\frac{x^7}{5040}+O\left(x^8\right)\right)\ln\left(x\right)\right. \\
\left.+\sqrt{x}\,O\left(x^8\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
y = c_1\sqrt{x}\left(1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+\frac{x^6}{720}+\frac{x^7}{5040}+O\left(x^8\right)\right) + c_2\left(\sqrt{x}\left(1+x+\frac{x^2}{2}+\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{120}+\frac{x^6}{720}+\frac{x^7}{5040}+O\left(x^8\right)\right)\ln\left(x\right)+\sqrt{x}\,O\left(x^8\right)\right)
$$

Verified OK.

20.2.1 Maple step by step solution

Let's solve

$4x^2y'' - 8x^2y' + \left(4x^2+1\right)y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = 2y' - \frac{(4x^2+1)y}{4x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - 2y' + \frac{(4x^2+1)y}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -2, P_3(x) = \frac{4x^2+1}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 0$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = \frac{1}{4}$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2y'' - 8x^2y' + (4x^2 + 1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^2 \cdot y'$ to series expansion

    $x^2 \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r+1}$

  - Shift index using $k- >k - 1$

    $x^2 \cdot y' = \sum_{k=1}^{\infty} a_{k-1} (k - 1 + r)\, x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\, (k - 1 + r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1 + 2r)^2\, x^r + \left(a_1(1 + 2r)^2 - 8a_0 r\right) x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(2k + 2r - 1)^2 - 8a_{k-1}(k - 1 + r) + 4a_k\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1 + 2r)^2 = 0$

- Values of r that satisfy the indicial equation

  $r = \frac{1}{2}$

- Each term must be 0

  $a_1(1+2r)^2 - 8a_0 r = 0$
- Solve for the dependent coefficient(s)

  $a_1 = \frac{8a_0 r}{4r^2+4r+1}$
- Each term in the series must be 0, giving the recursion relation

  $a_k(2k+2r-1)^2 + (-8k-8r+8)\, a_{k-1} + 4a_{k-2} = 0$
- Shift index using $k->k+2$

  $a_{k+2}(2k+3+2r)^2 + (-8k-8-8r)\, a_{k+1} + 4a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{4(2ka_{k+1}+2ra_{k+1}-a_k+2a_{k+1})}{(2k+3+2r)^2}$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = \frac{4(2ka_{k+1}-a_k+3a_{k+1})}{(2k+4)^2}$
- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{4(2ka_{k+1}-a_k+3a_{k+1})}{(2k+4)^2}, a_1 = a_0\right]$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.5. More on Regular Singular Points. Page 183
Problem number: 3(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[_Lienard]`

$$\boxed{y''x + 2y' + xy = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$y''x + 2y' + xy = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{2}{x}$$
$$q(x) = 1$$

Table 471: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = 1$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x + 2y' + xy = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x + 2\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + x\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + 2(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + 2r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + 2r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(1+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(1+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(1+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\
y_2(x) &= C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\
y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\
y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)
\end{aligned}
$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
a_1 = 0
$$

For $2 \leq n$ the recursive equation is

$$
a_n(n+r)(n+r-1) + 2a_n(n+r) + a_{n-2} = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2 + n + r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
a_n = -\frac{a_{n-2}}{n(1+n)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{r^2 + 5r + 6}$$

Which for the root $r = 0$ becomes

$$a_2 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{r^4 + 14r^3 + 71r^2 + 154r + 120}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{120}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{120}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{1}{(r^4 + 14r^3 + 71r^2 + 154r + 120)(r^2 + 13r + 42)}$$

Which for the root $r = 0$ becomes

$$a_6 = -\frac{1}{5040}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{120}$
a_5	0	0
a_6	$-\frac{1}{(r^4+14r^3+71r^2+154r+120)(r^2+13r+42)}$	$-\frac{1}{5040}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{120}$
a_5	0	0
a_6	$-\frac{1}{(r^4+14r^3+71r^2+154r+120)(r^2+13r+42)}$	$-\frac{1}{5040}$
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots \\ &= 1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if

C is zero or not. This is done by finding $\lim_{r \to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_1 \\ &= 0 \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} 0 &= \lim_{r \to -1} 0 \\ &= 0 \end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^{n-1} \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) + 2(n+r) b_n + b_{n-2} = 0 \tag{4}$$

Which for for the root $r = -1$ becomes

$$b_n(n-1)(n-2) + 2(n-1) b_n + b_{n-2} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{b_{n-2}}{n^2 + 2nr + r^2 + n + r} \tag{5}$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{b_{n-2}}{n^2 - n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{r^2 + 5r + 6}$$

Which for the root $r = -1$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{(r^2 + 5r + 6)(r^2 + 9r + 20)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{24}$
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = -\frac{1}{(r^2+5r+6)(r^2+9r+20)(r^2+13r+42)}$$

Which for the root $r = -1$ becomes

$$b_6 = -\frac{1}{720}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{24}$
b_5	0	0
b_6	$-\frac{1}{(r^2+5r+6)(r^2+9r+20)(r^2+13r+42)}$	$-\frac{1}{720}$

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2+5r+6}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{1}{r^4+14r^3+71r^2+154r+120}$	$\frac{1}{24}$
b_5	0	0
b_6	$-\frac{1}{(r^2+5r+6)(r^2+9r+20)(r^2+13r+42)}$	$-\frac{1}{720}$
b_7	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= 1\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots\right) \\ &= \frac{1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)}{x} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \left(1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8)\right) + \frac{c_2 \left(1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)\right)}{x} \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\left(1-\frac{x^2}{6}+\frac{x^4}{120}-\frac{x^6}{5040}+O(x^8)\right)+\frac{c_2\left(1-\frac{x^2}{2}+\frac{x^4}{24}-\frac{x^6}{720}+O(x^8)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1\left(1-\frac{x^2}{6}+\frac{x^4}{120}-\frac{x^6}{5040}+O(x^8)\right)+\frac{c_2\left(1-\frac{x^2}{2}+\frac{x^4}{24}-\frac{x^6}{720}+O(x^8)\right)}{x} \tag{1}
$$

Verification of solutions

$$
y = c_1\left(1-\frac{x^2}{6}+\frac{x^4}{120}-\frac{x^6}{5040}+O(x^8)\right)+\frac{c_2\left(1-\frac{x^2}{2}+\frac{x^4}{24}-\frac{x^6}{720}+O(x^8)\right)}{x}
$$

Verified OK.

20.3.1 Maple step by step solution

Let's solve

$y''x + 2y' + xy = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y'}{x} - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{x} + y = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - ◦ Define functions

    $\left[P_2(x) = \frac{2}{x}, P_3(x) = 1\right]$

  - ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 2$

  - ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + 2y' + xy = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions
  - Convert $x \cdot y$ to series expansion

    $$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$$

  - Shift index using $k- >k-1$

    $$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

  - Convert y' to series expansion

    $$y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$$

  - Shift index using $k- >k+1$

    $$y' = \sum_{k=-1}^{\infty} a_{k+1} (k+r+1)\, x^{k+r}$$

  - Convert $x \cdot y''$ to series expansion

    $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

  - Shift index using $k- >k+1$

    $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+r+1)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(1+r)\, x^{-1+r} + a_1 (1+r)\,(2+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)\,(k+2+r) + a_{k-1}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(1+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-1, 0\}$

- Each term must be 0

$a_1(1+r)(2+r) = 0$

- Each term in the series must be 0, giving the recursion relation

$a_{k+1}(k+r+1)(k+2+r) + a_{k-1} = 0$

- Shift index using $k- > k+1$

$a_{k+2}(k+2+r)(k+3+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{a_k}{(k+2+r)(k+3+r)}$

- Recursion relation for $r = -1$

$a_{k+2} = -\frac{a_k}{(k+1)(k+2)}$

- Solution for $r = -1$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a_k}{(k+1)(k+2)}, 0 = 0\right]$

- Recursion relation for $r = 0$

$a_{k+2} = -\frac{a_k}{(k+2)(k+3)}$

- Solution for $r = 0$

$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{(k+2)(k+3)}, 2a_1 = 0\right]$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = -\frac{a_k}{(k+1)(k+2)}, 0 = 0, b_{k+2} = -\frac{b_k}{(k+2)(k+3)}, 2b_1 = 0\right]$

Problem number: 3(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - x^2y' + (x^2 - 2)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' - x^2y' + (x^2 - 2)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -1$$
$$q(x) = \frac{x^2 - 2}{x^2}$$

Table 473: Table $p(x), q(x)$ singularites.

$p(x) = -1$	
singularity	type

$q(x) = \frac{x^2-2}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' - x^2y' + \left(x^2 - 2\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2} \right) - x^2 \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1} \right) + (x^2 - 2) \left(\sum_{n=0}^{\infty} a_n x^{n+r} \right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-x^{1+n+r} a_n(n+r)\right) \\
&+\left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right)+\sum_{n=0}^{\infty}\left(-2 a_n x^{n+r}\right)=0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty}\left(-x^{1+n+r} a_n(n+r)\right) &=\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1) x^{n+r}\right) \\
\sum_{n=0}^{\infty} x^{n+r+2} a_n &=\sum_{n=2}^{\infty} a_{n-2} x^{n+r}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right)+\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1) x^{n+r}\right) \\
&+\left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right)+\sum_{n=0}^{\infty}\left(-2 a_n x^{n+r}\right)=0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r} a_n(n+r)(n+r-1)-2 a_n x^{n+r}=0
$$

When $n=0$ the above becomes

$$
x^r a_0 r(-1+r)-2 a_0 x^r=0
$$

Or

$$
\left(x^r r(-1+r)-2 x^r\right) a_0=0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\left(r^2-r-2\right) x^r=0
$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - r - 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned}r_1 &= 2\\ r_2 &= -1\end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - r - 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 3$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned}y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)\\ y_2(x) &= C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)\end{aligned}$$

Or

$$\begin{aligned}y_1(x) &= x^2\left(\sum_{n=0}^{\infty} a_n x^n\right)\\ y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}\end{aligned}$$

Or

$$\begin{aligned}y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+2}\\ y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)\end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{r}{r^2 + r - 2}$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_{n-2} - 2a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{n a_{n-1} + r a_{n-1} - a_{n-2} - a_{n-1}}{n^2 + 2nr + r^2 - n - r - 2} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = \frac{n a_{n-1} - a_{n-2} + a_{n-1}}{n(n+3)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{2}{(r^2+r-2)\, r\, (r+3)}$$

Which for the root $r = 2$ becomes

$$a_2 = \frac{1}{20}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r^2 - 2r + 4}{(r+4)(r^2+r-2)\, r\, (r+3)}$$

Which for the root $r = 2$ becomes

$$a_3 = -\frac{1}{60}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{-r^2 - 3r + 2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$$

Which for the root $r = 2$ becomes

$$a_4 = -\frac{1}{210}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$
a_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{1}{210}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$$

Which for the root $r = 2$ becomes

$$a_5 = -\frac{1}{3360}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$
a_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{1}{210}$
a_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{3360}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{r^2 + 5r - 8}{(r+7)(r+4)(r+5)(-1+r)(r+2)r(r+3)(r+6)}$$

Which for the root $r = 2$ becomes

$$a_6 = \frac{1}{20160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$
a_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{1}{210}$
a_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{3360}$
a_6	$\frac{r^2+5r-8}{(r+7)(r+4)(r+5)(-1+r)(r+2)r(r+3)(r+6)}$	$\frac{1}{20160}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{r^2 + 6r - 4}{(r+8)(r+5)(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+7)}$$

Which for the root $r = 2$ becomes

$$a_7 = \frac{1}{100800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
a_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{20}$
a_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$-\frac{1}{60}$
a_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$-\frac{1}{210}$
a_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{3360}$
a_6	$\frac{r^2+5r-8}{(r+7)(r+4)(r+5)(-1+r)(r+2)r(r+3)(r+6)}$	$\frac{1}{20160}$
a_7	$\frac{r^2+6r-4}{(r+8)(r+5)(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+7)}$	$\frac{1}{100800}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \ldots\right) \\ &= x^2\left(1 + \frac{x}{2} + \frac{x^2}{20} - \frac{x^3}{60} - \frac{x^4}{210} - \frac{x^5}{3360} + \frac{x^6}{20160} + \frac{x^7}{100800} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 3$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_3(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_3 \\ &= \frac{-r^2 - 2r + 4}{(r+4)(r^2+r-2)\, r\, (r+3)} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{-r^2 - 2r + 4}{(r+4)(r^2+r-2)\, r\, (r+3)} &= \lim_{r \to -1} \frac{-r^2 - 2r + 4}{(r+4)(r^2+r-2)\, r\, (r+3)} \\ &= \frac{5}{12} \end{aligned}$$

The limit is $\frac{5}{12}$. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-1}
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$
b_1 = \frac{r}{r^2 + r - 2}
$$

For $2 \leq n$ the recursive equation is

$$
b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + b_{n-2} - 2b_n = 0 \tag{4}
$$

Which for for the root $r = -1$ becomes

$$
b_n(n-1)(n-2) - b_{n-1}(n-2) + b_{n-2} - 2b_n = 0 \tag{4A}
$$

Solving for b_n from the recursive equation (4) gives

$$
b_n = \frac{n b_{n-1} + r b_{n-1} - b_{n-2} - b_{n-1}}{n^2 + 2nr + r^2 - n - r - 2} \tag{5}
$$

Which for the root $r = -1$ becomes

$$
b_n = \frac{n b_{n-1} - b_{n-2} - 2b_{n-1}}{n^2 - 3n} \tag{6}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$
b_2 = \frac{2}{(r^2 + r - 2)\, r\, (r + 3)}
$$

Which for the root $r = -1$ becomes

$$b_2 = \frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{r^2 + 2r - 4}{(r + 4)(r^2 + r - 2) r (r + 3)}$$

Which for the root $r = -1$ becomes

$$b_3 = \frac{5}{12}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$

For $n = 4$, using the above recursive equation gives

$$b_4 = -\frac{r^2 + 3r - 2}{(r^2 + 7r + 10)(r + 3) r (-1 + r)(r + 4)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{1}{12}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$
b_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{1}{12}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{4}{(r^2+9r+18)\,r\,(r^2+r-2)\,(r+4)\,(r+5)}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{1}{60}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$
b_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{1}{12}$
b_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{60}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{r^2+5r-8}{(-1+r)\,r\,(r+3)\,(r^2+7r+10)\,(r+6)\,(r^2+11r+28)}$$

Which for the root $r = -1$ becomes

$$b_6 = -\frac{1}{120}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$
b_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{1}{12}$
b_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{60}$
b_6	$\frac{r^2+5r-8}{(r+7)(r+4)(r+5)(-1+r)(r+2)r(r+3)(r+6)}$	$-\frac{1}{120}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{r^2 + 6r - 4}{(r + 4)(r^2 + r - 2) r (r^2 + 9r + 18)(r + 7)(r^2 + 13r + 40)}$$

Which for the root $r = -1$ becomes

$$b_7 = -\frac{1}{1120}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{r}{r^2+r-2}$	$\frac{1}{2}$
b_2	$\frac{2}{(r^2+r-2)r(r+3)}$	$\frac{1}{2}$
b_3	$\frac{-r^2-2r+4}{(r+4)(r^2+r-2)r(r+3)}$	$\frac{5}{12}$
b_4	$\frac{-r^2-3r+2}{(r+5)(r+2)(r+3)r(-1+r)(r+4)}$	$\frac{1}{12}$
b_5	$-\frac{4}{(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+5)}$	$-\frac{1}{60}$
b_6	$\frac{r^2+5r-8}{(r+7)(r+4)(r+5)(-1+r)(r+2)r(r+3)(r+6)}$	$-\frac{1}{120}$
b_7	$\frac{r^2+6r-4}{(r+8)(r+5)(r+6)(r+3)r(r+2)(-1+r)(r+4)(r+7)}$	$-\frac{1}{1120}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= x^2 \left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots\right) \\ &= \frac{1 + \frac{x}{2} + \frac{x^2}{2} + \frac{5x^3}{12} + \frac{x^4}{12} - \frac{x^5}{60} - \frac{x^6}{120} - \frac{x^7}{1120} + O(x^8)}{x} \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2 \left(1+\frac{x}{2}+\frac{x^2}{20}-\frac{x^3}{60}-\frac{x^4}{210}-\frac{x^5}{3360}+\frac{x^6}{20160}+\frac{x^7}{100800}+O(x^8)\right) \\
&+ \frac{c_2 \left(1+\frac{x}{2}+\frac{x^2}{2}+\frac{5x^3}{12}+\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{120}-\frac{x^7}{1120}+O(x^8)\right)}{x}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2 \left(1+\frac{x}{2}+\frac{x^2}{20}-\frac{x^3}{60}-\frac{x^4}{210}-\frac{x^5}{3360}+\frac{x^6}{20160}+\frac{x^7}{100800}+O(x^8)\right) \\
&+ \frac{c_2 \left(1+\frac{x}{2}+\frac{x^2}{2}+\frac{5x^3}{12}+\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{120}-\frac{x^7}{1120}+O(x^8)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^2 \left(1+\frac{x}{2}+\frac{x^2}{20}-\frac{x^3}{60}-\frac{x^4}{210}-\frac{x^5}{3360}+\frac{x^6}{20160}+\frac{x^7}{100800}+O(x^8)\right) \\
&+ \frac{c_2 \left(1+\frac{x}{2}+\frac{x^2}{2}+\frac{5x^3}{12}+\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{120}-\frac{x^7}{1120}+O(x^8)\right)}{x}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x^2 \left(1+\frac{x}{2}+\frac{x^2}{20}-\frac{x^3}{60}-\frac{x^4}{210}-\frac{x^5}{3360}+\frac{x^6}{20160}+\frac{x^7}{100800}+O(x^8)\right) \\
&+ \frac{c_2 \left(1+\frac{x}{2}+\frac{x^2}{2}+\frac{5x^3}{12}+\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{120}-\frac{x^7}{1120}+O(x^8)\right)}{x}
\end{aligned}
$$

Verified OK.

20.4.1 Maple step by step solution

Let's solve

$x^2y'' - x^2y' + (x^2 - 2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = y' - \frac{(x^2-2)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - y' + \frac{(x^2-2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = -1, P_3(x) = \frac{x^2-2}{x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 0$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -2$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2y'' - x^2y' + (x^2 - 2)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^{m} \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^{2} \cdot y'$ to series expansion

  $x^{2} \cdot y'=\sum_{k=0}^{\infty} a_{k}(k+r)\, x^{k+r+1}$

- Shift index using $k->k-1$

  $x^{2} \cdot y'=\sum_{k=1}^{\infty} a_{k-1}(k-1+r)\, x^{k+r}$

- Convert $x^{2} \cdot y''$ to series expansion

  $x^{2} \cdot y''=\sum_{k=0}^{\infty} a_{k}(k+r)\,(k-1+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(1+r)\,(-2+r)\, x^{r}+\left(a_{1}(2+r)\,(-1+r)-a_{0} r\right) x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_{k}(k+r+1)\,(k+r-2)-a_{k-1}\right.\right.$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(1+r)\,(-2+r)=0$

- Values of r that satisfy the indicial equation

  $r \in\{-1,2\}$

- Each term must be 0

  $a_{1}(2+r)\,(-1+r)-a_{0} r=0$

- Solve for the dependent coefficient(s)

  $a_{1}=\frac{a_{0} r}{r^{2}+r-2}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k}(k+r+1)\,(k+r-2)-a_{k-1} k-a_{k-1} r+a_{k-2}+a_{k-1}=0$

- Shift index using $k->k+2$

  $a_{k+2}(k+3+r)\,(k+r)-a_{k+1}(k+2)-a_{k+1} r+a_{k}+a_{k+1}=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=\frac{k a_{k+1}+a_{k+1} r-a_{k}+a_{k+1}}{(k+3+r)(k+r)}$

- Recursion relation for $r=-1$

  $a_{k+2}=\frac{k a_{k+1}-a_{k}}{(k+2)(k-1)}$

- Series not valid for $r=-1$, division by 0 in the recursion relation at $k=1$

  $a_{k+2}=\frac{k a_{k+1}-a_k}{(k+2)(k-1)}$
- Recursion relation for $r=2$

  $a_{k+2}=\frac{k a_{k+1}-a_k+3 a_{k+1}}{(k+5)(k+2)}$
- Solution for $r=2$

  $$\left[y=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2}=\frac{k a_{k+1}-a_k+3 a_{k+1}}{(k+5)(k+2)}, a_1=\frac{a_0}{2}\right]$$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.5. More on Regular Singular Points. Page 183
Problem number: 3(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{y''x - y' + 4yx^3 = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$y''x - y' + 4yx^3 = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{x}$$
$$q(x) = 4x^2$$

Table 475: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = 4x^2$	
singularity	type
$x = \infty$	"regular"
$x = -\infty$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty, -\infty]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$y''x - y' + 4yx^3 = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x - \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) x^3 = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-(n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 4x^{3+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 4x^{3+n+r} a_n = \sum_{n=4}^{\infty} 4a_{n-4} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=4}^{\infty} 4a_{n-4} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) - (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) - r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) - r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-2+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-2+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x)\ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^2\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = C y_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = 0$$

Substituting $n = 3$ in Eq. (2B) gives

$$a_3 = 0$$

For $4 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_n(n+r) + 4a_{n-4} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{4a_{n-4}}{n^2 + 2nr + r^2 - 2n - 2r} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = -\frac{4a_{n-4}}{n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = -\frac{4}{r^2 + 6r + 8}$$

Which for the root $r = 2$ becomes

$$a_4 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{6}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{6}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{6}$
a_5	0	0
a_6	0	0

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{6}$
a_5	0	0
a_6	0	0
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= x^2\left(1 - \frac{x^4}{6} + O(x^8)\right)
\end{aligned}
$$

Now the second solution $y_2(x)$ is found. Let

$$
r_1 - r_2 = N
$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$
\begin{aligned}
a_N &= a_2 \\
&= 0
\end{aligned}
$$

Therefore

$$
\begin{aligned}
\lim_{r\to r_2} 0 &= \lim_{r\to 0} 0 \\
&= 0
\end{aligned}
$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$
\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^n
\end{aligned}
$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

Substituting $n = 2$ in Eq(3) gives

$$b_2 = 0$$

Substituting $n = 3$ in Eq(3) gives

$$b_3 = 0$$

For $4 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - (n+r) b_n + 4b_{n-4} = 0 \tag{4}$$

Which for for the root $r = 0$ becomes

$$b_n n(n-1) - nb_n + 4b_{n-4} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{4b_{n-4}}{n^2 + 2nr + r^2 - 2n - 2r} \tag{5}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{4b_{n-4}}{n^2 - 2n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = -\frac{4}{r^2 + 6r + 8}$$

Which for the root $r = 0$ becomes

$$b_4 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{2}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{2}$
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{2}$
b_5	0	0
b_6	0	0

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	$-\frac{4}{r^2+6r+8}$	$-\frac{1}{2}$
b_5	0	0
b_6	0	0
b_7	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= 1 - \frac{x^4}{2} + O(x^8)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2 \left(1 - \frac{x^4}{6} + O(x^8)\right) + c_2 \left(1 - \frac{x^4}{2} + O(x^8)\right)
\end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^2 \left(1 - \frac{x^4}{6} + O(x^8)\right) + c_2 \left(1 - \frac{x^4}{2} + O(x^8)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^2 \left(1 - \frac{x^4}{6} + O(x^8)\right) + c_2 \left(1 - \frac{x^4}{2} + O(x^8)\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x^2 \left(1 - \frac{x^4}{6} + O(x^8)\right) + c_2 \left(1 - \frac{x^4}{2} + O(x^8)\right)
$$

Verified OK.

20.5.1 Maple step by step solution

Let's solve

$y''x - y' + 4yx^3 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{x} - 4yx^2$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + 4yx^2 = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- Rewrite ODE with series expansions
  - Convert $x^3 \cdot y$ to series expansion

    $$x^3 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+3}$$

  - Shift index using $k- >k-3$

    $$x^3 \cdot y = \sum_{k=3}^{\infty} a_{k-3} x^{k+r}$$

  - Convert y' to series expansion

    $$y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$$

  - Shift index using $k- >k+1$

    $$y' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\, x^{k+r}$$

  - Convert $x \cdot y''$ to series expansion

    $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

  - Shift index using $k- >k+1$

    $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-2+r)\, x^{-1+r} + a_1(1+r)\,(-1+r)\, x^r + a_2(2+r)\, r\, x^{1+r} + a_3(3+r)\,(1+r)\, x^{2+r} + \left(\sum_{k=3}^{\infty} (a_k\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- The coefficients of each power of x must be 0

  $[a_1(1+r)(-1+r) = 0, a_2(2+r)r = 0, a_3(3+r)(1+r) = 0]$

- Solve for the dependent coefficient(s)

  $\{a_1 = 0, a_2 = 0, a_3 = 0\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k+r-1) + 4a_{k-3} = 0$

- Shift index using $k- > k+3$

  $a_{k+4}(k+4+r)(k+2+r) + 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+4} = -\frac{4a_k}{(k+4+r)(k+2+r)}$

- Recursion relation for $r = 0$

  $a_{k+4} = -\frac{4a_k}{(k+4)(k+2)}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{4a_k}{(k+4)(k+2)}, a_1 = 0, a_2 = 0, a_3 = 0\right]$

- Recursion relation for $r = 2$

  $a_{k+4} = -\frac{4a_k}{(k+6)(k+4)}$

- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+4} = -\frac{4a_k}{(k+6)(k+4)}, a_1 = 0, a_2 = 0, a_3 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+4} = -\frac{4a_k}{(k+4)(k+2)}, a_1 = 0, a_2 = 0, a_3 = 0, b_{k+4} = -\frac{4b_k}{(k+6)(k+4)}\right.$

Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x-1)^2 y'' - 3(x-1) y' + 2y = 0}$$

With the expansion point for the power series method at $x = 1$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\left(\frac{d^2}{dt^2}y(t)\right)t^2 - 3t\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the

homogeneous part of the ODE.

$$\left(\frac{d^2}{dt^2}y(t)\right)t^2 - 3t\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t) + p(t)\frac{d}{dt}y(t) + q(t)y(t) = 0$$

Where

$$p(t) = -\frac{3}{t}$$
$$q(t) = \frac{2}{t^2}$$

Table 477: Table $p(t), q(t)$ singularites.

$p(t) = -\frac{3}{t}$	
singularity	type
$t = 0$	"regular"

$q(t) = \frac{2}{t^2}$	
singularity	type
$t = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty]$

Irregular singular points : []

Since $t = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)t^2 - 3t\left(\frac{d}{dt}y(t)\right) + 2y(t) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$

$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n t^{n+r-2}\right)t^2-3t\left(\sum_{n=0}^{\infty}(n+r)\,a_n t^{n+r-1}\right)+2\left(\sum_{n=0}^{\infty}a_n t^{n+r}\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}t^{n+r}a_n(n+r)(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-3t^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}2a_n t^{n+r}\right)=0 \quad \text{(2A)}$$

The next step is to make all powers of t be $n+r$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty}t^{n+r}a_n(n+r)(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-3t^{n+r}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}2a_n t^{n+r}\right)=0 \quad \text{(2B)}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$t^{n+r}a_n(n+r)(n+r-1)-3t^{n+r}a_n(n+r)+2a_n t^{n+r}=0$$

When $n=0$ the above becomes

$$t^r a_0 r(-1+r)-3t^r a_0 r+2a_0 t^r=0$$

Or

$$\left(t^r r(-1+r)-3t^r r+2t^r\right)a_0=0$$

Since $a_0\neq 0$ then the above simplifies to

$$\left(r^2-4r+2\right)t^r=0$$

Since the above is true for all t then the indicial equation becomes

$$r^2-4r+2=0$$

Solving for r gives the roots of the indicial equation as

$$r_1=2+\sqrt{2}$$
$$r_2=2-\sqrt{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2-4r+2\right)t^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2\sqrt{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(t) = t^{r_1}\left(\sum_{n=0}^{\infty} a_n t^n\right)$$
$$y_2(t) = t^{r_2}\left(\sum_{n=0}^{\infty} b_n t^n\right)$$

Or

$$y_1(t) = \sum_{n=0}^{\infty} a_n t^{n+2+\sqrt{2}}$$
$$y_2(t) = \sum_{n=0}^{\infty} b_n t^{n+2-\sqrt{2}}$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $0 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - 3a_n(n+r) + 2a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = 0 \tag{4}$$

Which for the root $r = 2+\sqrt{2}$ becomes

$$a_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2+\sqrt{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0
a_6	0	0

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0
a_6	0	0
a_7	0	0

Using the above table, then the solution $y_1(t)$ is

$$\begin{aligned} y_1(t) &= t^{2+\sqrt{2}}\left(a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \dots\right) \\ &= t^{2+\sqrt{2}}\left(1 + O(t^8)\right) \end{aligned}$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $0 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - 3b_n(n+r) + 2b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = 0 \tag{4}$$

Which for the root $r = 2 - \sqrt{2}$ becomes

$$b_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 2 - \sqrt{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0
b_6	0	0

For $n=7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0
b_6	0	0
b_7	0	0

Using the above table, then the solution $y_2(t)$ is

$$\begin{aligned} y_2(t) &= t^{2+\sqrt{2}}\left(b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots\right) \\ &= t^{2-\sqrt{2}}\left(1 + O(t^8)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(t) &= c_1 y_1(t) + c_2 y_2(t) \\ &= c_1 t^{2+\sqrt{2}}\left(1 + O(t^8)\right) + c_2 t^{2-\sqrt{2}}\left(1 + O(t^8)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y(t) &= y_h \\ &= c_1 t^{2+\sqrt{2}}\left(1 + O(t^8)\right) + c_2 t^{2-\sqrt{2}}\left(1 + O(t^8)\right) \end{aligned}$$

Replacing t in the above with the original independent variable $x$using $t = x-1$ results in

$$y = c_1 (x-1)^{2+\sqrt{2}} \left(1 + O\left((x-1)^8\right)\right) + c_2 (x-1)^{2-\sqrt{2}} \left(1 + O\left((x-1)^8\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1(x-1)^{2+\sqrt{2}}\left(1+O\left((x-1)^8\right)\right)+c_2(x-1)^{2-\sqrt{2}}\left(1+O\left((x-1)^8\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1(x-1)^{2+\sqrt{2}}\left(1+O\left((x-1)^8\right)\right)+c_2(x-1)^{2-\sqrt{2}}\left(1+O\left((x-1)^8\right)\right)$$

Verified OK.

20.6.1 Maple step by step solution

Let's solve

$(x-1)^2 y''+(3-3x)\, y'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{3y'}{x-1}-\frac{2y}{(x-1)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{3y'}{x-1}+\frac{2y}{(x-1)^2}=0$

□ Check to see if $x_0=1$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{3}{x-1}, P_3(x)=\frac{2}{(x-1)^2}\right]$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.5. More on Regular Singular Points. Page 183
Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{3(1+x)^2 y'' - (1+x) y' - y = 0}$$

With the expansion point for the power series method at $x = -1$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = 1 + x$$

The ode is converted to be in terms of the new independent variable t. This results in

$$3\left(\frac{d^2}{dt^2}y(t)\right)t^2 - t\left(\frac{d}{dt}y(t)\right) - y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the

homogeneous part of the ODE.

$$3\left(\frac{d^2}{dt^2}y(t)\right)t^2 - t\left(\frac{d}{dt}y(t)\right) - y(t) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t) + p(t)\frac{d}{dt}y(t) + q(t)y(t) = 0$$

Where

$$p(t) = -\frac{1}{3t}$$
$$q(t) = -\frac{1}{3t^2}$$

Table 479: Table $p(t), q(t)$ singularites.

$p(t) = -\frac{1}{3t}$	
singularity	type
$t = 0$	"regular"

$q(t) = -\frac{1}{3t^2}$	
singularity	type
$t = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, \infty]$

Irregular singular points : $[]$

Since $t = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$3\left(\frac{d^2}{dt^2}y(t)\right)t^2 - t\left(\frac{d}{dt}y(t)\right) - y(t) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$

$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$3\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)\,a_n t^{n+r-2}\right)t^2 - t\left(\sum_{n=0}^{\infty}(n+r)\,a_n t^{n+r-1}\right) - \left(\sum_{n=0}^{\infty}a_n t^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}3t^{n+r}a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty}\left(-t^{n+r}a_n(n+r)\right) + \sum_{n=0}^{\infty}\left(-a_n t^{n+r}\right) = 0 \quad \text{(2A)}$$

The next step is to make all powers of t be $n+r$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r} and adjusting the power and the corresponding index gives Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty}3t^{n+r}a_n(n+r)(n+r-1)\right) + \sum_{n=0}^{\infty}\left(-t^{n+r}a_n(n+r)\right) + \sum_{n=0}^{\infty}\left(-a_n t^{n+r}\right) = 0 \quad \text{(2B)}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$3t^{n+r}a_n(n+r)(n+r-1) - t^{n+r}a_n(n+r) - a_n t^{n+r} = 0$$

When $n=0$ the above becomes

$$3t^r a_0 r(-1+r) - t^r a_0 r - a_0 t^r = 0$$

Or

$$\left(3t^r r(-1+r) - t^r r - t^r\right)a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(3r^2 - 4r - 1\right)t^r = 0$$

Since the above is true for all t then the indicial equation becomes

$$3r^2 - 4r - 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$
\begin{aligned}
r_1 &= \frac{2}{3}+\frac{\sqrt{7}}{3} \\
r_2 &= \frac{2}{3}-\frac{\sqrt{7}}{3}
\end{aligned}
$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$
\left(3r^2-4r-1\right) t^r = 0
$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{2\sqrt{7}}{3}$ is not an integer, then we can construct two linearly independent solutions

$$
\begin{aligned}
y_1(t) &= t^{r_1}\left(\sum_{n=0}^{\infty} a_n t^n\right) \\
y_2(t) &= t^{r_2}\left(\sum_{n=0}^{\infty} b_n t^n\right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(t) &= \sum_{n=0}^{\infty} a_n t^{n+\frac{2}{3}+\frac{\sqrt{7}}{3}} \\
y_2(t) &= \sum_{n=0}^{\infty} b_n t^{n+\frac{2}{3}-\frac{\sqrt{7}}{3}}
\end{aligned}
$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $0 \leq n$ the recursive equation is

$$
3a_n(n+r)(n+r-1) - a_n(n+r) - a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = 0 \tag{4}
$$

Which for the root $r = \frac{2}{3}+\frac{\sqrt{7}}{3}$ becomes

$$
a_n = 0 \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{2}{3}+\frac{\sqrt{7}}{3}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0
a_6	0	0

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	0	0
a_3	0	0
a_4	0	0
a_5	0	0
a_6	0	0
a_7	0	0

Using the above table, then the solution $y_1(t)$ is

$$\begin{aligned} y_1(t) &= t^{\frac{2}{3}+\frac{\sqrt{7}}{3}} \left(a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \dots\right) \\ &= t^{\frac{2}{3}+\frac{\sqrt{7}}{3}} \left(1 + O(t^8)\right) \end{aligned}$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $0 \leq n$ the recursive equation is

$$3b_n(n + r)(n + r - 1) - b_n(n + r) - b_n = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = 0 \tag{4}$$

Which for the root $r = \frac{2}{3} - \frac{\sqrt{7}}{3}$ becomes

$$b_n = 0 \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = \frac{2}{3} - \frac{\sqrt{7}}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0
b_6	0	0

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	0	0
b_3	0	0
b_4	0	0
b_5	0	0
b_6	0	0
b_7	0	0

Using the above table, then the solution $y_2(t)$ is

$$\begin{aligned} y_2(t) &= t^{\frac{2}{3}+\frac{\sqrt{7}}{3}}\left(b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots\right) \\ &= t^{\frac{2}{3}-\frac{\sqrt{7}}{3}}\left(1 + O(t^8)\right) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(t) &= c_1 y_1(t) + c_2 y_2(t) \\ &= c_1 t^{\frac{2}{3}+\frac{\sqrt{7}}{3}}\left(1 + O(t^8)\right) + c_2 t^{\frac{2}{3}-\frac{\sqrt{7}}{3}}\left(1 + O(t^8)\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y(t) &= y_h \\ &= c_1 t^{\frac{2}{3}+\frac{\sqrt{7}}{3}} \left(1+O(t^8)\right) + c_2 t^{\frac{2}{3}-\frac{\sqrt{7}}{3}} \left(1+O(t^8)\right) \end{aligned}$$

Replacing t in the above with the original independent variable $x$using $t = 1 + x$ results in

$$y = c_1 (1+x)^{\frac{2}{3}+\frac{\sqrt{7}}{3}} \left(1+O\left((1+x)^8\right)\right) + c_2 (1+x)^{\frac{2}{3}-\frac{\sqrt{7}}{3}} \left(1+O\left((1+x)^8\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 (1+x)^{\frac{2}{3}+\frac{\sqrt{7}}{3}} \left(1+O\left((1+x)^8\right)\right) + c_2 (1+x)^{\frac{2}{3}-\frac{\sqrt{7}}{3}} \left(1+O\left((1+x)^8\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 (1+x)^{\frac{2}{3}+\frac{\sqrt{7}}{3}} \left(1+O\left((1+x)^8\right)\right) + c_2 (1+x)^{\frac{2}{3}-\frac{\sqrt{7}}{3}} \left(1+O\left((1+x)^8\right)\right)$$

Verified OK.

20.7.1 Maple step by step solution

Let's solve

$3(1+x)^2 y'' + (-1-x) y' - y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y}{3(1+x)^2} + \frac{y'}{3(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{3(1+x)} - \frac{y}{3(1+x)^2} = 0$

□ Check to see if $x_0 = -1$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = -\frac{1}{3(1+x)}, P_3(x) = -\frac{1}{3(1+x)^2}\right]$

- ○ $(1+x) \cdot P_2(x)$ is analytic at $x = -1$

$((1+x)\cdot P_2(x))\bigg|_{x=-1} = -\frac{1}{3}$

- $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\bigg|_{x=-1} = -\frac{1}{3}$

- $x=-1$is a regular singular point

  Check to see if $x_0=-1$ is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $3(1+x)^2\, y'' + (-1-x)\, y' - y = 0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $3u^2\left(\frac{d^2}{du^2}y(u)\right) - u\left(\frac{d}{du}y(u)\right) - y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite DE with series expansions

- Convert $u\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r}$

- Convert $u^2\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u^2\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r}$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} a_k(3k^2+6kr+3r^2-4k-4r-1)\, u^{k+r} = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r=0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(3k^2-4k-1)=0$

- Recursion relation that defines series solution to ODE

  $a_k=0$

- Recursion relation for $r = 0$

  $a_k = 0$
- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_k = 0\right]$$
- Revert the change of variables $u = 1 + x$

  $$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^k, a_k = 0\right]$$

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[_Bessel]
```

$$\boxed{x^2y'' + xy' + \left(x^2 - 1\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + xy' + \left(x^2 - 1\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{x^2 - 1}{x^2}$$

Table 481: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{x^2-1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + xy' + (x^2 - 1)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + x \left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + (x^2 - 1) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\
&+ \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\
&+ \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-a_n x^{n+r}\right) = 0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - a_n x^{n+r} = 0
$$

When $n=0$ the above becomes

$$
x^r a_0 r(-1+r) + x^r a_0 r - a_0 x^r = 0
$$

Or

$$
\left(x^r r(-1+r) + x^r r - x^r\right) a_0 = 0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
\left(r^2 - 1\right) x^r = 0
$$

Since the above is true for all x then the indicial equation becomes

$$
r^2 - 1 = 0
$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = -1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n + r)(n + r - 1) + a_n(n + r) + a_{n-2} - a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2 - 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = -\frac{a_{n-2}}{n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{r^2 + 4r + 3}$$

Which for the root $r = 1$ becomes

$$a_2 = -\frac{1}{8}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+4r+3}$	$-\frac{1}{8}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+4r+3}$	$-\frac{1}{8}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(r+3)^2 (1+r)(r+5)}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1}{192}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+4r+3}$	$-\frac{1}{8}$
a_3	0	0
a_4	$\frac{1}{(r+3)^2(1+r)(r+5)}$	$\frac{1}{192}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+4r+3}$	$-\frac{1}{8}$
a_3	0	0
a_4	$\frac{1}{(r+3)^2(1+r)(r+5)}$	$\frac{1}{192}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{1}{(r+3)^2 (1+r)(r+5)^2 (r+7)}$$

Which for the root $r = 1$ becomes

$$a_6 = -\frac{1}{9216}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+4r+3}$	$-\frac{1}{8}$
a_3	0	0
a_4	$\frac{1}{(r+3)^2(1+r)(r+5)}$	$\frac{1}{192}$
a_5	0	0
a_6	$-\frac{1}{(r+3)^2(1+r)(r+5)^2(r+7)}$	$-\frac{1}{9216}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2+4r+3}$	$-\frac{1}{8}$
a_3	0	0
a_4	$\frac{1}{(r+3)^2(1+r)(r+5)}$	$\frac{1}{192}$
a_5	0	0
a_6	$-\frac{1}{(r+3)^2(1+r)(r+5)^2(r+7)}$	$-\frac{1}{9216}$
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= x\left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_2 \\ &= -\frac{1}{r^2+4r+3} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} -\frac{1}{r^2+4r+3} &= \lim_{r\to -1} -\frac{1}{r^2+4r+3} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned} \frac{d}{dx} y_2(x) &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\ &= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right) \\ \frac{d^2}{dx^2} y_2(x) &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} \\ &\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\ &= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right) \end{aligned}$$

Substituting these back into the given ode $x^2 y'' + x y' + (x^2 - 1) y = 0$ gives

$$x^2 \left(C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2} \right) \right) + x \left(C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x} \right) \right) + (x^2 - 1) \left(C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2} \right) \right) = 0$$

Which can be written as

$$\left(\left(x^2 y_1''(x) + y_1'(x) x + (x^2 - 1) y_1(x) \right) \ln(x) + x^2 \left(\frac{2 y_1'(x)}{x} - \frac{y_1(x)}{x^2} \right) + y_1(x) \right) C + x^2 \left(\sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2} \right) \right) + x \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x} \right) + (x^2 - 1) \left(\sum_{n=0}^{\infty} b_n x^{n+r_2} \right) = 0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$x^2 y_1''(x) + y_1'(x) x + (x^2 - 1) y_1(x) = 0$$

Eq (7) simplifes to

$$\left(x^2 \left(\frac{2 y_1'(x)}{x} - \frac{y_1(x)}{x^2} \right) + y_1(x) \right) C + x^2 \left(\sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2} \right) \right) + x \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x} \right) + (x^2 - 1) \left(\sum_{n=0}^{\infty} b_n x^{n+r_2} \right) = 0 \tag{8}$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$
\begin{aligned}
&2x\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right) C + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) x^2 \\
&+ \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) x^2 \\
&+ \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) x - \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0
\end{aligned}
\tag{9}
$$

Since $r_1 = 1$ and $r_2 = -1$ then the above becomes

$$
\begin{aligned}
&2x\left(\sum_{n=0}^{\infty} x^{n} a_n (n+1)\right) C + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right) x^2 + \left(\sum_{n=0}^{\infty} x^{-3+n} b_n (n-1)(n-2)\right) x^2 \\
&+ \left(\sum_{n=0}^{\infty} x^{n-2} b_n (n-1)\right) x - \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right) = 0
\end{aligned}
\tag{10}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\, x^{n+1} a_n (n+1)\right) + \left(\sum_{n=0}^{\infty} x^{n+1} b_n\right) + \left(\sum_{n=0}^{\infty} x^{n-1} b_n (n^2-3n+2)\right) \\
&+ \left(\sum_{n=0}^{\infty} x^{n-1} b_n (n-1)\right) + \sum_{n=0}^{\infty} \left(-b_n x^{n-1}\right) = 0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-1} and adjusting the power and the corresponding index gives

$$
\sum_{n=0}^{\infty} 2C\, x^{n+1} a_n (n+1) = \sum_{n=2}^{\infty} 2C a_{n-2} (n-1)\, x^{n-1}
$$

$$
\sum_{n=0}^{\infty} x^{n+1} b_n = \sum_{n=2}^{\infty} b_{n-2} x^{n-1}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-1$.

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty} 2 C a_{n-2}(n-1)\, x^{n-1}\right)+\left(\sum_{n=2}^{\infty} b_{n-2} x^{n-1}\right) \\
&+\left(\sum_{n=0}^{\infty} x^{n-1} b_{n}\left(n^{2}-3 n+2\right)\right)+\left(\sum_{n=0}^{\infty} x^{n-1} b_{n}(n-1)\right)+\sum_{n=0}^{\infty}\left(-b_{n} x^{n-1}\right)=0
\end{aligned} \tag{2B}
$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0=1$. For $n=1$, Eq (2B) gives

$$-b_1=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-b_1=0$$

Solving the above for b_1 gives

$$b_1=0$$

For $n=N$, where $N=2$ which is the difference between the two roots, we are free to choose $b_2=0$. Hence for $n=2$, Eq (2B) gives

$$2C+1=0$$

Which is solved for C. Solving for C gives

$$C=-\frac{1}{2}$$

For $n=3$, Eq (2B) gives

$$4Ca_1+b_1+3b_3=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$3b_3=0$$

Solving the above for b_3 gives

$$b_3=0$$

For $n=4$, Eq (2B) gives

$$6Ca_2+b_2+8b_4=0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8b_4+\frac{3}{8}=0$$

Solving the above for b_4 gives

$$b_4 = -\frac{3}{64}$$

For $n = 5$, Eq (2B) gives

$$8Ca_3 + b_3 + 15b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$15b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

For $n = 6$, Eq (2B) gives

$$10Ca_4 + b_4 + 24b_6 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$24b_6 - \frac{7}{96} = 0$$

Solving the above for b_6 gives

$$b_6 = \frac{7}{2304}$$

For $n = 7$, Eq (2B) gives

$$12Ca_5 + b_5 + 35b_7 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$35b_7 = 0$$

Solving the above for b_7 gives

$$b_7 = 0$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -\frac{1}{2}$ and all b_n, then the second solution becomes

$$y_2(x) = -\frac{1}{2}\left(x\left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right)\right)\ln(x) + \frac{1 - \frac{3x^4}{64} + \frac{7x^6}{2304} + O(x^8)}{x}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x \left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right) \\
&\quad + c_2 \left(-\frac{1}{2}\left(x\left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right)\right)\ln(x) + \frac{1 - \frac{3x^4}{64} + \frac{7x^6}{2304} + O(x^8)}{x}\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x \left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right) \\
&\quad + c_2 \left(-\frac{x\left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right)\ln(x)}{2} + \frac{1 - \frac{3x^4}{64} + \frac{7x^6}{2304} + O(x^8)}{x}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x \left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right) \\
&\quad + c_2 \left(-\frac{x\left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right)\ln(x)}{2} + \frac{1 - \frac{3x^4}{64} + \frac{7x^6}{2304} + O(x^8)}{x}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 x \left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right) \\
&\quad + c_2 \left(-\frac{x\left(1 - \frac{x^2}{8} + \frac{x^4}{192} - \frac{x^6}{9216} + O(x^8)\right)\ln(x)}{2} + \frac{1 - \frac{3x^4}{64} + \frac{7x^6}{2304} + O(x^8)}{x}\right)
\end{aligned}
$$

Verified OK.

20.8.1 Maple step by step solution

Let's solve

$x^2y'' + xy' + (x^2-1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2-1)y}{x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(x^2-1)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{x^2-1}{x^2}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = 1$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -1$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2y'' + xy' + (x^2-1)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $$x^{m}\cdot y=\sum_{k=m}^{\infty} a_{k-m}x^{k+r}$$

- Convert $x\cdot y'$ to series expansion

  $$x\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$$

- Convert $x^{2}\cdot y''$ to series expansion

  $$x^{2}\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(1+r)\,(-1+r)\, x^{r}+a_1(2+r)\, r\, x^{1+r}+\left(\sum_{k=2}^{\infty} (a_k(k+r+1)\,(k+r-1)+a_{k-2})\, x^{k+r}\right)=0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(1+r)\,(-1+r)=0$$

- Values of r that satisfy the indicial equation

  $$r\in\{-1,1\}$$

- Each term must be 0

  $$a_1(2+r)\, r=0$$

- Solve for the dependent coefficient(s)

  $$a_1=0$$

- Each term in the series must be 0, giving the recursion relation

  $$a_k(k+r+1)\,(k+r-1)+a_{k-2}=0$$

- Shift index using $k->k+2$

  $$a_{k+2}(k+3+r)\,(k+r+1)+a_k=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{a_k}{(k+3+r)(k+r+1)}$$

- Recursion relation for $r=-1$

  $$a_{k+2}=-\frac{a_k}{(k+2)k}$$

- Solution for $r=-1$

  $$\left[y=\sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2}=-\frac{a_k}{(k+2)k}, a_1=0\right]$$

- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k}{(k+4)(k+2)}$

- Solution for $r = 1$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+4)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+1}\right), a_{k+2} = -\frac{a_k}{(k+2)k}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+4)(k+2)}, b_1 = 0\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.5. More on Regular Singular Points. Page 183
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{4x^2 - 1}{4x^2}$$

Table 483: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{4x^2-1}{4x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2y'' + xy' + \left(x^2 - \frac{1}{4}\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) + x\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(x^2 - \frac{1}{4}\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \sum_{n=0}^{\infty} \left(-\frac{a_n x^{n+r}}{4}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-\frac{a_n x^{n+r}}{4}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - \frac{a_n x^{n+r}}{4} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r - \frac{a_0 x^r}{4} = 0$$

Or

$$\left(x^r r(-1+r) + x^r r - \frac{x^r}{4}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\frac{(4r^2-1)\, x^r}{4} = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - \frac{1}{4} = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= \frac{1}{2} \\ r_2 &= -\frac{1}{2} \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\frac{(4r^2 - 1)\, x^r}{4} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sqrt{x} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{\sqrt{x}} \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}} \\ y_2(x) &= C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}\right) \end{aligned}$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1)+a_n(n+r)+a_{n-2}-\frac{a_n}{4}=0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n=-\frac{4a_{n-2}}{4n^2+8nr+4r^2-1} \tag{4}$$

Which for the root $r=\frac{1}{2}$ becomes

$$a_n=-\frac{a_{n-2}}{n(n+1)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r=\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n=2$, using the above recursive equation gives

$$a_2=-\frac{4}{4r^2+16r+15}$$

Which for the root $r=\frac{1}{2}$ becomes

$$a_2=-\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$

For $n=3$, using the above recursive equation gives

$$a_3=0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16}{(4r^2 + 16r + 15)(4r^2 + 32r + 63)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{120}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{120}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{64}{(4r^2 + 16r + 15)(4r^2 + 32r + 63)(4r^2 + 48r + 143)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = -\frac{1}{5040}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{120}$
a_5	0	0
a_6	$-\frac{64}{(4r^2+16r+15)(4r^2+32r+63)(4r^2+48r+143)}$	$-\frac{1}{5040}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{6}$
a_3	0	0
a_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{120}$
a_5	0	0
a_6	$-\frac{64}{(4r^2+16r+15)(4r^2+32r+63)(4r^2+48r+143)}$	$-\frac{1}{5040}$
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= \sqrt{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned}
a_N &= a_1 \\
&= 0
\end{aligned}$$

Therefore

$$\begin{aligned}
\lim_{r\to r_2} 0 &= \lim_{r\to -\frac{1}{2}} 0 \\
&= 0
\end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned}
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\
&= \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}}
\end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) + b_n(n+r) + b_{n-2} - \frac{b_n}{4} = 0 \tag{4}$$

Which for for the root $r = -\frac{1}{2}$ becomes

$$b_n \left(n - \frac{1}{2}\right) \left(n - \frac{3}{2}\right) + b_n \left(n - \frac{1}{2}\right) + b_{n-2} - \frac{b_n}{4} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{4b_{n-2}}{4n^2 + 8nr + 4r^2 - 1} \tag{5}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = -\frac{4b_{n-2}}{4n^2 - 4n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{4}{4r^2 + 16r + 15}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{16}{(4r^2 + 16r + 15)(4r^2 + 32r + 63)}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{24}$
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = -\frac{64}{(4r^2 + 16r + 15)(4r^2 + 32r + 63)(4r^2 + 48r + 143)}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_6 = -\frac{1}{720}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{24}$
b_5	0	0
b_6	$-\frac{64}{(4r^2+16r+15)(4r^2+32r+63)(4r^2+48r+143)}$	$-\frac{1}{720}$

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{4}{4r^2+16r+15}$	$-\frac{1}{2}$
b_3	0	0
b_4	$\frac{16}{(4r^2+16r+15)(4r^2+32r+63)}$	$\frac{1}{24}$
b_5	0	0
b_6	$-\frac{64}{(4r^2+16r+15)(4r^2+32r+63)(4r^2+48r+143)}$	$-\frac{1}{720}$
b_7	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= \sqrt{x}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots\right) \\ &= \frac{1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)}{\sqrt{x}} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)\right)}{\sqrt{x}} \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)\right)}{\sqrt{x}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = c_1 \sqrt{x}\left(1 - \frac{x^2}{6} + \frac{x^4}{120} - \frac{x^6}{5040} + O(x^8)\right) + \frac{c_2\left(1 - \frac{x^2}{2} + \frac{x^4}{24} - \frac{x^6}{720} + O(x^8)\right)}{\sqrt{x}}$$

Verified OK.

20.9.1 Maple step by step solution

Let's solve

$x^2 y'' + x y' + \left(x^2 - \frac{1}{4}\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(4x^2-1)y}{4x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} + \frac{(4x^2-1)y}{4x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{4x^2-1}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = -\frac{1}{4}$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $4x^2y'' + 4xy' + (4x^2 - 1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(1+2r)(-1+2r) x^r + a_1(3+2r)(1+2r) x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r+1)(2k+2r-1) + 4a_{k-}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(1+2r)(-1+2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{-\frac{1}{2}, \frac{1}{2}\right\}$

- Each term must be 0

  $a_1(3+2r)(1+2r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(4k^2 + 8kr + 4r^2 - 1) + 4a_{k-2} = 0$

- Shift index using $k- > k+2$

  $a_{k+2}\left(4(k+2)^2 + 8(k+2) r + 4r^2 - 1\right) + 4a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{4a_k}{4k^2+8kr+4r^2+16k+16r+15}$

- Recursion relation for $r = -\frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+12k+8}$

- Solution for $r = -\frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+2} = -\frac{4a_k}{4k^2+20k+24}$

- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = -\frac{4a_k}{4k^2+20k+24}, a_1 = 0\right]$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{k+2} = -\frac{4a_k}{4k^2+12k+8}, a_1 = 0, b_{k+2} = -\frac{4b_k}{4k^2+20k+24}, b_1 = 0\right]$$

Problem number: 2(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[_Jacobi]
```

$$\boxed{x(1-x)\, y''+\left(\frac{3}{2}-2x\right) y'+2y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-x^2+x\right) y''+\left(\frac{3}{2}-2x\right) y'+2y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{-3+4x}{2x\,(x-1)}$$
$$q(x)=-\frac{2}{x\,(x-1)}$$

Table 485: Table $p(x), q(x)$ singularites.

$p(x) = \frac{-3+4x}{2x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = -\frac{2}{x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 1, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-y''x(x-1) + \left(\frac{3}{2} - 2x\right) y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) x(x-1) + \left(\frac{3}{2} - 2x\right) \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty}\left(-x^{n+r} a_n (n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-2x^{n+r} a_n (n+r)\right)+\left(\sum_{n=0}^{\infty}\frac{3(n+r)\, a_n x^{n+r-1}}{2}\right)+\left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-x^{n+r} a_n (n+r)(n+r-1)\right)=\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty}\left(-2x^{n+r} a_n (n+r)\right)=\sum_{n=1}^{\infty}\left(-2a_{n-1}(n+r-1)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} 2a_n x^{n+r}=\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right)+\sum_{n=1}^{\infty}\left(-2a_{n-1}(n+r-1)\, x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty}\frac{3(n+r)\, a_n x^{n+r-1}}{2}\right)+\left(\sum_{n=1}^{\infty} 2a_{n-1} x^{n+r-1}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1)+\frac{3(n+r)\, a_n x^{n+r-1}}{2}=0$$

When $n = 0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + \frac{3r a_0 x^{-1+r}}{2} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + \frac{3r\, x^{-1+r}}{2}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r} \left(\frac{1}{2} + r\right) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 + \frac{1}{2} r = 0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= 0 \\ r_2 &= -\frac{1}{2} \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r} \left(\frac{1}{2} + r\right) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^n \\ y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n-\frac{1}{2}} \end{aligned}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
\begin{aligned}
&-a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) \\
&- 2a_{n-1}(n+r-1) + \frac{3a_n(n+r)}{2} + 2a_{n-1} = 0
\end{aligned} \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = \frac{2a_{n-1}(n^2 + 2nr + r^2 - n - r - 2)}{2n^2 + 4nr + 2r^2 + n + r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
a_n = \frac{2a_{n-1}(n^2 - n - 2)}{2n^2 + n} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$
a_1 = \frac{2r^2 + 2r - 4}{2r^2 + 5r + 3}
$$

Which for the root $r = 0$ becomes

$$
a_1 = -\frac{4}{3}
$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$

For $n = 2$, using the above recursive equation gives

$$
a_2 = \frac{4(-1+r)\,r(r+3)}{4r^3 + 20r^2 + 31r + 15}
$$

Which for the root $r = 0$ becomes

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$
a_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	0

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{8(-1+r)\,r(r+4)}{8r^3+60r^2+142r+105}$$

Which for the root $r = 0$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$
a_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	0
a_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16(r+5)\,(r+2)\,r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$$

Which for the root $r = 0$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$
a_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	0
a_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	0
a_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$$

Which for the root $r = 0$ becomes

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$
a_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	0
a_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	0
a_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	0
a_5	$\frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	0

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{64(r+7)(r+4)(r+2)(-1+r)r(r+3)}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$$

Which for the root $r = 0$ becomes

$$a_6 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$
a_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	0
a_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	0
a_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	0
a_5	$\frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	0
a_6	$\frac{64(r+7)(r+4)(r+2)(-1+r)r(r+3)}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	0

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{128(r+8)(r+5)(-1+r)r(r+3)(r+2)(r+4)}{128r^7+4032r^6+52640r^5+367920r^4+1480472r^3+3411828r^2+4142430r+2027025}$$

Which for the root $r = 0$ becomes

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{4}{3}$
a_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	0
a_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	0
a_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	0
a_5	$\frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	0
a_6	$\frac{64(r+7)(r+4)(r+2)(-1+r)r(r+3)}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	0
a_7	$\frac{128(r+8)(r+5)(-1+r)r(r+3)(r+2)(r+4)}{128r^7+4032r^6+52640r^5+367920r^4+1480472r^3+3411828r^2+4142430r+2027025}$	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots \\ &= 1 - \frac{4x}{3} + O(x^8) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} -b_{n-1}(n+r-1)(n+r-2) + b_n(n+r)(n+r-1) \\ - 2b_{n-1}(n+r-1) + \frac{3(n+r) b_n}{2} + 2b_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{2b_{n-1}(n^2 + 2nr + r^2 - n - r - 2)}{2n^2 + 4nr + 2r^2 + n + r} \tag{4}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_n = \frac{b_{n-1}(4n^2 - 8n - 5)}{4n^2 - 2n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{2r^2 + 2r - 4}{2r^2 + 5r + 3}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_1 = -\frac{9}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{4(-1+r)\, r(r+3)}{4r^3 + 20r^2 + 31r + 15}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_2 = \frac{15}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$
b_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	$\frac{15}{8}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{8(-1+r)\, r(r+4)}{8r^3+60r^2+142r+105}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_3 = \frac{7}{16}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$
b_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	$\frac{15}{8}$
b_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	$\frac{7}{16}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{16(r+5)\,(r+2)\, r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_4 = \frac{27}{128}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$
b_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	$\frac{15}{8}$
b_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	$\frac{7}{16}$
b_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{27}{128}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_5 = \frac{33}{256}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$
b_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	$\frac{15}{8}$
b_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	$\frac{7}{16}$
b_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{27}{128}$
b_5	$\frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{33}{256}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{64(r+7)(r+4)(r+2)(-1+r)r(r+3)}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_6 = \frac{91}{1024}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$
b_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	$\frac{15}{8}$
b_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	$\frac{7}{16}$
b_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{27}{128}$
b_5	$\frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{33}{256}$
b_6	$\frac{64(r+7)(r+4)(r+2)(-1+r)r(r+3)}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	$\frac{91}{1024}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{128(r+8)(r+5)(-1+r)r(r+3)(r+2)(r+4)}{128r^7+4032r^6+52640r^5+367920r^4+1480472r^3+3411828r^2+4142430r+2027025}$$

Which for the root $r = -\frac{1}{2}$ becomes

$$b_7 = \frac{135}{2048}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{2r^2+2r-4}{2r^2+5r+3}$	$-\frac{9}{2}$
b_2	$\frac{4(-1+r)r(r+3)}{4r^3+20r^2+31r+15}$	$\frac{15}{8}$
b_3	$\frac{8(-1+r)r(r+4)}{8r^3+60r^2+142r+105}$	$\frac{7}{16}$
b_4	$\frac{16(r+5)(r+2)r(-1+r)}{16r^4+192r^3+824r^2+1488r+945}$	$\frac{27}{128}$
b_5	$\frac{32(r+6)(r+3)(-1+r)r(r+2)}{32r^5+560r^4+3760r^3+12040r^2+18258r+10395}$	$\frac{33}{256}$
b_6	$\frac{64(r+7)(r+4)(r+2)(-1+r)r(r+3)}{64r^6+1536r^5+14800r^4+72960r^3+193036r^2+258144r+135135}$	$\frac{91}{1024}$
b_7	$\frac{128(r+8)(r+5)(-1+r)r(r+3)(r+2)(r+4)}{128r^7+4032r^6+52640r^5+367920r^4+1480472r^3+3411828r^2+4142430r+2027025}$	$\frac{135}{2048}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= 1\left(b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + b_8x^8 \dots\right) \\
&= \frac{1 - \frac{9x}{2} + \frac{15x^2}{8} + \frac{7x^3}{16} + \frac{27x^4}{128} + \frac{33x^5}{256} + \frac{91x^6}{1024} + \frac{135x^7}{2048} + O(x^8)}{\sqrt{x}}
\end{aligned}$$

Therefore the homogeneous solution is

$$y_h(x) = c_1y_1(x) + c_2y_2(x)$$

$$= c_1\left(1-\frac{4x}{3}+O\left(x^8\right)\right)+\frac{c_2\left(1-\frac{9x}{2}+\frac{15x^2}{8}+\frac{7x^3}{16}+\frac{27x^4}{128}+\frac{33x^5}{256}+\frac{91x^6}{1024}+\frac{135x^7}{2048}+O(x^8)\right)}{\sqrt{x}}$$

Hence the final solution is

$$y = y_h$$

$$= c_1\left(1-\frac{4x}{3}+O\left(x^8\right)\right)+\frac{c_2\left(1-\frac{9x}{2}+\frac{15x^2}{8}+\frac{7x^3}{16}+\frac{27x^4}{128}+\frac{33x^5}{256}+\frac{91x^6}{1024}+\frac{135x^7}{2048}+O(x^8)\right)}{\sqrt{x}}$$

Summary

The solution(s) found are the following

$$y = c_1\left(1-\frac{4x}{3}+O\left(x^8\right)\right) + \frac{c_2\left(1-\frac{9x}{2}+\frac{15x^2}{8}+\frac{7x^3}{16}+\frac{27x^4}{128}+\frac{33x^5}{256}+\frac{91x^6}{1024}+\frac{135x^7}{2048}+O(x^8)\right)}{\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = c_1\left(1-\frac{4x}{3}+O\left(x^8\right)\right)+\frac{c_2\left(1-\frac{9x}{2}+\frac{15x^2}{8}+\frac{7x^3}{16}+\frac{27x^4}{128}+\frac{33x^5}{256}+\frac{91x^6}{1024}+\frac{135x^7}{2048}+O(x^8)\right)}{\sqrt{x}}$$

Verified OK.

21.1.1 Maple step by step solution

Let's solve

$-y''x(x-1)+\left(\frac{3}{2}-2x\right)y'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(-3+4x)y'}{2x(x-1)}+\frac{2y}{x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y'' + \frac{(-3+4x)y'}{2x(x-1)} - \frac{2y}{x(x-1)} = 0$$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $$\left[P_2(x) = \frac{-3+4x}{2x(x-1)}, P_3(x) = -\frac{2}{x(x-1)}\right]$$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{3}{2}$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $$x_0 = 0$$

- Multiply by denominators

  $$2y''x(x-1) + (-3+4x)\, y' - 4y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

  $$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

$$-a_0 r(2r+1)\,x^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)\,(2k+3+2r)+2a_k(k+r+2)\,(k+r-1)\right)x^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(2r+1)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{0,-\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-2(k+1+r)\left(k+\frac{3}{2}+r\right)a_{k+1}+2a_k(k+r+2)\,(k+r-1)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{2a_k(k+r+2)(k+r-1)}{(k+1+r)(2k+3+2r)}$

- Recursion relation for $r=0$; series terminates at $k=1$

  $a_{k+1}=\frac{2a_k(k+2)(k-1)}{(k+1)(2k+3)}$

- Apply recursion relation for $k=0$

  $a_1=-\frac{4a_0}{3}$

- Terminating series solution of the ODE for $r=0$. Use reduction of order to find the second li

  $y=a_0\cdot\left(1-\frac{4x}{3}\right)$

- Recursion relation for $r=-\frac{1}{2}$

  $a_{k+1}=\frac{2a_k\left(k+\frac{3}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{1}{2}\right)(2k+2)}$

- Solution for $r=-\frac{1}{2}$

  $\left[y=\sum_{k=0}^{\infty}a_k x^{k-\frac{1}{2}},a_{k+1}=\frac{2a_k\left(k+\frac{3}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{1}{2}\right)(2k+2)}\right]$

- Combine solutions and rename parameters

  $\left[y=a_0\cdot\left(1-\frac{4x}{3}\right)+\left(\sum_{k=0}^{\infty}b_k x^{k-\frac{1}{2}}\right),b_{k+1}=\frac{2b_k\left(k+\frac{3}{2}\right)\left(k-\frac{3}{2}\right)}{\left(k+\frac{1}{2}\right)(2k+2)}\right]$

Problem number: 2(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(2x^2 + 2x)\, y'' + (5x + 1)\, y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(2x^2 + 2x)\, y'' + (5x + 1)\, y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{5x + 1}{2x\,(1 + x)}$$
$$q(x) = \frac{1}{2x\,(1 + x)}$$

Table 487: Table $p(x), q(x)$ singularites.

$p(x) = \frac{5x+1}{2x(1+x)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{1}{2x(1+x)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2y''x(1+x) + (5x+1)\,y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x(1+x) + (5x+1)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} 5x^{n+r} a_n (n+r) = \sum_{n=1}^{\infty} 5a_{n-1}(n+r-1)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty} 2a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} 5a_{n-1}(n+r-1)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r}r(-1+r)+r\,x^{-1+r}\right)a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\,x^{-1+r}(2r-1)=0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2-r=0$$

Solving for r gives the roots of the indicial equation as

$$r_1=\frac{1}{2}$$
$$r_2=0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}(2r-1)=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=\frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x)=x^{r_1}\left(\sum_{n=0}^{\infty}a_n x^n\right)$$
$$y_2(x)=x^{r_2}\left(\sum_{n=0}^{\infty}b_n x^n\right)$$

Or

$$y_1(x)=\sum_{n=0}^{\infty}a_n x^{n+\frac{1}{2}}$$
$$y_2(x)=\sum_{n=0}^{\infty}b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. For $1\leq n$ the recursive equation is

$$\begin{aligned}&2a_{n-1}(n+r-1)\,(n+r-2)+2a_n(n+r)\,(n+r-1)\\&+5a_{n-1}(n+r-1)+a_n(n+r)+a_{n-1}=0\end{aligned}\tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -a_{n-1} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = -a_{n-1} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1

For $n = 2$, using the above recursive equation gives

$$a_2 = 1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = 1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1
a_2	1	1

For $n = 3$, using the above recursive equation gives

$$a_3 = -1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1
a_2	1	1
a_3	-1	-1

For $n = 4$, using the above recursive equation gives

$$a_4 = 1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = 1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1
a_2	1	1
a_3	-1	-1
a_4	1	1

For $n = 5$, using the above recursive equation gives

$$a_5 = -1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1
a_2	1	1
a_3	-1	-1
a_4	1	1
a_5	-1	-1

For $n = 6$, using the above recursive equation gives

$$a_6 = 1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = 1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1
a_2	1	1
a_3	-1	-1
a_4	1	1
a_5	-1	-1
a_6	1	1

For $n = 7$, using the above recursive equation gives

$$a_7 = -1$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_7 = -1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-1	-1
a_2	1	1
a_3	-1	-1
a_4	1	1
a_5	-1	-1
a_6	1	1
a_7	-1	-1

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \sqrt{x}\big(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\big) \\ &= \sqrt{x}\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} &2b_{n-1}(n+r-1)(n+r-2) + 2b_n(n+r)(n+r-1) \\ &+ 5b_{n-1}(n+r-1) + (n+r)b_n + b_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -b_{n-1} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = -b_{n-1} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = -1$$

Which for the root $r = 0$ becomes

$$b_1 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = 1$$

Which for the root $r = 0$ becomes

$$b_2 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1
b_2	1	1

For $n = 3$, using the above recursive equation gives

$$b_3 = -1$$

Which for the root $r = 0$ becomes

$$b_3 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1
b_2	1	1
b_3	-1	-1

For $n = 4$, using the above recursive equation gives

$$b_4 = 1$$

Which for the root $r = 0$ becomes

$$b_4 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1
b_2	1	1
b_3	-1	-1
b_4	1	1

For $n = 5$, using the above recursive equation gives

$$b_5 = -1$$

Which for the root $r = 0$ becomes

$$b_5 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1
b_2	1	1
b_3	-1	-1
b_4	1	1
b_5	-1	-1

For $n = 6$, using the above recursive equation gives

$$b_6 = 1$$

Which for the root $r = 0$ becomes

$$b_6 = 1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1
b_2	1	1
b_3	-1	-1
b_4	1	1
b_5	-1	-1
b_6	1	1

For $n = 7$, using the above recursive equation gives

$$b_7 = -1$$

Which for the root $r = 0$ becomes

$$b_7 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-1	-1
b_2	1	1
b_3	-1	-1
b_4	1	1
b_5	-1	-1
b_6	1	1
b_7	-1	-1

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= 1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)
\end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1\sqrt{x}\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right) \\
&\quad + c_2\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\sqrt{x}\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right) \\
&\quad + c_2\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = c_1\sqrt{x}\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right) \\
+ c_2\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = c_1\sqrt{x}\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right) \\
+ c_2\left(1 - x + x^2 - x^3 + x^4 - x^5 + x^6 - x^7 + O(x^8)\right)
\end{aligned}
$$

Verified OK.

21.2.1 Maple step by step solution

Let's solve

$2y''x(1+x) + (5x+1)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{2x(1+x)} - \frac{(5x+1)y'}{2x(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(5x+1)y'}{2x(1+x)} + \frac{y}{2x(1+x)} = 0$

□ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x)=\frac{5x+1}{2x(1+x)}, P_3(x)=\frac{1}{2x(1+x)}\right]$

- $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $((1+x)\cdot P_2(x))\bigg|_{x=-1}=2$

- $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $((1+x)^2\cdot P_3(x))\bigg|_{x=-1}=0$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $2y''x(1+x)+(5x+1)\,y'+y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(2u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(5u-4)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$$-2a_0r(1+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+r+1)\,(k+2+r)+a_k(k+r+1)\,(2k+2r+1)\right)u^{k+r}\right)$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2r(1+r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\{-1,0\}$$

- Each term in the series must be 0, giving the recursion relation

$$2(k+r+1)\left((-k-r-2)\,a_{k+1}+a_k\left(k+r+\frac{1}{2}\right)\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{a_k(2k+2r+1)}{2(k+2+r)}$$

- Recursion relation for $r=-1$

$$a_{k+1}=\frac{a_k(2k-1)}{2(k+1)}$$

- Solution for $r=-1$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k-1},a_{k+1}=\frac{a_k(2k-1)}{2(k+1)}\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k-1},a_{k+1}=\frac{a_k(2k-1)}{2(k+1)}\right]$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{a_k(2k+1)}{2(k+2)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k},a_{k+1}=\frac{a_k(2k+1)}{2(k+2)}\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k},a_{k+1}=\frac{a_k(2k+1)}{2(k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_k(1+x)^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_k(1+x)^{k}\right),a_{k+1}=\frac{a_k(2k-1)}{2(k+1)},b_{k+1}=\frac{b_k(2k+1)}{2(k+2)}\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.6. Gauss's Hypergeometric Equation. Page 187
Problem number: 2(x).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2-1)\,y''+(5x+4)\,y'+4y=0}$$

With the expansion point for the power series method at $x=-1$.

The ode does not have its expansion point at $x=0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t=1+x$$

The ode is converted to be in terms of the new independent variable t. This results in

$$((t-1)^2-1)\left(\frac{d^2}{dt^2}y(t)\right)+(-1+5t)\left(\frac{d}{dt}y(t)\right)+4y(t)=0$$

With its expansion point and initial conditions now at $t=0$. The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the

homogeneous part of the ODE.

$$(t^2-2t)\left(\frac{d^2}{dt^2}y(t)\right)+(-1+5t)\left(\frac{d}{dt}y(t)\right)+4y(t)=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t)+p(t)\frac{d}{dt}y(t)+q(t)y(t)=0$$

Where

$$p(t)=\frac{-1+5t}{t\,(-2+t)}$$
$$q(t)=\frac{4}{(-2+t)\,t}$$

Table 489: Table $p(t), q(t)$ singularites.

$p(t)=\frac{-1+5t}{t(-2+t)}$	
singularity	type
$t=0$	"regular"
$t=2$	"regular"

$q(t)=\frac{4}{(-2+t)t}$	
singularity	type
$t=0$	"regular"
$t=2$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0,2,\infty]$

Irregular singular points : $[]$

Since $t=0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)t(-2+t)+(-1+5t)\left(\frac{d}{dt}y(t)\right)+4y(t)=0$$

Let the solution be represented as Frobenius power series of the form

$$y(t)=\sum_{n=0}^{\infty}a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$

$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}\right) t(-2+t) + (-1+5t)\left(\sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}\right) + 4\left(\sum_{n=0}^{\infty} a_n t^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} t^{n+r} a_n (n+r)\,(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-2t^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5t^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-(n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 4a_n t^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of t be $n+r-1$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} t^{n+r} a_n (n+r)\,(n+r-1) = \sum_{n=1}^{\infty} a_{n-1} (n+r-1)\,(n+r-2)\, t^{n+r-1}$$

$$\sum_{n=0}^{\infty} 5t^{n+r} a_n (n+r) = \sum_{n=1}^{\infty} 5a_{n-1} (n+r-1)\, t^{n+r-1}$$

$$\sum_{n=0}^{\infty} 4a_n t^{n+r} = \sum_{n=1}^{\infty} 4a_{n-1} t^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n+r-1$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\,(n+r-2)\,t^{n+r-1}\right) + \sum_{n\,=0}^{\infty} \left(-2t^{n+r-1} a_n(n+r)\,(n+r-1)\right) + \left(\sum_{n=1}^{\infty} 5a_{n-1}(n+r-1)\,t^{n+r-1}\right) + \sum_{n\,=0}^{\infty} \left(-(n+r)\,a_n t^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 4a_{n-1}t^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$-2t^{n+r-1}a_n(n+r)\,(n+r-1) - (n+r)\,a_n t^{n+r-1} = 0$$

When $n=0$ the above becomes

$$-2t^{-1+r}a_0 r(-1+r) - r a_0 t^{-1+r} = 0$$

Or

$$\left(-2t^{-1+r}r(-1+r) - r\,t^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(-2r^2+r\right) t^{-1+r} = 0$$

Since the above is true for all t then the indicial equation becomes

$$-2r^2+r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(-2r^2+r\right) t^{-1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(t) = t^{r_1}\left(\sum_{n=0}^{\infty} a_n t^n\right)$$
$$y_2(t) = t^{r_2}\left(\sum_{n=0}^{\infty} b_n t^n\right)$$

Or

$$y_1(t) = \sum_{n=0}^{\infty} a_n t^{n+\frac{1}{2}}$$
$$y_2(t) = \sum_{n=0}^{\infty} b_n t^n$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_{n-1}(n+r-1)(n+r-2) - 2a_n(n+r)(n+r-1) + 5a_{n-1}(n+r-1) - a_n(n+r) + 4a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n^2 + 2nr + r^2 + 2n + 2r + 1)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = \frac{a_{n-1}(3+2n)^2}{8n^2 + 4n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{(r+2)^2}{2r^2 + 3r + 1}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = \frac{25}{12}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{(r+3)^2 (r+2)}{4r^3 + 12r^2 + 11r + 3}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = \frac{245}{96}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$
a_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	$\frac{245}{96}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{(r+4)^2 (r+2) (r+3)}{8r^4 + 44r^3 + 82r^2 + 61r + 15}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = \frac{315}{128}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$
a_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	$\frac{245}{96}$
a_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{315}{128}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(r+5)^2 (r+3) (r+2) (r+4)}{16r^5 + 144r^4 + 472r^3 + 696r^2 + 457r + 105}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{4235}{2048}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$
a_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	$\frac{245}{96}$
a_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{315}{128}$
a_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{4235}{2048}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(r+6)^2 (r+4) (r+2) (r+3) (r+5)}{32r^6 + 432r^5 + 2240r^4 + 5640r^3 + 7178r^2 + 4323r + 945}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = \frac{13013}{8192}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$
a_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	$\frac{245}{96}$
a_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{315}{128}$
a_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{4235}{2048}$
a_5	$\frac{(r+6)^2(r+4)(r+2)(r+3)(r+5)}{32r^6+432r^5+2240r^4+5640r^3+7178r^2+4323r+945}$	$\frac{13013}{8192}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{(r+7)^2 (r+5) (r+3) (r+2) (r+4) (r+6)}{64r^7 + 1216r^6 + 9232r^5 + 35920r^4 + 76396r^3 + 87604r^2 + 49443r + 10395}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = \frac{75075}{65536}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$
a_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	$\frac{245}{96}$
a_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{315}{128}$
a_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{4235}{2048}$
a_5	$\frac{(r+6)^2(r+4)(r+2)(r+3)(r+5)}{32r^6+432r^5+2240r^4+5640r^3+7178r^2+4323r+945}$	$\frac{13013}{8192}$
a_6	$\frac{(r+7)^2(r+5)(r+3)(r+2)(r+4)(r+6)}{64r^7+1216r^6+9232r^5+35920r^4+76396r^3+87604r^2+49443r+10395}$	$\frac{75075}{65536}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{(r+8)^2 (r+6) (r+4) (r+2) (r+3) (r+5) (r+7)}{128r^8 + 3264r^7 + 34272r^6 + 191856r^5 + 619752r^4 + 1168356r^3 + 1237738r^2 + 663549r + 135135}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_7 = \frac{206635}{262144}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(r+2)^2}{2r^2+3r+1}$	$\frac{25}{12}$
a_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	$\frac{245}{96}$
a_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{315}{128}$
a_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{4235}{2048}$
a_5	$\frac{(r+6)^2(r+4)(r+2)(r+3)(r+5)}{32r^6+432r^5+2240r^4+5640r^3+7178r^2+4323r+945}$	$\frac{13013}{8192}$
a_6	$\frac{(r+7)^2(r+5)(r+3)(r+2)(r+4)(r+6)}{64r^7+1216r^6+9232r^5+35920r^4+76396r^3+87604r^2+49443r+10395}$	$\frac{75075}{65536}$
a_7	$\frac{(r+8)^2(r+6)(r+4)(r+2)(r+3)(r+5)(r+7)}{128r^8+3264r^7+34272r^6+191856r^5+619752r^4+1168356r^3+1237738r^2+663549r+135135}$	$\frac{206635}{262144}$

Using the above table, then the solution $y_1(t)$ is

$$
\begin{aligned}
y_1(t) &= \sqrt{t}\left(a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \dots\right) \\
&= \sqrt{t}\left(1 + \frac{25t}{12} + \frac{245t^2}{96} + \frac{315t^3}{128} + \frac{4235t^4}{2048} + \frac{13013t^5}{8192} + \frac{75075t^6}{65536} + \frac{206635t^7}{262144} + O(t^8)\right)
\end{aligned}
$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$
\begin{aligned}
&b_{n-1}(n+r-1)(n+r-2) - 2b_n(n+r)(n+r-1) \\
&+ 5b_{n-1}(n+r-1) - (n+r)b_n + 4b_{n-1} = 0
\end{aligned}
\tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{b_{n-1}(n^2 + 2nr + r^2 + 2n + 2r + 1)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
b_n = \frac{b_{n-1}(n+1)^2}{2n^2 - n} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{(r+2)^2}{2r^2+3r+1}$$

Which for the root $r = 0$ becomes

$$b_1 = 4$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{(r+3)^2 (r+2)}{4r^3+12r^2+11r+3}$$

Which for the root $r = 0$ becomes

$$b_2 = 6$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4
b_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	6

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{(r+4)^2 (r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{32}{5}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4
b_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	6
b_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{32}{5}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(r+5)^2 (r+3) (r+2) (r+4)}{16r^5 + 144r^4 + 472r^3 + 696r^2 + 457r + 105}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{40}{7}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4
b_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	6
b_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{32}{5}$
b_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{40}{7}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{(r+6)^2 (r+4) (r+2) (r+3) (r+5)}{32r^6 + 432r^5 + 2240r^4 + 5640r^3 + 7178r^2 + 4323r + 945}$$

Which for the root $r = 0$ becomes

$$b_5 = \frac{32}{7}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4
b_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	6
b_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{32}{5}$
b_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{40}{7}$
b_5	$\frac{(r+6)^2(r+4)(r+2)(r+3)(r+5)}{32r^6+432r^5+2240r^4+5640r^3+7178r^2+4323r+945}$	$\frac{32}{7}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{(r+7)^2 (r+5)(r+3)(r+2)(r+4)(r+6)}{64r^7 + 1216r^6 + 9232r^5 + 35920r^4 + 76396r^3 + 87604r^2 + 49443r + 10395}$$

Which for the root $r = 0$ becomes

$$b_6 = \frac{112}{33}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4
b_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	6
b_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{32}{5}$
b_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{40}{7}$
b_5	$\frac{(r+6)^2(r+4)(r+2)(r+3)(r+5)}{32r^6+432r^5+2240r^4+5640r^3+7178r^2+4323r+945}$	$\frac{32}{7}$
b_6	$\frac{(r+7)^2(r+5)(r+3)(r+2)(r+4)(r+6)}{64r^7+1216r^6+9232r^5+35920r^4+76396r^3+87604r^2+49443r+10395}$	$\frac{112}{33}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{(r+8)^2 (r+6)(r+4)(r+2)(r+3)(r+5)(r+7)}{128r^8 + 3264r^7 + 34272r^6 + 191856r^5 + 619752r^4 + 1168356r^3 + 1237738r^2 + 663549r + 135135}$$

Which for the root $r = 0$ becomes

$$b_7 = \frac{1024}{429}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{(r+2)^2}{2r^2+3r+1}$	4
b_2	$\frac{(r+3)^2(r+2)}{4r^3+12r^2+11r+3}$	6
b_3	$\frac{(r+4)^2(r+2)(r+3)}{8r^4+44r^3+82r^2+61r+15}$	$\frac{32}{5}$
b_4	$\frac{(r+5)^2(r+3)(r+2)(r+4)}{16r^5+144r^4+472r^3+696r^2+457r+105}$	$\frac{40}{7}$
b_5	$\frac{(r+6)^2(r+4)(r+2)(r+3)(r+5)}{32r^6+432r^5+2240r^4+5640r^3+7178r^2+4323r+945}$	$\frac{32}{7}$
b_6	$\frac{(r+7)^2(r+5)(r+3)(r+2)(r+4)(r+6)}{64r^7+1216r^6+9232r^5+35920r^4+76396r^3+87604r^2+49443r+10395}$	$\frac{112}{33}$
b_7	$\frac{(r+8)^2(r+6)(r+4)(r+2)(r+3)(r+5)(r+7)}{128r^8+3264r^7+34272r^6+191856r^5+619752r^4+1168356r^3+1237738r^2+663549r+135135}$	$\frac{1024}{429}$

Using the above table, then the solution $y_2(t)$ is

$$\begin{aligned}
y_2(t) &= b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots \\
&= 1 + 4t + 6t^2 + \frac{32t^3}{5} + \frac{40t^4}{7} + \frac{32t^5}{7} + \frac{112t^6}{33} + \frac{1024t^7}{429} + O(t^8)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(t) &= c_1 y_1(t) + c_2 y_2(t) \\
&= c_1 \sqrt{t}\left(1+\frac{25t}{12}+\frac{245t^2}{96}+\frac{315t^3}{128}+\frac{4235t^4}{2048}+\frac{13013t^5}{8192}+\frac{75075t^6}{65536}+\frac{206635t^7}{262144}+O(t^8)\right) \\
&\quad + c_2\left(1 + 4t + 6t^2 + \frac{32t^3}{5} + \frac{40t^4}{7} + \frac{32t^5}{7} + \frac{112t^6}{33} + \frac{1024t^7}{429} + O(t^8)\right)
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y(t) &= y_h \\
&= c_1 \sqrt{t}\left(1+\frac{25t}{12}+\frac{245t^2}{96}+\frac{315t^3}{128}+\frac{4235t^4}{2048}+\frac{13013t^5}{8192}+\frac{75075t^6}{65536}+\frac{206635t^7}{262144}+O(t^8)\right) \\
&\quad + c_2\left(1 + 4t + 6t^2 + \frac{32t^3}{5} + \frac{40t^4}{7} + \frac{32t^5}{7} + \frac{112t^6}{33} + \frac{1024t^7}{429} + O(t^8)\right)
\end{aligned}$$

Replacing t in the above with the original independent variable $x$using $t = 1 + x$ results in

$$y = c_1\sqrt{1+x}\left(\frac{37}{12}+\frac{25x}{12}+\frac{245(1+x)^2}{96}+\frac{315(1+x)^3}{128}+\frac{4235(1+x)^4}{2048}+\frac{13013(1+x)^5}{8192}+\frac{75075(1+x)^6}{65536}+\frac{206635(1+x)^7}{262144}+O\left((1+x)^8\right)\right)+c_2\left(5+4x+6(1+x)^2+\frac{32(1+x)^3}{5}+\frac{40(1+x)^4}{7}+\frac{32(1+x)^5}{7}+\frac{112(1+x)^6}{33}+\frac{1024(1+x)^7}{429}+O\left((1+x)^8\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{1+x}\left(\frac{37}{12}+\frac{25x}{12}+\frac{245(1+x)^2}{96}+\frac{315(1+x)^3}{128}+\frac{4235(1+x)^4}{2048}+\frac{13013(1+x)^5}{8192}+\frac{75075(1+x)^6}{65536}+\frac{206635(1+x)^7}{262144}+O\left((1+x)^8\right)\right)+c_2\left(5+4x+6(1+x)^2+\frac{32(1+x)^3}{5}+\frac{40(1+x)^4}{7}+\frac{32(1+x)^5}{7}+\frac{112(1+x)^6}{33}+\frac{1024(1+x)^7}{429}+O\left((1+x)^8\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{1+x}\left(\frac{37}{12}+\frac{25x}{12}+\frac{245(1+x)^2}{96}+\frac{315(1+x)^3}{128}+\frac{4235(1+x)^4}{2048}+\frac{13013(1+x)^5}{8192}+\frac{75075(1+x)^6}{65536}+\frac{206635(1+x)^7}{262144}+O\left((1+x)^8\right)\right)+c_2\left(5+4x+6(1+x)^2+\frac{32(1+x)^3}{5}+\frac{40(1+x)^4}{7}+\frac{32(1+x)^5}{7}+\frac{112(1+x)^6}{33}+\frac{1024(1+x)^7}{429}+O\left((1+x)^8\right)\right)$$

Verified OK.

21.3.1 Maple step by step solution

Let's solve

$(x^2-1)\,y''+(5x+4)\,y'+4y=0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y''=-\frac{(5x+4)y'}{x^2-1}-\frac{4y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''+\frac{(5x+4)y'}{x^2-1}+\frac{4y}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x)=\frac{5x+4}{x^2-1}, P_3(x)=\frac{4}{x^2-1}\right]$

- ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

$\left((1+x)\cdot P_2(x)\right)\bigg|_{x=-1}=\frac{1}{2}$

- ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

$\left((1+x)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$

- ◦ $x=-1$is a regular singular point

Check to see if x_0 is a regular singular point

$x_0=-1$

- Multiply by denominators

$(x^2-1)\,y''+(5x+4)\,y'+4y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(5u-1)\left(\frac{d}{du}y(u)\right)+4y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 r(-1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)(2k+1+2r) + a_k(k+r+2)^2\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r+2)^2 - 2\left(k+r+\frac{1}{2}\right) a_{k+1}(k+1+r) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(k+r+2)^2}{(2k+1+2r)(k+1+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{a_k(k+2)^2}{(2k+1)(k+1)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k+2)^2}{(2k+1)(k+1)}\right]$$

- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+1} = \frac{a_k(k+2)^2}{(2k+1)(k+1)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = \frac{a_k \left(k+\frac{5}{2}\right)^2}{(2k+2)\left(k+\frac{3}{2}\right)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k \left(k+\frac{5}{2}\right)^2}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k \left(k+\frac{5}{2}\right)^2}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (1+x)^{k}\right) + \left(\sum_{k=0}^{\infty} b_k (1+x)^{k+\frac{1}{2}}\right), a_{k+1} = \frac{a_k (k+2)^2}{(2k+1)(k+1)}, b_{k+1} = \frac{b_k \left(k+\frac{5}{2}\right)^2}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

Problem number: 2(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x^2 - x - 6)\, y'' + (3x + 5)\, y' + y = 0}$$

With the expansion point for the power series method at $x = 3$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 3$$

The ode is converted to be in terms of the new independent variable t. This results in

$$((t+3)^2 - t - 9)\left(\frac{d^2}{dt^2}y(t)\right) + (3t + 14)\left(\frac{d}{dt}y(t)\right) + y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the

homogeneous part of the ODE.

$$\left(t^2+5t\right)\left(\frac{d^2}{dt^2}y(t)\right)+(3t+14)\left(\frac{d}{dt}y(t)\right)+y(t)=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t)+p(t)\frac{d}{dt}y(t)+q(t)y(t)=0$$

Where

$$p(t)=\frac{3t+14}{t\,(t+5)}$$
$$q(t)=\frac{1}{(t+5)\,t}$$

Table 491: Table $p(t), q(t)$ singularites.

$p(t)=\frac{3t+14}{t(t+5)}$	
singularity	type
$t=-5$	"regular"
$t=0$	"regular"

$q(t)=\frac{1}{(t+5)t}$	
singularity	type
$t=-5$	"regular"
$t=0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-5, 0, \infty]$

Irregular singular points : []

Since $t=0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)t(t+5)+(3t+14)\left(\frac{d}{dt}y(t)\right)+y(t)=0$$

Let the solution be represented as Frobenius power series of the form

$$y(t)=\sum_{n=0}^{\infty}a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$

$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}\right) t(t+5) + (3t+14)\left(\sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n t^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} t^{n+r} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 5t^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 3t^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 14(n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n t^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of t be $n+r-1$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} t^{n+r} a_n (n+r)\,(n+r-1) = \sum_{n=1}^{\infty} a_{n-1} (n+r-1)\,(n+r-2)\, t^{n+r-1}$$

$$\sum_{n=0}^{\infty} 3t^{n+r} a_n (n+r) = \sum_{n=1}^{\infty} 3a_{n-1} (n+r-1)\, t^{n+r-1}$$

$$\sum_{n=0}^{\infty} a_n t^{n+r} = \sum_{n=1}^{\infty} a_{n-1} t^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n + r - 1$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 5t^{n+r-1} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} 3a_{n-1}(n+r-1)\, t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} 14(n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} t^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$5t^{n+r-1} a_n(n+r)(n+r-1) + 14(n+r)\, a_n t^{n+r-1} = 0$$

When $n = 0$ the above becomes

$$5t^{-1+r} a_0 r(-1+r) + 14r a_0 t^{-1+r} = 0$$

Or

$$\left(5t^{-1+r} r(-1+r) + 14r\, t^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, t^{-1+r}(9+5r) = 0$$

Since the above is true for all t then the indicial equation becomes

$$5r^2 + 9r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = -\frac{9}{5}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, t^{-1+r}(9+5r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{9}{5}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(t) = t^{r_1}\left(\sum_{n=0}^{\infty} a_n t^n\right)$$
$$y_2(t) = t^{r_2}\left(\sum_{n=0}^{\infty} b_n t^n\right)$$

Or

$$y_1(t) = \sum_{n=0}^{\infty} a_n t^n$$
$$y_2(t) = \sum_{n=0}^{\infty} b_n t^{n-\frac{9}{5}}$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_{n-1}(n+r-1)(n+r-2) + 5a_n(n+r)(n+r-1) + 3a_{n-1}(n+r-1) + 14a_n(n+r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{(n+r)\, a_{n-1}}{5n+9+5r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{n a_{n-1}}{5n+9} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-1-r}{14+5r}$$

Which for the root $r = 0$ becomes

$$a_1 = -\frac{1}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2 + 3r + 2}{25r^2 + 165r + 266}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{133}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$
a_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$\frac{1}{133}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r^3 - 6r^2 - 11r - 6}{125r^3 + 1425r^2 + 5290r + 6384}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{1}{1064}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$
a_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$\frac{1}{133}$
a_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$-\frac{1}{1064}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r^4 + 10r^3 + 35r^2 + 50r + 24}{625r^4 + 10750r^3 + 67775r^2 + 185330r + 185136}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{7714}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$
a_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$\frac{1}{133}$
a_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$-\frac{1}{1064}$
a_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$\frac{1}{7714}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-r^5 - 15r^4 - 85r^3 - 225r^2 - 274r - 120}{3125r^5 + 75000r^4 + 704375r^3 + 3231000r^2 + 7226900r + 6294624}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{5}{262276}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$
a_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$\frac{1}{133}$
a_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$-\frac{1}{1064}$
a_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$\frac{1}{7714}$
a_5	$\frac{-r^5-15r^4-85r^3-225r^2-274r-120}{3125r^5+75000r^4+704375r^3+3231000r^2+7226900r+6294624}$	$-\frac{5}{262276}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{r^6 + 21r^5 + 175r^4 + 735r^3 + 1624r^2 + 1764r + 720}{15625r^6 + 496875r^5 + 6446875r^4 + 43625625r^3 + 162143500r^2 + 313322220r + 245490336}$$

Which for the root $r = 0$ becomes

$$a_6 = \frac{5}{1704794}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$
a_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$\frac{1}{133}$
a_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$-\frac{1}{1064}$
a_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$\frac{1}{7714}$
a_5	$\frac{-r^5-15r^4-85r^3-225r^2-274r-120}{3125r^5+75000r^4+704375r^3+3231000r^2+7226900r+6294624}$	$-\frac{5}{262276}$
a_6	$\frac{r^6+21r^5+175r^4+735r^3+1624r^2+1764r+720}{15625r^6+496875r^5+6446875r^4+43625625r^3+162143500r^2+313322220r+245490336}$	$\frac{5}{1704794}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{-r^7 - 28r^6 - 322r^5 - 1960r^4 - 6769r^3 - 13132r^2 - 13068r - 5040}{78125r^7 + 3171875r^6 + 54096875r^5 + 501790625r^4 + 2730245000r^3 + 8700925100r^2 + 15013629360}$$

Which for the root $r = 0$ becomes

$$a_7 = -\frac{5}{10715848}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1-r}{14+5r}$	$-\frac{1}{14}$
a_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$\frac{1}{133}$
a_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$-\frac{1}{1064}$
a_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$\frac{1}{7714}$
a_5	$\frac{-r^5-15r^4-85r^3-225r^2-274r-120}{3125r^5+75000r^4+704375r^3+3231000r^2+7226900r+6294624}$	$-\frac{5}{262276}$
a_6	$\frac{r^6+21r^5+175r^4+735r^3+1624r^2+1764r+720}{15625r^6+496875r^5+6446875r^4+43625625r^3+162143500r^2+313322220r+245490336}$	$\frac{5}{1704794}$
a_7	$\frac{-r^7-28r^6-322r^5-1960r^4-6769r^3-13132r^2-13068r-5040}{78125r^7+3171875r^6+54096875r^5+501790625r^4+2730245000r^3+8700925100r^2+15013629360r+10801574784}$	$-\frac{5}{10715848}$

Using the above table, then the solution $y_1(t)$ is

$$\begin{aligned}
y_1(t) &= a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \ldots \\
&= 1 - \frac{t}{14} + \frac{t^2}{133} - \frac{t^3}{1064} + \frac{t^4}{7714} - \frac{5t^5}{262276} + \frac{5t^6}{1704794} - \frac{5t^7}{10715848} + O(t^8)
\end{aligned}$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned}
&b_{n-1}(n+r-1)(n+r-2) + 5b_n(n+r)(n+r-1) \\
&+ 3b_{n-1}(n+r-1) + 14(n+r)\, b_n + b_{n-1} = 0
\end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{(n+r)\, b_{n-1}}{5n+9+5r} \tag{4}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_n = -\frac{(5n-9)\, b_{n-1}}{25n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{9}{5}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-1-r}{14+5r}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_1 = \frac{4}{25}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r^2 + 3r + 2}{25r^2 + 165r + 266}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_2 = -\frac{2}{625}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$
b_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$-\frac{2}{625}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{-r^3 - 6r^2 - 11r - 6}{125r^3 + 1425r^2 + 5290r + 6384}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_3 = \frac{4}{15625}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$
b_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$-\frac{2}{625}$
b_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$\frac{4}{15625}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r^4 + 10r^3 + 35r^2 + 50r + 24}{625r^4 + 10750r^3 + 67775r^2 + 185330r + 185136}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_4 = -\frac{11}{390625}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$
b_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$-\frac{2}{625}$
b_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$\frac{4}{15625}$
b_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$-\frac{11}{390625}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{-r^5 - 15r^4 - 85r^3 - 225r^2 - 274r - 120}{3125r^5 + 75000r^4 + 704375r^3 + 3231000r^2 + 7226900r + 6294624}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_5 = \frac{176}{48828125}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$
b_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$-\frac{2}{625}$
b_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$\frac{4}{15625}$
b_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$-\frac{11}{390625}$
b_5	$\frac{-r^5-15r^4-85r^3-225r^2-274r-120}{3125r^5+75000r^4+704375r^3+3231000r^2+7226900r+6294624}$	$\frac{176}{48828125}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{r^6 + 21r^5 + 175r^4 + 735r^3 + 1624r^2 + 1764r + 720}{15625r^6 + 496875r^5 + 6446875r^4 + 43625625r^3 + 162143500r^2 + 313322220r + 245490336}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_6 = -\frac{616}{1220703125}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$
b_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$-\frac{2}{625}$
b_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$\frac{4}{15625}$
b_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$-\frac{11}{390625}$
b_5	$\frac{-r^5-15r^4-85r^3-225r^2-274r-120}{3125r^5+75000r^4+704375r^3+3231000r^2+7226900r+6294624}$	$\frac{176}{48828125}$
b_6	$\frac{r^6+21r^5+175r^4+735r^3+1624r^2+1764r+720}{15625r^6+496875r^5+6446875r^4+43625625r^3+162143500r^2+313322220r+245490336}$	$-\frac{616}{1220703125}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{-r^7 - 28r^6 - 322r^5 - 1960r^4 - 6769r^3 - 13132r^2 - 13068r - 5040}{78125r^7 + 3171875r^6 + 54096875r^5 + 501790625r^4 + 2730245000r^3 + 8700925100r^2 + 15013629360}$$

Which for the root $r = -\frac{9}{5}$ becomes

$$b_7 = \frac{2288}{30517578125}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1-r}{14+5r}$	$\frac{4}{25}$
b_2	$\frac{r^2+3r+2}{25r^2+165r+266}$	$-\frac{2}{625}$
b_3	$\frac{-r^3-6r^2-11r-6}{125r^3+1425r^2+5290r+6384}$	$\frac{4}{15625}$
b_4	$\frac{r^4+10r^3+35r^2+50r+24}{625r^4+10750r^3+67775r^2+185330r+185136}$	$-\frac{11}{390625}$
b_5	$\frac{-r^5-15r^4-85r^3-225r^2-274r-120}{3125r^5+75000r^4+704375r^3+3231000r^2+7226900r+6294624}$	$\frac{176}{48828125}$
b_6	$\frac{r^6+21r^5+175r^4+735r^3+1624r^2+1764r+720}{15625r^6+496875r^5+6446875r^4+43625625r^3+162143500r^2+313322220r+245490336}$	$-\frac{616}{1220703125}$
b_7	$\frac{-r^7-28r^6-322r^5-1960r^4-6769r^3-13132r^2-13068r-5040}{78125r^7+3171875r^6+54096875r^5+501790625r^4+2730245000r^3+8700925100r^2+15013629360r+10801574784}$	$\frac{2288}{30517578125}$

Using the above table, then the solution $y_2(t)$ is

$$\begin{aligned} y_2(t) &= 1\left(b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots\right) \\ &= \frac{1 + \frac{4t}{25} - \frac{2t^2}{625} + \frac{4t^3}{15625} - \frac{11t^4}{390625} + \frac{176t^5}{48828125} - \frac{616t^6}{1220703125} + \frac{2288t^7}{30517578125} + O(t^8)}{t^{\frac{9}{5}}} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(t) &= c_1 y_1(t) + c_2 y_2(t) \\ &= c_1\left(1 - \frac{t}{14} + \frac{t^2}{133} - \frac{t^3}{1064} + \frac{t^4}{7714} - \frac{5t^5}{262276} + \frac{5t^6}{1704794} - \frac{5t^7}{10715848} + O(t^8)\right) \\ &\quad + \frac{c_2\left(1 + \frac{4t}{25} - \frac{2t^2}{625} + \frac{4t^3}{15625} - \frac{11t^4}{390625} + \frac{176t^5}{48828125} - \frac{616t^6}{1220703125} + \frac{2288t^7}{30517578125} + O(t^8)\right)}{t^{\frac{9}{5}}} \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y(t) &= y_h \\ &= c_1\left(1 - \frac{t}{14} + \frac{t^2}{133} - \frac{t^3}{1064} + \frac{t^4}{7714} - \frac{5t^5}{262276} + \frac{5t^6}{1704794} - \frac{5t^7}{10715848} + O(t^8)\right) \\ &\quad + \frac{c_2\left(1 + \frac{4t}{25} - \frac{2t^2}{625} + \frac{4t^3}{15625} - \frac{11t^4}{390625} + \frac{176t^5}{48828125} - \frac{616t^6}{1220703125} + \frac{2288t^7}{30517578125} + O(t^8)\right)}{t^{\frac{9}{5}}} \end{aligned}$$

Replacing t in the above with the original independent variable $x$using $t = x - 3$ results in

$$\begin{aligned} y &= c_1\left(\frac{17}{14} - \frac{x}{14} + \frac{(x-3)^2}{133} - \frac{(x-3)^3}{1064} + \frac{(x-3)^4}{7714} - \frac{5(x-3)^5}{262276} + \frac{5(x-3)^6}{1704794} \right. \\ &\quad \left. - \frac{5(x-3)^7}{10715848} + O\left((x-3)^8\right)\right) \\ &\quad + \frac{c_2\left(\frac{13}{25} + \frac{4x}{25} - \frac{2(x-3)^2}{625} + \frac{4(x-3)^3}{15625} - \frac{11(x-3)^4}{390625} + \frac{176(x-3)^5}{48828125} - \frac{616(x-3)^6}{1220703125} + \frac{2288(x-3)^7}{30517578125} + O\left((x-3)^8\right)\right)}{(x-3)^{\frac{9}{5}}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(\frac{17}{14}-\frac{x}{14}+\frac{(x-3)^2}{133}-\frac{(x-3)^3}{1064}+\frac{(x-3)^4}{7714}-\frac{5(x-3)^5}{262276}+\frac{5(x-3)^6}{1704794}-\frac{5(x-3)^7}{10715848}+O\left((x-3)^8\right)\right) + \frac{c_2\left(\frac{13}{25}+\frac{4x}{25}-\frac{2(x-3)^2}{625}+\frac{4(x-3)^3}{15625}-\frac{11(x-3)^4}{390625}+\frac{176(x-3)^5}{48828125}-\frac{616(x-3)^6}{1220703125}+\frac{2288(x-3)^7}{30517578125}+O\left((x-3)^8\right)\right)}{(x-3)^{\frac{9}{5}}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(\frac{17}{14}-\frac{x}{14}+\frac{(x-3)^2}{133}-\frac{(x-3)^3}{1064}+\frac{(x-3)^4}{7714}-\frac{5(x-3)^5}{262276}+\frac{5(x-3)^6}{1704794}-\frac{5(x-3)^7}{10715848}+O\left((x-3)^8\right)\right) + \frac{c_2\left(\frac{13}{25}+\frac{4x}{25}-\frac{2(x-3)^2}{625}+\frac{4(x-3)^3}{15625}-\frac{11(x-3)^4}{390625}+\frac{176(x-3)^5}{48828125}-\frac{616(x-3)^6}{1220703125}+\frac{2288(x-3)^7}{30517578125}+O\left((x-3)^8\right)\right)}{(x-3)^{\frac{9}{5}}}$$

Verified OK.

21.4.1 Maple step by step solution

Let's solve

$(x^2-x-6)\,y''+(3x+5)\,y'+y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y}{x^2-x-6}-\frac{(3x+5)y'}{x^2-x-6}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(3x+5)y'}{x^2-x-6}+\frac{y}{x^2-x-6}=0$

☐ Check to see if x_0 is a regular singular point

  ○ Define functions

  $\left[P_2(x)=\frac{3x+5}{x^2-x-6}, P_3(x)=\frac{1}{x^2-x-6}\right]$

- $(x+2) \cdot P_2(x)$ is analytic at $x=-2$

  $$\left((x+2) \cdot P_2(x)\right)\bigg|_{x=-2} = \frac{1}{5}$$

- $(x+2)^2 \cdot P_3(x)$ is analytic at $x=-2$

  $$\left((x+2)^2 \cdot P_3(x)\right)\bigg|_{x=-2} = 0$$

- $x=-2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -2$

- Multiply by denominators

  $$\left(x^2-x-6\right) y'' + (3x+5)\, y' + y = 0$$

- Change variables using $x = u-2$ so that the regular singular point is at $u=0$

  $$\left(u^2-5u\right)\left(\frac{d^2}{du^2}y(u)\right) + (3u-1)\left(\frac{d}{du}y(u)\right) + y(u) = 0$$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0 r(-4+5r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+r+1)(5k+1+5r) + a_k (k+r+1)^2\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-r(-4+5r)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{0,\frac{4}{5}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $\left(\left(-5k-5r-1\right)a_{k+1}+a_k(k+r+1)\right)\left(k+r+1\right)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k(k+r+1)}{5k+1+5r}$

- Recursion relation for $r=0$

  $a_{k+1}=\frac{a_k(k+1)}{5k+1}$

- Solution for $r=0$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{a_k(k+1)}{5k+1}\right]$

- Revert the change of variables $u=x+2$

  $\left[y=\sum_{k=0}^{\infty}a_k(x+2)^k, a_{k+1}=\frac{a_k(k+1)}{5k+1}\right]$

- Recursion relation for $r=\frac{4}{5}$

  $a_{k+1}=\frac{a_k\left(k+\frac{9}{5}\right)}{5k+5}$

- Solution for $r=\frac{4}{5}$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k+\frac{4}{5}}, a_{k+1}=\frac{a_k\left(k+\frac{9}{5}\right)}{5k+5}\right]$

- Revert the change of variables $u=x+2$

  $\left[y=\sum_{k=0}^{\infty}a_k(x+2)^{k+\frac{4}{5}}, a_{k+1}=\frac{a_k\left(k+\frac{9}{5}\right)}{5k+5}\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_k(x+2)^k\right)+\left(\sum_{k=0}^{\infty}b_k(x+2)^{k+\frac{4}{5}}\right), a_{k+1}=\frac{a_k(k+1)}{5k+1}, b_{k+1}=\frac{b_k\left(k+\frac{9}{5}\right)}{5k+5}\right]$

Section: Chapter 4. Power Series Solutions and Special Functions. Section 4.6. Gauss's Hypergeometric Equation. Page 187
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[_Gegenbauer, [_2nd_order, _linear, `_with_symmetry_[0,F(x)]`]]
```

$$\boxed{(-x^2+1)\, y'' - xy' + p^2 y = 0}$$

With the expansion point for the power series method at $x = 1$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$(-(t+1)^2+1)\left(\frac{d^2}{dt^2}y(t)\right) - (t+1)\left(\frac{d}{dt}y(t)\right) + p^2 y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the

homogeneous part of the ODE.

$$\left(-t^2-2t\right)\left(\frac{d^2}{dt^2}y(t)\right)+(-t-1)\left(\frac{d}{dt}y(t)\right)+p^2y(t)=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t)+p(t)\frac{d}{dt}y(t)+q(t)y(t)=0$$

Where

$$p(t)=\frac{t+1}{t\,(t+2)}$$
$$q(t)=-\frac{p^2}{t\,(t+2)}$$

Table 493: Table $p(t), q(t)$ singularites.

$p(t)=\frac{t+1}{t(t+2)}$	
singularity	type
$t=-2$	"regular"
$t=0$	"regular"

$q(t)=-\frac{p^2}{t(t+2)}$	
singularity	type
$t=-2$	"regular"
$t=0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-2,0,\infty]$

Irregular singular points : $[]$

Since $t=0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-\left(\frac{d^2}{dt^2}y(t)\right)t(t+2)+(-t-1)\left(\frac{d}{dt}y(t)\right)+p^2y(t)=0$$

Let the solution be represented as Frobenius power series of the form

$$y(t)=\sum_{n=0}^{\infty}a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$

$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}\right) t(t+2) + (-t-1)\left(\sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}\right) + p^2 \left(\sum_{n=0}^{\infty} a_n t^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty} \left(-t^{n+r} a_n(n+r)\,(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-2t^{n+r-1} a_n(n+r)\,(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-t^{n+r} a_n(n+r)\right) + \sum_{n=0}^{\infty} \left(-(n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} p^2 a_n t^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of t be $n+r-1$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-t^{n+r} a_n(n+r)\,(n+r-1)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\,(n+r-2)\, t^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} \left(-t^{n+r} a_n(n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, t^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} p^2 a_n t^{n+r} = \sum_{n=1}^{\infty} a_{n-1} p^2 t^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n + r - 1$.

$$\sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)(n+r-2)\, t^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-2t^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, t^{n+r-1}\right) + \sum_{n=0}^{\infty} \left(-(n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} p^2 t^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$-2t^{n+r-1} a_n (n+r)(n+r-1) - (n+r)\, a_n t^{n+r-1} = 0$$

When $n = 0$ the above becomes

$$-2t^{-1+r} a_0 r(-1+r) - r a_0 t^{-1+r} = 0$$

Or

$$\left(-2t^{-1+r} r(-1+r) - r\, t^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(-2r^2 + r\right) t^{-1+r} = 0$$

Since the above is true for all t then the indicial equation becomes

$$-2r^2 + r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(-2r^2 + r\right) t^{-1+r} = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(t) = t^{r_1} \left(\sum_{n=0}^{\infty} a_n t^n\right)$$
$$y_2(t) = t^{r_2} \left(\sum_{n=0}^{\infty} b_n t^n\right)$$

Or

$$
\begin{aligned}
y_1(t) &= \sum_{n=0}^{\infty} a_n t^{n+\frac{1}{2}} \\
y_2(t) &= \sum_{n=0}^{\infty} b_n t^n
\end{aligned}
$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
\begin{aligned}
&-a_{n-1}(n+r-1)(n+r-2) - 2a_n(n+r)(n+r-1) \\
&- a_{n-1}(n+r-1) - a_n(n+r) + a_{n-1}p^2 = 0
\end{aligned} \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = -\frac{a_{n-1}(n^2 + 2nr - p^2 + r^2 - 2n - 2r + 1)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}
$$

Which for the root $r = \frac{1}{2}$ becomes

$$
a_n = -\frac{a_{n-1}(4n^2 - 4p^2 - 4n + 1)}{8n^2 + 4n} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$
a_1 = \frac{p^2 - r^2}{2r^2 + 3r + 1}
$$

Which for the root $r = \frac{1}{2}$ becomes

$$
a_1 = \frac{p^2}{3} - \frac{1}{12}
$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3}-\frac{1}{12}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{(p^2 - r^2 - 2r - 1)(p^2 - r^2)}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = \frac{1}{30}p^4 - \frac{1}{12}p^2 + \frac{3}{160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3}-\frac{1}{12}$
a_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{(p^2 - r^2 - 4r - 4)(p^2 - r^2 - 2r - 1)(p^2 - r^2)}{8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = \frac{1}{630}p^6 - \frac{1}{72}p^4 + \frac{37}{1440}p^2 - \frac{5}{896}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3}-\frac{1}{12}$
a_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}$
a_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{1440}p^2-\frac{5}{896}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(p^2 - r^2 - 6r - 9)(p^2 - r^2 - 4r - 4)(p^2 - r^2 - 2r - 1)(p^2 - r^2)}{(8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90)(2r + 7)(r + 4)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = \frac{(4p^2 - 49)(4p^2 - 25)(4p^2 - 9)(4p^2 - 1)}{5806080}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3} - \frac{1}{12}$
a_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{30}p^4 - \frac{1}{12}p^2 + \frac{3}{160}$
a_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{1}{630}p^6 - \frac{1}{72}p^4 + \frac{37}{1440}p^2 - \frac{5}{896}$
a_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)}{5806080}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(p^2 - r^2 - 8r - 16)(p^2 - r^2 - 6r - 9)(p^2 - r^2 - 4r - 4)(p^2 - r^2 - 2r - 1)(p^2 - r^2)}{(8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90)(2r + 7)(r + 4)(r + 5)(2r + 9)}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = \frac{(4p^2 - 81)(4p^2 - 49)(4p^2 - 25)(4p^2 - 9)(4p^2 - 1)}{1277337600}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3} - \frac{1}{12}$
a_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{30}p^4 - \frac{1}{12}p^2 + \frac{3}{160}$
a_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{1}{630}p^6 - \frac{1}{72}p^4 + \frac{37}{1440}p^2 - \frac{5}{896}$
a_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)}{5806080}$
a_5	$\frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$	$\frac{(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)}{1277337600}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{(p^2 - r^2 - 10r - 25)(p^2 - r^2 - 8r - 16)(p^2 - r^2 - 6r - 9)(p^2 - r^2 - 4r - 4)(p^2 - r^2 - 2r - 1)(p^2}{(8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90)(2r + 7)(r + 4)(r + 5)(2r + 9)(2r + 11)(6 +}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = \frac{(4p^2 - 121)(4p^2 - 81)(4p^2 - 49)(4p^2 - 25)(4p^2 - 9)(4p^2 - 1)}{398529331200}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3} - \frac{1}{12}$
a_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{30}p^4 - \frac{1}{12}p^2 + \frac{3}{160}$
a_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{1}{630}p^6 - \frac{1}{72}p^4 + \frac{37}{1440}p^2 - \frac{5}{896}$
a_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)}{5806080}$
a_5	$\frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$	$\frac{(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2}{1277337600}$
a_6	$\frac{(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+r)}$	$\frac{(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4}{398529331200}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{(p^2 - r^2 - 12r - 36)(p^2 - r^2 - 10r - 25)(p^2 - r^2 - 8r - 16)(p^2 - r^2 - 6r - 9)(p^2 - r^2 - 4r - 4)(}{(8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90)(2r + 7)(r + 4)(r + 5)(2r + 9)(2r + 11)(6}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_7 = \frac{(4p^2 - 169)(4p^2 - 121)(4p^2 - 81)(4p^2 - 49)(4p^2 - 25)(4p^2 - 9)(4p^2 - 1)}{167382319104000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{p^2-r^2}{2r^2+3r+1}$	$\frac{p^2}{3}-\frac{1}{12}$
a_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}$
a_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{144}$
a_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{(4p^2-49)(4p^2-25)(4p^2}{5806080}$
a_5	$\frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$	$\frac{(4p^2-81)(4p^2-49)(4p^2}{127733}$
a_6	$\frac{(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+r)}$	$\frac{(4p^2-121)(4p^2-81)(4p}{39}$
a_7	$\frac{(p^2-r^2-12r-36)(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+r)(7+r)(2r+13)}$	$\frac{(4p^2-169)(4p^2-121)(4}{}$

Using the above table, then the solution $y_1(t)$ is

$$
\begin{aligned}
y_1(t) &= \sqrt{t}\left(a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \dots\right) \\
&= \sqrt{t}\left(1 + \left(\frac{p^2}{3} - \frac{1}{12}\right)t + \left(\frac{1}{30}p^4 - \frac{1}{12}p^2 + \frac{3}{160}\right)t^2 + \left(\frac{1}{630}p^6 - \frac{1}{72}p^4 + \frac{37}{1440}p^2 - \frac{5}{896}\right)t^3 + \frac{(4p^2
\end{aligned}
$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \le n$ the recursive equation is

$$
\begin{aligned}
&-b_{n-1}(n+r-1)(n+r-2) - 2b_n(n+r)(n+r-1) \\
&- b_{n-1}(n+r-1) - (n+r)\, b_n + b_{n-1}p^2 = 0
\end{aligned} \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = -\frac{b_{n-1}(n^2 + 2nr - p^2 + r^2 - 2n - 2r + 1)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}
$$

Which for the root $r = 0$ becomes

$$
b_n = -\frac{b_{n-1}(n^2 - p^2 - 2n + 1)}{n\,(2n-1)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{p^2 - r^2}{2r^2 + 3r + 1}$$

Which for the root $r = 0$ becomes

$$b_1 = p^2$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{(p^2 - r^2 - 2r - 1)(p^2 - r^2)}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{6}p^4 - \frac{1}{6}p^2$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2
b_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{6}p^4 - \frac{1}{6}p^2$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{(p^2 - r^2 - 4r - 4)(p^2 - r^2 - 2r - 1)(p^2 - r^2)}{8r^6 + 84r^5 + 350r^4 + 735r^3 + 812r^2 + 441r + 90}$$

Which for the root $r = 0$ becomes

$$b_3 = \frac{p^2(p^4 - 5p^2 + 4)}{90}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2
b_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{6}p^4-\frac{1}{6}p^2$
b_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{p^2(p^4-5p^2+4)}{90}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{p^2(p^6-14p^4+49p^2-36)}{2520}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2
b_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{6}p^4-\frac{1}{6}p^2$
b_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{p^2(p^4-5p^2+4)}{90}$
b_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{p^2(p^6-14p^4+49p^2-36)}{2520}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$$

Which for the root $r = 0$ becomes

$$b_5 = \frac{p^2(p^8-30p^6+273p^4-820p^2+576)}{113400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2
b_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{6}p^4-\frac{1}{6}p^2$
b_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{p^2(p^4-5p^2+4)}{90}$
b_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{p^2(p^6-14p^4+49p^2-36)}{2520}$
b_5	$\frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$	$\frac{p^2(p^8-30p^6+273p^4-820p^2+576)}{113400}$

For $n=6$, using the above recursive equation gives

$$b_6=\frac{(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+}$$

Which for the root $r=0$ becomes

$$b_6=\frac{(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2}{7484400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2
b_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{6}p^4-\frac{1}{6}p^2$
b_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{p^2(p^4-5p^2+4)}{90}$
b_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{p^2(p^6-14p^4+49p^2-36)}{2520}$
b_5	$\frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$	$\frac{p^2(p^8-30p^6+273p^4-820p^2+576)}{113400}$
b_6	$\frac{(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+r)}$	$\frac{(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2}{7484400}$

For $n=7$, using the above recursive equation gives

$$b_7=\frac{(p^2-r^2-12r-36)(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6}$$

Which for the root $r = 0$ becomes

$$b_7 = \frac{(p^2-36)(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2}{681080400}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{p^2-r^2}{2r^2+3r+1}$	p^2
b_2	$\frac{(p^2-r^2-2r-1)(p^2-r^2)}{4r^4+20r^3+35r^2+25r+6}$	$\frac{1}{6}p^4 - \frac{1}{6}p^2$
b_3	$\frac{(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{8r^6+84r^5+350r^4+735r^3+812r^2+441r+90}$	$\frac{p^2(p^4-5p^2+4)}{90}$
b_4	$\frac{(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)}$	$\frac{p^2(p^6-14p^4+49p^2-36)}{2520}$
b_5	$\frac{(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)}$	$\frac{p^2(p^8-30p^6+273p^4-820}{113400}$
b_6	$\frac{(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+r)}$	$\frac{(p^2-25)(p^2-16)(p^2-9)}{7484400}$
b_7	$\frac{(p^2-r^2-12r-36)(p^2-r^2-10r-25)(p^2-r^2-8r-16)(p^2-r^2-6r-9)(p^2-r^2-4r-4)(p^2-r^2-2r-1)(p^2-r^2)}{(8r^6+84r^5+350r^4+735r^3+812r^2+441r+90)(2r+7)(r+4)(r+5)(2r+9)(2r+11)(6+r)(7+r)(2r+13)}$	$\frac{(p^2-36)(p^2-25)(p^2-16}{6810}$

Using the above table, then the solution $y_2(t)$ is

$$\begin{aligned} y_2(t) &= b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots \\ &= 1 + p^2 t + \left(\frac{1}{6}p^4 - \frac{1}{6}p^2\right) t^2 + \frac{p^2(p^4-5p^2+4)\, t^3}{90} + \frac{p^2(p^6-14p^4+49p^2-36)\, t^4}{2520} + \frac{p^2(p^8-30p^6+}{} \end{aligned}$$

Therefore the homogeneous solution is

$$y_h(t) = c_1 y_1(t) + c_2 y_2(t)$$

$$
\begin{aligned}
&= c_1\sqrt{t}\left(1+\left(\frac{p^2}{3}-\frac{1}{12}\right)t+\left(\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}\right)t^2\right. \\
&\quad +\left(\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{1440}p^2-\frac{5}{896}\right)t^3 \\
&\quad +\frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)\,t^4}{5806080} \\
&\quad +\frac{(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)\,t^5}{1277337600} \\
&\quad +\frac{(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)\,t^6}{398529331200} \\
&\quad +\frac{(4p^2-169)(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)\,t^7}{167382319104000} \\
&\quad \left.+O(t^8)\right)+c_2\left(1+p^2t+\left(\frac{1}{6}p^4-\frac{1}{6}p^2\right)t^2+\frac{p^2(p^4-5p^2+4)\,t^3}{90}\right. \\
&\quad +\frac{p^2(p^6-14p^4+49p^2-36)\,t^4}{2520}+\frac{p^2(p^8-30p^6+273p^4-820p^2+576)\,t^5}{113400} \\
&\quad +\frac{(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)\,p^2t^6}{7484400} \\
&\quad \left.+\frac{(p^2-36)(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)\,p^2t^7}{681080400}+O(t^8)\right)
\end{aligned}
$$

Hence the final solution is

$y(t) = y_h$

$$
\begin{aligned}
&= c_1\sqrt{t}\left(1+\left(\frac{p^2}{3}-\frac{1}{12}\right)t+\left(\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}\right)t^2\right.\\
&\quad+\left(\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{1440}p^2-\frac{5}{896}\right)t^3+\frac{(4p^2-49)\,(4p^2-25)\,(4p^2-9)\,(4p^2-1)\,t^4}{5806080}\\
&\quad+\frac{(4p^2-81)\,(4p^2-49)\,(4p^2-25)\,(4p^2-9)\,(4p^2-1)\,t^5}{1277337600}\\
&\quad+\frac{(4p^2-121)\,(4p^2-81)\,(4p^2-49)\,(4p^2-25)\,(4p^2-9)\,(4p^2-1)\,t^6}{398529331200}\\
&\quad+\frac{(4p^2-169)\,(4p^2-121)\,(4p^2-81)\,(4p^2-49)\,(4p^2-25)\,(4p^2-9)\,(4p^2-1)\,t^7}{167382319104000}\\
&\quad\left.+O(t^8)\right)+c_2\left(1+p^2t+\left(\frac{1}{6}p^4-\frac{1}{6}p^2\right)t^2+\frac{p^2(p^4-5p^2+4)\,t^3}{90}\right.\\
&\quad+\frac{p^2(p^6-14p^4+49p^2-36)\,t^4}{2520}+\frac{p^2(p^8-30p^6+273p^4-820p^2+576)\,t^5}{113400}\\
&\quad+\frac{(p^2-25)\,(p^2-16)\,(p^2-9)\,(p^2-4)\,(p^2-1)\,p^2t^6}{7484400}\\
&\quad\left.+\frac{(p^2-36)\,(p^2-25)\,(p^2-16)\,(p^2-9)\,(p^2-4)\,(p^2-1)\,p^2t^7}{681080400}+O(t^8)\right)
\end{aligned}
$$

Replacing t in the above with the original independent variable $x$using $t = x-1$ results in

$$y = c_1\sqrt{x-1}\left(1+\left(\frac{p^2}{3}-\frac{1}{12}\right)(x-1)+\left(\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}\right)(x-1)^2\right.$$
$$+\left(\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{1440}p^2-\frac{5}{896}\right)(x-1)^3$$
$$+\frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^4}{5806080}$$
$$+\frac{(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^5}{1277337600}$$
$$+\frac{(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^6}{398529331200}$$
$$+\frac{(4p^2-169)(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^7}{167382319104000}$$
$$\left.+O\big((x-1)^8\big)\right)+c_2\left(1+p^2(x-1)+\left(\frac{1}{6}p^4-\frac{1}{6}p^2\right)(x-1)^2\right.$$
$$+\frac{p^2(p^4-5p^2+4)(x-1)^3}{90}+\frac{p^2(p^6-14p^4+49p^2-36)(x-1)^4}{2520}$$
$$+\frac{p^2(p^8-30p^6+273p^4-820p^2+576)(x-1)^5}{113400}$$
$$+\frac{(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2(x-1)^6}{7484400}$$
$$\left.+\frac{(p^2-36)(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2(x-1)^7}{681080400}+O\big((x-1)^8\big)\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x-1}\left(1+\left(\frac{p^2}{3}-\frac{1}{12}\right)(x-1)+\left(\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}\right)(x-1)^2 \right. \tag{1}$$
$$+\left(\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{1440}p^2-\frac{5}{896}\right)(x-1)^3$$
$$+\frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^4}{5806080}$$
$$+\frac{(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^5}{1277337600}$$
$$+\frac{(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^6}{398529331200}$$
$$+\frac{(4p^2-169)(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^7}{167382319104000}$$
$$\left.+O\left((x-1)^8\right)\right)+c_2\left(1+p^2(x-1)+\left(\frac{1}{6}p^4-\frac{1}{6}p^2\right)(x-1)^2\right.$$
$$+\frac{p^2(p^4-5p^2+4)(x-1)^3}{90}+\frac{p^2(p^6-14p^4+49p^2-36)(x-1)^4}{2520}$$

$$\left.+\frac{(p^2-36)(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2(x-1)^7}{681080400}+O\left((x-1)^8\right)\right)$$

Verification of solutions

$$y = c_1\sqrt{x-1}\left(1+\left(\frac{p^2}{3}-\frac{1}{12}\right)(x-1)+\left(\frac{1}{30}p^4-\frac{1}{12}p^2+\frac{3}{160}\right)(x-1)^2 + \left(\frac{1}{630}p^6-\frac{1}{72}p^4+\frac{37}{1440}p^2-\frac{5}{896}\right)(x-1)^3 + \frac{(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^4}{5806080} + \frac{(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^5}{1277337600} + \frac{(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^6}{398529331200} + \frac{(4p^2-169)(4p^2-121)(4p^2-81)(4p^2-49)(4p^2-25)(4p^2-9)(4p^2-1)(x-1)^7}{167382319104000} + O\left((x-1)^8\right)\right) + c_2\left(1+p^2(x-1)+\left(\frac{1}{6}p^4-\frac{1}{6}p^2\right)(x-1)^2 + \frac{p^2(p^4-5p^2+4)(x-1)^3}{90} + \frac{p^2(p^6-14p^4+49p^2-36)(x-1)^4}{2520} + \frac{p^2(p^8-30p^6+273p^4-820p^2+576)(x-1)^5}{113400} + \frac{(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2(x-1)^6}{7484400} + \frac{(p^2-36)(p^2-25)(p^2-16)(p^2-9)(p^2-4)(p^2-1)p^2(x-1)^7}{681080400} + O\left((x-1)^8\right)\right)$$

Verified OK.

21.5.1 Maple step by step solution

Let's solve

$(-x^2+1)\,y''-xy'+p^2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{xy'}{x^2-1}+\frac{p^2y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{xy'}{x^2-1}-\frac{p^2y}{x^2-1}=0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x)=\frac{x}{x^2-1}, P_3(x)=-\frac{p^2}{x^2-1}\right]$
  - $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1}=\frac{1}{2}$
  - $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$
  - $x=-1$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0=-1$
- Multiply by denominators

  $(x^2-1)\,y''+xy'-p^2y=0$
- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(u-1)\left(\frac{d}{du}y(u)\right)-p^2y(u)=0$
- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$
  - Shift index using $k->k+2-m$

$$u^{m}\cdot\left(\frac{d^{2}}{d u^{2}}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_{0}r(-1+2r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)\,(2k+1+2r)+a_{k}(k+p+r)\,(k-p+r)\right)u^{k+r}\right)$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

$$-r(-1+2r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2\left(k+\frac{1}{2}+r\right)(k+1+r)\,a_{k+1}+a_{k}(k+p+r)\,(k-p+r)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{a_{k}(k+p+r)(k-p+r)}{(2k+1+2r)(k+1+r)}$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_{k}u^{k},a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_{k}(1+x)^{k},a_{k+1}=\frac{a_{k}(k+p)(k-p)}{(2k+1)(k+1)}\right]$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+1}=\frac{a_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}$$

- Solution for $r=\frac{1}{2}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_{k}u^{k+\frac{1}{2}},a_{k+1}=\frac{a_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_{k}(1+x)^{k+\frac{1}{2}},a_{k+1}=\frac{a_{k}\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k(1+x)^k\right)+\left(\sum_{k=0}^{\infty} b_k(1+x)^{k+\frac{1}{2}}\right), a_{k+1}=\frac{a_k(k+p)(k-p)}{(2k+1)(k+1)}, b_{k+1}=\frac{b_k\left(k+p+\frac{1}{2}\right)\left(k-p+\frac{1}{2}\right)}{(2k+2)\left(k+\frac{3}{2}\right)}\right]$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(1-\mathrm{e}^{x})\,y''+\frac{y'}{2}+\mathrm{e}^{x}y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(1-\mathrm{e}^{x})\,y''+\frac{y'}{2}+\mathrm{e}^{x}y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$\begin{aligned}
p(x) &= -\frac{1}{2\,(\mathrm{e}^{x}-1)}\\
q(x) &= -\frac{\mathrm{e}^{x}}{\mathrm{e}^{x}-1}
\end{aligned}$$

Table 495: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{2(e^x-1)}$	
singularity	type
$x = 2i\pi Z$	"regular"

$q(x) = -\frac{e^x}{e^x-1}$	
singularity	type
$x = 2i\pi Z$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[2i\pi Z, 2i\pi Z]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$(1-e^x)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \frac{\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right)}{2} + e^x \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Expanding $1-e^x$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned} 1-e^x &= -x - \frac{1}{2}x^2 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 - \frac{1}{720}x^6 - \frac{1}{5040}x^7 - \frac{1}{40320}x^8 + \dots \\ &= -x - \frac{1}{2}x^2 - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{120}x^5 - \frac{1}{720}x^6 - \frac{1}{5040}x^7 - \frac{1}{40320}x^8 \end{aligned}$$

Expanding e^{x} as Taylor series around $x=0$ and keeping only the first 8 terms gives

$$\begin{aligned}
\mathrm{e}^{x} &= 1+x+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{24}x^{4}+\frac{1}{120}x^{5}+\frac{1}{720}x^{6}+\frac{1}{5040}x^{7}+\frac{1}{40320}x^{8}+\dots \\
&= 1+x+\frac{1}{2}x^{2}+\frac{1}{6}x^{3}+\frac{1}{24}x^{4}+\frac{1}{120}x^{5}+\frac{1}{720}x^{6}+\frac{1}{5040}x^{7}+\frac{1}{40320}x^{8}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
&\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+6}a_{n}(n+r)(n+r-1)}{40320}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+5}a_{n}(n+r)(n+r-1)}{5040}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+4}a_{n}(n+r)(n+r-1)}{720}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+3}a_{n}(n+r)(n+r-1)}{120}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+2}a_{n}(n+r)(n+r-1)}{24}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{x^{1+n+r}a_{n}(n+r)(n+r-1)}{6}\right) \\
&+\sum_{n=0}^{\infty}\left(-\frac{x^{n+r}a_{n}(n+r)(n+r-1)}{2}\right) \\
&+\sum_{n=0}^{\infty}\left(-x^{n+r-1}a_{n}(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty}\frac{(n+r)\,a_{n}x^{n+r-1}}{2}\right) \\
&+\left(\sum_{n=0}^{\infty}a_{n}x^{n+r}\right)+\left(\sum_{n=0}^{\infty}x^{1+n+r}a_{n}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+2}a_{n}}{2}\right) \\
&+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+3}a_{n}}{6}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+4}a_{n}}{24}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+5}a_{n}}{120}\right) \\
&+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+6}a_{n}}{720}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+7}a_{n}}{5040}\right)+\left(\sum_{n=0}^{\infty}\frac{x^{n+r+8}a_{n}}{40320}\right)=0
\end{aligned} \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+6}a_n(n+r)(n+r-1)}{40320}\right)=\sum_{n=7}^{\infty}\left(-\frac{a_{n-7}(n+r-7)(n+r-8)x^{n+r-1}}{40320}\right)$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+5}a_n(n+r)(n+r-1)}{5040}\right)=\sum_{n=6}^{\infty}\left(-\frac{a_{n-6}(n+r-6)(n+r-7)x^{n+r-1}}{5040}\right)$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+4}a_n(n+r)(n+r-1)}{720}\right)=\sum_{n=5}^{\infty}\left(-\frac{a_{n-5}(-5+n+r)(n+r-6)x^{n+r-1}}{720}\right)$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+3}a_n(n+r)(n+r-1)}{120}\right)=\sum_{n=4}^{\infty}\left(-\frac{a_{n-4}(n+r-4)(-5+n+r)x^{n+r-1}}{120}\right)$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+r+2}a_n(n+r)(n+r-1)}{24}\right)=\sum_{n=3}^{\infty}\left(-\frac{a_{n-3}(n+r-3)(n+r-4)x^{n+r-1}}{24}\right)$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{1+n+r}a_n(n+r)(n+r-1)}{6}\right)=\sum_{n=2}^{\infty}\left(-\frac{a_{n-2}(n+r-2)(n+r-3)x^{n+r-1}}{6}\right)$$

$$\sum_{n=0}^{\infty}\left(-\frac{x^{n+r}a_n(n+r)(n+r-1)}{2}\right)=\sum_{n=1}^{\infty}\left(-\frac{a_{n-1}(n+r-1)(n+r-2)x^{n+r-1}}{2}\right)$$

$$\sum_{n=0}^{\infty}a_nx^{n+r}=\sum_{n=1}^{\infty}a_{n-1}x^{n+r-1}$$

$$\sum_{n=0}^{\infty}x^{1+n+r}a_n=\sum_{n=2}^{\infty}a_{n-2}x^{n+r-1}$$

$$\sum_{n=0}^{\infty}\frac{x^{n+r+2}a_n}{2}=\sum_{n=3}^{\infty}\frac{a_{n-3}x^{n+r-1}}{2}$$

$$\sum_{n=0}^{\infty}\frac{x^{n+r+3}a_n}{6}=\sum_{n=4}^{\infty}\frac{a_{n-4}x^{n+r-1}}{6}$$

$$\sum_{n=0}^{\infty}\frac{x^{n+r+4}a_n}{24}=\sum_{n=5}^{\infty}\frac{a_{n-5}x^{n+r-1}}{24}$$

$$\sum_{n=0}^{\infty}\frac{x^{n+r+5}a_n}{120}=\sum_{n=6}^{\infty}\frac{a_{n-6}x^{n+r-1}}{120}$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+6} a_n}{720} = \sum_{n=7}^{\infty} \frac{a_{n-7} x^{n+r-1}}{720}$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+7} a_n}{5040} = \sum_{n=8}^{\infty} \frac{a_{n-8} x^{n+r-1}}{5040}$$

$$\sum_{n=0}^{\infty} \frac{x^{n+r+8} a_n}{40320} = \sum_{n=9}^{\infty} \frac{a_{n-9} x^{n+r-1}}{40320}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\sum_{n=7}^{\infty} \left(-\frac{a_{n-7}(n+r-7)(n+r-8)\, x^{n+r-1}}{40320}\right) + \sum_{n=6}^{\infty} \left(-\frac{a_{n-6}(n+r-6)(n+r-7)\, x^{n+r-1}}{5040}\right) + \sum_{n=5}^{\infty} \left(-\frac{a_{n-5}(-5+n+r)(n+r-6)\, x^{n+r-1}}{720}\right) + \sum_{n=4}^{\infty} \left(-\frac{a_{n-4}(n+r-4)(-5+n+r)\, x^{n+r-1}}{120}\right) + \sum_{n=3}^{\infty} \left(-\frac{a_{n-3}(n+r-3)(n+r-4)\, x^{n+r-1}}{24}\right) + \sum_{n=2}^{\infty} \left(-\frac{a_{n-2}(n+r-2)(n+r-3)\, x^{n+r-1}}{6}\right) + \sum_{n=1}^{\infty} \left(-\frac{a_{n-1}(n+r-1)(n+r-2)\, x^{n+r-1}}{2}\right) + \sum_{n=0}^{\infty} \left(-x^{n+r-1} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} \frac{(n+r)\, a_n x^{n+r-1}}{2}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}\right) + \left(\sum_{n=3}^{\infty} \frac{a_{n-3} x^{n+r-1}}{2}\right) + \left(\sum_{n=4}^{\infty} \frac{a_{n-4} x^{n+r-1}}{6}\right) + \left(\sum_{n=5}^{\infty} \frac{a_{n-5} x^{n+r-1}}{24}\right) + \left(\sum_{n=6}^{\infty} \frac{a_{n-6} x^{n+r-1}}{120}\right) + \left(\sum_{n=7}^{\infty} \frac{a_{n-7} x^{n+r-1}}{720}\right) + \left(\sum_{n=8}^{\infty} \frac{a_{n-8} x^{n+r-1}}{5040}\right) + \left(\sum_{n=9}^{\infty} \frac{a_{n-9} x^{n+r-1}}{40320}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$-x^{n+r-1} a_n(n+r)(n+r-1) + \frac{(n+r)\, a_n x^{n+r-1}}{2} = 0$$

When $n=0$ the above becomes

$$-x^{-1+r} a_0 r(-1+r) + \frac{r a_0 x^{-1+r}}{2} = 0$$

Or

$$\left(-x^{-1+r} r(-1+r)+\frac{r\,x^{-1+r}}{2}\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\,x^{-1+r}\left(\frac{3}{2}-r\right)=0$$

Since the above is true for all x then the indicial equation becomes

$$-r^2+\frac{3}{2} r=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= \frac{3}{2} \\ r_2 &= 0 \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\,x^{-1+r}\left(\frac{3}{2}-r\right)=0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{3}{2}$ is not an integer, then we can construct two linearly independent solutions

$$\begin{aligned} y_1(x) &= x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right) \\ y_2(x) &= x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right) \end{aligned}$$

Or

$$\begin{aligned} y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+\frac{3}{2}} \\ y_2(x) &= \sum_{n=0}^{\infty} b_n x^n \end{aligned}$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. Substituting $n=1$ in Eq. (2B) gives

$$a_1=\frac{-r+2}{2r-1}$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = \frac{r^2 - 2r + 3}{12r^2 - 3}$$

Substituting $n = 3$ in Eq. (2B) gives

$$a_3 = \frac{-4r^2 + 5r + 12}{96r^3 + 144r^2 - 24r - 36}$$

Substituting $n = 4$ in Eq. (2B) gives

$$a_4 = \frac{-4r^4 + 24r^3 - 44r^2 + 39r + 225}{2880r^4 + 11520r^3 + 10080r^2 - 2880r - 2700}$$

Substituting $n = 5$ in Eq. (2B) gives

$$a_5 = \frac{8r^4 - 6r^3 - 158r^2 + 291r + 630}{360\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)}$$

Substituting $n = 6$ in Eq. (2B) gives

$$a_6 = \frac{32r^6 - 96r^5 + 224r^4 + 948r^3 - 8311r^2 + 16653r + 39690}{15120\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)\left(2r + 9\right)}$$

Substituting $n = 7$ in Eq. (2B) gives

$$a_7 = \frac{-128r^6 - 864r^5 + 2944r^4 - 1176r^3 - 51308r^2 + 125943r + 249480}{60480\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)\left(2r + 9\right)\left(2r + 11\right)}$$

Substituting $n = 8$ in Eq. (2B) gives

$$a_8 = \frac{224r^9 + 4128r^8 + 28272r^7 + 70968r^6 + 47004r^5 + 213042r^4 - 779417r^3 - 3196848r^2 + 15434577r +}{453600\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)\left(2r + 9\right)\left(2r + 11\right)\left(2r^2 + 29r + 104\right)}$$

For $9 \leq n$ the recursive equation is

$$\begin{aligned}
&-\frac{a_{n-7}(n + r - 7)\left(n + r - 8\right)}{40320} - \frac{a_{n-6}(n + r - 6)\left(n + r - 7\right)}{5040} \\
&- \frac{a_{n-5}(-5 + n + r)\left(n + r - 6\right)}{720} - \frac{a_{n-4}(n + r - 4)\left(-5 + n + r\right)}{120} \\
&- \frac{a_{n-3}(n + r - 3)\left(n + r - 4\right)}{24} - \frac{a_{n-2}(n + r - 2)\left(n + r - 3\right)}{6} \\
&- \frac{a_{n-1}(n + r - 1)\left(n + r - 2\right)}{2} - a_n(n + r)\left(n + r - 1\right) + \frac{a_n(n + r)}{2} + a_{n-1} \\
&+ a_{n-2} + \frac{a_{n-3}}{2} + \frac{a_{n-4}}{6} + \frac{a_{n-5}}{24} + \frac{a_{n-6}}{120} + \frac{a_{n-7}}{720} + \frac{a_{n-8}}{5040} + \frac{a_{n-9}}{40320} = 0
\end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{n^2 a_{n-7} + 8n^2 a_{n-6} + 56n^2 a_{n-5} + 336n^2 a_{n-4} + 1680n^2 a_{n-3} + 6720n^2 a_{n-2} + 20160n^2 a_{n-1} + 2nra_{n-}}{} \tag{4}$$

Which for the root $r = \frac{3}{2}$ becomes

$$a_n = \frac{(-80640a_{n-1} - 4a_{n-7} - 32a_{n-6} - 224a_{n-5} - 1344a_{n-4} - 6720a_{n-3} - 26880a_{n-2})\, n^2 + (48a_{n-7} + 32}{} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{3}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r+2}{2r-1}$	$\frac{1}{4}$
a_2	$\frac{r^2-2r+3}{12r^2-3}$	$\frac{3}{32}$
a_3	$\frac{-4r^2+5r+12}{96r^3+144r^2-24r-36}$	$\frac{7}{384}$
a_4	$\frac{-4r^4+24r^3-44r^2+39r+225}{2880r^4+11520r^3+10080r^2-2880r-2700}$	$\frac{109}{30720}$
a_5	$\frac{8r^4-6r^3-158r^2+291r+630}{360(16r^4+64r^3+56r^2-16r-15)(2r+7)}$	$\frac{13}{24576}$
a_6	$\frac{32r^6-96r^5+224r^4+948r^3-8311r^2+16653r+39690}{15120(16r^4+64r^3+56r^2-16r-15)(2r+7)(2r+9)}$	$\frac{4439}{61931520}$
a_7	$\frac{-128r^6-864r^5+2944r^4-1176r^3-51308r^2+125943r+249480}{60480(16r^4+64r^3+56r^2-16r-15)(2r+7)(2r+9)(2r+11)}$	$\frac{2069}{247726080}$
a_8	$\frac{224r^9+4128r^8+28272r^7+70968r^6+47004r^5+213042r^4-779417r^3-3196848r^2+15434577r+24324300}{453600(16r^4+64r^3+56r^2-16r-15)(2r+7)(2r+9)(2r+11)(2r^2+29r+104)}$	$\frac{685613}{753087283200}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^{\frac{3}{2}}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= x^{\frac{3}{2}}\left(1 + \frac{x}{4} + \frac{3x^2}{32} + \frac{7x^3}{384} + \frac{109x^4}{30720} + \frac{13x^5}{24576} + \frac{4439x^6}{61931520} + \frac{2069x^7}{247726080} + \frac{685613x^8}{753087283200} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$b_1 = \frac{-r+2}{2r-1}$$

Substituting $n = 2$ in Eq. (2B) gives

$$b_2 = \frac{r^2 - 2r + 3}{12r^2 - 3}$$

Substituting $n = 3$ in Eq. (2B) gives

$$b_3 = \frac{-4r^2 + 5r + 12}{96r^3 + 144r^2 - 24r - 36}$$

Substituting $n = 4$ in Eq. (2B) gives

$$b_4 = \frac{-4r^4 + 24r^3 - 44r^2 + 39r + 225}{2880r^4 + 11520r^3 + 10080r^2 - 2880r - 2700}$$

Substituting $n = 5$ in Eq. (2B) gives

$$b_5 = \frac{8r^4 - 6r^3 - 158r^2 + 291r + 630}{360\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)}$$

Substituting $n = 6$ in Eq. (2B) gives

$$b_6 = \frac{32r^6 - 96r^5 + 224r^4 + 948r^3 - 8311r^2 + 16653r + 39690}{15120\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)\left(2r + 9\right)}$$

Substituting $n = 7$ in Eq. (2B) gives

$$b_7 = \frac{-128r^6 - 864r^5 + 2944r^4 - 1176r^3 - 51308r^2 + 125943r + 249480}{60480\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)\left(2r + 9\right)\left(2r + 11\right)}$$

Substituting $n = 8$ in Eq. (2B) gives

$$b_8 = \frac{224r^9 + 4128r^8 + 28272r^7 + 70968r^6 + 47004r^5 + 213042r^4 - 779417r^3 - 3196848r^2 + 15434577r +}{453600\left(16r^4 + 64r^3 + 56r^2 - 16r - 15\right)\left(2r + 7\right)\left(2r + 9\right)\left(2r + 11\right)\left(2r^2 + 29r + 104\right)}$$

For $9 \leq n$ the recursive equation is

$$\begin{aligned}
&-\frac{b_{n-7}(n + r - 7)\left(n + r - 8\right)}{40320} - \frac{b_{n-6}(n + r - 6)\left(n + r - 7\right)}{5040} \\
&- \frac{b_{n-5}(-5 + n + r)\left(n + r - 6\right)}{720} - \frac{b_{n-4}(n + r - 4)\left(-5 + n + r\right)}{120} \\
&- \frac{b_{n-3}(n + r - 3)\left(n + r - 4\right)}{24} - \frac{b_{n-2}(n + r - 2)\left(n + r - 3\right)}{6} \\
&- \frac{b_{n-1}(n + r - 1)\left(n + r - 2\right)}{2} - b_n(n + r)\left(n + r - 1\right) + \frac{\left(n + r\right)b_n}{2} \\
&+ b_{n-1} + b_{n-2} + \frac{b_{n-3}}{2} + \frac{b_{n-4}}{6} + \frac{b_{n-5}}{24} + \frac{b_{n-6}}{120} + \frac{b_{n-7}}{720} + \frac{b_{n-8}}{5040} + \frac{b_{n-9}}{40320} = 0
\end{aligned} \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = -\frac{n^2 b_{n-7} + 8n^2 b_{n-6} + 56n^2 b_{n-5} + 336n^2 b_{n-4} + 1680n^2 b_{n-3} + 6720n^2 b_{n-2} + 20160n^2 b_{n-1} + 2nrb_{n-7} +}{} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = \frac{(-20160b_{n-1} - b_{n-7} - 8b_{n-6} - 56b_{n-5} - 336b_{n-4} - 1680b_{n-3} - 6720b_{n-2})\, n^2 + (60480b_{n-1} + 15b_{n-7}}{40320n^2 - 60480n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-r+2}{2r-1}$	-2
b_2	$\frac{r^2-2r+3}{12r^2-3}$	-1
b_3	$\frac{-4r^2+5r+12}{96r^3+144r^2-24r-36}$	$-\frac{1}{3}$
b_4	$\frac{-4r^4+24r^3-44r^2+39r+225}{2880r^4+11520r^3+10080r^2-2880r-2700}$	$-\frac{1}{12}$
b_5	$\frac{8r^4-6r^3-158r^2+291r+630}{360(16r^4+64r^3+56r^2-16r-15)(2r+7)}$	$-\frac{1}{60}$
b_6	$\frac{32r^6-96r^5+224r^4+948r^3-8311r^2+16653r+39690}{15120(16r^4+64r^3+56r^2-16r-15)(2r+7)(2r+9)}$	$-\frac{1}{360}$
b_7	$\frac{-128r^6-864r^5+2944r^4-1176r^3-51308r^2+125943r+249480}{60480(16r^4+64r^3+56r^2-16r-15)(2r+7)(2r+9)(2r+11)}$	$-\frac{1}{2520}$
b_8	$\frac{224r^9+4128r^8+28272r^7+70968r^6+47004r^5+213042r^4-779417r^3-3196848r^2+15434577r+24324300}{453600(16r^4+64r^3+56r^2-16r-15)(2r+7)(2r+9)(2r+11)(2r^2+29r+104)}$	$-\frac{1}{20160}$

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\ &= 1 - 2x - x^2 - \frac{x^3}{3} - \frac{x^4}{12} - \frac{x^5}{60} - \frac{x^6}{360} - \frac{x^7}{2520} - \frac{x^8}{20160} + O(x^8) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^{\frac{3}{2}} \left(1 + \frac{x}{4} + \frac{3x^2}{32} + \frac{7x^3}{384} + \frac{109x^4}{30720} + \frac{13x^5}{24576} + \frac{4439x^6}{61931520} + \frac{2069x^7}{247726080} + \frac{685613x^8}{753087283200} \right. \\ &\quad \left. + O(x^8)\right) + c_2 \left(1 - 2x - x^2 - \frac{x^3}{3} - \frac{x^4}{12} - \frac{x^5}{60} - \frac{x^6}{360} - \frac{x^7}{2520} - \frac{x^8}{20160} + O(x^8)\right) \end{aligned}$$

Hence the final solution is

$$y = y_h$$
$$= c_1 x^{\frac{3}{2}} \left(1+\frac{x}{4}+\frac{3x^2}{32}+\frac{7x^3}{384}+\frac{109x^4}{30720}+\frac{13x^5}{24576}+\frac{4439x^6}{61931520}+\frac{2069x^7}{247726080}+\frac{685613x^8}{753087283200}+O(x^8)\right)+c_2\left(1-2x-x^2-\frac{x^3}{3}-\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{360}-\frac{x^7}{2520}-\frac{x^8}{20160}+O(x^8)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{3}{2}} \left(1+\frac{x}{4}+\frac{3x^2}{32}+\frac{7x^3}{384}+\frac{109x^4}{30720}+\frac{13x^5}{24576}+\frac{4439x^6}{61931520}+\frac{2069x^7}{247726080}+\frac{685613x^8}{753087283200}+O(x^8)(1)\right)+c_2\left(1-2x-x^2-\frac{x^3}{3}-\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{360}-\frac{x^7}{2520}-\frac{x^8}{20160}+O(x^8)\right)$$

Verification of solutions

$$y = c_1 x^{\frac{3}{2}} \left(1+\frac{x}{4}+\frac{3x^2}{32}+\frac{7x^3}{384}+\frac{109x^4}{30720}+\frac{13x^5}{24576}+\frac{4439x^6}{61931520}+\frac{2069x^7}{247726080}+\frac{685613x^8}{753087283200}+O(x^8)\right)+c_2\left(1-2x-x^2-\frac{x^3}{3}-\frac{x^4}{12}-\frac{x^5}{60}-\frac{x^6}{360}-\frac{x^7}{2520}-\frac{x^8}{20160}+O(x^8)\right)$$

Verified OK.

Problem number: 1(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_airy", "second_order_bessel_ode", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 2xy = x^2}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{723}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{724}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -2xy + x^2 \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= -2xy' - 2y + 2x \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= 4yx^2 - 2x^3 - 4y' + 2 \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= 4x\left(xy' - \frac{5x}{2} + 4y\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= -8yx^3 + 4x^4 + 24xy' + 16y - 20x \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= -8y'x^3 - 72yx^2 + 40x^3 + 40y' - 20 \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= -8x\left(-2yx^3 + x^4 + 12xy' + 28y - 20x\right)
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 0 \\
F_1 &= -2y(0) \\
F_2 &= -4y'(0) + 2 \\
F_3 &= 0 \\
F_4 &= 16y(0) \\
F_5 &= 40y'(0) - 20 \\
F_6 &= 0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - \frac{1}{3}x^3 + \frac{1}{45}x^6\right) y(0) + \left(x - \frac{1}{6}x^4 + \frac{1}{126}x^7\right) y'(0) + \frac{x^4}{12} - \frac{x^7}{252} + O(x^8)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = -2x \left(\sum_{n=0}^{\infty} a_n x^n\right) + x^2 \tag{1}
$$

Expanding x^2 as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$
\begin{aligned}
x^2 &= x^2 + \dots \\
&= x^2
\end{aligned}
$$

Hence the ODE in Eq (1) becomes

$$
\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + 2x \left(\sum_{n=0}^{\infty} a_n x^n\right) = x^2
$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=0}^{\infty} 2x^{1+n} a_n\right) = x^2 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n$$

$$\sum_{n=0}^{\infty} 2x^{1+n} a_n = \sum_{n=1}^{\infty} 2a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(1+n)\, x^n\right) + \left(\sum_{n=1}^{\infty} 2a_{n-1} x^n\right) = x^2 \tag{3}$$

For $1 \leq n$, the recurrence equation is

$$\left((n+2)\, a_{n+2}(1+n) + 2a_{n-1}\right) x^n = x^2 \tag{4}$$

For $n = 1$ the recurrence equation gives

$$(6a_3 + 2a_0)\, x = 0$$
$$6a_3 + 2a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_0}{3}$$

For $n = 2$ the recurrence equation gives

$$(12a_4 + 2a_1)\, x^2 = x^2$$
$$12a_4 + 2a_1 = 1$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{12} - \frac{a_1}{6}$$

For $n = 3$ the recurrence equation gives

$$\left(20a_5 + 2a_2\right) x^3 = 0$$
$$20a_5 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$\left(30a_6 + 2a_3\right) x^4 = 0$$
$$30a_6 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{45}$$

For $n = 5$ the recurrence equation gives

$$\left(42a_7 + 2a_4\right) x^5 = 0$$
$$42a_7 + 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{1}{252} + \frac{a_1}{126}$$

For $n = 6$ the recurrence equation gives

$$\left(56a_8 + 2a_5\right) x^6 = 0$$
$$56a_8 + 2a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = 0$$

For $n = 7$ the recurrence equation gives

$$\begin{aligned}(72a_9 + 2a_6)\, x^7 &= 0\\ 72a_9 + 2a_6 &= 0\end{aligned}$$

Which after substituting the earlier terms found becomes

$$a_9 = -\frac{a_0}{1620}$$

And so on. Therefore the solution is

$$\begin{aligned}y &= \sum_{n=0}^{\infty} a_n x^n\\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots\end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{a_0 x^3}{3} + \left(\frac{1}{12} - \frac{a_1}{6}\right) x^4 + \frac{a_0 x^6}{45} + \left(-\frac{1}{252} + \frac{a_1}{126}\right) x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{3}x^3 + \frac{1}{45}x^6\right) a_0 + \left(x - \frac{1}{6}x^4 + \frac{1}{126}x^7\right) a_1 + \frac{x^4}{12} - \frac{x^7}{252} + O(x^8) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{3}x^3 + \frac{1}{45}x^6\right) c_1 + \left(x - \frac{1}{6}x^4 + \frac{1}{126}x^7\right) c_2 + \frac{x^4}{12} - \frac{x^7}{252} + O(x^8)$$

Summary

The solution(s) found are the following

$$y = \left(1 - \frac{1}{3}x^3 + \frac{1}{45}x^6\right) y(0) + \left(x - \frac{1}{6}x^4 + \frac{1}{126}x^7\right) y'(0) + \frac{x^4}{12} - \frac{x^7}{252} + O(x^8) \tag{1}$$

$$y = \left(1 - \frac{1}{3}x^3 + \frac{1}{45}x^6\right) c_1 + \left(x - \frac{1}{6}x^4 + \frac{1}{126}x^7\right) c_2 + \frac{x^4}{12} - \frac{x^7}{252} + O(x^8) \tag{2}$$

Verification of solutions

$$y=\left(1-\frac{1}{3}x^{3}+\frac{1}{45}x^{6}\right)y(0)+\left(x-\frac{1}{6}x^{4}+\frac{1}{126}x^{7}\right)y'(0)+\frac{x^{4}}{12}-\frac{x^{7}}{252}+O\left(x^{8}\right)$$

Verified OK.

$$y=\left(1-\frac{1}{3}x^{3}+\frac{1}{45}x^{6}\right)c_{1}+\left(x-\frac{1}{6}x^{4}+\frac{1}{126}x^{7}\right)c_{2}+\frac{x^{4}}{12}-\frac{x^{7}}{252}+O\left(x^{8}\right)$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 1(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_2", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' - xy' + y = x}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (726) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (727) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= xy' - y + x \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= x^2 y' - xy + x^2 + 1 \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(x^3 + x\right) y' + x^3 - yx^2 + 2x - y \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= y'x^4 - yx^3 + x^4 + 3x^2 y' - 3xy + 4x^2 + 2 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(x^5 + 6x^3 + 3x\right) y' + \left(-x^4 - 6x^2 - 3\right) y + x^5 + 7x^3 + 8x \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(x^6 + 10x^4 + 15x^2\right) y' + \left(-x^5 - 10x^3 - 15x\right) y + x^6 + 11x^4 + 24x^2 + 8 \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(x^7 + 15x^5 + 45x^3 + 15x\right) y' + \left(-x^6 - 15x^4 - 45x^2 - 15\right) y + x^7 + 16x^5 + 59x^3 + 48x
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and

$y'(0) = y'(0)$ gives

$$\begin{aligned} F_0 &= -y(0) \\ F_1 &= 1 \\ F_2 &= -y(0) \\ F_3 &= 2 \\ F_4 &= -3y(0) \\ F_5 &= 8 \\ F_6 &= -15y(0) \end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{24}x^4 - \frac{1}{240}x^6 - \frac{1}{2688}x^8\right) y(0) + xy'(0) + \frac{x^3}{6} + \frac{x^5}{60} + \frac{x^7}{630} + O(x^8)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$\begin{aligned} y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\ y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} \end{aligned}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) + x \tag{1}$$

Expanding x as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned} x &= x + \dots \\ &= x \end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) - x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \sum_{n=1}^{\infty} (-n\, x^n a_n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$((n+2) a_{n+2}(n+1) - n a_n + a_n) x^n = x \tag{4}$$

For $n = 1$ the recurrence equation gives

$$(6a_3) x = x$$
$$6a_3 = 1$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{1}{6}$$

For $n = 2$ the recurrence equation gives

$$
\begin{aligned}
(12a_4 - a_2) x^2 &= 0 \\
12a_4 - a_2 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_4 = -\frac{a_0}{24}
$$

For $n = 3$ the recurrence equation gives

$$
\begin{aligned}
(20a_5 - 2a_3) x^3 &= 0 \\
20a_5 - 2a_3 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_5 = \frac{1}{60}
$$

For $n = 4$ the recurrence equation gives

$$
\begin{aligned}
(30a_6 - 3a_4) x^4 &= 0 \\
30a_6 - 3a_4 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_6 = -\frac{a_0}{240}
$$

For $n = 5$ the recurrence equation gives

$$
\begin{aligned}
(42a_7 - 4a_5) x^5 &= 0 \\
42a_7 - 4a_5 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_7 = \frac{1}{630}
$$

For $n = 6$ the recurrence equation gives

$$(56a_8 - 5a_6)\,x^6 = 0$$
$$56a_8 - 5a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = -\frac{a_0}{2688}$$

For $n = 7$ the recurrence equation gives

$$(72a_9 - 6a_7)\,x^7 = 0$$
$$72a_9 - 6a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{1}{7560}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 + \frac{1}{6} x^3 - \frac{1}{24} a_0 x^4 + \frac{1}{60} x^5 - \frac{1}{240} a_0 x^6 + \frac{1}{630} x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2} x^2 - \frac{1}{24} x^4 - \frac{1}{240} x^6\right) a_0 + a_1 x + \frac{x^3}{6} + \frac{x^5}{60} + \frac{x^7}{630} + O(x^8) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2} x^2 - \frac{1}{24} x^4 - \frac{1}{240} x^6\right) c_1 + c_2 x + \frac{x^3}{6} + \frac{x^5}{60} + \frac{x^7}{630} + O(x^8)$$

Summary

The solution(s) found are the following

$$y = \left(1-\frac{1}{2}x^2-\frac{1}{24}x^4-\frac{1}{240}x^6-\frac{1}{2688}x^8\right)y(0)+xy'(0)+\frac{x^3}{6}+\frac{x^5}{60}+\frac{x^7}{630}+O(x^8) \tag{1}$$

$$y = \left(1-\frac{1}{2}x^2-\frac{1}{24}x^4-\frac{1}{240}x^6\right)c_1+c_2x+\frac{x^3}{6}+\frac{x^5}{60}+\frac{x^7}{630}+O(x^8) \tag{2}$$

Verification of solutions

$$y = \left(1-\frac{1}{2}x^2-\frac{1}{24}x^4-\frac{1}{240}x^6-\frac{1}{2688}x^8\right)y(0)+xy'(0)+\frac{x^3}{6}+\frac{x^5}{60}+\frac{x^7}{630}+O(x^8)$$

Verified OK.

$$y = \left(1-\frac{1}{2}x^2-\frac{1}{24}x^4-\frac{1}{240}x^6\right)c_1+c_2x+\frac{x^3}{6}+\frac{x^5}{60}+\frac{x^7}{630}+O(x^8)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_linear_constant_coeff", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + y' + y = x^3 - x}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (729) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (730) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -y' - y + x^3 - x \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= y - x^3 + x + 3x^2 - 1 \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= y' - 3x^2 + 1 + 6x \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= -y' - y + x^3 - 7x + 6 \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= y - x^3 + x + 3x^2 - 7 \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= y' - 3x^2 + 1 + 6x \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= -y' - y + x^3 - 7x + 6
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$\begin{aligned}
F_0 &= -y'(0) - y(0) \\
F_1 &= y(0) - 1 \\
F_2 &= y'(0) + 1 \\
F_3 &= -y(0) - y'(0) + 6 \\
F_4 &= y(0) - 7 \\
F_5 &= y'(0) + 1 \\
F_6 &= -y(0) - y'(0) + 6
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$\begin{aligned}
y = &\left(1 - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{40320}x^8\right) y(0) \\
&+ \left(x - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{5040}x^7 - \frac{1}{40320}x^8\right) y'(0) \\
&- \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{20} - \frac{7x^6}{720} + \frac{x^7}{5040} + \frac{x^8}{6720} + O(x^8)
\end{aligned}$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}$$

Substituting the above back into the ode gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) - \left(\sum_{n=0}^{\infty} a_n x^n\right) + x^3 - x \tag{1}$$

Expanding $x^3 - x$ as Taylor series around $x = 0$ and keeping only the first 8 terms gives

$$\begin{aligned}
x^3 - x &= x^3 - x + \dots \\
&= x^3 - x
\end{aligned}$$

Hence the ODE in Eq (1) becomes

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x^3 - x$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x^3 - x \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

$$\sum_{n=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1)\, a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=0}^{\infty} (n+1)\, a_{n+1} x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = x^3 - x \tag{3}$$

For $0 \leq n$, the recurrence equation is

$$((n+2)\, a_{n+2}(n+1) + (n+1)\, a_{n+1} + a_n)\, x^n = x^3 - x \tag{4}$$

For $n = 0$ the recurrence equation gives

$$(2a_2 + a_1 + a_0)\, 1 = 0$$
$$2a_2 + a_1 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_2 = -\frac{a_1}{2} - \frac{a_0}{2}$$

For $n = 1$ the recurrence equation gives

$$\left(6a_3 + 2a_2 + a_1\right) x = -x$$
$$6a_3 + 2a_2 + a_1 = -1$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{1}{6} + \frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$\left(12a_4 + 3a_3 + a_2\right) x^2 = 0$$
$$12a_4 + 3a_3 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{1}{24} + \frac{a_1}{24}$$

For $n = 3$ the recurrence equation gives

$$\left(20a_5 + 4a_4 + a_3\right) x^3 = x^3$$
$$20a_5 + 4a_4 + a_3 = 1$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{1}{20} - \frac{a_1}{120} - \frac{a_0}{120}$$

For $n = 4$ the recurrence equation gives

$$\left(30a_6 + 5a_5 + a_4\right) x^4 = 0$$
$$30a_6 + 5a_5 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{7}{720} + \frac{a_0}{720}$$

For $n = 5$ the recurrence equation gives

$$
\begin{aligned}
(42a_7 + 6a_6 + a_5)\, x^5 &= 0 \\
42a_7 + 6a_6 + a_5 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_7 = \frac{1}{5040} + \frac{a_1}{5040}
$$

For $n = 6$ the recurrence equation gives

$$
\begin{aligned}
(56a_8 + 7a_7 + a_6)\, x^6 &= 0 \\
56a_8 + 7a_7 + a_6 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_8 = \frac{1}{6720} - \frac{a_1}{40320} - \frac{a_0}{40320}
$$

For $n = 7$ the recurrence equation gives

$$
\begin{aligned}
(72a_9 + 8a_8 + a_7)\, x^7 &= 0 \\
72a_9 + 8a_8 + a_7 &= 0
\end{aligned}
$$

Which after substituting the earlier terms found becomes

$$
a_9 = -\frac{1}{51840} + \frac{a_0}{362880}
$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
\begin{aligned}
y = a_0 + a_1 x + \left(-\frac{a_1}{2} - \frac{a_0}{2}\right) x^2 + \left(-\frac{1}{6} + \frac{a_0}{6}\right) x^3 + \left(\frac{1}{24} + \frac{a_1}{24}\right) x^4 \\
+ \left(\frac{1}{20} - \frac{a_1}{120} - \frac{a_0}{120}\right) x^5 + \left(-\frac{7}{720} + \frac{a_0}{720}\right) x^6 + \left(\frac{1}{5040} + \frac{a_1}{5040}\right) x^7 + \dots
\end{aligned}
$$

Collecting terms, the solution becomes

$$y = \left(1-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{120}x^5+\frac{1}{720}x^6\right)a_0+\left(x-\frac{1}{2}x^2+\frac{1}{24}x^4-\frac{1}{120}x^5+\frac{1}{5040}x^7\right)a_1 \tag{3}$$
$$-\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{20}-\frac{7x^6}{720}+\frac{x^7}{5040}+O(x^8)$$

At $x = 0$ the solution above becomes

$$y = \left(1-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{120}x^5+\frac{1}{720}x^6\right)c_1+\left(x-\frac{1}{2}x^2+\frac{1}{24}x^4-\frac{1}{120}x^5+\frac{1}{5040}x^7\right)c_2$$
$$-\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{20}-\frac{7x^6}{720}+\frac{x^7}{5040}+O(x^8)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & \left(1-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{120}x^5+\frac{1}{720}x^6-\frac{1}{40320}x^8\right)y(0) \\ & +\left(x-\frac{1}{2}x^2+\frac{1}{24}x^4-\frac{1}{120}x^5+\frac{1}{5040}x^7-\frac{1}{40320}x^8\right)y'(0) \\ & -\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{20}-\frac{7x^6}{720}+\frac{x^7}{5040}+\frac{x^8}{6720}+O(x^8) \end{aligned} \tag{1}$$

$$\begin{aligned} y = {} & \left(1-\frac{1}{2}x^2+\frac{1}{6}x^3-\frac{1}{120}x^5+\frac{1}{720}x^6\right)c_1+\left(x-\frac{1}{2}x^2+\frac{1}{24}x^4-\frac{1}{120}x^5+\frac{1}{5040}x^7\right)c_2 \\ & -\frac{x^3}{6}+\frac{x^4}{24}+\frac{x^5}{20}-\frac{7x^6}{720}+\frac{x^7}{5040}+O(x^8) \end{aligned} \tag{2}$$

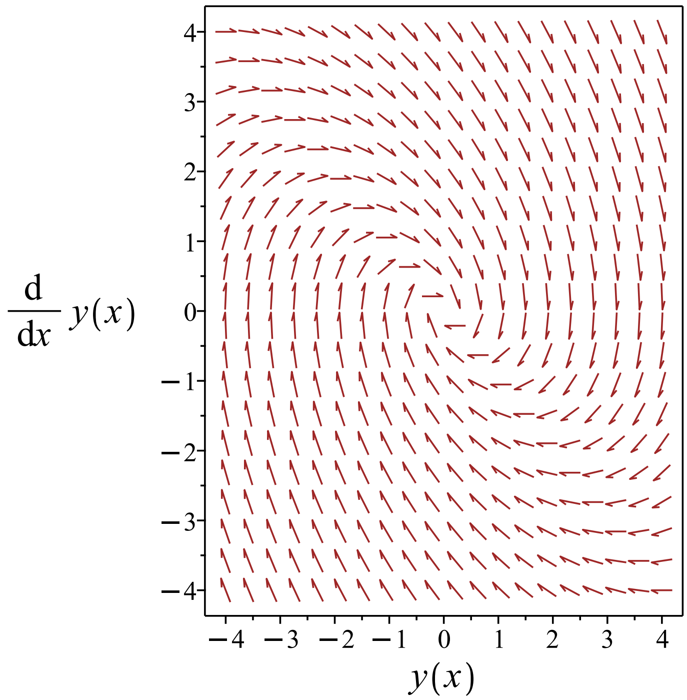

Figure 473: Slope field plot

Verification of solutions

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{720}x^6 - \frac{1}{40320}x^8\right)y(0) + \left(x - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{5040}x^7 - \frac{1}{40320}x^8\right)y'(0) - \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{20} - \frac{7x^6}{720} + \frac{x^7}{5040} + \frac{x^8}{6720} + O(x^8)$$

Verified OK.

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{6}x^3 - \frac{1}{120}x^5 + \frac{1}{720}x^6\right)c_1 + \left(x - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{120}x^5 + \frac{1}{5040}x^7\right)c_2 - \frac{x^3}{6} + \frac{x^4}{24} + \frac{x^5}{20} - \frac{7x^6}{720} + \frac{x^7}{5040} + O(x^8)$$

Verified OK.

22.3.1 Maple step by step solution

Let's solve

$y'' = -y' - y + x^3 - x$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + y' + y = x^3 - x$

- Characteristic polynomial of homogeneous ODE

  $r^2 + r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1)\pm(\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - \frac{I\sqrt{3}}{2}, -\frac{1}{2} + \frac{I\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = x^3 - x\right]$

- ○ Wronskian of solutions of the homogeneous equation

$$W(y_1(x), y_2(x)) = \begin{bmatrix} e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) & e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) \\ -\frac{e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)}{2} - \frac{e^{-\frac{x}{2}}\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} & -\frac{e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)}{2} + \frac{e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)\sqrt{3}}{2} \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = \frac{\sqrt{3}\,e^{-x}}{2}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -\frac{2\sqrt{3}\,e^{-\frac{x}{2}}\left(\cos\left(\frac{\sqrt{3}\,x}{2}\right)\left(\int (x^3-x)\,e^{\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right)dx\right) - \sin\left(\frac{\sqrt{3}\,x}{2}\right)\left(\int (x^3-x)\,e^{\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right)dx\right)\right)}{3}$$

- Compute integrals

  $$y_p(x) = x^3 - 3x^2 - x + 7$$

- Substitute particular solution into general solution to ODE

  $$y = e^{-\frac{x}{2}} \cos\left(\frac{\sqrt{3}\,x}{2}\right) c_1 + e^{-\frac{x}{2}} \sin\left(\frac{\sqrt{3}\,x}{2}\right) c_2 + x^3 - 3x^2 - x + 7$$

Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 1(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{2y'' + xy' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using

Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\ &= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y_0'} \end{aligned}$$

But

$$\begin{aligned} \frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (732) \\ &= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (733) \\ \frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\ &= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\ \frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\ &= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\ &\vdots \end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{xy'}{2} - \frac{y}{2} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{x^2 y'}{4} + \frac{xy}{4} - y' \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-x^3 + 10x)\, y'}{8} + \frac{(-x^2 + 6)\, y}{8} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(x^4 - 18x^2 + 32)\, y'}{16} + \frac{yx(x^2 - 14)}{16} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-x^5 + 28x^3 - 132x)\, y'}{32} - \frac{y(x^4 - 24x^2 + 60)}{32} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{(x^6 - 40x^4 + 348x^2 - 384)\, y'}{64} + \frac{yx(x^4 - 36x^2 + 228)}{64} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \frac{(-x^7 + 54x^5 - 740x^3 + 2232x)\, y'}{128} - \frac{y(x^2 - 14)\,(x^4 - 36x^2 + 60)}{128}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -\frac{y(0)}{2} \\
F_1 &= -y'(0) \\
F_2 &= \frac{3y(0)}{4} \\
F_3 &= 2y'(0) \\
F_4 &= -\frac{15y(0)}{8} \\
F_5 &= -6y'(0) \\
F_6 &= \frac{105y(0)}{16}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1-\frac{1}{4}x^2+\frac{1}{32}x^4-\frac{1}{384}x^6+\frac{1}{6144}x^8\right)y(0)+\left(x-\frac{1}{6}x^3+\frac{1}{60}x^5-\frac{1}{840}x^7\right)y'(0)+O\left(x^8\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = -\frac{x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)}{2} - \frac{\left(\sum_{n=0}^{\infty} a_n x^n\right)}{2} \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} 2n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} 2n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} 2(n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=0}^{\infty} 2(n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=1}^{\infty} n\, x^n a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$4a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{4}$$

For $1 \leq n$, the recurrence equation is

$$2(n+2)\, a_{n+2}(n+1) + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n}{2\,(n+2)} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$12a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_1}{6}$$

For $n = 2$ the recurrence equation gives

$$24a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{32}$$

For $n = 3$ the recurrence equation gives

$$40a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{60}$$

For $n = 4$ the recurrence equation gives

$$60a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{384}$$

For $n = 5$ the recurrence equation gives

$$84a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{a_1}{840}$$

For $n = 6$ the recurrence equation gives

$$112a_8 + 7a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{a_0}{6144}$$

For $n = 7$ the recurrence equation gives

$$144a_9 + 8a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{a_1}{15120}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - \frac{1}{4} a_0 x^2 - \frac{1}{6} a_1 x^3 + \frac{1}{32} a_0 x^4 + \frac{1}{60} a_1 x^5 - \frac{1}{384} a_0 x^6 - \frac{1}{840} a_1 x^7 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6\right) a_0 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{840}x^7\right) a_1 + O(x^8) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6\right) c_1 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{840}x^7\right) c_2 + O(x^8)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &\left(1 - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6 + \frac{1}{6144}x^8\right) y(0) \\ &+ \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{840}x^7\right) y'(0) + O(x^8) \end{aligned} \quad (1)$$

$$y = \left(1 - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6\right) c_1 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{840}x^7\right) c_2 + O(x^8) \quad (2)$$

Verification of solutions

$$y = \left(1 - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6 + \frac{1}{6144}x^8\right) y(0) + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{840}x^7\right) y'(0) + O(x^8)$$

Verified OK.

$$y = \left(1 - \frac{1}{4}x^2 + \frac{1}{32}x^4 - \frac{1}{384}x^6\right) c_1 + \left(x - \frac{1}{6}x^3 + \frac{1}{60}x^5 - \frac{1}{840}x^7\right) c_2 + O(x^8)$$

Verified OK.

22.4.1 Maple step by step solution

Let's solve

$y'' = -\frac{xy'}{2} - \frac{y}{2}$

- Highest derivative means the order of the ODE is 2

y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{xy'}{2} + \frac{y}{2} = 0$

- Multiply by denominators

$2y'' + xy' + y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$

  ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- > k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite DE with series expansions

$\sum_{k=0}^{\infty} (2a_{k+2}(k+2)\,(k+1) + a_k(k+1))\, x^k = 0$

- Each term in the series must be 0, giving the recursion relation

$(k+1)\,(2ka_{k+2} + a_k + 4a_{k+2}) = 0$

- Recursion relation that defines the series solution to the ODE

$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k}{2(k+2)}\right]$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 1(e).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+4)\, y''-y'+y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\, y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy'_0+\frac{x^2}{2}\, f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}\, f'|_{x_0,y_0,y'_0}+\cdots \\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\, \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{735}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{736}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{-y'+y}{x^2+4}\\
F_1 &= \frac{dF_0}{dx}\\
&= \frac{\partial F_0}{\partial x}+\frac{\partial F_0}{\partial y}y'+\frac{\partial F_0}{\partial y'}F_0\\
&= \frac{\left(-x^2-2x-3\right)y'+\left(2x-1\right)y}{\left(x^2+4\right)^2}\\
F_2 &= \frac{dF_1}{dx}\\
&= \frac{\partial F_1}{\partial x}+\frac{\partial F_1}{\partial y}y'+\frac{\partial F_1}{\partial y'}F_1\\
&= \frac{\left(4x^3+4x^2+10x-15\right)y'-5yx^2+6xy+11y}{\left(x^2+4\right)^3}\\
F_3 &= \frac{dF_2}{dx}\\
&= \frac{\partial F_2}{\partial x}+\frac{\partial F_2}{\partial y}y'+\frac{\partial F_2}{\partial y'}F_2\\
&= \frac{\left(-17x^4-6x^3-7x^2+156x+69\right)y'+16y\left(x^3-\frac{17}{8}x^2-\frac{29}{4}x+\frac{39}{16}\right)}{\left(x^2+4\right)^4}\\
F_4 &= \frac{dF_3}{dx}\\
&= \frac{\partial F_3}{\partial x}+\frac{\partial F_3}{\partial y}y'+\frac{\partial F_3}{\partial y'}F_3\\
&= \frac{\left(84x^5-21x^4-288x^3-1268x^2-916x+849\right)y'-63\left(x^4-\frac{10}{3}x^3-\frac{337}{21}x^2+\frac{740}{63}x+\frac{533}{63}\right)y}{\left(x^2+4\right)^5}\\
F_5 &= \frac{dF_4}{dx}\\
&= \frac{\partial F_4}{\partial x}+\frac{\partial F_4}{\partial y}y'+\frac{\partial F_4}{\partial y'}F_4\\
&= \frac{\left(-483x^6+420x^5+4434x^4+9620x^3+7031x^2-22510x-4947\right)y'+294y\left(x^5-\frac{69}{14}x^4-\frac{1468}{49}x^3+\right.}{\left(x^2+4\right)^6}\\
F_6 &= \frac{dF_5}{dx}\\
&= \frac{\partial F_5}{\partial x}+\frac{\partial F_5}{\partial y}y'+\frac{\partial F_5}{\partial y'}F_5\\
&= \frac{\left(3192x^7-4872x^6-54276x^5-69094x^4-10644x^3+408064x^2+150438x-110223\right)y'-1575y\left(x^6\right.}{\left(x^2+4\right)^7}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= \frac{y'(0)}{4} - \frac{y(0)}{4} \\
F_1 &= -\frac{y(0)}{16} - \frac{3y'(0)}{16} \\
F_2 &= \frac{11y(0)}{64} - \frac{15y'(0)}{64} \\
F_3 &= \frac{39y(0)}{256} + \frac{69y'(0)}{256} \\
F_4 &= -\frac{533y(0)}{1024} + \frac{849y'(0)}{1024} \\
F_5 &= -\frac{3809y(0)}{4096} - \frac{4947y'(0)}{4096} \\
F_6 &= \frac{62283y(0)}{16384} - \frac{110223y'(0)}{16384}
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = {} & \left(1 - \frac{1}{8}x^2 - \frac{1}{96}x^3 + \frac{11}{1536}x^4 + \frac{13}{10240}x^5 - \frac{533}{737280}x^6 - \frac{3809}{20643840}x^7 \right. \\
& \left. + \frac{20761}{220200960}x^8\right) y(0) + \left(x + \frac{1}{8}x^2 - \frac{1}{32}x^3 - \frac{5}{512}x^4 + \frac{23}{10240}x^5 + \frac{283}{245760}x^6 \right. \\
& \left. - \frac{1649}{6881280}x^7 - \frac{12247}{73400320}x^8\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(x^2 + 4)\, y'' - y' + y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$(x^2+4)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) - \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} 4n(n-1)\,a_n x^{n-2}\right) + \sum_{n=1}^{\infty} \left(-n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} 4n(n-1)\,a_n x^{n-2} = \sum_{n=0}^{\infty} 4(n+2)\,a_{n+2}(n+1)\,x^n$$

$$\sum_{n=1}^{\infty} \left(-n a_n x^{n-1}\right) = \sum_{n=0}^{\infty} \left(-(n+1)\,a_{n+1} x^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{gathered}\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} 4(n+2)\,a_{n+2}(n+1)\,x^n\right) \\ + \sum_{n=0}^{\infty} \left(-(n+1)\,a_{n+1} x^n\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0\end{gathered} \tag{3}$$

$n=0$ gives

$$8a_2 - a_1 + a_0 = 0$$

$$a_2 = -\frac{a_0}{8} + \frac{a_1}{8}$$

$n=1$ gives

$$24a_3 - 2a_2 + a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_0}{96} - \frac{a_1}{32}$$

For $2 \leq n$, the recurrence equation is

$$n a_n (n-1) + 4(n+2)\, a_{n+2}(n+1) - (n+1)\, a_{n+1} + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_n - n a_n - n a_{n+1} + a_n - a_{n+1}}{4\,(n+2)\,(n+1)} \\ &= -\frac{(n^2 - n + 1)\, a_n}{4\,(n+2)\,(n+1)} - \frac{(-n-1)\, a_{n+1}}{4\,(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$3a_2 + 48a_4 - 3a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{11a_0}{1536} - \frac{5a_1}{512}$$

For $n = 3$ the recurrence equation gives

$$7a_3 + 80a_5 - 4a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{13a_0}{10240} + \frac{23a_1}{10240}$$

For $n = 4$ the recurrence equation gives

$$13a_4 + 120a_6 - 5a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{533a_0}{737280} + \frac{283a_1}{245760}$$

For $n = 5$ the recurrence equation gives

$$21a_5 + 168a_7 - 6a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{3809a_0}{20643840} - \frac{1649a_1}{6881280}$$

For $n = 6$ the recurrence equation gives

$$31a_6 + 224a_8 - 7a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{20761a_0}{220200960} - \frac{12247a_1}{73400320}$$

For $n = 7$ the recurrence equation gives

$$43a_7 + 288a_9 - 8a_8 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{717431a_0}{23781703680} + \frac{246887a_1}{7927234560}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1x &+ \left(-\frac{a_0}{8} + \frac{a_1}{8}\right)x^2 + \left(-\frac{a_0}{96} - \frac{a_1}{32}\right)x^3 \\ &+ \left(\frac{11a_0}{1536} - \frac{5a_1}{512}\right)x^4 + \left(\frac{13a_0}{10240} + \frac{23a_1}{10240}\right)x^5 \\ &+ \left(-\frac{533a_0}{737280} + \frac{283a_1}{245760}\right)x^6 + \left(-\frac{3809a_0}{20643840} - \frac{1649a_1}{6881280}\right)x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{8}x^2 - \frac{1}{96}x^3 + \frac{11}{1536}x^4 + \frac{13}{10240}x^5 - \frac{533}{737280}x^6 - \frac{3809}{20643840}x^7\right) a_0 + \left(x + \frac{1}{8}x^2 - \frac{1}{32}x^3 - \frac{5}{512}x^4 + \frac{23}{10240}x^5 + \frac{283}{245760}x^6 - \frac{1649}{6881280}x^7\right) a_1 + O(x^8) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{8}x^2 - \frac{1}{96}x^3 + \frac{11}{1536}x^4 + \frac{13}{10240}x^5 - \frac{533}{737280}x^6 - \frac{3809}{20643840}x^7\right) c_1 + \left(x + \frac{1}{8}x^2 - \frac{1}{32}x^3 - \frac{5}{512}x^4 + \frac{23}{10240}x^5 + \frac{283}{245760}x^6 - \frac{1649}{6881280}x^7\right) c_2 + O(x^8)$$

Summary

The solution(s) found are the following

$$y = \left(1 - \frac{1}{8}x^2 - \frac{1}{96}x^3 + \frac{11}{1536}x^4 + \frac{13}{10240}x^5 - \frac{533}{737280}x^6 - \frac{3809}{20643840}x^7 + \frac{20761}{220200960}x^8\right) y(0) + \left(x + \frac{1}{8}x^2 - \frac{1}{32}x^3 - \frac{5}{512}x^4 + \frac{23}{10240}x^5 + \frac{283}{245760}x^6 - \frac{1649}{6881280}x^7 - \frac{12247}{73400320}x^8\right) y'(0) + O(x^8) \tag{1}$$

$$y = \left(1 - \frac{1}{8}x^2 - \frac{1}{96}x^3 + \frac{11}{1536}x^4 + \frac{13}{10240}x^5 - \frac{533}{737280}x^6 - \frac{3809}{20643840}x^7\right) c_1 + \left(x + \frac{1}{8}x^2 - \frac{1}{32}x^3 - \frac{5}{512}x^4 + \frac{23}{10240}x^5 + \frac{283}{245760}x^6 - \frac{1649}{6881280}x^7\right) c_2 + O(x^8) \tag{2}$$

Verification of solutions

$$y = \left(1-\frac{1}{8}x^2-\frac{1}{96}x^3+\frac{11}{1536}x^4+\frac{13}{10240}x^5-\frac{533}{737280}x^6-\frac{3809}{20643840}x^7+\frac{20761}{220200960}x^8\right)y(0)+\left(x+\frac{1}{8}x^2-\frac{1}{32}x^3-\frac{5}{512}x^4+\frac{23}{10240}x^5+\frac{283}{245760}x^6-\frac{1649}{6881280}x^7-\frac{12247}{73400320}x^8\right)y'(0)+O(x^8)$$

Verified OK.

$$y = \left(1-\frac{1}{8}x^2-\frac{1}{96}x^3+\frac{11}{1536}x^4+\frac{13}{10240}x^5-\frac{533}{737280}x^6-\frac{3809}{20643840}x^7\right)c_1+\left(x+\frac{1}{8}x^2-\frac{1}{32}x^3-\frac{5}{512}x^4+\frac{23}{10240}x^5+\frac{283}{245760}x^6-\frac{1649}{6881280}x^7\right)c_2+O(x^8)$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 1(f).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_2", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\,y''-xy'+y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0,y_0,y_0'} + \frac{x^3}{3!} f'|_{x_0,y_0,y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \left.\frac{d^n f}{dx^n}\right|_{x_0,y_0,y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (738) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (739) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{-y + xy'}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= -\frac{(-y + xy')\, x}{(x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-y + xy')\,(2x^2-1)}{(x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= -\frac{6\left(x^2-\frac{3}{2}\right)(-y + xy')\, x}{(x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{24\left(x^4-3x^2+\frac{3}{8}\right)(-y + xy')}{(x^2+1)^5} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= -\frac{120(-y + xy')\, x\left(x^4-5x^2+\frac{15}{8}\right)}{(x^2+1)^6} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \frac{45(-y + xy')\,(16x^6-120x^4+90x^2-5)}{(x^2+1)^7}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y(0) \\
F_1 &= 0 \\
F_2 &= y(0) \\
F_3 &= 0 \\
F_4 &= -9y(0) \\
F_5 &= 0 \\
F_6 &= 225y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6 + \frac{5}{896}x^8\right) y(0) + xy'(0) + O(x^8)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x^2 + 1) y'' - xy' + y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$(x^2 + 1)\left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) - x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-n a_n x^n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=1}^{\infty} (-n a_n x^n) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $2 \leq n$, the recurrence equation is

$$n a_n (n-1) + (n+2)\, a_{n+2}(n+1) - n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n(n^2 - 2n + 1)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$4a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$9a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{a_0}{80}$$

For $n = 5$ the recurrence equation gives

$$16a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

For $n = 6$ the recurrence equation gives

$$25a_6 + 56a_8 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{5a_0}{896}$$

For $n = 7$ the recurrence equation gives

$$36a_7 + 72a_9 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = 0$$

And so on. Therefore the solution is

$$
\begin{aligned}
y &= \sum_{n=0}^{\infty} a_n x^n \\
&= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y = a_0 + a_1 x - \frac{1}{2} a_0 x^2 + \frac{1}{24} a_0 x^4 - \frac{1}{80} a_0 x^6 + \dots
$$

Collecting terms, the solution becomes

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6\right) a_0 + a_1 x + O(x^8) \tag{3}
$$

At $x = 0$ the solution above becomes

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6\right) c_1 + c_2 x + O(x^8)
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6 + \frac{5}{896}x^8\right) y(0) + x y'(0) + O(x^8) \tag{1}
$$

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6\right) c_1 + c_2 x + O(x^8) \tag{2}
$$

<u>Verification of solutions</u>

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6 + \frac{5}{896}x^8\right) y(0) + x y'(0) + O(x^8)
$$

Verified OK.

$$
y = \left(1 - \frac{1}{2}x^2 + \frac{1}{24}x^4 - \frac{1}{80}x^6\right) c_1 + c_2 x + O(x^8)
$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - (1 + x) y' - xy = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0) y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n + 2)!} \left.\frac{d^n f}{dx^n}\right|_{x_0, y_0, y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} &(1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' &(741)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f &(742)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f &(2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f &(3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= xy' + xy + y' \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \left(x^2 + 3x + 2\right) y' + y\left(x^2 + x + 1\right) \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \left(x^3 + 5x^2 + 8x + 6\right) y' + y\left(x^3 + 3x^2 + 4x + 1\right) \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \left(x^4 + 7x^3 + 19x^2 + 28x + 15\right) y' + y(x + 2) \left(x^3 + 3x^2 + 5x + 2\right) \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \left(x^5 + 9x^4 + 35x^3 + 79x^2 + 93x + 47\right) y' + y\left(x^5 + 7x^4 + 23x^3 + 43x^2 + 37x + 12\right) \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \left(x^6 + 11x^5 + 56x^4 + 173x^3 + 320x^2 + 335x + 152\right) y' + y\left(x^6 + 9x^5 + 40x^4 + 107x^3 + 162x^2 + 133x \right. \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \left(x^7 + 13x^6 + 82x^5 + 324x^4 + 824x^3 + 1336x^2 + 1260x + 524\right) y' + y\left(x^7 + 11x^6 + 62x^5 + 218x^4 + 4\right.
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y'(0) \\
F_1 &= 2y'(0) + y(0) \\
F_2 &= 6y'(0) + y(0) \\
F_3 &= 15y'(0) + 4y(0) \\
F_4 &= 47y'(0) + 12y(0) \\
F_5 &= 152y'(0) + 37y(0) \\
F_6 &= 524y'(0) + 133y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{30}x^5 + \frac{1}{60}x^6 + \frac{37}{5040}x^7 + \frac{19}{5760}x^8\right) y(0) \\
&+ \left(x + \frac{1}{2}x^2 + \frac{1}{3}x^3 + \frac{1}{4}x^4 + \frac{1}{8}x^5 + \frac{47}{720}x^6 + \frac{19}{630}x^7 + \frac{131}{10080}x^8\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = x\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + x\left(\sum_{n=0}^{\infty} a_n x^n\right) + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) \tag{1}
$$

Which simplifies to

$$
\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=1}^{\infty} \left(-n a_n x^{n-1}\right) + \sum_{n=1}^{\infty} \left(-n a_n x^n\right) + \sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) = 0 \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} &= \sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n \\
\sum_{n=1}^{\infty} \left(-n a_n x^{n-1}\right) &= \sum_{n=0}^{\infty} \left(-(1+n) a_{1+n} x^n\right) \\
\sum_{n=0}^{\infty} \left(-x^{1+n} a_n\right) &= \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right)
\end{aligned}
$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n\right) + \sum_{n=0}^{\infty} \left(-(1+n) a_{1+n} x^n\right) \\
&+ \sum_{n=1}^{\infty} \left(-n a_n x^n\right) + \sum_{n=1}^{\infty} \left(-a_{n-1} x^n\right) = 0
\end{aligned} \tag{3}
$$

$n = 0$ gives

$$
2a_2 - a_1 = 0
$$

$$
a_2 = \frac{a_1}{2}
$$

For $1 \leq n$, the recurrence equation is

$$
(n+2) a_{n+2}(1+n) - (1+n) a_{1+n} - n a_n - a_{n-1} = 0 \tag{4}
$$

Solving for a_{n+2}, gives

$$
\begin{aligned}
a_{n+2} &= \frac{n a_n + n a_{1+n} + a_{1+n} + a_{n-1}}{(n+2)(1+n)} \\
&= \frac{n a_n}{(n+2)(1+n)} + \frac{a_{1+n}}{n+2} + \frac{a_{n-1}}{(n+2)(1+n)}
\end{aligned} \tag{5}
$$

For $n = 1$ the recurrence equation gives

$$6a_3 - 2a_2 - a_1 - a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_1}{3} + \frac{a_0}{6}$$

For $n = 2$ the recurrence equation gives

$$12a_4 - 3a_3 - 2a_2 - a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_1}{4} + \frac{a_0}{24}$$

For $n = 3$ the recurrence equation gives

$$20a_5 - 4a_4 - 3a_3 - a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{8} + \frac{a_0}{30}$$

For $n = 4$ the recurrence equation gives

$$30a_6 - 5a_5 - 4a_4 - a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{47a_1}{720} + \frac{a_0}{60}$$

For $n = 5$ the recurrence equation gives

$$42a_7 - 6a_6 - 5a_5 - a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{19a_1}{630} + \frac{37a_0}{5040}$$

For $n = 6$ the recurrence equation gives

$$56a_8 - 7a_7 - 6a_6 - a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{131a_1}{10080} + \frac{19a_0}{5760}$$

For $n = 7$ the recurrence equation gives

$$72a_9 - 8a_8 - 7a_7 - a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{71a_1}{13440} + \frac{17a_0}{12960}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x + \frac{a_1 x^2}{2} + \left(\frac{a_1}{3} + \frac{a_0}{6}\right) x^3 + \left(\frac{a_1}{4} + \frac{a_0}{24}\right) x^4 \\ + \left(\frac{a_1}{8} + \frac{a_0}{30}\right) x^5 + \left(\frac{47a_1}{720} + \frac{a_0}{60}\right) x^6 + \left(\frac{19a_1}{630} + \frac{37a_0}{5040}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$\begin{aligned} y = \left(1 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{30}x^5 + \frac{1}{60}x^6 + \frac{37}{5040}x^7\right) a_0 \\ + \left(x + \frac{1}{2}x^2 + \frac{1}{3}x^3 + \frac{1}{4}x^4 + \frac{1}{8}x^5 + \frac{47}{720}x^6 + \frac{19}{630}x^7\right) a_1 + O(x^8) \end{aligned} \tag{3}$$

At $x = 0$ the solution above becomes

$$\begin{aligned} y = \left(1 + \frac{1}{6}x^3 + \frac{1}{24}x^4 + \frac{1}{30}x^5 + \frac{1}{60}x^6 + \frac{37}{5040}x^7\right) c_1 \\ + \left(x + \frac{1}{2}x^2 + \frac{1}{3}x^3 + \frac{1}{4}x^4 + \frac{1}{8}x^5 + \frac{47}{720}x^6 + \frac{19}{630}x^7\right) c_2 + O(x^8) \end{aligned}$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{6}x^{3}+\frac{1}{24}x^{4}+\frac{1}{30}x^{5}+\frac{1}{60}x^{6}+\frac{37}{5040}x^{7}+\frac{19}{5760}x^{8}\right) y(0) \\
& + \left(x+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{1}{4}x^{4}+\frac{1}{8}x^{5}+\frac{47}{720}x^{6}+\frac{19}{630}x^{7}+\frac{131}{10080}x^{8}\right) y'(0)+O\left(x^{8}\right)
\end{aligned} \tag{1}
$$

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{6}x^{3}+\frac{1}{24}x^{4}+\frac{1}{30}x^{5}+\frac{1}{60}x^{6}+\frac{37}{5040}x^{7}\right) c_{1} \\
& + \left(x+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{1}{4}x^{4}+\frac{1}{8}x^{5}+\frac{47}{720}x^{6}+\frac{19}{630}x^{7}\right) c_{2}+O\left(x^{8}\right)
\end{aligned} \tag{2}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{6}x^{3}+\frac{1}{24}x^{4}+\frac{1}{30}x^{5}+\frac{1}{60}x^{6}+\frac{37}{5040}x^{7}+\frac{19}{5760}x^{8}\right) y(0) \\
& + \left(x+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{1}{4}x^{4}+\frac{1}{8}x^{5}+\frac{47}{720}x^{6}+\frac{19}{630}x^{7}+\frac{131}{10080}x^{8}\right) y'(0)+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{6}x^{3}+\frac{1}{24}x^{4}+\frac{1}{30}x^{5}+\frac{1}{60}x^{6}+\frac{37}{5040}x^{7}\right) c_{1} \\
& + \left(x+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{1}{4}x^{4}+\frac{1}{8}x^{5}+\frac{47}{720}x^{6}+\frac{19}{630}x^{7}\right) c_{2}+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

22.7.1 Maple step by step solution

Let's solve

$y'' = xy' + xy + y'$

- Highest derivative means the order of the ODE is 2

  y''

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (-1 - x)\, y' - xy = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- Convert $x \cdot y$ to series expansion

  $$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+1}$$

- Shift index using $k- >k - 1$

  $$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^k$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $$x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$$

- Convert y'' to series expansion

  $$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k + 2$

  $$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

  Rewrite ODE with series expansions

  $$2a_2 - a_1 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a_{k+1}(k+1) - a_k k - a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

  $$2a_2 - a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$k^2 a_{k+2} + (-a_k - a_{k+1} + 3a_{k+2})\, k - a_{k-1} - a_{k+1} + 2a_{k+2} = 0$$

- Shift index using $k- >k + 1$

  $$(k+1)^2 a_{k+3} + (-a_{k+1} - a_{k+2} + 3a_{k+3})\,(k+1) - a_k - a_{k+2} + 2a_{k+3} = 0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = \frac{a_{k+1}k + k a_{k+2} + a_k + a_{k+1} + 2a_{k+2}}{k^2+5k+6}, 2a_2 - a_1 = 0\right]$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 1(h).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is", "second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_1", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x-1)\,y''+(1+x)\,y'+y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (744) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (745) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{xy' + y' + y}{x - 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(x^2 + x + 4)\, y' + (x + 2)\, y}{(x - 1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-x^3 - x^2 - 7x - 15)\, y' - y(x^2 + 2x + 9)}{(x - 1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(x^4 + x^3 + 11x^2 + 31x + 76)\, y' + y(x^3 + 2x^2 + 13x + 44)}{(x - 1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-x^5 - x^4 - 16x^3 - 56x^2 - 191x - 455)\, y' - y(x^4 + 2x^3 + 18x^2 + 74x + 265)}{(x - 1)^5} \\
F_5 &= \frac{dF_4}{dx} \\
&= \frac{\partial F_4}{\partial x} + \frac{\partial F_4}{\partial y} y' + \frac{\partial F_4}{\partial y'} F_4 \\
&= \frac{(x^6 + x^5 + 22x^4 + 92x^3 + 407x^2 + 1331x + 3186)\, y' + y(x^5 + 2x^4 + 24x^3 + 116x^2 + 523x + 1854)}{(x - 1)^6} \\
F_6 &= \frac{dF_5}{dx} \\
&= \frac{\partial F_5}{\partial x} + \frac{\partial F_5}{\partial y} y' + \frac{\partial F_5}{\partial y'} F_5 \\
&= \frac{(-x^7 - x^6 - 29x^5 - 141x^4 - 771x^3 - 3235x^2 - 10655x - 25487)\, y' - y(x^6 + 2x^5 + 31x^4 + 172x^3 +}{(x - 1)^7}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) + y'(0) \\
F_1 &= 2y(0) + 4y'(0) \\
F_2 &= 9y(0) + 15y'(0) \\
F_3 &= 44y(0) + 76y'(0) \\
F_4 &= 265y(0) + 455y'(0) \\
F_5 &= 1854y(0) + 3186y'(0) \\
F_6 &= 14833y(0) + 25487y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1 + \frac{1}{2}x^2 + \frac{1}{3}x^3 + \frac{3}{8}x^4 + \frac{11}{30}x^5 + \frac{53}{144}x^6 + \frac{103}{280}x^7 + \frac{2119}{5760}x^8\right) y(0) \\
&+ \left(x + \frac{1}{2}x^2 + \frac{2}{3}x^3 + \frac{5}{8}x^4 + \frac{19}{30}x^5 + \frac{91}{144}x^6 + \frac{177}{280}x^7 + \frac{3641}{5760}x^8\right) y'(0) + O(x^8)
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(x - 1)\, y'' + (1 + x)\, y' + y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^n
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_n x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(x - 1)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + (1 + x)\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \quad (1)
$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\, x^{n-1} a_n (n-1)\right)+\sum_{n\,=2}^{\infty} \left(-n (n-1)\, a_n x^{n-2}\right) \\ + \left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)+\left(\sum_{n=1}^{\infty} n a_n x^n\right)+\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n\,=2}^{\infty} n\, x^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, x^n$$

$$\sum_{n\,=2}^{\infty} \left(-n (n-1)\, a_n x^{n-2}\right) = \sum_{n=0}^{\infty} \left(-(n+2)\, a_{n+2} (n+1)\, x^n\right)$$

$$\sum_{n\,=1}^{\infty} n a_n x^{n-1} = \sum_{n=0}^{\infty} (n+1)\, a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, x^n\right)+\sum_{n\,=0}^{\infty} \left(-(n+2)\, a_{n+2} (n+1)\, x^n\right) \\ + \left(\sum_{n=0}^{\infty} (n+1)\, a_{n+1} x^n\right)+\left(\sum_{n=1}^{\infty} n a_n x^n\right)+\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$-2 a_2 + a_1 + a_0 = 0$$

$$a_2 = \frac{a_0}{2} + \frac{a_1}{2}$$

For $1 \leq n$, the recurrence equation is

$$(n+1)\, a_{n+1} n - (n+2)\, a_{n+2} (n+1) + (n+1)\, a_{n+1} + n a_n + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{n a_{n+1} + a_n + a_{n+1}}{n+2}$$

(5)

$$= \frac{a_n}{n+2} + \frac{(n+1)\, a_{n+1}}{n+2}$$

For $n = 1$ the recurrence equation gives

$$4a_2 - 6a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_0}{3} + \frac{2a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$9a_3 - 12a_4 + 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{3a_0}{8} + \frac{5a_1}{8}$$

For $n = 3$ the recurrence equation gives

$$16a_4 - 20a_5 + 4a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{11a_0}{30} + \frac{19a_1}{30}$$

For $n = 4$ the recurrence equation gives

$$25a_5 - 30a_6 + 5a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{53a_0}{144} + \frac{91a_1}{144}$$

For $n = 5$ the recurrence equation gives

$$36a_6 - 42a_7 + 6a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{103a_0}{280} + \frac{177a_1}{280}$$

For $n = 6$ the recurrence equation gives

$$49a_7 - 56a_8 + 7a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_8 = \frac{2119a_0}{5760} + \frac{3641a_1}{5760}$$

For $n = 7$ the recurrence equation gives

$$64a_8 - 72a_9 + 8a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_9 = \frac{16687a_0}{45360} + \frac{28673a_1}{45360}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y = a_0 + a_1 x + \left(\frac{a_0}{2} + \frac{a_1}{2}\right) x^2 + \left(\frac{a_0}{3} + \frac{2a_1}{3}\right) x^3 + \left(\frac{3a_0}{8} + \frac{5a_1}{8}\right) x^4 \\ + \left(\frac{11a_0}{30} + \frac{19a_1}{30}\right) x^5 + \left(\frac{53a_0}{144} + \frac{91a_1}{144}\right) x^6 + \left(\frac{103a_0}{280} + \frac{177a_1}{280}\right) x^7 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{3}{8}x^{4}+\frac{11}{30}x^{5}+\frac{53}{144}x^{6}+\frac{103}{280}x^{7}\right) a_{0} \\
& + \left(x+\frac{1}{2}x^{2}+\frac{2}{3}x^{3}+\frac{5}{8}x^{4}+\frac{19}{30}x^{5}+\frac{91}{144}x^{6}+\frac{177}{280}x^{7}\right) a_{1}+O\left(x^{8}\right)
\end{aligned} \tag{3}
$$

At $x = 0$ the solution above becomes

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{3}{8}x^{4}+\frac{11}{30}x^{5}+\frac{53}{144}x^{6}+\frac{103}{280}x^{7}\right) c_{1} \\
& + \left(x+\frac{1}{2}x^{2}+\frac{2}{3}x^{3}+\frac{5}{8}x^{4}+\frac{19}{30}x^{5}+\frac{91}{144}x^{6}+\frac{177}{280}x^{7}\right) c_{2}+O\left(x^{8}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{3}{8}x^{4}+\frac{11}{30}x^{5}+\frac{53}{144}x^{6}+\frac{103}{280}x^{7}+\frac{2119}{5760}x^{8}\right) y(0) \\
& + \left(x+\frac{1}{2}x^{2}+\frac{2}{3}x^{3}+\frac{5}{8}x^{4}+\frac{19}{30}x^{5}+\frac{91}{144}x^{6}+\frac{177}{280}x^{7}+\frac{3641}{5760}x^{8}\right) y'(0)+O\left(x^{8}\right)
\end{aligned} \tag{1}
$$

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{3}{8}x^{4}+\frac{11}{30}x^{5}+\frac{53}{144}x^{6}+\frac{103}{280}x^{7}\right) c_{1} \\
& + \left(x+\frac{1}{2}x^{2}+\frac{2}{3}x^{3}+\frac{5}{8}x^{4}+\frac{19}{30}x^{5}+\frac{91}{144}x^{6}+\frac{177}{280}x^{7}\right) c_{2}+O\left(x^{8}\right)
\end{aligned} \tag{2}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & \left(1+\frac{1}{2}x^{2}+\frac{1}{3}x^{3}+\frac{3}{8}x^{4}+\frac{11}{30}x^{5}+\frac{53}{144}x^{6}+\frac{103}{280}x^{7}+\frac{2119}{5760}x^{8}\right) y(0) \\
& + \left(x+\frac{1}{2}x^{2}+\frac{2}{3}x^{3}+\frac{5}{8}x^{4}+\frac{19}{30}x^{5}+\frac{91}{144}x^{6}+\frac{177}{280}x^{7}+\frac{3641}{5760}x^{8}\right) y'(0)+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

$$
\begin{aligned}

& + \left(x+\frac{1}{2}x^{2}+\frac{2}{3}x^{3}+\frac{5}{8}x^{4}+\frac{19}{30}x^{5}+\frac{91}{144}x^{6}+\frac{177}{280}x^{7}\right) c_{2}+O\left(x^{8}\right)
\end{aligned}
$$

Verified OK.

22.8.1 Maple step by step solution

Let's solve

$(x-1)\,y''+(1+x)\,y'+y=0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y''=-\frac{y}{x-1}-\frac{(1+x)y'}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y''+\frac{(1+x)y'}{x-1}+\frac{y}{x-1}=0$

□ Check to see if $x_0=1$ is a regular singular point

  ○ Define functions

  $\left[P_2(x)=\frac{1+x}{x-1}, P_3(x)=\frac{1}{x-1}\right]$

  ○ $(x-1)\cdot P_2(x)$ is analytic at $x=1$

  $\left((x-1)\cdot P_2(x)\right)\Big|_{x=1}=2$

  ○ $(x-1)^2\cdot P_3(x)$ is analytic at $x=1$

  $\left((x-1)^2\cdot P_3(x)\right)\Big|_{x=1}=0$

  ○ $x=1$is a regular singular point

Check to see if $x_0=1$ is a regular singular point

$x_0=1$

- Multiply by denominators

$(x-1)\,y''+(1+x)\,y'+y=0$

- Change variables using $x=u+1$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(2+u)\left(\frac{d}{du}y(u)\right)+y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

$$u^{m} \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-1}$$

- Shift index using $k->k+1$

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0r(1+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+2+r) + a_k(k+1+r)\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k+1+r)\,(a_{k+1}(k+2+r) + a_k) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k}{k+2+r}$$

- Recursion relation for $r = -1$

$$a_{k+1} = -\frac{a_k}{k+1}$$

- Solution for $r = -1$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-1}, a_{k+1} = -\frac{a_k}{k+1}\right]$$

- Revert the change of variables $u = x-1$

$$\left[y = \sum_{k=0}^{\infty} a_k(x-1)^{k-1}, a_{k+1} = -\frac{a_k}{k+1}\right]$$

- Recursion relation for $r = 0$

$a_{k+1} = -\frac{a_k}{k+2}$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = -\frac{a_k}{k+2}\right]$$

- Revert the change of variables $u = x - 1$

$$\left[y = \sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1} = -\frac{a_k}{k+2}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k (x-1)^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k (x-1)^k\right), a_{k+1} = -\frac{a_k}{k+1}, b_{k+1} = -\frac{b_k}{k+2}\right]$$

Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 2(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\, x^2 y'' - x y' + (x+2)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^4 + x^2)\, y'' - x y' + (x+2)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{1}{x\,(x^2+1)}$$
$$q(x) = \frac{x+2}{(x^2+1)\, x^2}$$

Table 500: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{1}{x(x^2+1)}$	
singularity	type
$x = 0$	"regular"
$x = -i$	"regular"
$x = i$	"regular"

$q(x) = \frac{x+2}{(x^2+1)x^2}$	
singularity	type
$x = 0$	"regular"
$x = -i$	"regular"
$x = i$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, -i, i, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$(x^2 + 1) x^2 y'' - x y' + (x + 2) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) (x^2 + 1) - x \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + (x + 2) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2A}$$
$$+ \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)(n+r-1) = \sum_{n=2}^{\infty} a_{n-2}(n+r-2)(n-3+r)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)(n-3+r)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \tag{2B}$$
$$+ \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) - x^{n+r} a_n (n+r) + 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + 2a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 2r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 2r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1 + i$$
$$r_2 = 1 - i$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r^2 - 2r + 2)\, x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+1+i}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+1-i}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = -\frac{1}{r^2 + 1}$$

For $2 \leq n$ the recursive equation is

$$a_{n-2}(n + r - 2)(n - 3 + r) + a_n(n + r)(n + r - 1) - a_n(n + r) + a_{n-1} + 2a_n = 0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{n^2 a_{n-2} + 2nr a_{n-2} + r^2 a_{n-2} - 5n a_{n-2} - 5r a_{n-2} + 6a_{n-2} + a_{n-1}}{n^2 + 2nr + r^2 - 2n - 2r + 2} \quad (4)$$

Which for the root $r = 1+i$ becomes

$$a_n = \frac{\left(-n^2+(3-2i)\, n-1+3i\right) a_{n-2}-a_{n-1}}{n\left(n+2i\right)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1+i$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+\frac{2i}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-r^4+r^3-r^2+r+1}{\left(r^2+1\right)\left(r^2+2r+2\right)}$$

Which for the root $r = 1+i$ becomes

$$a_2 = -\frac{1}{40}-\frac{13i}{40}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{-r^4+r^3-r^2+r+1}{(r^2+1)(r^2+2r+2)}$	$-\frac{1}{40}-\frac{13i}{40}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{2r^4+2r^3+5r^2+r-1}{\left(r^2+1\right)\left(r^2+2r+2\right)\left(r^2+4r+5\right)}$$

Which for the root $r = 1+i$ becomes

$$a_3 = \frac{71}{520}-\frac{17i}{520}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{-r^4+r^3-r^2+r+1}{(r^2+1)(r^2+2r+2)}$	$-\frac{1}{40}-\frac{13i}{40}$
a_3	$\frac{2r^4+2r^3+5r^2+r-1}{(r^2+1)(r^2+2r+2)(r^2+4r+5)}$	$\frac{71}{520}-\frac{17i}{520}$

For $n=4$, using the above recursive equation gives

$$a_4 = \frac{r^8+6r^7+13r^6+10r^5-4r^4-15r^3-37r^2-34r-9}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$$

Which for the root $r=1+i$ becomes

$$a_4 = -\frac{31}{832}+\frac{541i}{4160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{-r^4+r^3-r^2+r+1}{(r^2+1)(r^2+2r+2)}$	$-\frac{1}{40}-\frac{13i}{40}$
a_3	$\frac{2r^4+2r^3+5r^2+r-1}{(r^2+1)(r^2+2r+2)(r^2+4r+5)}$	$\frac{71}{520}-\frac{17i}{520}$
a_4	$\frac{r^8+6r^7+13r^6+10r^5-4r^4-15r^3-37r^2-34r-9}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$-\frac{31}{832}+\frac{541i}{4160}$

For $n=5$, using the above recursive equation gives

$$a_5 = \frac{-3r^8-30r^7-132r^6-330r^5-528r^4-570r^3-303r^2+60r+69}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$$

Which for the root $r=1+i$ becomes

$$a_5 = -\frac{1423}{20800}-\frac{7i}{4160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{-r^4+r^3-r^2+r+1}{(r^2+1)(r^2+2r+2)}$	$-\frac{1}{40}-\frac{13i}{40}$
a_3	$\frac{2r^4+2r^3+5r^2+r-1}{(r^2+1)(r^2+2r+2)(r^2+4r+5)}$	$\frac{71}{520}-\frac{17i}{520}$
a_4	$\frac{r^8+6r^7+13r^6+10r^5-4r^4-15r^3-37r^2-34r-9}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$-\frac{31}{832}+\frac{541i}{4160}$
a_5	$\frac{-3r^8-30r^7-132r^6-330r^5-528r^4-570r^3-303r^2+60r+69}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1423}{20800}-\frac{7i}{4160}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{-r^{12} - 21r^{11} - 188r^{10} - 930r^9 - 2742r^8 - 4764r^7 - 4068r^6 + 1014r^5 + 8233r^4 + 14610r^3 + 15926r}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$$

Which for the root $r = 1 + i$ becomes

$$a_6 = \frac{12849}{416000} - \frac{10853i}{156000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{-r^4+r^3-r^2+r+1}{(r^2+1)(r^2+2r+2)}$	$-\frac{1}{40}-\frac{13i}{40}$
a_3	$\frac{2r^4+2r^3+5r^2+r-1}{(r^2+1)(r^2+2r+2)(r^2+4r+5)}$	$\frac{71}{520}-\frac{17i}{520}$
a_4	$\frac{r^8+6r^7+13r^6+10r^5-4r^4-15r^3-37r^2-34r-9}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$-\frac{31}{832}+\frac{541i}{4160}$
a_5	$\frac{-3r^8-30r^7-132r^6-330r^5-528r^4-570r^3-303r^2+60r+69}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1423}{20800}-\frac{7i}{4160}$
a_6	$\frac{-r^{12}-21r^{11}-188r^{10}-930r^9-2742r^8-4764r^7-4068r^6+1014r^5+8233r^4+14610r^3+15926r^2+8811r+1767}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{12849}{416000}-\frac{10853i}{156000}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{4r^{12} + 108r^{11} + 1298r^{10} + 9150r^9 + 42072r^8 + 133134r^7 + 298869r^6 + 482955r^5 + 553706r^4 + 4038}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$$

Which for the root $r = 1 + i$ becomes

$$a_7 = \frac{209609}{5088000} + \frac{106907i}{17808000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+1}$	$-\frac{1}{5}+$
a_2	$\frac{-r^4+r^3-r^2+r+1}{(r^2+1)(r^2+2r+2)}$	$-\frac{1}{40}-$
a_3	$\frac{2r^4+2r^3+5r^2+r-1}{(r^2+1)(r^2+2r+2)(r^2+4r+5)}$	$\frac{71}{520}-$
a_4	$\frac{r^8+6r^7+13r^6+10r^5-4r^4-15r^3-37r^2-34r-9}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$-\frac{31}{832}$
a_5	$\frac{-3r^8-30r^7-132r^6-330r^5-528r^4-570r^3-303r^2+60r+69}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1423}{20800}$
a_6	$\frac{-r^{12}-21r^{11}-188r^{10}-930r^9-2742r^8-4764r^7-4068r^6+1014r^5+8233r^4+14610r^3+15926r^2+8811r+1767}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{12849}{416000}$
a_7	$\frac{4r^{12}+108r^{11}+1298r^{10}+9150r^9+42072r^8+133134r^7+298869r^6+482955r^5+553706r^4+403821r^3+106210r^2-69957r-37647}{(r^2+1)(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)}$	$\frac{209609}{5088000}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^{1+i}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\
&= x^{1+i}\left(1 + \left(-\frac{1}{5} + \frac{2i}{5}\right) x + \left(-\frac{1}{40} - \frac{13i}{40}\right) x^2 + \left(\frac{71}{520} - \frac{17i}{520}\right) x^3 \right. \\
&\quad + \left(-\frac{31}{832} + \frac{541i}{4160}\right) x^4 + \left(-\frac{1423}{20800} - \frac{7i}{4160}\right) x^5 + \left(\frac{12849}{416000} - \frac{10853i}{156000}\right) x^6 \\
&\quad \left. + \left(\frac{209609}{5088000} + \frac{106907i}{17808000}\right) x^7 + O\left(x^8\right)\right)
\end{aligned}
$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$
\begin{aligned}
y_2(x) &= x^{1-i}\left(1 + \left(-\frac{1}{5} - \frac{2i}{5}\right) x + \left(-\frac{1}{40} + \frac{13i}{40}\right) x^2 + \left(\frac{71}{520} + \frac{17i}{520}\right) x^3 \right. \\
&\quad + \left(-\frac{31}{832} - \frac{541i}{4160}\right) x^4 + \left(-\frac{1423}{20800} + \frac{7i}{4160}\right) x^5 + \left(\frac{12849}{416000} + \frac{10853i}{156000}\right) x^6 \\
&\quad \left. + \left(\frac{209609}{5088000} - \frac{106907i}{17808000}\right) x^7 + O\left(x^8\right)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{1+i}\left(1+\left(-\frac{1}{5}+\frac{2i}{5}\right)x+\left(-\frac{1}{40}-\frac{13i}{40}\right)x^2+\left(\frac{71}{520}-\frac{17i}{520}\right)x^3\right. \\
&\quad +\left(-\frac{31}{832}+\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}-\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}-\frac{10853i}{156000}\right)x^6 \\
&\quad \left.+\left(\frac{209609}{5088000}+\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right) \\
&\quad + c_2 x^{1-i}\left(1+\left(-\frac{1}{5}-\frac{2i}{5}\right)x+\left(-\frac{1}{40}+\frac{13i}{40}\right)x^2+\left(\frac{71}{520}+\frac{17i}{520}\right)x^3\right. \\
&\quad +\left(-\frac{31}{832}-\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}+\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}+\frac{10853i}{156000}\right)x^6 \\
&\quad \left.+\left(\frac{209609}{5088000}-\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{1+i}\left(1+\left(-\frac{1}{5}+\frac{2i}{5}\right)x+\left(-\frac{1}{40}-\frac{13i}{40}\right)x^2+\left(\frac{71}{520}-\frac{17i}{520}\right)x^3+\left(-\frac{31}{832}+\frac{541i}{4160}\right)x^4\right. \\
&\quad +\left(-\frac{1423}{20800}-\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}-\frac{10853i}{156000}\right)x^6+\left(\frac{209609}{5088000}+\frac{106907i}{17808000}\right)x^7 \\
&\quad \left.+O\left(x^8\right)\right)+c_2 x^{1-i}\left(1+\left(-\frac{1}{5}-\frac{2i}{5}\right)x+\left(-\frac{1}{40}+\frac{13i}{40}\right)x^2+\left(\frac{71}{520}+\frac{17i}{520}\right)x^3\right. \\
&\quad +\left(-\frac{31}{832}-\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}+\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}+\frac{10853i}{156000}\right)x^6 \\
&\quad \left.+\left(\frac{209609}{5088000}-\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 x^{1+i}\left(1+\left(-\frac{1}{5}+\frac{2i}{5}\right)x+\left(-\frac{1}{40}-\frac{13i}{40}\right)x^2+\left(\frac{71}{520}-\frac{17i}{520}\right)x^3+\left(-\frac{31}{832}+\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}-\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}-\frac{10853i}{156000}\right)x^6+\left(\frac{209609}{5088000}+\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right)+c_2 x^{1-i}\left(1+\left(-\frac{1}{5}-\frac{2i}{5}\right)x+\left(-\frac{1}{40}+\frac{13i}{40}\right)x^2+\left(\frac{71}{520}+\frac{17i}{520}\right)x^3+\left(-\frac{31}{832}-\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}+\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}+\frac{10853i}{156000}\right)x^6+\left(\frac{209609}{5088000}-\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^{1+i}\left(1+\left(-\frac{1}{5}+\frac{2i}{5}\right)x+\left(-\frac{1}{40}-\frac{13i}{40}\right)x^2+\left(\frac{71}{520}-\frac{17i}{520}\right)x^3+\left(-\frac{31}{832}+\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}-\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}-\frac{10853i}{156000}\right)x^6+\left(\frac{209609}{5088000}+\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right)+c_2 x^{1-i}\left(1+\left(-\frac{1}{5}-\frac{2i}{5}\right)x+\left(-\frac{1}{40}+\frac{13i}{40}\right)x^2+\left(\frac{71}{520}+\frac{17i}{520}\right)x^3+\left(-\frac{31}{832}-\frac{541i}{4160}\right)x^4+\left(-\frac{1423}{20800}+\frac{7i}{4160}\right)x^5+\left(\frac{12849}{416000}+\frac{10853i}{156000}\right)x^6+\left(\frac{209609}{5088000}-\frac{106907i}{17808000}\right)x^7+O\left(x^8\right)\right)$$

Verified OK.

22.9.1 Maple step by step solution

Let's solve

$x^2 y''(x^2+1) - xy' + (x+2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x+2)y}{(x^2+1)x^2} + \frac{y'}{x(x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x(x^2+1)} + \frac{(x+2)y}{(x^2+1)x^2} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{1}{x(x^2+1)}, P_3(x) = \frac{x+2}{(x^2+1)x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = 2$

  ◦ $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $x^2y''(x^2+1) - xy' + (x+2)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  ◦ Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  ◦ Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

  ◦ Convert $x^m \cdot y''$ to series expansion for $m = 2..4$

    $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $$x^{m}\cdot y''=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(r^2-2r+2)\,x^r+((r^2+1)\,a_1+a_0)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(k^2+2kr+r^2-2k-2r+2)+a_{k-1}+a_{\ldots}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r^2-2r+2=0$$

- Values of r that satisfy the indicial equation

  $$r\in\{1-\mathrm{I},1+\mathrm{I}\}$$

- Each term must be 0

  $$(r^2+1)\,a_1+a_0=0$$

- Solve for the dependent coefficient(s)

  $$a_1=-\frac{a_0}{r^2+1}$$

- Each term in the series must be 0, giving the recursion relation

  $$a_{k-2}(k-2+r)\,(k-3+r)+(k^2+(2r-2)\,k+r^2-2r+2)\,a_k+a_{k-1}=0$$

- Shift index using $k->k+2$

  $$a_k(k+r)\,(k+r-1)+\left((k+2)^2+(2r-2)\,(k+2)+r^2-2r+2\right)a_{k+2}+a_{k+1}=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=-\frac{k^2a_k+2kra_k+r^2a_k-ka_k-ra_k+a_{k+1}}{k^2+2kr+r^2+2k+2r+2}$$

- Recursion relation for $r=1-\mathrm{I}$

  $$a_{k+2}=-\frac{k^2a_k+(2-2\,\mathrm{I})ka_k-(1+\mathrm{I})a_k-ka_k+a_{k+1}}{k^2+(2-2\,\mathrm{I})k+4-4\,\mathrm{I}+2k}$$

- Solution for $r=1-\mathrm{I}$

  $$\left[y=\sum_{k=0}^{\infty}a_kx^{k+1-\mathrm{I}},a_{k+2}=-\frac{k^2a_k+(2-2\,\mathrm{I})ka_k-(1+\mathrm{I})a_k-ka_k+a_{k+1}}{k^2+(2-2\,\mathrm{I})k+4-4\,\mathrm{I}+2k},a_1=\left(-\frac{1}{5}-\frac{2\,\mathrm{I}}{5}\right)a_0\right]$$

- Recursion relation for $r=1+\mathrm{I}$

  $$a_{k+2}=-\frac{k^2a_k+(2+2\,\mathrm{I})ka_k+(-1+\mathrm{I})a_k-ka_k+a_{k+1}}{k^2+(2+2\,\mathrm{I})k+4+4\,\mathrm{I}+2k}$$

- Solution for $r=1+\mathrm{I}$

  $$\left[y=\sum_{k=0}^{\infty}a_kx^{k+1+\mathrm{I}},a_{k+2}=-\frac{k^2a_k+(2+2\,\mathrm{I})ka_k+(-1+\mathrm{I})a_k-ka_k+a_{k+1}}{k^2+(2+2\,\mathrm{I})k+4+4\,\mathrm{I}+2k},a_1=\left(-\frac{1}{5}+\frac{2\,\mathrm{I}}{5}\right)a_0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+1-\mathrm{I}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+1+\mathrm{I}}\right), a_{k+2} = -\frac{k^2 a_k + (2-2\,\mathrm{I})k a_k - (1+\mathrm{I})a_k - k a_k + a_{k+1}}{k^2 + (2-2\,\mathrm{I})k + 4 - 4\,\mathrm{I} + 2k}, a_1 = \left(-\frac{1}{5} - \frac{2\,\mathrm{I}}{5}\right.$$

Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 2(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + xy' + (1 + x)\, y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + xy' + (1 + x)\, y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = \frac{1 + x}{x^2}$$

Table 502: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1+x}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' + xy' + (1 + x) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) + x \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + (1 + x) \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=1}^{\infty} a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1) + x^{n+r} a_n(n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2+1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 + 1 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = i$$
$$r_2 = -i$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 + 1\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+i}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n-i}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n + r)(n + r - 1) + a_n(n + r) + a_n + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{n^2 + 2nr + r^2 + 1} \tag{4}$$

Which for the root $r = i$ becomes

$$a_n = -\frac{a_{n-1}}{n(2i + n)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = i$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{r^2 + 2r + 2}$$

Which for the root $r = i$ becomes

$$a_1 = -\frac{1}{5} + \frac{2i}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5} + \frac{2i}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{(r^2 + 2r + 2)(r^2 + 4r + 5)}$$

Which for the root $r = i$ becomes

$$a_2 = -\frac{1}{40} - \frac{3i}{40}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5} + \frac{2i}{5}$
a_2	$\frac{1}{(r^2+2r+2)(r^2+4r+5)}$	$-\frac{1}{40} - \frac{3i}{40}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{(r^2 + 2r + 2)(r^2 + 4r + 5)(r^2 + 6r + 10)}$$

Which for the root $r = i$ becomes

$$a_3 = \frac{3}{520} + \frac{7i}{1560}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5} + \frac{2i}{5}$
a_2	$\frac{1}{(r^2+2r+2)(r^2+4r+5)}$	$-\frac{1}{40} - \frac{3i}{40}$
a_3	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{3}{520} + \frac{7i}{1560}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(r^2 + 2r + 2)(r^2 + 4r + 5)(r^2 + 6r + 10)(r^2 + 8r + 17)}$$

Which for the root $r = i$ becomes

$$a_4 = -\frac{1}{2496} - \frac{i}{12480}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5} + \frac{2i}{5}$
a_2	$\frac{1}{(r^2+2r+2)(r^2+4r+5)}$	$-\frac{1}{40} - \frac{3i}{40}$
a_3	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{3}{520} + \frac{7i}{1560}$
a_4	$\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1}{2496} - \frac{i}{12480}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(r^2 + 2r + 2)(r^2 + 4r + 5)(r^2 + 6r + 10)(r^2 + 8r + 17)(r^2 + 10r + 26)}$$

Which for the root $r = i$ becomes

$$a_5 = \frac{9}{603200} - \frac{i}{361920}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{1}{(r^2+2r+2)(r^2+4r+5)}$	$-\frac{1}{40}-\frac{3i}{40}$
a_3	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{3}{520}+\frac{7i}{1560}$
a_4	$\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1}{2496}-\frac{i}{12480}$
a_5	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{9}{603200}-\frac{i}{361920}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{1}{(r^2 + 2r + 2)(r^2 + 4r + 5)(r^2 + 6r + 10)(r^2 + 8r + 17)(r^2 + 10r + 26)(r^2 + 12r + 37)}$$

Which for the root $r = i$ becomes

$$a_6 = -\frac{19}{54288000} + \frac{7i}{36192000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{1}{(r^2+2r+2)(r^2+4r+5)}$	$-\frac{1}{40}-\frac{3i}{40}$
a_3	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{3}{520}+\frac{7i}{1560}$
a_4	$\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1}{2496}-\frac{i}{12480}$
a_5	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{9}{603200}-\frac{i}{361920}$
a_6	$\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)}$	$-\frac{19}{54288000}+\frac{7i}{36192000}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{1}{(r^2 + 2r + 2)(r^2 + 4r + 5)(r^2 + 6r + 10)(r^2 + 8r + 17)(r^2 + 10r + 26)(r^2 + 12r + 37)(r^2 + 14r}$$

Which for the root $r = i$ becomes

$$a_7 = \frac{1}{179829000} - \frac{223i}{40281696000}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{r^2+2r+2}$	$-\frac{1}{5}+\frac{2i}{5}$
a_2	$\frac{1}{(r^2+2r+2)(r^2+4r+5)}$	$-\frac{1}{40}-\frac{3i}{40}$
a_3	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{3}{520}+\frac{7i}{1560}$
a_4	$\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$-\frac{1}{2496}-\frac{i}{12480}$
a_5	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{9}{603200}-\frac{i}{361920}$
a_6	$\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)}$	$-\frac{19}{54288000}+\frac{7i}{36192000}$
a_7	$-\frac{1}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)(r^2+14r+50)}$	$\frac{1}{179829000}-\frac{223i}{40281696000}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^i\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots\right) \\
&= x^i\left(1 + \left(-\frac{1}{5}+\frac{2i}{5}\right)x + \left(-\frac{1}{40}-\frac{3i}{40}\right)x^2 + \left(\frac{3}{520}+\frac{7i}{1560}\right)x^3 \right. \\
&\quad + \left(-\frac{1}{2496}-\frac{i}{12480}\right)x^4 + \left(\frac{9}{603200}-\frac{i}{361920}\right)x^5 \\
&\quad \left. + \left(-\frac{19}{54288000}+\frac{7i}{36192000}\right)x^6 + \left(\frac{1}{179829000}-\frac{223i}{40281696000}\right)x^7 + O(x^8)\right)
\end{aligned}$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$\begin{aligned}
y_2(x) &= x^{-i}\left(1 + \left(-\frac{1}{5}-\frac{2i}{5}\right)x + \left(-\frac{1}{40}+\frac{3i}{40}\right)x^2 + \left(\frac{3}{520}-\frac{7i}{1560}\right)x^3 \right. \\
&\quad + \left(-\frac{1}{2496}+\frac{i}{12480}\right)x^4 + \left(\frac{9}{603200}+\frac{i}{361920}\right)x^5 \\
&\quad \left. + \left(-\frac{19}{54288000}-\frac{7i}{36192000}\right)x^6 + \left(\frac{1}{179829000}+\frac{223i}{40281696000}\right)x^7 + O(x^8)\right)
\end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^i \left(1 + \left(-\frac{1}{5} + \frac{2i}{5}\right) x + \left(-\frac{1}{40} - \frac{3i}{40}\right) x^2 + \left(\frac{3}{520} + \frac{7i}{1560}\right) x^3 \right. \\
&\quad + \left(-\frac{1}{2496} - \frac{i}{12480}\right) x^4 + \left(\frac{9}{603200} - \frac{i}{361920}\right) x^5 \\
&\quad \left. + \left(-\frac{19}{54288000} + \frac{7i}{36192000}\right) x^6 + \left(\frac{1}{179829000} - \frac{223i}{40281696000}\right) x^7 + O\left(x^8\right)\right) \\
&\quad + c_2 x^{-i} \left(1 + \left(-\frac{1}{5} - \frac{2i}{5}\right) x + \left(-\frac{1}{40} + \frac{3i}{40}\right) x^2 + \left(\frac{3}{520} - \frac{7i}{1560}\right) x^3 \right. \\
&\quad + \left(-\frac{1}{2496} + \frac{i}{12480}\right) x^4 + \left(\frac{9}{603200} + \frac{i}{361920}\right) x^5 \\
&\quad \left. + \left(-\frac{19}{54288000} - \frac{7i}{36192000}\right) x^6 + \left(\frac{1}{179829000} + \frac{223i}{40281696000}\right) x^7 + O\left(x^8\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^i \left(1 + \left(-\frac{1}{5} + \frac{2i}{5}\right) x + \left(-\frac{1}{40} - \frac{3i}{40}\right) x^2 + \left(\frac{3}{520} + \frac{7i}{1560}\right) x^3 \right. \\
&\quad + \left(-\frac{1}{2496} - \frac{i}{12480}\right) x^4 + \left(\frac{9}{603200} - \frac{i}{361920}\right) x^5 \\

\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^{i}\left(1+\left(-\frac{1}{5}+\frac{2i}{5}\right)x+\left(-\frac{1}{40}-\frac{3i}{40}\right)x^{2}+\left(\frac{3}{520}+\frac{7i}{1560}\right)x^{3}\right. \\
& +\left(-\frac{1}{2496}-\frac{i}{12480}\right)x^{4}+\left(\frac{9}{603200}-\frac{i}{361920}\right)x^{5} \\
& \left.+\left(-\frac{19}{54288000}+\frac{7i}{36192000}\right)x^{6}+\left(\frac{1}{179829000}-\frac{223i}{40281696000}\right)x^{7}+O\left(x^{8}\right)\right) \\
& + c_2 x^{-i}\left(1+\left(-\frac{1}{5}-\frac{2i}{5}\right)x+\left(-\frac{1}{40}+\frac{3i}{40}\right)x^{2}+\left(\frac{3}{520}-\frac{7i}{1560}\right)x^{3}\right. \\
& +\left(-\frac{1}{2496}+\frac{i}{12480}\right)x^{4}+\left(\frac{9}{603200}+\frac{i}{361920}\right)x^{5} \\
& \left.+\left(-\frac{19}{54288000}-\frac{7i}{36192000}\right)x^{6}+\left(\frac{1}{179829000}+\frac{223i}{40281696000}\right)x^{7}+O\left(x^{8}\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 x^{i}\left(1+\left(-\frac{1}{5}+\frac{2i}{5}\right)x+\left(-\frac{1}{40}-\frac{3i}{40}\right)x^{2}+\left(\frac{3}{520}+\frac{7i}{1560}\right)x^{3}\right. \\
& +\left(-\frac{1}{2496}-\frac{i}{12480}\right)x^{4}+\left(\frac{9}{603200}-\frac{i}{361920}\right)x^{5} \\
& \left.+\left(-\frac{19}{54288000}+\frac{7i}{36192000}\right)x^{6}+\left(\frac{1}{179829000}-\frac{223i}{40281696000}\right)x^{7}+O\left(x^{8}\right)\right) \\
& + c_2 x^{-i}\left(1+\left(-\frac{1}{5}-\frac{2i}{5}\right)x+\left(-\frac{1}{40}+\frac{3i}{40}\right)x^{2}+\left(\frac{3}{520}-\frac{7i}{1560}\right)x^{3}\right. \\
& +\left(-\frac{1}{2496}+\frac{i}{12480}\right)x^{4}+\left(\frac{9}{603200}+\frac{i}{361920}\right)x^{5} \\

\end{aligned}
$$

Verified OK.

22.10.1 Maple step by step solution

Let's solve

$x^2 y'' + x y' + (1+x) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{y'}{x} - \frac{(1+x)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{y'}{x} + \frac{(1+x)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- ◦ Define functions

$\left[P_2(x) = \frac{1}{x}, P_3(x) = \frac{1+x}{x^2}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 1$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 1$

- ◦ $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$x^2 y'' + x y' + (1+x) y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ◦ Shift index using $k- >k - m$

$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ◦ Convert $x \cdot y'$ to series expansion

$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- ◦ Convert $x^2 \cdot y''$ to series expansion

$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r}$

Rewrite ODE with series expansions

$a_0(r^2+1) x^r + \left(\sum_{k=1}^{\infty} (a_k(k^2+2kr+r^2+1) + a_{k-1}) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2+1=0$

- Values of r that satisfy the indicial equation

  $r \in \{-\mathrm{I}, \mathrm{I}\}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k^2+2kr+r^2+1) + a_{k-1} = 0$

- Shift index using $k- >k+1$

  $a_{k+1}\left((k+1)^2 + 2(k+1) r + r^2 + 1\right) + a_k = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k^2+2kr+r^2+2k+2r+2}$

- Recursion relation for $r = -\mathrm{I}$

  $a_{k+1} = -\frac{a_k}{k^2-2\,\mathrm{I}k+1-2\,\mathrm{I}+2k}$

- Solution for $r = -\mathrm{I}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-\mathrm{I}}, a_{k+1} = -\frac{a_k}{k^2-2\,\mathrm{I}k+1-2\,\mathrm{I}+2k}\right]$

- Recursion relation for $r = \mathrm{I}$

  $a_{k+1} = -\frac{a_k}{k^2+2\,\mathrm{I}k+1+2\,\mathrm{I}+2k}$

- Solution for $r = \mathrm{I}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\mathrm{I}}, a_{k+1} = -\frac{a_k}{k^2+2\,\mathrm{I}k+1+2\,\mathrm{I}+2k}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-\mathrm{I}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\mathrm{I}}\right), a_{k+1} = -\frac{a_k}{k^2-2\,\mathrm{I}k+1-2\,\mathrm{I}+2k}, b_{k+1} = -\frac{b_k}{k^2+2\,\mathrm{I}k+1+2\,\mathrm{I}+2k}\right]$

Problem number: 2(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[_Lienard]`

$$\boxed{xy'' - 4y' + xy = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' - 4y' + xy = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{4}{x}$$
$$q(x) = 1$$

Table 504: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{4}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = 1$	
singularity	type

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' - 4y' + xy = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x - 4\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + x\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)\,(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-4(n+r)\, a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} x^{1+n+r} a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-4(n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) - 4(n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) - 4r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) - 4r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-5+r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$r(-5+r) = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 5$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-5+r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 5$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = x^5 \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+5}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - 4a_n(n+r) + a_{n-2} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}}{n^2 + 2nr + r^2 - 5n - 5r} \tag{4}$$

Which for the root $r = 5$ becomes

$$a_n = -\frac{a_{n-2}}{n(n+5)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 5$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{1}{r^2 - r - 6}$$

Which for the root $r = 5$ becomes

$$a_2 = -\frac{1}{14}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2-r-6}$	$-\frac{1}{14}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2-r-6}$	$-\frac{1}{14}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{r^4 + 2r^3 - 13r^2 - 14r + 24}$$

Which for the root $r = 5$ becomes

$$a_4 = \frac{1}{504}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2-r-6}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{504}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2-r-6}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{504}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{1}{r^6 + 9r^5 + 7r^4 - 93r^3 - 152r^2 + 84r + 144}$$

Which for the root $r = 5$ becomes

$$a_6 = -\frac{1}{33264}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2-r-6}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{504}$
a_5	0	0
a_6	$-\frac{1}{r^6+9r^5+7r^4-93r^3-152r^2+84r+144}$	$-\frac{1}{33264}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{1}{r^2-r-6}$	$-\frac{1}{14}$
a_3	0	0
a_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{504}$
a_5	0	0
a_6	$-\frac{1}{r^6+9r^5+7r^4-93r^3-152r^2+84r+144}$	$-\frac{1}{33264}$
a_7	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^5\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots\right) \\ &= x^5\left(1 - \frac{x^2}{14} + \frac{x^4}{504} - \frac{x^6}{33264} + O(x^8)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 5$. Now we need to determine if

C is zero or not. This is done by finding $\lim_{r\to r_2} a_5(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_5 \\ &= 0 \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} 0 &= \lim_{r\to 0} 0 \\ &= 0 \end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^n \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$b_n(n+r)(n+r-1) - 4(n+r)b_n + b_{n-2} = 0 \tag{4}$$

Which for for the root $r = 0$ becomes

$$b_n n(n-1) - 4nb_n + b_{n-2} = 0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{b_{n-2}}{n^2 + 2nr + r^2 - 5n - 5r} \tag{5}$$

Which for the root $r = 0$ becomes

$$b_n = -\frac{b_{n-2}}{n^2 - 5n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{1}{r^2 - r - 6}$$

Which for the root $r = 0$ becomes

$$b_2 = \frac{1}{6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2-r-6}$	$\frac{1}{6}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2-r-6}$	$\frac{1}{6}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{1}{(r^2 - r - 6)(r^2 + 3r - 4)}$$

Which for the root $r = 0$ becomes

$$b_4 = \frac{1}{24}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2-r-6}$	$\frac{1}{6}$
b_3	0	0
b_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2-r-6}$	$\frac{1}{6}$
b_3	0	0
b_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{24}$
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = -\frac{1}{(r^2 - r - 6)(r^2 + 3r - 4)(r^2 + 7r + 6)}$$

Which for the root $r = 0$ becomes

$$b_6 = -\frac{1}{144}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2-r-6}$	$\frac{1}{6}$
b_3	0	0
b_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{24}$
b_5	0	0
b_6	$-\frac{1}{r^6+9r^5+7r^4-93r^3-152r^2+84r+144}$	$-\frac{1}{144}$

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{1}{r^2-r-6}$	$\frac{1}{6}$
b_3	0	0
b_4	$\frac{1}{r^4+2r^3-13r^2-14r+24}$	$\frac{1}{24}$
b_5	0	0
b_6	$-\frac{1}{r^6+9r^5+7r^4-93r^3-152r^2+84r+144}$	$-\frac{1}{144}$
b_7	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned}
y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= 1 + \frac{x^2}{6} + \frac{x^4}{24} - \frac{x^6}{144} + O(x^8)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^5 \left(1 - \frac{x^2}{14} + \frac{x^4}{504} - \frac{x^6}{33264} + O(x^8)\right) + c_2 \left(1 + \frac{x^2}{6} + \frac{x^4}{24} - \frac{x^6}{144} + O(x^8)\right)
\end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 x^5 \left(1-\frac{x^2}{14}+\frac{x^4}{504}-\frac{x^6}{33264}+O(x^8)\right)+c_2\left(1+\frac{x^2}{6}+\frac{x^4}{24}-\frac{x^6}{144}+O(x^8)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^5 \left(1-\frac{x^2}{14}+\frac{x^4}{504}-\frac{x^6}{33264}+O(x^8)\right)+c_2\left(1+\frac{x^2}{6}+\frac{x^4}{24}-\frac{x^6}{144}+O(x^8)\right) \quad (1)$$

Verification of solutions

$$y = c_1 x^5 \left(1-\frac{x^2}{14}+\frac{x^4}{504}-\frac{x^6}{33264}+O(x^8)\right)+c_2\left(1+\frac{x^2}{6}+\frac{x^4}{24}-\frac{x^6}{144}+O(x^8)\right)$$

Verified OK.

22.11.1 Maple step by step solution

Let's solve

$y''x - 4y' + xy = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4y'}{x} - y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{x} + y = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{4}{x}, P_3(x) = 1\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -4$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x - 4y' + xy = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- □ Rewrite ODE with series expansions

  - Convert $x \cdot y$ to series expansion

    $$x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$$

  - Shift index using $k- > k-1$

    $$x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$$

  - Convert y' to series expansion

    $$y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1}$$

  - Shift index using $k- > k+1$

    $$y' = \sum_{k=-1}^{\infty} a_{k+1} (k+r+1)\, x^{k+r}$$

  - Convert $x \cdot y''$ to series expansion

    $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

  - Shift index using $k- > k+1$

    $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+r+1)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-5+r)\, x^{-1+r} + a_1(1+r)\,(-4+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+r+1)\,(k-4+r) + a_{k-1}\right) x^{k+r}\right) =$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-5+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 5\}$

- Each term must be 0

  $a_1(1+r)(-4+r)=0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+r+1)(k-4+r)+a_{k-1}=0$

- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)(k-3+r)+a_k=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a_k}{(k+2+r)(k-3+r)}$

- Recursion relation for $r=0$

  $a_{k+2}=-\frac{a_k}{(k+2)(k-3)}$

- Solution for $r=0$

  $\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{a_k}{(k+2)(k-3)}, -4a_1=0\right]$

- Recursion relation for $r=5$

  $a_{k+2}=-\frac{a_k}{(k+7)(k+2)}$

- Solution for $r=5$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+5}, a_{k+2}=-\frac{a_k}{(k+7)(k+2)}, 6a_1=0\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+5}\right), a_{k+2}=-\frac{a_k}{(k+2)(k-3)}, -4a_1=0, b_{k+2}=-\frac{b_k}{(k+7)(k+2)}, 6b_1=0\right]$

Problem number: 2(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2y'' + 4x^2y' + 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$4x^2y'' + 4x^2y' + 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = 1$$
$$q(x) = \frac{1}{2x^2}$$

Table 506: Table $p(x), q(x)$ singularites.

$p(x) = 1$	
singularity	type

$q(x) = \frac{1}{2x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$4x^2y'' + 4x^2y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$4x^2 \left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) + 4x^2 \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 4x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 4x^{1+n+r}a_n(n+r) = \sum_{n=1}^{\infty} 4a_{n-1}(n+r-1)\, x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} 4x^{n+r}a_n(n+r)\,(n+r-1)\right) + \left(\sum_{n=1}^{\infty} 4a_{n-1}(n+r-1)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$4x^{n+r}a_n(n+r)\,(n+r-1) + 2a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$4x^r a_0 r(-1+r) + 2a_0 x^r = 0$$

Or

$$(4x^r r(-1+r) + 2x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(4r^2 - 4r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$4r^2 - 4r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2} + \frac{i}{2}$$
$$r_2 = \frac{1}{2} - \frac{i}{2}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(4r^2 - 4r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}+\frac{i}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^{n+\frac{1}{2}-\frac{i}{2}}$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$4a_n(n+r)(n+r-1) + 4a_{n-1}(n+r-1) + 2a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-1}(n+r-1)}{2n^2+4nr+2r^2-2n-2r+1} \tag{4}$$

Which for the root $r = \frac{1}{2}+\frac{i}{2}$ becomes

$$a_n = -\frac{a_{n-1}(2n-1+i)}{2n(n+i)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}+\frac{i}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{2r}{2r^2+2r+1}$$

Which for the root $r = \frac{1}{2} + \frac{i}{2}$ becomes

$$a_1 = -\frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{4r(1+r)}{4r^4 + 16r^3 + 24r^2 + 16r + 5}$$

Which for the root $r = \frac{1}{2} + \frac{i}{2}$ becomes

$$a_2 = \frac{7}{40} - \frac{i}{40}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$
a_2	$\frac{4r(1+r)}{4r^4+16r^3+24r^2+16r+5}$	$\frac{7}{40} - \frac{i}{40}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{8r(1+r)(2+r)}{8r^6 + 72r^5 + 260r^4 + 480r^3 + 482r^2 + 258r + 65}$$

Which for the root $r = \frac{1}{2} + \frac{i}{2}$ becomes

$$a_3 = -\frac{11}{240} + \frac{i}{80}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$
a_2	$\frac{4r(1+r)}{4r^4+16r^3+24r^2+16r+5}$	$\frac{7}{40}-\frac{i}{40}$
a_3	$-\frac{8r(1+r)(2+r)}{8r^6+72r^5+260r^4+480r^3+482r^2+258r+65}$	$-\frac{11}{240}+\frac{i}{80}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{16r(1+r)(2+r)(3+r)}{16r^8+256r^7+1728r^6+6400r^5+14184r^4+19264r^3+15792r^2+7360r+1625}$$

Which for the root $r = \frac{1}{2}+\frac{i}{2}$ becomes

$$a_4 = \frac{31}{3264}-\frac{i}{272}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$
a_2	$\frac{4r(1+r)}{4r^4+16r^3+24r^2+16r+5}$	$\frac{7}{40}-\frac{i}{40}$
a_3	$-\frac{8r(1+r)(2+r)}{8r^6+72r^5+260r^4+480r^3+482r^2+258r+65}$	$-\frac{11}{240}+\frac{i}{80}$
a_4	$\frac{16r(1+r)(2+r)(3+r)}{16r^8+256r^7+1728r^6+6400r^5+14184r^4+19264r^3+15792r^2+7360r+1625}$	$\frac{31}{3264}-\frac{i}{272}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{r(1+r)(2+r)(3+r)(4+r)}{\left(r^2+5r+\frac{13}{2}\right)\left(r^2+3r+\frac{5}{2}\right)\left(r^2+7r+\frac{25}{2}\right)\left(r^2+9r+\frac{41}{2}\right)\left(r^2+r+\frac{1}{2}\right)}$$

Which for the root $r = \frac{1}{2}+\frac{i}{2}$ becomes

$$a_5 = -\frac{53}{32640}+\frac{13i}{16320}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$
a_2	$\frac{4r(1+r)}{4r^4+16r^3+24r^2+16r+5}$	$\frac{7}{40}-\frac{i}{40}$
a_3	$-\frac{8r(1+r)(2+r)}{8r^6+72r^5+260r^4+480r^3+482r^2+258r+65}$	$-\frac{11}{240}+\frac{i}{80}$
a_4	$\frac{16r(1+r)(2+r)(3+r)}{16r^8+256r^7+1728r^6+6400r^5+14184r^4+19264r^3+15792r^2+7360r+1625}$	$\frac{31}{3264}-\frac{i}{272}$
a_5	$-\frac{r(1+r)(2+r)(3+r)(4+r)}{\left(r^2+5r+\frac{13}{2}\right)\left(r^2+3r+\frac{5}{2}\right)\left(r^2+7r+\frac{25}{2}\right)\left(r^2+9r+\frac{41}{2}\right)\left(r^2+r+\frac{1}{2}\right)}$	$-\frac{53}{32640}+\frac{13i}{16320}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{64r(1+r)(2+r)(3+r)(4+r)(5+r)}{(2r^2+10r+13)(2r^2+6r+5)(2r^2+14r+25)(2r^2+18r+41)(2r^2+2r+1)(2r^2+22r+61)}$$

Which for the root $r = \frac{1}{2} + \frac{i}{2}$ becomes

$$a_6 = \frac{3421}{14492160} - \frac{223i}{1610240}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$
a_2	$\frac{4r(1+r)}{4r^4+16r^3+24r^2+16r+5}$	$\frac{7}{40}-\frac{i}{40}$
a_3	$-\frac{8r(1+r)(2+r)}{8r^6+72r^5+260r^4+480r^3+482r^2+258r+65}$	$-\frac{11}{240}+\frac{i}{80}$
a_4	$\frac{16r(1+r)(2+r)(3+r)}{16r^8+256r^7+1728r^6+6400r^5+14184r^4+19264r^3+15792r^2+7360r+1625}$	$\frac{31}{3264}-\frac{i}{272}$
a_5	$-\frac{r(1+r)(2+r)(3+r)(4+r)}{\left(r^2+5r+\frac{13}{2}\right)\left(r^2+3r+\frac{5}{2}\right)\left(r^2+7r+\frac{25}{2}\right)\left(r^2+9r+\frac{41}{2}\right)\left(r^2+r+\frac{1}{2}\right)}$	$-\frac{53}{32640}+\frac{13i}{16320}$
a_6	$\frac{64r(1+r)(2+r)(3+r)(4+r)(5+r)}{(2r^2+10r+13)(2r^2+6r+5)(2r^2+14r+25)(2r^2+18r+41)(2r^2+2r+1)(2r^2+22r+61)}$	$\frac{3421}{14492160}-\frac{223i}{1610240}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{128r(1+r)(2+r)(3+r)(4+r)(5+r)(6+r)}{(2r^2+10r+13)(2r^2+6r+5)(2r^2+14r+25)(2r^2+18r+41)(2r^2+2r+1)(2r^2+22r+61)}$$

Which for the root $r = \frac{1}{2} + \frac{i}{2}$ becomes

$$a_7 = -\frac{30269}{1014451200} + \frac{977i}{48307200}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{2r}{2r^2+2r+1}$	$-\frac{1}{2}$
a_2	$\frac{4r(1+r)}{4r^4+16r^3+24r^2+16r+5}$	$\frac{7}{40}-\frac{i}{40}$
a_3	$-\frac{8r(1+r)(2+r)}{8r^6+72r^5+260r^4+480r^3+482r^2+258r+65}$	$-\frac{11}{240}+\frac{i}{80}$
a_4	$\frac{16r(1+r)(2+r)(3+r)}{16r^8+256r^7+1728r^6+6400r^5+14184r^4+19264r^3+15792r^2+7360r+1625}$	$\frac{31}{3264}-\frac{i}{272}$
a_5	$-\frac{r(1+r)(2+r)(3+r)(4+r)}{\left(r^2+5r+\frac{13}{2}\right)\left(r^2+3r+\frac{5}{2}\right)\left(r^2+7r+\frac{25}{2}\right)\left(r^2+9r+\frac{41}{2}\right)\left(r^2+r+\frac{1}{2}\right)}$	$-\frac{53}{32640}+\frac{13i}{16320}$
a_6	$\frac{64r(1+r)(2+r)(3+r)(4+r)(5+r)}{(2r^2+10r+13)(2r^2+6r+5)(2r^2+14r+25)(2r^2+18r+41)(2r^2+2r+1)(2r^2+22r+61)}$	$\frac{3421}{14492160}-\frac{223i}{1610240}$
a_7	$-\frac{128r(1+r)(2+r)(3+r)(4+r)(5+r)(6+r)}{(2r^2+10r+13)(2r^2+6r+5)(2r^2+14r+25)(2r^2+18r+41)(2r^2+2r+1)(2r^2+22r+61)(2r^2+26r+85)}$	$-\frac{30269}{1014451200}+\frac{977i}{48307200}$

Using the above table, then the solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x^{\frac{1}{2}+\frac{i}{2}}\left(a_0+a_1x+a_2x^2+a_3x^3+a_4x^4+a_5x^5+a_6x^6+a_7x^7+a_8x^8\dots\right) \\
&= x^{\frac{1}{2}+\frac{i}{2}}\left(1-\frac{x}{2}+\left(\frac{7}{40}-\frac{i}{40}\right)x^2+\left(-\frac{11}{240}+\frac{i}{80}\right)x^3+\left(\frac{31}{3264}-\frac{i}{272}\right)x^4\right. \\
&\quad+\left(-\frac{53}{32640}+\frac{13i}{16320}\right)x^5+\left(\frac{3421}{14492160}-\frac{223i}{1610240}\right)x^6 \\
&\quad\left.+\left(-\frac{30269}{1014451200}+\frac{977i}{48307200}\right)x^7+O\left(x^8\right)\right)
\end{aligned}
$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$
\begin{aligned}
y_2(x) &= x^{\frac{1}{2}-\frac{i}{2}}\left(1-\frac{x}{2}+\left(\frac{7}{40}+\frac{i}{40}\right)x^2+\left(-\frac{11}{240}-\frac{i}{80}\right)x^3+\left(\frac{31}{3264}+\frac{i}{272}\right)x^4\right. \\
&\quad+\left(-\frac{53}{32640}-\frac{13i}{16320}\right)x^5+\left(\frac{3421}{14492160}+\frac{223i}{1610240}\right)x^6 \\
&\quad\left.+\left(-\frac{30269}{1014451200}-\frac{977i}{48307200}\right)x^7+O\left(x^8\right)\right)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{\frac{1}{2}+\frac{i}{2}} \left(1 - \frac{x}{2} + \left(\frac{7}{40} - \frac{i}{40}\right) x^2 + \left(-\frac{11}{240} + \frac{i}{80}\right) x^3 + \left(\frac{31}{3264} - \frac{i}{272}\right) x^4 \right. \\
&\quad + \left(-\frac{53}{32640} + \frac{13i}{16320}\right) x^5 + \left(\frac{3421}{14492160} - \frac{223i}{1610240}\right) x^6 \\
&\quad \left. + \left(-\frac{30269}{1014451200} + \frac{977i}{48307200}\right) x^7 + O(x^8)\right) + c_2 x^{\frac{1}{2}-\frac{i}{2}} \left(1 - \frac{x}{2} + \left(\frac{7}{40} + \frac{i}{40}\right) x^2 \right. \\
&\quad + \left(-\frac{11}{240} - \frac{i}{80}\right) x^3 + \left(\frac{31}{3264} + \frac{i}{272}\right) x^4 + \left(-\frac{53}{32640} - \frac{13i}{16320}\right) x^5 \\
&\quad \left. + \left(\frac{3421}{14492160} + \frac{223i}{1610240}\right) x^6 + \left(-\frac{30269}{1014451200} - \frac{977i}{48307200}\right) x^7 + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{\frac{1}{2}+\frac{i}{2}} \left(1 - \frac{x}{2} + \left(\frac{7}{40} - \frac{i}{40}\right) x^2 + \left(-\frac{11}{240} + \frac{i}{80}\right) x^3 + \left(\frac{31}{3264} - \frac{i}{272}\right) x^4 \right. \\
&\quad + \left(-\frac{53}{32640} + \frac{13i}{16320}\right) x^5 + \left(\frac{3421}{14492160} - \frac{223i}{1610240}\right) x^6 \\
&\quad \left. + \left(-\frac{30269}{1014451200} + \frac{977i}{48307200}\right) x^7 + O(x^8)\right) + c_2 x^{\frac{1}{2}-\frac{i}{2}} \left(1 - \frac{x}{2} + \left(\frac{7}{40} + \frac{i}{40}\right) x^2 \right. \\
&\quad + \left(-\frac{11}{240} - \frac{i}{80}\right) x^3 + \left(\frac{31}{3264} + \frac{i}{272}\right) x^4 + \left(-\frac{53}{32640} - \frac{13i}{16320}\right) x^5 \\
&\quad \left. + \left(\frac{3421}{14492160} + \frac{223i}{1610240}\right) x^6 + \left(-\frac{30269}{1014451200} - \frac{977i}{48307200}\right) x^7 + O(x^8)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^{\frac{1}{2}+\frac{i}{2}} \left(1-\frac{x}{2}+\left(\frac{7}{40}-\frac{i}{40}\right) x^2+\left(-\frac{11}{240}+\frac{i}{80}\right) x^3+\left(\frac{31}{3264}-\frac{i}{272}\right) x^4 \right. \\
& + \left(-\frac{53}{32640}+\frac{13i}{16320}\right) x^5+\left(\frac{3421}{14492160}-\frac{223i}{1610240}\right) x^6 \\
& \left. + \left(-\frac{30269}{1014451200}+\frac{977i}{48307200}\right) x^7+O\left(x^8\right)\right) + c_2 x^{\frac{1}{2}-\frac{i}{2}} \left(1-\frac{x}{2}+\left(\frac{7}{40}+\frac{i}{40}\right) x^2 \right. \\
& + \left(-\frac{11}{240}-\frac{i}{80}\right) x^3+\left(\frac{31}{3264}+\frac{i}{272}\right) x^4+\left(-\frac{53}{32640}-\frac{13i}{16320}\right) x^5 \\
& \left. + \left(\frac{3421}{14492160}+\frac{223i}{1610240}\right) x^6+\left(-\frac{30269}{1014451200}-\frac{977i}{48307200}\right) x^7+O\left(x^8\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 x^{\frac{1}{2}+\frac{i}{2}} \left(1-\frac{x}{2}+\left(\frac{7}{40}-\frac{i}{40}\right) x^2+\left(-\frac{11}{240}+\frac{i}{80}\right) x^3+\left(\frac{31}{3264}-\frac{i}{272}\right) x^4 \right. \\
& + \left(-\frac{53}{32640}+\frac{13i}{16320}\right) x^5+\left(\frac{3421}{14492160}-\frac{223i}{1610240}\right) x^6 \\
& \left. + \left(-\frac{30269}{1014451200}+\frac{977i}{48307200}\right) x^7+O\left(x^8\right)\right) + c_2 x^{\frac{1}{2}-\frac{i}{2}} \left(1-\frac{x}{2}+\left(\frac{7}{40}+\frac{i}{40}\right) x^2 \right. \\
& + \left(-\frac{11}{240}-\frac{i}{80}\right) x^3+\left(\frac{31}{3264}+\frac{i}{272}\right) x^4+\left(-\frac{53}{32640}-\frac{13i}{16320}\right) x^5 \\
& \left. + \left(\frac{3421}{14492160}+\frac{223i}{1610240}\right) x^6+\left(-\frac{30269}{1014451200}-\frac{977i}{48307200}\right) x^7+O\left(x^8\right)\right)
\end{aligned}
$$

Verified OK.

22.12.1 Maple step by step solution

Let's solve

$4x^2y''+4x^2y'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-y'-\frac{y}{2x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+y'+\frac{y}{2x^2}=0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = 1, P_3(x) = \frac{1}{2x^2}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 0$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = \frac{1}{2}$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $2x^2 y' + 2x^2 y'' + y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^2 \cdot y'$ to series expansion

    $x^2 \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r+1}$
  - Shift index using $k- >k-1$

    $x^2 \cdot y' = \sum_{k=1}^{\infty} a_{k-1} (k-1+r)\, x^{k+r}$
  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k-1+r)\, x^{k+r}$

    Rewrite ODE with series expansions

    $a_0(2r^2 - 2r + 1)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(2k^2 + 4kr + 2r^2 - 2k - 2r + 1) + 2a_{k-1}(k-1+r)\right) x^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $2r^2 - 2r + 1 = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{\frac{1}{2}-\frac{\mathrm{I}}{2}, \frac{1}{2}+\frac{\mathrm{I}}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $\left(2k^{2}+\left(4r-2\right)k+2r^{2}-2r+1\right)a_{k}+2a_{k-1}\left(k-1+r\right)=0$
- Shift index using $k->k+1$

  $\left(2\left(k+1\right)^{2}+\left(4r-2\right)\left(k+1\right)+2r^{2}-2r+1\right)a_{k+1}+2a_{k}\left(k+r\right)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{2a_{k}\left(k+r\right)}{2k^{2}+4kr+2r^{2}+2k+2r+1}$
- Recursion relation for $r=\frac{1}{2}-\frac{\mathrm{I}}{2}$

  $a_{k+1}=-\frac{2a_{k}\left(k+\frac{1}{2}-\frac{\mathrm{I}}{2}\right)}{2k^{2}+\left(2-2\,\mathrm{I}\right)k+2-2\,\mathrm{I}+2k}$
- Solution for $r=\frac{1}{2}-\frac{\mathrm{I}}{2}$

  $\left[y=\sum_{k=0}^{\infty}a_{k}x^{k+\frac{1}{2}-\frac{\mathrm{I}}{2}}, a_{k+1}=-\frac{2a_{k}\left(k+\frac{1}{2}-\frac{\mathrm{I}}{2}\right)}{2k^{2}+\left(2-2\,\mathrm{I}\right)k+2-2\,\mathrm{I}+2k}\right]$
- Recursion relation for $r=\frac{1}{2}+\frac{\mathrm{I}}{2}$

  $a_{k+1}=-\frac{2a_{k}\left(k+\frac{1}{2}+\frac{\mathrm{I}}{2}\right)}{2k^{2}+\left(2+2\,\mathrm{I}\right)k+2+2\,\mathrm{I}+2k}$
- Solution for $r=\frac{1}{2}+\frac{\mathrm{I}}{2}$

  $\left[y=\sum_{k=0}^{\infty}a_{k}x^{k+\frac{1}{2}+\frac{\mathrm{I}}{2}}, a_{k+1}=-\frac{2a_{k}\left(k+\frac{1}{2}+\frac{\mathrm{I}}{2}\right)}{2k^{2}+\left(2+2\,\mathrm{I}\right)k+2+2\,\mathrm{I}+2k}\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_{k}x^{k+\frac{1}{2}-\frac{\mathrm{I}}{2}}\right)+\left(\sum_{k=0}^{\infty}b_{k}x^{k+\frac{1}{2}+\frac{\mathrm{I}}{2}}\right), a_{k+1}=-\frac{2a_{k}\left(k+\frac{1}{2}-\frac{\mathrm{I}}{2}\right)}{2k^{2}+\left(2-2\,\mathrm{I}\right)k+2-2\,\mathrm{I}+2k}, b_{k+1}=-\frac{2b_{k}\left(k+\frac{1}{2}+\frac{\mathrm{I}}{2}\right)}{2k^{2}+\left(2+2\,\mathrm{I}\right)k+2+2\right.$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{2xy'' + (1-x)\,y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$2xy'' + (1-x)\,y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x-1}{2x}$$
$$q(x) = \frac{1}{2x}$$

Table 508: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-1}{2x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{2x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$2xy'' + (1 - x) y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$2\left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) x + (1 - x) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} 2x^{n+r-1} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$2x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(2x^{-1+r} r(-1+r) + r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$r\, x^{-1+r}(-1+2r) = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 - r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = \frac{1}{2}$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$r\, x^{-1+r}(-1 + 2r) = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = \frac{1}{2}$ is not an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+\frac{1}{2}}$$
$$y_2(x) = \sum_{n=0}^{\infty} b_n x^n$$

We start by finding $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$2a_n(n + r)(n + r - 1) - a_{n-1}(n + r - 1) + a_n(n + r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n + r - 2)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_n = \frac{2na_{n-1} - 3a_{n-1}}{4n^2 + 2n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = \frac{1}{2}$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-1+r}{2r^2+3r+1}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_1 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_2 = -\frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$
a_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	$-\frac{1}{120}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_3 = -\frac{1}{1680}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$
a_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	$-\frac{1}{120}$
a_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	$-\frac{1}{1680}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(-1+r)}{16r^6 + 240r^5 + 1432r^4 + 4296r^3 + 6697r^2 + 4959r + 1260}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_4 = -\frac{1}{24192}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$
a_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	$-\frac{1}{120}$
a_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	$-\frac{1}{1680}$
a_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	$-\frac{1}{24192}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{r(-1+r)}{32r^7 + 688r^6 + 6080r^5 + 28360r^4 + 74378r^3 + 107347r^2 + 76065r + 18900}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_5 = -\frac{1}{380160}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$
a_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	$-\frac{1}{120}$
a_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	$-\frac{1}{1680}$
a_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	$-\frac{1}{24192}$
a_5	$\frac{r(-1+r)}{32r^7+688r^6+6080r^5+28360r^4+74378r^3+107347r^2+76065r+18900}$	$-\frac{1}{380160}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{r(-1+r)}{64r^8 + 1856r^7 + 22672r^6 + 151280r^5 + 597196r^4 + 1408364r^3 + 1896603r^2 + 1285785r + 311850}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_6 = -\frac{1}{6589440}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$
a_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	$-\frac{1}{120}$
a_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	$-\frac{1}{1680}$
a_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	$-\frac{1}{24192}$
a_5	$\frac{r(-1+r)}{32r^7+688r^6+6080r^5+28360r^4+74378r^3+107347r^2+76065r+18900}$	$-\frac{1}{380160}$
a_6	$\frac{r(-1+r)}{64r^8+1856r^7+22672r^6+151280r^5+597196r^4+1408364r^3+1896603r^2+1285785r+311850}$	$-\frac{1}{6589440}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{r(-1+r)}{128r^9 + 4800r^8 + 77280r^7 + 697200r^6 + 3856104r^5 + 13426980r^4 + 29028970r^3 + 36796125r^2 + 23}$$

Which for the root $r = \frac{1}{2}$ becomes

$$a_7 = -\frac{1}{125798400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-1+r}{2r^2+3r+1}$	$-\frac{1}{6}$
a_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	$-\frac{1}{120}$
a_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	$-\frac{1}{1680}$
a_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	$-\frac{1}{24192}$
a_5	$\frac{r(-1+r)}{32r^7+688r^6+6080r^5+28360r^4+74378r^3+107347r^2+76065r+18900}$	$-\frac{1}{380160}$
a_6	$\frac{r(-1+r)}{64r^8+1856r^7+22672r^6+151280r^5+597196r^4+1408364r^3+1896603r^2+1285785r+311850}$	$-\frac{1}{6589440}$
a_7	$\frac{r(-1+r)}{128r^9+4800r^8+77280r^7+697200r^6+3856104r^5+13426980r^4+29028970r^3+36796125r^2+23950143r+5675670}$	$-\frac{1}{125798400}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= \sqrt{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \ldots\right) \\
&= \sqrt{x}\left(1 - \frac{x}{6} - \frac{x^2}{120} - \frac{x^3}{1680} - \frac{x^4}{24192} - \frac{x^5}{380160} - \frac{x^6}{6589440} - \frac{x^7}{125798400} + O(x^8)\right)
\end{aligned}$$

Now the second solution $y_2(x)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. For $1 \leq n$ the recursive equation is

$$2b_n(n+r)(n+r-1) - b_{n-1}(n+r-1) + (n+r)b_n + b_{n-1} = 0 \tag{3}$$

Solving for b_n from recursive equation (4) gives

$$b_n = \frac{b_{n-1}(n+r-2)}{2n^2 + 4nr + 2r^2 - n - r} \tag{4}$$

Which for the root $r = 0$ becomes

$$b_n = \frac{b_{n-1}(n-2)}{n(2n-1)} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1

For $n = 1$, using the above recursive equation gives

$$b_1 = \frac{-1 + r}{2r^2 + 3r + 1}$$

Which for the root $r = 0$ becomes

$$b_1 = -1$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{r(-1 + r)}{4r^4 + 20r^3 + 35r^2 + 25r + 6}$$

Which for the root $r = 0$ becomes

$$b_2 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1
b_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	0

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{r(-1 + r)}{8r^5 + 76r^4 + 274r^3 + 461r^2 + 351r + 90}$$

Which for the root $r = 0$ becomes

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1
b_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	0
b_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{r(-1+r)}{16r^6 + 240r^5 + 1432r^4 + 4296r^3 + 6697r^2 + 4959r + 1260}$$

Which for the root $r = 0$ becomes

$$b_4 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1
b_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	0
b_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	0
b_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	0

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{r(-1+r)}{32r^7 + 688r^6 + 6080r^5 + 28360r^4 + 74378r^3 + 107347r^2 + 76065r + 18900}$$

Which for the root $r = 0$ becomes

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1
b_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	0
b_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	0
b_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	0
b_5	$\frac{r(-1+r)}{32r^7+688r^6+6080r^5+28360r^4+74378r^3+107347r^2+76065r+18900}$	0

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{r(-1+r)}{64r^8 + 1856r^7 + 22672r^6 + 151280r^5 + 597196r^4 + 1408364r^3 + 1896603r^2 + 1285785r + 311850}$$

Which for the root $r = 0$ becomes

$$b_6 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1
b_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	0
b_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	0
b_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	0
b_5	$\frac{r(-1+r)}{32r^7+688r^6+6080r^5+28360r^4+74378r^3+107347r^2+76065r+18900}$	0
b_6	$\frac{r(-1+r)}{64r^8+1856r^7+22672r^6+151280r^5+597196r^4+1408364r^3+1896603r^2+1285785r+311850}$	0

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{r(-1+r)}{128r^9 + 4800r^8 + 77280r^7 + 697200r^6 + 3856104r^5 + 13426980r^4 + 29028970r^3 + 36796125r^2 + 239}$$

Which for the root $r = 0$ becomes

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{-1+r}{2r^2+3r+1}$	-1
b_2	$\frac{r(-1+r)}{4r^4+20r^3+35r^2+25r+6}$	0
b_3	$\frac{r(-1+r)}{8r^5+76r^4+274r^3+461r^2+351r+90}$	0
b_4	$\frac{r(-1+r)}{16r^6+240r^5+1432r^4+4296r^3+6697r^2+4959r+1260}$	0
b_5	$\frac{r(-1+r)}{32r^7+688r^6+6080r^5+28360r^4+74378r^3+107347r^2+76065r+18900}$	0
b_6	$\frac{r(-1+r)}{64r^8+1856r^7+22672r^6+151280r^5+597196r^4+1408364r^3+1896603r^2+1285785r+311850}$	0
b_7	$\frac{r(-1+r)}{128r^9+4800r^8+77280r^7+697200r^6+3856104r^5+13426980r^4+29028970r^3+36796125r^2+23950143r+5675670}$	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\ &= 1 - x + O(x^8) \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \sqrt{x}\left(1 - \frac{x}{6} - \frac{x^2}{120} - \frac{x^3}{1680} - \frac{x^4}{24192} - \frac{x^5}{380160} - \frac{x^6}{6589440} - \frac{x^7}{125798400} + O(x^8)\right) \\ &\quad + c_2(1 - x + O(x^8)) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= c_1 \sqrt{x}\left(1 - \frac{x}{6} - \frac{x^2}{120} - \frac{x^3}{1680} - \frac{x^4}{24192} - \frac{x^5}{380160} - \frac{x^6}{6589440} - \frac{x^7}{125798400} + O(x^8)\right) \\ &\quad + c_2(1 - x + O(x^8)) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = c_1 \sqrt{x}\left(1 - \frac{x}{6} - \frac{x^2}{120} - \frac{x^3}{1680} - \frac{x^4}{24192} - \frac{x^5}{380160} - \frac{x^6}{6589440} - \frac{x^7}{125798400} + O(x^8)\right) \\ + c_2(1 - x + O(x^8)) \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\left(1-\frac{x}{6}-\frac{x^2}{120}-\frac{x^3}{1680}-\frac{x^4}{24192}-\frac{x^5}{380160}-\frac{x^6}{6589440}-\frac{x^7}{125798400}+O(x^8)\right) + c_2(1-x+O(x^8))$$

Verified OK.

22.13.1 Maple step by step solution

Let's solve

$2y''x + (1-x)\,y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(x-1)y'}{2x} - \frac{y}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(x-1)y'}{2x} + \frac{y}{2x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{x-1}{2x}, P_3(x) = \frac{1}{2x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = \frac{1}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x + (1-x)\,y' + y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$
  - Shift index using $k- >k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(2k+1+2r) - a_k(k+r-1)\right) x^{k+r}\right) = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $2(k+1+r)\left(k+\frac{1}{2}+r\right) a_{k+1} - a_k(k+r-1) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k+r-1)}{(k+1+r)(2k+1+2r)}$
- Recursion relation for $r = 0$; series terminates at $k = 1$

  $a_{k+1} = \frac{a_k(k-1)}{(k+1)(2k+1)}$
- Apply recursion relation for $k = 0$

  $a_1 = -a_0$
- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

$$y = a_0 \cdot (1 - x)$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = \frac{a_k \left(k - \frac{1}{2}\right)}{\left(k + \frac{3}{2}\right) (2k + 2)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k \left(k - \frac{1}{2}\right)}{\left(k + \frac{3}{2}\right) (2k + 2)}\right]$$

- Combine solutions and rename parameters

$$\left[y = a_0 \cdot (1 - x) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), b_{k+1} = \frac{b_k \left(k - \frac{1}{2}\right)}{\left(k + \frac{3}{2}\right) (2k + 2)}\right]$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[_Laguerre]`

$$\boxed{xy'' - (x-1)\,y' + 2y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + (1-x)\,y' + 2y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x-1}{x}$$
$$q(x) = \frac{2}{x}$$

Table 510: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{2}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + (1 - x)\, y' + 2y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r)\, (n + r - 1)\, a_n x^{n+r-2}\right) x + (1 - x) \left(\sum_{n=0}^{\infty} (n + r)\, a_n x^{n+r-1}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r) (n+r-1)\right)+\sum_{n=0}^{\infty}\left(-x^{n+r} a_n (n+r)\right) \\
&\quad+\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right)+\left(\sum_{n=0}^{\infty} 2 a_n x^{n+r}\right)=0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty}\left(-x^{n+r} a_n (n+r)\right) &= \sum_{n=1}^{\infty}\left(-a_{n-1} (n+r-1) x^{n+r-1}\right) \\
\sum_{n=0}^{\infty} 2 a_n x^{n+r} &= \sum_{n=1}^{\infty} 2 a_{n-1} x^{n+r-1}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r) (n+r-1)\right)+\sum_{n=1}^{\infty}\left(-a_{n-1} (n+r-1) x^{n+r-1}\right) \\
&\quad+\left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right)+\left(\sum_{n=1}^{\infty} 2 a_{n-1} x^{n+r-1}\right)=0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r-1} a_n (n+r) (n+r-1)+(n+r) a_n x^{n+r-1}=0
$$

When $n=0$ the above becomes

$$
x^{-1+r} a_0 r(-1+r)+r a_0 x^{-1+r}=0
$$

Or

$$
\left(x^{-1+r} r(-1+r)+r\, x^{-1+r}\right) a_0=0
$$

Since $a_0 \neq 0$ then the above simplifies to

$$
x^{-1+r} r^2=0
$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r} r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_n(n+r) + 2a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n+r-3)}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{a_{n-1}(n-3)}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-2+r}{(r+1)^2}$$

Which for the root $r = 0$ becomes

$$a_1 = -2$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{(-2+r)(-1+r)}{(r+1)^2 (r+2)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2
a_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$$

Which for the root $r = 0$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2
a_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$
a_3	$\frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(-2+r)(-1+r)r}{(r+1)(r+2)^2(r+3)^2(r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2
a_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$
a_3	$\frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$	0
a_4	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)^2(r+3)^2(r+4)^2}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)^2(r+4)^2(r+5)^2}$$

Which for the root $r = 0$ becomes

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2
a_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$
a_3	$\frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$	0
a_4	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)^2(r+3)^2(r+4)^2}$	0
a_5	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)^2(r+4)^2(r+5)^2}$	0

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)^2(r+5)^2(r+6)^2}$$

Which for the root $r = 0$ becomes

$$a_6 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2
a_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$
a_3	$\frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$	0
a_4	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)^2(r+3)^2(r+4)^2}$	0
a_5	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)^2(r+4)^2(r+5)^2}$	0
a_6	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)^2(r+5)^2(r+6)^2}$	0

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)(r+5)^2(r+6)^2(r+7)^2}$$

Which for the root $r = 0$ becomes

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-2+r}{(r+1)^2}$	-2
a_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$
a_3	$\frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$	0
a_4	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)^2(r+3)^2(r+4)^2}$	0
a_5	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)^2(r+4)^2(r+5)^2}$	0
a_6	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)^2(r+5)^2(r+6)^2}$	0
a_7	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)(r+5)^2(r+6)^2(r+7)^2}$	0

Using the above table, then the first solution $y_1(x)$ becomes

$$\begin{aligned} y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots \\ &= 1 - 2x + \frac{x^2}{2} + O(x^8) \end{aligned}$$

Now the second solution is found. The second solution is given by

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)$$

Where b_n is found using

$$b_n = \frac{d}{dr} a_{n,r}$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$
b_0	1	1	N/A since b_n starts from 1
b_1	$\frac{-2+r}{(r+1)^2}$	-2	$\frac{-r+5}{(r+1)^3}$
b_2	$\frac{(-2+r)(-1+r)}{(r+1)^2(r+2)^2}$	$\frac{1}{2}$	$\frac{-2r^3+9r^2+5r-18}{(r+1)^3(r+2)^3}$
b_3	$\frac{(-2+r)(-1+r)r}{(r+1)^2(r+2)^2(r+3)^2}$	0	$\frac{-3r^5+6r^4+37r^3-18r^2-58r+12}{(r+1)^3(r+2)^3(r+3)^3}$
b_4	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)^2(r+3)^2(r+4)^2}$	0	$\frac{-4r^6-6r^5+72r^4+124r^3-158r^2-196r+48}{(r+1)^2(r+2)^3(r+3)^3(r+4)^3}$
b_5	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)^2(r+4)^2(r+5)^2}$	0	$\frac{-5r^7-30r^6+50r^5+510r^4+431r^3-1008r^2-908r+240}{(r+1)^2(r+2)^2(r+3)^3(r+4)^3(r+5)^3}$
b_6	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)^2(r+5)^2(r+6)^2}$	0	$\frac{-6r^8-69r^7-145r^6+855r^5+3587r^4+1542r^3-7036r^2-5208r+1440}{(r+1)^2(r+2)^2(r+3)^2(r+4)^3(r+5)^3(r+6)^3}$
b_7	$\frac{(-2+r)(-1+r)r}{(r+1)(r+2)(r+3)(r+4)(r+5)^2(r+6)^2(r+7)^2}$	0	$\frac{-7r^9-126r^8-700r^7-238r^6+9863r^5+27356r^4+3900r^3-55072r^2-35376r+1008}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^3(r+6)^3(r+7)^3}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 + b_7 x^7 + b_8 x^8 \dots \\
&= \left(1 - 2x + \frac{x^2}{2} + O(x^8)\right)\ln(x) + 5x - \frac{9x^2}{4} + \frac{x^3}{18} + \frac{x^4}{288} + \frac{x^5}{3600} + \frac{x^6}{43200} + \frac{x^7}{529200} \\
&\quad + O(x^8)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1\left(1 - 2x + \frac{x^2}{2} + O(x^8)\right) + c_2\left(\left(1 - 2x + \frac{x^2}{2} + O(x^8)\right)\ln(x) + 5x - \frac{9x^2}{4}\right. \\
&\quad \left. + \frac{x^3}{18} + \frac{x^4}{288} + \frac{x^5}{3600} + \frac{x^6}{43200} + \frac{x^7}{529200} + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1\left(1 - 2x + \frac{x^2}{2} + O(x^8)\right) + c_2\left(\left(1 - 2x + \frac{x^2}{2} + O(x^8)\right)\ln(x) + 5x - \frac{9x^2}{4} + \frac{x^3}{18}\right. \\
&\quad \left. + \frac{x^4}{288} + \frac{x^5}{3600} + \frac{x^6}{43200} + \frac{x^7}{529200} + O(x^8)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1\left(1-2x+\frac{x^2}{2}+O\left(x^8\right)\right)+c_2\left(\left(1-2x+\frac{x^2}{2}+O\left(x^8\right)\right)\ln\left(x\right)+5x-\frac{9x^2}{4}+\frac{x^3}{18}+\frac{x^4}{288}+\frac{x^5}{3600}+\frac{x^6}{43200}+\frac{x^7}{529200}+O\left(x^8\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1\left(1-2x+\frac{x^2}{2}+O\left(x^8\right)\right)+c_2\left(\left(1-2x+\frac{x^2}{2}+O\left(x^8\right)\right)\ln\left(x\right)+5x-\frac{9x^2}{4}+\frac{x^3}{18}+\frac{x^4}{288}+\frac{x^5}{3600}+\frac{x^6}{43200}+\frac{x^7}{529200}+O\left(x^8\right)\right)$$

Verified OK.

22.14.1 Maple step by step solution

Let's solve

$y''x+(1-x)\,y'+2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{(x-1)y'}{x}-\frac{2y}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(x-1)y'}{x}+\frac{2y}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=-\frac{x-1}{x}, P_3(x)=\frac{2}{x}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=1$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left.(x^2\cdot P_3(x))\right|_{x=0}=0$

  ◦ $x=0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$y''x + (1-x)\, y' + 2y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ○ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

  ○ Shift index using $k- > k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

  ○ Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$

  ○ Shift index using $k- > k+1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

Rewrite ODE with series expansions

$$a_0 r^2 x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)^2 - a_k(k+r-2)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r^2 = 0$

- Values of r that satisfy the indicial equation

$r = 0$

- Each term in the series must be 0, giving the recursion relation

$a_{k+1}(k+1)^2 - a_k(k-2) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = \frac{a_k(k-2)}{(k+1)^2}$

- Recursion relation for $r = 0$; series terminates at $k = 2$

$a_{k+1} = \frac{a_k(k-2)}{(k+1)^2}$

- Apply recursion relation for $k = 0$

  $a_1 = -2a_0$

- Apply recursion relation for $k = 1$

  $a_2 = -\frac{a_1}{4}$

- Express in terms of a_0

  $a_2 = \frac{a_0}{2}$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

  $y = a_0 \cdot \left(1 - 2x + \frac{1}{2}x^2\right)$

Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (A) Drill Exercises . Page 194
Problem number: 2(g).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Complex roots"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + x(1-x)\, y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$x^2y'' + \left(-x^2 + x\right) y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = -\frac{x-1}{x}$$
$$q(x) = \frac{1}{x^2}$$

Table 512: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x-1}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{x^2}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2 y'' + \left(-x^2 + x\right) y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2 \left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n x^{n+r-2}\right) + \left(-x^2 + x\right) \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} \left(-x^{1+n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \sum_{n=1}^{\infty} \left(-a_{n-1}(n+r-1)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2+1\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2+1 = 0$$

Solving for r gives the roots of the indicial equation as

$$
\begin{aligned}
r_1 &= i \\
r_2 &= -i
\end{aligned}
$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$
(r^2 + 1)\, x^r = 0
$$

Solving for r gives the roots of the indicial equation as Since the roots are complex conjugates, then two linearly independent solutions can be constructed using

$$
\begin{aligned}
y_1(x) &= x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right) \\
y_2(x) &= x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)
\end{aligned}
$$

Or

$$
\begin{aligned}
y_1(x) &= \sum_{n=0}^{\infty} a_n x^{n+i} \\
y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n-i}
\end{aligned}
$$

$y_1(x)$ is found first. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$
a_n(n+r)(n+r-1) - a_{n-1}(n+r-1) + a_n(n+r) + a_n = 0 \tag{3}
$$

Solving for a_n from recursive equation (4) gives

$$
a_n = \frac{a_{n-1}(n+r-1)}{n^2 + 2nr + r^2 + 1} \tag{4}
$$

Which for the root $r = i$ becomes

$$
a_n = \frac{a_{n-1}(n-1+i)}{n\,(2i+n)} \tag{5}
$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = i$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{r}{r^2 + 2r + 2}$$

Which for the root $r = i$ becomes

$$a_1 = \frac{2}{5} + \frac{i}{5}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5} + \frac{i}{5}$

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r(r+1)}{(r^2 + 2r + 2)(r^2 + 4r + 5)}$$

Which for the root $r = i$ becomes

$$a_2 = \frac{1}{10} + \frac{i}{20}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5} + \frac{i}{5}$
a_2	$\frac{r(r+1)}{(r^2+2r+2)(r^2+4r+5)}$	$\frac{1}{10} + \frac{i}{20}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{r(r+1)(2+r)}{(r^2 + 2r + 2)(r^2 + 4r + 5)(r^2 + 6r + 10)}$$

Which for the root $r = i$ becomes

$$a_3 = \frac{17}{780} + \frac{i}{130}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5}+\frac{i}{5}$
a_2	$\frac{r(r+1)}{(r^2+2r+2)(r^2+4r+5)}$	$\frac{1}{10}+\frac{i}{20}$
a_3	$\frac{r(r+1)(2+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{17}{780}+\frac{i}{130}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r(r+1)(2+r)(3+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$$

Which for the root $r = i$ becomes

$$a_4 = \frac{5}{1248} + \frac{i}{1248}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5}+\frac{i}{5}$
a_2	$\frac{r(r+1)}{(r^2+2r+2)(r^2+4r+5)}$	$\frac{1}{10}+\frac{i}{20}$
a_3	$\frac{r(r+1)(2+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{17}{780}+\frac{i}{130}$
a_4	$\frac{r(r+1)(2+r)(3+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$\frac{5}{1248}+\frac{i}{1248}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{r(r+1)(2+r)(3+r)(4+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$$

Which for the root $r = i$ becomes

$$a_5 = \frac{113}{180960} + \frac{7i}{180960}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5}+\frac{i}{5}$
a_2	$\frac{r(r+1)}{(r^2+2r+2)(r^2+4r+5)}$	$\frac{1}{10}+\frac{i}{20}$
a_3	$\frac{r(r+1)(2+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{17}{780}+\frac{i}{130}$
a_4	$\frac{r(r+1)(2+r)(3+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$\frac{5}{1248}+\frac{i}{1248}$
a_5	$\frac{r(r+1)(2+r)(3+r)(4+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{113}{180960}+\frac{7i}{180960}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{r(r+1)(2+r)(3+r)(4+r)(5+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)}$$

Which for the root $r = i$ becomes

$$a_6 = \frac{911}{10857600} - \frac{19i}{3619200}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5}+\frac{i}{5}$
a_2	$\frac{r(r+1)}{(r^2+2r+2)(r^2+4r+5)}$	$\frac{1}{10}+\frac{i}{20}$
a_3	$\frac{r(r+1)(2+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{17}{780}+\frac{i}{130}$
a_4	$\frac{r(r+1)(2+r)(3+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$\frac{5}{1248}+\frac{i}{1248}$
a_5	$\frac{r(r+1)(2+r)(3+r)(4+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{113}{180960}+\frac{7i}{180960}$
a_6	$\frac{r(r+1)(2+r)(3+r)(4+r)(5+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)}$	$\frac{911}{10857600}-\frac{19i}{3619200}$

For $n = 7$, using the above recursive equation gives

$$a_7 = \frac{r(r+1)(2+r)(3+r)(4+r)(5+r)(6+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)(r^2+14r+}$$

Which for the root $r = i$ becomes

$$a_7 = \frac{39799}{4028169600} - \frac{1009i}{575452800}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{r}{r^2+2r+2}$	$\frac{2}{5}+\frac{i}{5}$
a_2	$\frac{r(r+1)}{(r^2+2r+2)(r^2+4r+5)}$	$\frac{1}{10}+\frac{i}{20}$
a_3	$\frac{r(r+1)(2+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)}$	$\frac{17}{780}+\frac{i}{130}$
a_4	$\frac{r(r+1)(2+r)(3+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)}$	$\frac{5}{1248}+\frac{i}{1248}$
a_5	$\frac{r(r+1)(2+r)(3+r)(4+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)}$	$\frac{113}{180960}+\frac{7i}{180960}$
a_6	$\frac{r(r+1)(2+r)(3+r)(4+r)(5+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)}$	$\frac{911}{10857600}-\frac{19i}{3619200}$
a_7	$\frac{r(r+1)(2+r)(3+r)(4+r)(5+r)(6+r)}{(r^2+2r+2)(r^2+4r+5)(r^2+6r+10)(r^2+8r+17)(r^2+10r+26)(r^2+12r+37)(r^2+14r+50)}$	$\frac{39799}{4028169600}-\frac{1009i}{575452800}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned}
y_1(x) &= x^i\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 + a_7x^7 + a_8x^8 \dots\right) \\
&= x^i\left(1 + \left(\frac{2}{5}+\frac{i}{5}\right)x + \left(\frac{1}{10}+\frac{i}{20}\right)x^2 + \left(\frac{17}{780}+\frac{i}{130}\right)x^3 + \left(\frac{5}{1248}+\frac{i}{1248}\right)x^4 \right. \\
&\quad + \left(\frac{113}{180960}+\frac{7i}{180960}\right)x^5 + \left(\frac{911}{10857600}-\frac{19i}{3619200}\right)x^6 \\
&\quad \left. + \left(\frac{39799}{4028169600}-\frac{1009i}{575452800}\right)x^7 + O(x^8)\right)
\end{aligned}$$

The second solution $y_2(x)$ is found by taking the complex conjugate of $y_1(x)$ which gives

$$\begin{aligned}
y_2(x) &= x^{-i}\left(1 + \left(\frac{2}{5}-\frac{i}{5}\right)x + \left(\frac{1}{10}-\frac{i}{20}\right)x^2 + \left(\frac{17}{780}-\frac{i}{130}\right)x^3 + \left(\frac{5}{1248}-\frac{i}{1248}\right)x^4 \right. \\
&\quad + \left(\frac{113}{180960}-\frac{7i}{180960}\right)x^5 + \left(\frac{911}{10857600}+\frac{19i}{3619200}\right)x^6 \\
&\quad \left. + \left(\frac{39799}{4028169600}+\frac{1009i}{575452800}\right)x^7 + O(x^8)\right)
\end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^{i}\left(1+\left(\frac{2}{5}+\frac{i}{5}\right)x+\left(\frac{1}{10}+\frac{i}{20}\right)x^{2}+\left(\frac{17}{780}+\frac{i}{130}\right)x^{3}+\left(\frac{5}{1248}+\frac{i}{1248}\right)x^{4}\right. \\
&\quad +\left(\frac{113}{180960}+\frac{7i}{180960}\right)x^{5}+\left(\frac{911}{10857600}-\frac{19i}{3619200}\right)x^{6} \\
&\quad \left.+\left(\frac{39799}{4028169600}-\frac{1009i}{575452800}\right)x^{7}+O\left(x^{8}\right)\right) \\
&\quad + c_2 x^{-i}\left(1+\left(\frac{2}{5}-\frac{i}{5}\right)x+\left(\frac{1}{10}-\frac{i}{20}\right)x^{2}+\left(\frac{17}{780}-\frac{i}{130}\right)x^{3}+\left(\frac{5}{1248}-\frac{i}{1248}\right)x^{4}\right. \\
&\quad +\left(\frac{113}{180960}-\frac{7i}{180960}\right)x^{5}+\left(\frac{911}{10857600}+\frac{19i}{3619200}\right)x^{6} \\
&\quad \left.+\left(\frac{39799}{4028169600}+\frac{1009i}{575452800}\right)x^{7}+O\left(x^{8}\right)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 x^{i}\left(1+\left(\frac{2}{5}+\frac{i}{5}\right)x+\left(\frac{1}{10}+\frac{i}{20}\right)x^{2}+\left(\frac{17}{780}+\frac{i}{130}\right)x^{3}+\left(\frac{5}{1248}+\frac{i}{1248}\right)x^{4}\right. \\
&\quad +\left(\frac{113}{180960}+\frac{7i}{180960}\right)x^{5}+\left(\frac{911}{10857600}-\frac{19i}{3619200}\right)x^{6} \\
&\quad \left.+\left(\frac{39799}{4028169600}-\frac{1009i}{575452800}\right)x^{7}+O\left(x^{8}\right)\right)+c_2 x^{-i}\left(1+\left(\frac{2}{5}-\frac{i}{5}\right)x\right. \\
&\quad +\left(\frac{1}{10}-\frac{i}{20}\right)x^{2}+\left(\frac{17}{780}-\frac{i}{130}\right)x^{3}+\left(\frac{5}{1248}-\frac{i}{1248}\right)x^{4}+\left(\frac{113}{180960}-\frac{7i}{180960}\right)x^{5} \\
&\quad \left.+\left(\frac{911}{10857600}+\frac{19i}{3619200}\right)x^{6}+\left(\frac{39799}{4028169600}+\frac{1009i}{575452800}\right)x^{7}+O\left(x^{8}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 x^i \left(1+\left(\frac{2}{5}+\frac{i}{5}\right) x +\left(\frac{1}{10}+\frac{i}{20}\right) x^2+\left(\frac{17}{780}+\frac{i}{130}\right) x^3+\left(\frac{5}{1248}+\frac{i}{1248}\right) x^4 +\left(\frac{113}{180960}+\frac{7i}{180960}\right) x^5+\left(\frac{911}{10857600}-\frac{19i}{3619200}\right) x^6 +\left(\frac{39799}{4028169600}-\frac{1009i}{575452800}\right) x^7+O\left(x^8\right)\right) + c_2 x^{-i} \left(1+\left(\frac{2}{5}-\frac{i}{5}\right) x +\left(\frac{1}{10}-\frac{i}{20}\right) x^2+\left(\frac{17}{780}-\frac{i}{130}\right) x^3 +\left(\frac{5}{1248}-\frac{i}{1248}\right) x^4+\left(\frac{113}{180960}-\frac{7i}{180960}\right) x^5+\left(\frac{911}{10857600}+\frac{19i}{3619200}\right) x^6 +\left(\frac{39799}{4028169600}+\frac{1009i}{575452800}\right) x^7+O\left(x^8\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^i \left(1+\left(\frac{2}{5}+\frac{i}{5}\right) x +\left(\frac{1}{10}+\frac{i}{20}\right) x^2+\left(\frac{17}{780}+\frac{i}{130}\right) x^3+\left(\frac{5}{1248}+\frac{i}{1248}\right) x^4 +\left(\frac{113}{180960}+\frac{7i}{180960}\right) x^5+\left(\frac{911}{10857600}-\frac{19i}{3619200}\right) x^6 +\left(\frac{39799}{4028169600}-\frac{1009i}{575452800}\right) x^7+O\left(x^8\right)\right) + c_2 x^{-i} \left(1+\left(\frac{2}{5}-\frac{i}{5}\right) x +\left(\frac{1}{10}-\frac{i}{20}\right) x^2+\left(\frac{17}{780}-\frac{i}{130}\right) x^3 +\left(\frac{5}{1248}-\frac{i}{1248}\right) x^4+\left(\frac{113}{180960}-\frac{7i}{180960}\right) x^5 +\left(\frac{911}{10857600}+\frac{19i}{3619200}\right) x^6 +\left(\frac{39799}{4028169600}+\frac{1009i}{575452800}\right) x^7+O\left(x^8\right)\right)$$

Verified OK.

22.15.1 Maple step by step solution

Let's solve

$x^2 y'' + (-x^2 + x) y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{x^2} + \frac{(x-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(x-1)y'}{x}+\frac{y}{x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=-\frac{x-1}{x}, P_3(x)=\frac{1}{x^2}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left(x\cdot P_2(x)\right)\bigg|_{x=0}=1$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=1$

  - $x=0$is a regular singular point

    Check to see if $x_0=0$ is a regular singular point

    $x_0=0$

- Multiply by denominators

  $x^2y''-x(x-1)\,y'+y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m\cdot y'$ to series expansion for $m=1..2$

    $x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^2\cdot y''$ to series expansion

    $x^2\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

    Rewrite ODE with series expansions

    $a_0(r^2+1)\,x^r+\left(\sum_{k=1}^{\infty}\left(a_k(k^2+2kr+r^2+1)-a_{k-1}(k+r-1)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2+1=0$

- Values of r that satisfy the indicial equation

  $r \in \{-\mathrm{I}, \mathrm{I}\}$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k^2+2kr+r^2+1)-a_{k-1}(k+r-1)=0$

- Shift index using $k->k+1$

  $a_{k+1}\left((k+1)^2+2(k+1)\,r+r^2+1\right)-a_k(k+r)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k(k+r)}{k^2+2kr+r^2+2k+2r+2}$

- Recursion relation for $r=-\mathrm{I}$

  $a_{k+1}=\frac{a_k(k-\mathrm{I})}{k^2-2\,\mathrm{I}k+1-2\,\mathrm{I}+2k}$

- Solution for $r=-\mathrm{I}$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-\mathrm{I}}, a_{k+1}=\frac{a_k(k-\mathrm{I})}{k^2-2\,\mathrm{I}k+1-2\,\mathrm{I}+2k}\right]$

- Recursion relation for $r=\mathrm{I}$

  $a_{k+1}=\frac{a_k(k+\mathrm{I})}{k^2+2\,\mathrm{I}k+1+2\,\mathrm{I}+2k}$

- Solution for $r=\mathrm{I}$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+\mathrm{I}}, a_{k+1}=\frac{a_k(k+\mathrm{I})}{k^2+2\,\mathrm{I}k+1+2\,\mathrm{I}+2k}\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k-\mathrm{I}}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k+\mathrm{I}}\right), a_{k+1}=\frac{a_k(k-\mathrm{I})}{k^2-2\,\mathrm{I}k+1-2\,\mathrm{I}+2k}, b_{k+1}=\frac{b_k(k+\mathrm{I})}{k^2+2\,\mathrm{I}k+1+2\,\mathrm{I}+2k}\right]$

Problem number: 2(h).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{xy'' + (1 + x) y' + y = 0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$xy'' + (1 + x) y' + y = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y'' + p(x)y' + q(x)y = 0$$

Where

$$p(x) = \frac{1 + x}{x}$$
$$q(x) = \frac{1}{x}$$

Table 514: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1+x}{x}$	
singularity	type
$x = 0$	"regular"

$q(x) = \frac{1}{x}$	
singularity	type
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$xy'' + (1 + x) y' + y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=0}^{\infty} (n + r) (n + r - 1) a_n x^{n+r-2}\right) x + (1 + x) \left(\sum_{n=0}^{\infty} (n + r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r-1$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r} a_n (n+r) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r-1}$$

$$\sum_{n=0}^{\infty} a_n x^{n+r} = \sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} x^{n+r-1} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)\, x^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} (n+r) a_n x^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} a_{n-1} x^{n+r-1}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r-1} a_n (n+r)(n+r-1) + (n+r) a_n x^{n+r-1} = 0$$

When $n=0$ the above becomes

$$x^{-1+r} a_0 r(-1+r) + r a_0 x^{-1+r} = 0$$

Or

$$\left(x^{-1+r} r(-1+r) + r\, x^{-1+r}\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^{-1+r} r^2 = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 0$$
$$r_2 = 0$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^{-1+r} r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_{n-1}(n+r-1) + a_n(n+r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{n+r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{a_{n-1}}{n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{1+r}$$

Which for the root $r = 0$ becomes

$$a_1 = -1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{(1+r)(2+r)}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1
a_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{(3+r)(1+r)(2+r)}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{1}{6}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1
a_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$
a_3	$-\frac{1}{(3+r)(1+r)(2+r)}$	$-\frac{1}{6}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(4+r)(3+r)(1+r)(2+r)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1
a_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$
a_3	$-\frac{1}{(3+r)(1+r)(2+r)}$	$-\frac{1}{6}$
a_4	$\frac{1}{(4+r)(3+r)(1+r)(2+r)}$	$\frac{1}{24}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{1}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1
a_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$
a_3	$-\frac{1}{(3+r)(1+r)(2+r)}$	$-\frac{1}{6}$
a_4	$\frac{1}{(4+r)(3+r)(1+r)(2+r)}$	$\frac{1}{24}$
a_5	$-\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)}$	$-\frac{1}{120}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$$

Which for the root $r = 0$ becomes

$$a_6 = \frac{1}{720}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1
a_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$
a_3	$-\frac{1}{(3+r)(1+r)(2+r)}$	$-\frac{1}{6}$
a_4	$\frac{1}{(4+r)(3+r)(1+r)(2+r)}$	$\frac{1}{24}$
a_5	$-\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)}$	$-\frac{1}{120}$
a_6	$\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$	$\frac{1}{720}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{1}{(7+r)(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$$

Which for the root $r = 0$ becomes

$$a_7 = -\frac{1}{5040}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{1+r}$	-1
a_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$
a_3	$-\frac{1}{(3+r)(1+r)(2+r)}$	$-\frac{1}{6}$
a_4	$\frac{1}{(4+r)(3+r)(1+r)(2+r)}$	$\frac{1}{24}$
a_5	$-\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)}$	$-\frac{1}{120}$
a_6	$\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$	$\frac{1}{720}$
a_7	$-\frac{1}{(7+r)(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$	$-\frac{1}{5040}$

Using the above table, then the first solution $y_1(x)$ becomes

$$
\begin{aligned}
y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 + a_7 x^7 + a_8 x^8 \dots \\
&= 1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)
\end{aligned}
$$

Now the second solution is found. The second solution is given by

$$
y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)
$$

Where b_n is found using

$$
b_n = \frac{d}{dr} a_{n,r}
$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n(r=0)$
b_0	1	1	N/A since b_n starts from 1	N/A
b_1	$-\frac{1}{1+r}$	-1	$\frac{1}{(1+r)^2}$	1
b_2	$\frac{1}{(1+r)(2+r)}$	$\frac{1}{2}$	$\frac{-3-2r}{(1+r)^2(2+r)^2}$	$-\frac{3}{4}$
b_3	$-\frac{1}{(3+r)(1+r)(2+r)}$	$-\frac{1}{6}$	$\frac{3r^2+12r+11}{(3+r)^2(1+r)^2(2+r)^2}$	$\frac{11}{36}$
b_4	$\frac{1}{(4+r)(3+r)(1+r)(2+r)}$	$\frac{1}{24}$	$\frac{-4r^3-30r^2-70r-50}{(4+r)^2(3+r)^2(1+r)^2(2+r)^2}$	$-\frac{25}{288}$
b_5	$-\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)}$	$-\frac{1}{120}$	$\frac{5r^4+60r^3+255r^2+450r+274}{(5+r)^2(4+r)^2(3+r)^2(1+r)^2(2+r)^2}$	$\frac{137}{7200}$
b_6	$\frac{1}{(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$	$\frac{1}{720}$	$\frac{-6r^5-105r^4-700r^3-2205r^2-3248r-1764}{(5+r)^2(4+r)^2(3+r)^2(1+r)^2(2+r)^2(6+r)^2}$	$-\frac{49}{14400}$
b_7	$-\frac{1}{(7+r)(5+r)(4+r)(3+r)(1+r)(2+r)(6+r)}$	$-\frac{1}{5040}$	$\frac{7r^6+168r^5+1610r^4+7840r^3+20307r^2+26264r+13068}{(7+r)^2(5+r)^2(4+r)^2(3+r)^2(1+r)^2(2+r)^2(6+r)^2}$	$\frac{121}{235200}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 + b_7x^7 + b_8x^8\dots \\
&= \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right)\ln(x) \\
&\quad + x - \frac{3x^2}{4} + \frac{11x^3}{36} - \frac{25x^4}{288} + \frac{137x^5}{7200} - \frac{49x^6}{14400} + \frac{121x^7}{235200} + O(x^8)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1\left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) \\
&\quad + c_2\left(\left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right)\ln(x) + x - \frac{3x^2}{4}\right. \\
&\quad\left. + \frac{11x^3}{36} - \frac{25x^4}{288} + \frac{137x^5}{7200} - \frac{49x^6}{14400} + \frac{121x^7}{235200} + O(x^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
y = y_h
$$

$$= c_1 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) + c_2 \left(\left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) \ln(x) + x - \frac{3x^2}{4} + \frac{11x^3}{36} - \frac{25x^4}{288} + \frac{137x^5}{7200} - \frac{49x^6}{14400} + \frac{121x^7}{235200} + O(x^8)\right)$$

Summary
The solution(s) found are the following

$$y = c_1 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) + c_2 \left(\left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) \ln(x) + x - \frac{3x^2}{4} + \frac{11x^3}{36} - \frac{25x^4}{288} + \frac{137x^5}{7200} - \frac{49x^6}{14400} + \frac{121x^7}{235200} + O(x^8)\right) \quad (1)$$

Verification of solutions

$$y = c_1 \left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) + c_2 \left(\left(1 - x + \frac{x^2}{2} - \frac{x^3}{6} + \frac{x^4}{24} - \frac{x^5}{120} + \frac{x^6}{720} - \frac{x^7}{5040} + O(x^8)\right) \ln(x) + x - \frac{3x^2}{4} + \frac{11x^3}{36} - \frac{25x^4}{288} + \frac{137x^5}{7200} - \frac{49x^6}{14400} + \frac{121x^7}{235200} + O(x^8)\right)$$

Verified OK.

22.16.1 Maple step by step solution

Let's solve

$y''x + (1 + x) y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(1+x)y'}{x} - \frac{y}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(1+x)y'}{x} + \frac{y}{x} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

- Define functions

  $\left[P_2(x) = \frac{1+x}{x}, P_3(x) = \frac{1}{x}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 1$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

• Multiply by denominators

  $y''x + (1 + x)\, y' + y = 0$

• Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$

- Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r-1}$

- Shift index using $k- >k + 1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k + 1 + r)\,(k + r)\, x^{k+r}$

  Rewrite ODE with series expansions

$$a_0 r^2 x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)^2 + a_k(k+1+r)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2 = 0$
- Values of r that satisfy the indicial equation

  $r = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k+1)\left(a_{k+1}(k+1) + a_k\right) = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{k+1}$
- Recursion relation for $r = 0$

  $a_{k+1} = -\frac{a_k}{k+1}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{a_k}{k+1}\right]$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (B) Challenge Problems . Page 194
Problem number: 1(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^3y'' + x^2y' + y = 0}$$

With the expansion point for the power series method at $x = \infty$.

Since expansion is around ∞, then the independent variable x is replaced by $\frac{1}{t}$ and the expansion is made around $t = 0$ and after solving, the solution is changed back to x using $x = \frac{1}{t}$. Changing variables results in the new ode

$$-\frac{-\left(\frac{d^2}{dt^2}y(t)\right)t^2 - 2t\left(\frac{d}{dt}y(t)\right)}{t} - \frac{d}{dt}y(t) + y(t) = 0$$

The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(\frac{d^2}{dt^2}y(t)\right)t + \frac{d}{dt}y(t) + y(t) = 0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t) + p(t)\frac{d}{dt}y(t) + q(t)y(t) = 0$$

Where

$$
\begin{aligned}
p(t) &= \frac{1}{t} \\
q(t) &= \frac{1}{t}
\end{aligned}
$$

Table 516: Table $p(t), q(t)$ singularites.

$p(t) = \frac{1}{t}$	
singularity	type
$t = 0$	"regular"

$q(t) = \frac{1}{t}$	
singularity	type
$t = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : [0]

Irregular singular points : [∞]

Since $t = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$
\left(\frac{d^2}{dt^2}y(t)\right)t + \frac{d}{dt}y(t) + y(t) = 0
$$

Let the solution be represented as Frobenius power series of the form

$$
y(t) = \sum_{n=0}^{\infty} a_n t^{n+r}
$$

Then

$$
\begin{aligned}
\frac{d}{dt}y(t) &= \sum_{n=0}^{\infty} (n+r) a_n t^{n+r-1} \\
\frac{d^2}{dt^2}y(t) &= \sum_{n=0}^{\infty} (n+r)(n+r-1) a_n t^{n+r-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\left(\sum_{n=0}^{\infty} (n+r)(n+r-1) a_n t^{n+r-2}\right) t + \left(\sum_{n=0}^{\infty} (n+r) a_n t^{n+r-1}\right) + \left(\sum_{n=0}^{\infty} a_n t^{n+r}\right) = 0 \quad (1)
$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} t^{n+r-1} a_n (n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} (n+r) a_n t^{n+r-1}\right)+\left(\sum_{n=0}^{\infty} a_n t^{n+r}\right)=0 \quad \text{(2A)}$$

The next step is to make all powers of t be $n+r-1$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r-1} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} a_n t^{n+r} = \sum_{n=1}^{\infty} a_{n-1} t^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n+r-1$.

$$\left(\sum_{n=0}^{\infty} t^{n+r-1} a_n (n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} (n+r) a_n t^{n+r-1}\right)+\left(\sum_{n=1}^{\infty} a_{n-1} t^{n+r-1}\right)=0 \quad \text{(2B)}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$t^{n+r-1} a_n (n+r)(n+r-1)+(n+r) a_n t^{n+r-1}=0$$

When $n=0$ the above becomes

$$t^{-1+r} a_0 r(-1+r)+r a_0 t^{-1+r}=0$$

Or

$$\left(t^{-1+r} r(-1+r)+r\, t^{-1+r}\right) a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$t^{-1+r} r^2=0$$

Since the above is true for all t then the indicial equation becomes

$$r^2=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned} r_1 &= 0 \\ r_2 &= 0 \end{aligned}$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$t^{-1+r}r^2 = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(t) = \sum_{n=0}^{\infty} a_n t^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(t) = y_1(t) \ln(t) + \left(\sum_{n=1}^{\infty} b_n t^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y(t) = c_1 y_1(t) + c_2 y_2(t)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. We start by finding the first solution $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$a_n(n+r)(n+r-1) + a_n(n+r) + a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-1}}{n^2 + 2nr + r^2} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = -\frac{a_{n-1}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = -\frac{1}{(r+1)^2}$$

Which for the root $r = 0$ becomes

$$a_1 = -1$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{1}{(r+1)^2 (r+2)^2}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{1}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1
a_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$

For $n = 3$, using the above recursive equation gives

$$a_3 = -\frac{1}{(r+1)^2 (r+2)^2 (r+3)^2}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{1}{36}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1
a_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$
a_3	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{1}{36}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{1}{(r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{1}{576}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1
a_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$
a_3	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{1}{36}$
a_4	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{576}$

For $n = 5$, using the above recursive equation gives

$$a_5 = -\frac{1}{(r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{1}{14400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1
a_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$
a_3	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{1}{36}$
a_4	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{576}$
a_5	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{14400}$

For $n = 6$, using the above recursive equation gives

$$a_6 = \frac{1}{(r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2 (r+6)^2}$$

Which for the root $r = 0$ becomes

$$a_6 = \frac{1}{518400}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1
a_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$
a_3	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{1}{36}$
a_4	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{576}$
a_5	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{14400}$
a_6	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2(r+6)^2}$	$\frac{1}{518400}$

For $n = 7$, using the above recursive equation gives

$$a_7 = -\frac{1}{(r+1)^2 (r+2)^2 (r+3)^2 (r+4)^2 (r+5)^2 (r+6)^2 (r+7)^2}$$

Which for the root $r = 0$ becomes

$$a_7 = -\frac{1}{25401600}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$-\frac{1}{(r+1)^2}$	-1
a_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$
a_3	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{1}{36}$
a_4	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{576}$
a_5	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{14400}$
a_6	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2(r+6)^2}$	$\frac{1}{518400}$
a_7	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2(r+6)^2(r+7)^2}$	$-\frac{1}{25401600}$

Using the above table, then the first solution $y_1(t)$ becomes

$$
\begin{aligned}
y_1(t) &= a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \dots \\
&= -t + 1 + \frac{t^2}{4} - \frac{t^3}{36} + \frac{t^4}{576} - \frac{t^5}{14400} + \frac{t^6}{518400} - \frac{t^7}{25401600} + O\left(t^8\right)
\end{aligned}
$$

Now the second solution is found. The second solution is given by

$$
y_2(t) = y_1(t) \ln(t) + \left(\sum_{n=1}^{\infty} b_n t^{n+r}\right)
$$

Where b_n is found using

$$
b_n = \frac{d}{dr} a_{n,r}
$$

And the above is then evaluated at $r = 0$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a_{n,r}$	$b_n($
b_0	1	1	N/A since b_n starts from 1	N/
b_1	$-\frac{1}{(r+1)^2}$	-1	$\frac{2}{(r+1)^3}$	2
b_2	$\frac{1}{(r+1)^2(r+2)^2}$	$\frac{1}{4}$	$\frac{-4r-6}{(r+1)^3(r+2)^3}$	$-\frac{3}{4}$
b_3	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2}$	$-\frac{1}{36}$	$\frac{6r^2+24r+22}{(r+1)^3(r+2)^3(r+3)^3}$	$\frac{11}{108}$
b_4	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2}$	$\frac{1}{576}$	$\frac{-8r^3-60r^2-140r-100}{(r+1)^3(r+2)^3(r+3)^3(r+4)^3}$	$-\frac{}{3}$
b_5	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2}$	$-\frac{1}{14400}$	$\frac{10r^4+120r^3+510r^2+900r+548}{(r+1)^3(r+2)^3(r+3)^3(r+4)^3(r+5)^3}$	$\frac{13}{432}$
b_6	$\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2(r+6)^2}$	$\frac{1}{518400}$	$\frac{-12r^5-210r^4-1400r^3-4410r^2-6496r-3528}{(r+1)^3(r+2)^3(r+3)^3(r+4)^3(r+5)^3(r+6)^3}$	$-\frac{}{5}$
b_7	$-\frac{1}{(r+1)^2(r+2)^2(r+3)^2(r+4)^2(r+5)^2(r+6)^2(r+7)^2}$	$-\frac{1}{25401600}$	$\frac{14r^6+336r^5+3220r^4+15680r^3+40614r^2+52528r+26136}{(r+1)^3(r+2)^3(r+3)^3(r+4)^3(r+5)^3(r+6)^3(r+7)^3}$	$\frac{}{592}$

The above table gives all values of b_n needed. Hence the second solution is

$$
\begin{aligned}
y_2(t) &= y_1(t)\ln(t) + b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots \\
&= \left(-t + 1 + \frac{t^2}{4} - \frac{t^3}{36} + \frac{t^4}{576} - \frac{t^5}{14400} + \frac{t^6}{518400} - \frac{t^7}{25401600} + O(t^8)\right)\ln(t) \\
&\quad + 2t - \frac{3t^2}{4} + \frac{11t^3}{108} - \frac{25t^4}{3456} + \frac{137t^5}{432000} - \frac{49t^6}{5184000} + \frac{121t^7}{592704000} + O(t^8)
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(t) &= c_1 y_1(t) + c_2 y_2(t) \\
&= c_1\left(-t + 1 + \frac{t^2}{4} - \frac{t^3}{36} + \frac{t^4}{576} - \frac{t^5}{14400} + \frac{t^6}{518400} - \frac{t^7}{25401600} + O(t^8)\right) \\
&\quad + c_2\left(\left(-t + 1 + \frac{t^2}{4} - \frac{t^3}{36} + \frac{t^4}{576} - \frac{t^5}{14400} + \frac{t^6}{518400} - \frac{t^7}{25401600} + O(t^8)\right)\ln(t) \right. \\
&\qquad \left. + 2t - \frac{3t^2}{4} + \frac{11t^3}{108} - \frac{25t^4}{3456} + \frac{137t^5}{432000} - \frac{49t^6}{5184000} + \frac{121t^7}{592704000} + O(t^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
y(t) = y_h
$$

$$= c_1\left(-t+1+\frac{t^2}{4}-\frac{t^3}{36}+\frac{t^4}{576}-\frac{t^5}{14400}+\frac{t^6}{518400}-\frac{t^7}{25401600}+O(t^8)\right) + c_2\left(\left(-t+1+\frac{t^2}{4}-\frac{t^3}{36}+\frac{t^4}{576}-\frac{t^5}{14400}+\frac{t^6}{518400}-\frac{t^7}{25401600}+O(t^8)\right)\ln(t) + 2t-\frac{3t^2}{4}+\frac{11t^3}{108}-\frac{25t^4}{3456}+\frac{137t^5}{432000}-\frac{49t^6}{5184000}+\frac{121t^7}{592704000}+O(t^8)\right)$$

Replacing t by $\frac{1}{x}$ gives

$$y = c_1\left(-\frac{1}{x}+1+\frac{1}{4x^2}-\frac{1}{36x^3}+\frac{1}{576x^4}-\frac{1}{14400x^5}+\frac{1}{518400x^6}-\frac{1}{25401600x^7}+O\left(\frac{1}{x^8}\right)\right)+c_2\left(\left(-\frac{1}{x}\right.\right.$$

Summary

The solution(s) found are the following

$$y = c_1\left(-\frac{1}{x}+1+\frac{1}{4x^2}-\frac{1}{36x^3}+\frac{1}{576x^4}-\frac{1}{14400x^5}+\frac{1}{518400x^6}-\frac{1}{25401600x^7}+O\left(\frac{1}{x^8}\right)\right)+c_2\left(\left(-\frac{1}{x}+1+\frac{1}{4x^2}-\frac{1}{36x^3}+\frac{1}{576x^4}-\frac{1}{14400x^5}+\frac{1}{518400x^6}-\frac{1}{25401600x^7}+O\left(\frac{1}{x^8}\right)\right)\ln\left(\frac{1}{x}\right)+\frac{2}{x}-\frac{3}{4x^2}+\frac{11}{108x^3}-\frac{25}{3456x^4}+\frac{137}{432000x^5}-\frac{49}{5184000x^6}+\frac{121}{592704000x^7}+O\left(\frac{1}{x^8}\right)\right) \tag{1}$$

Verification of solutions

$$y = c_1\left(-\frac{1}{x}+1+\frac{1}{4x^2}-\frac{1}{36x^3}+\frac{1}{576x^4}-\frac{1}{14400x^5}+\frac{1}{518400x^6}-\frac{1}{25401600x^7}+O\left(\frac{1}{x^8}\right)\right)+c_2\left(\left(-\frac{1}{x}+1+\frac{1}{4x^2}-\frac{1}{36x^3}+\frac{1}{576x^4}-\frac{1}{14400x^5}+\frac{1}{518400x^6}-\frac{1}{25401600x^7}+O\left(\frac{1}{x^8}\right)\right)\ln\left(\frac{1}{x}\right)+\frac{2}{x}-\frac{3}{4x^2}+\frac{11}{108x^3}-\frac{25}{3456x^4}+\frac{137}{432000x^5}-\frac{49}{5184000x^6}+\frac{121}{592704000x^7}+O\left(\frac{1}{x^8}\right)\right)$$

Verified OK.

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 4. Power Series Solutions and Special Functions. Problems for review and discovert. (B) Challenge Problems . Page 194
Problem number: 1(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{9(-2+x)^2\,(x-3)\,y''+6x(-2+x)\,y'+16y=0}$$

With the expansion point for the power series method at $x=\infty$.

Since expansion is around ∞, then the independent variable x is replaced by $\frac{1}{t}$ and the expansion is made around $t=0$ and after solving, the solution is changed back to x using $x=\frac{1}{t}$. Changing variables results in the new ode

$$-9\left(-2+\frac{1}{t}\right)^2\left(\frac{1}{t}-3\right)\left(-\left(\frac{d^2}{dt^2}y(t)\right)t^2-2t\left(\frac{d}{dt}y(t)\right)\right)t^2-\left(\frac{6}{t^2}-\frac{12}{t}\right)\left(\frac{d}{dt}y(t)\right)t^2+16y(t)=0$$

The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-108t^4+144t^3-63t^2+9t\right)\left(\frac{d^2}{dt^2}y(t)\right)+\left(-216t^3+288t^2-114t+12\right)\left(\frac{d}{dt}y(t)\right)+16y(t)=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^2}{dt^2}y(t)+p(t)\frac{d}{dt}y(t)+q(t)y(t)=0$$

Where

$$p(t) = \frac{12t^2 - 10t + \frac{4}{3}}{t(-1+3t)(2t-1)}$$
$$q(t) = -\frac{16}{9(2t-1)^2(-1+3t)t}$$

Table 517: Table $p(t), q(t)$ singularites.

$p(t) = \frac{12t^2-10t+\frac{4}{3}}{t(-1+3t)(2t-1)}$	
singularity	type
$t = 0$	"regular"
$t = \frac{1}{2}$	"regular"
$t = \frac{1}{3}$	"regular"

$q(t) = -\frac{16}{9(2t-1)^2(-1+3t)t}$	
singularity	type
$t = 0$	"regular"
$t = \frac{1}{2}$	"regular"
$t = \frac{1}{3}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, \frac{1}{2}, \frac{1}{3}, \infty\right]$

Irregular singular points : []

Since $t = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-9t(12t^3 - 16t^2 + 7t - 1)\left(\frac{d^2}{dt^2}y(t)\right) + (-216t^3 + 288t^2 - 114t + 12)\left(\frac{d}{dt}y(t)\right) + 16y(t) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$
$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
&-9t\left(12t^{3}-16t^{2}+7t-1\right)\left(\sum_{n=0}^{\infty}(n+r)\,(n+r-1)\,a_{n}t^{n+r-2}\right) \\
&+\left(-216t^{3}+288t^{2}-114t+12\right)\left(\sum_{n=0}^{\infty}(n+r)\,a_{n}t^{n+r-1}\right)+16\left(\sum_{n=0}^{\infty}a_{n}t^{n+r}\right)=0
\end{aligned}
\tag{1}
$$

Which simplifies to

$$
\begin{aligned}
&\sum_{n=0}^{\infty}\left(-108t^{n+r+2}a_{n}(n+r)\,(n+r-1)\right) \\
&\quad+\left(\sum_{n=0}^{\infty}144t^{1+n+r}a_{n}(n+r)\,(n+r-1)\right) \\
&\quad+\sum_{n=0}^{\infty}\left(-63t^{n+r}a_{n}(n+r)\,(n+r-1)\right) \\
&\quad+\left(\sum_{n=0}^{\infty}9t^{n+r-1}a_{n}(n+r)\,(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-216t^{n+r+2}a_{n}(n+r)\right) \\
&\quad+\left(\sum_{n=0}^{\infty}288t^{1+n+r}a_{n}(n+r)\right)+\sum_{n=0}^{\infty}\left(-114t^{n+r}a_{n}(n+r)\right) \\
&\quad+\left(\sum_{n=0}^{\infty}12(n+r)\,a_{n}t^{n+r-1}\right)+\left(\sum_{n=0}^{\infty}16a_{n}t^{n+r}\right)=0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of t be $n+r-1$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r-1} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty}\left(-108t^{n+r+2}a_{n}(n+r)\,(n+r-1)\right)&=\sum_{n=3}^{\infty}\left(-108a_{n-3}(n+r-3)\,(n-4+r)\,t^{n+r-1}\right) \\
\sum_{n=0}^{\infty}144t^{1+n+r}a_{n}(n+r)\,(n+r-1)&=\sum_{n=2}^{\infty}144a_{n-2}(n+r-2)\,(n+r-3)\,t^{n+r-1} \\
\sum_{n=0}^{\infty}\left(-63t^{n+r}a_{n}(n+r)\,(n+r-1)\right)&=\sum_{n=1}^{\infty}\left(-63a_{n-1}(n+r-1)\,(n+r-2)\,t^{n+r-1}\right)
\end{aligned}
$$

$$\sum_{n=0}^{\infty} \left(-216 t^{n+r+2} a_n (n+r)\right) = \sum_{n=3}^{\infty} \left(-216 a_{n-3} (n+r-3)\, t^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} 288 t^{1+n+r} a_n (n+r) = \sum_{n=2}^{\infty} 288 a_{n-2} (n+r-2)\, t^{n+r-1}$$

$$\sum_{n=0}^{\infty} \left(-114 t^{n+r} a_n (n+r)\right) = \sum_{n=1}^{\infty} \left(-114 a_{n-1} (n+r-1)\, t^{n+r-1}\right)$$

$$\sum_{n=0}^{\infty} 16 a_n t^{n+r} = \sum_{n=1}^{\infty} 16 a_{n-1} t^{n+r-1}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n+r-1$.

$$\begin{aligned}
&\sum_{n=3}^{\infty} \left(-108 a_{n-3} (n+r-3) (n-4+r)\, t^{n+r-1}\right) \\
&+ \left(\sum_{n=2}^{\infty} 144 a_{n-2} (n+r-2) (n+r-3)\, t^{n+r-1}\right) \\
&+ \sum_{n=1}^{\infty} \left(-63 a_{n-1} (n+r-1) (n+r-2)\, t^{n+r-1}\right) \\
&+ \left(\sum_{n=0}^{\infty} 9 t^{n+r-1} a_n (n+r) (n+r-1)\right) \\
&+ \sum_{n=3}^{\infty} \left(-216 a_{n-3} (n+r-3)\, t^{n+r-1}\right) \\
&+ \left(\sum_{n=2}^{\infty} 288 a_{n-2} (n+r-2)\, t^{n+r-1}\right) + \sum_{n=1}^{\infty} \left(-114 a_{n-1} (n+r-1)\, t^{n+r-1}\right) \\
&+ \left(\sum_{n=0}^{\infty} 12 (n+r)\, a_n t^{n+r-1}\right) + \left(\sum_{n=1}^{\infty} 16 a_{n-1} t^{n+r-1}\right) = 0
\end{aligned} \tag{2B}$$

The indicial equation is obtained from $n = 0$. From Eq (2B) this gives

$$9 t^{n+r-1} a_n (n+r) (n+r-1) + 12 (n+r)\, a_n t^{n+r-1} = 0$$

When $n = 0$ the above becomes

$$9 t^{-1+r} a_0 r (-1+r) + 12 r a_0 t^{-1+r} = 0$$

Or

$$\left(9t^{-1+r}r(-1+r)+12r\,t^{-1+r}\right)a_0=0$$

Since $a_0\neq 0$ then the above simplifies to

$$\left(9r^2+3r\right)t^{-1+r}=0$$

Since the above is true for all t then the indicial equation becomes

$$9r^2+3r=0$$

Solving for r gives the roots of the indicial equation as

$$\begin{aligned}r_1&=0\\ r_2&=-\frac{1}{3}\end{aligned}$$

Since $a_0\neq 0$ then the indicial equation becomes

$$\left(9r^2+3r\right)t^{-1+r}=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=\frac{1}{3}$ is not an integer, then we can construct two linearly independent solutions

$$\begin{aligned}y_1(t)&=t^{r_1}\left(\sum_{n=0}^{\infty}a_n t^n\right)\\ y_2(t)&=t^{r_2}\left(\sum_{n=0}^{\infty}b_n t^n\right)\end{aligned}$$

Or

$$\begin{aligned}y_1(t)&=\sum_{n=0}^{\infty}a_n t^n\\ y_2(t)&=\sum_{n=0}^{\infty}b_n t^{n-\frac{1}{3}}\end{aligned}$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0=1$. Substituting $n=1$ in Eq. (2B) gives

$$a_1=\frac{63r^2+51r-16}{9r^2+21r+12}$$

Substituting $n = 2$ in Eq. (2B) gives

$$a_2 = \frac{2673r^4 + 10044r^3 + 9441r^2 + 438r - 1568}{81r^4 + 540r^3 + 1305r^2 + 1350r + 504}$$

For $3 \leq n$ the recursive equation is

$$\begin{aligned} -108a_{n-3}(n+r-3)(n-4+r) + 144a_{n-2}(n+r-2)(n+r-3) \\ -63a_{n-1}(n+r-1)(n+r-2) + 9a_n(n+r)(n+r-1) - 216a_{n-3}(n+r-3) \\ +288a_{n-2}(n+r-2) - 114a_{n-1}(n+r-1) + 12a_n(n+r) + 16a_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{108n^2a_{n-3} - 144n^2a_{n-2} + 63n^2a_{n-1} + 216nra_{n-3} - 288nra_{n-2} + 126nra_{n-1} + 108r^2a_{n-3} - 144r^2a_{r}}{9n^2 +} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{(108a_{n-3} - 144a_{n-2} + 63a_{n-1})n^2 + (-540a_{n-3} + 432a_{n-2} - 75a_{n-1})n + 648a_{n-3} - 288a_{n-2} - 4a_{n-}}{9n^2 + 3n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$	$-\frac{4}{3}$
a_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$	$-\frac{28}{9}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{95499r^6 + 844911r^5 + 2671137r^4 + 3571317r^3 + 1572804r^2 - 419508r - 336448}{729r^6 + 9477r^5 + 49815r^4 + 135135r^3 + 198936r^2 + 150228r + 45360}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{3004}{405}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$	$-\frac{4}{3}$
a_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$	$-\frac{28}{9}$
a_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$	$-\frac{3004}{405}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{3103353r^8 + 49898592r^7 + 320994738r^6 + 1054759968r^5 + 1851078825r^4 + 1583317152r^3 + 348879}{81\,(3r^2 + 25r + 52)\,(27r^6 + 351r^5 + 1845r^4 + 5005r^3 + 7368r^2 + 5564r +}$$

Which for the root $r = 0$ becomes

$$a_4 = -\frac{285704}{15795}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$	$-\frac{4}{3}$
a_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$	$-\frac{28}{9}$
a_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$	$-\frac{300}{405}$
a_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$	$-\frac{285}{157}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{95127939r^{10} + 2420949951r^9 + 26064871578r^8 + 154759665150r^7 + 552318920667r^6 + 12044507640}{243\,(3r^2 + 31r + 80)\,(3r^2 + 25r + 52)\,(27r^6 + 351r}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{822592}{18225}$$

And the table now becomes

n	$a_{n,r}$
a_0	1
a_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$
a_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$
a_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$
a_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
a_5	$\frac{95127939r^{10}+2420949951r^9+26064871578r^8+154759665150r^7+552318920667r^6+1204450764687r^5+1536667458552r^4+964786860468r}{243(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$

For $n=6$, using the above recursive equation gives

$$a_6 = \frac{2806539921r^{12}+103709648268r^{11}+1676277992835r^{10}+15583794209910r^9+92090095190235r^8+}{729\left(3r^2+31r+80\right)}$$

Which for the root $r=0$ becomes

$$a_6 = -\frac{4666732192}{40514175}$$

And the table now becomes

n	$a_{n,r}$
a_0	1
a_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$
a_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$
a_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$
a_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
a_5	$\frac{95127939r^{10}+2420949951r^9+26064871578r^8+154759665150r^7+552318920667r^6+1204450764687r^5+1536667458552r^4+964786860468r}{243(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
a_6	$\frac{2806539921r^{12}+103709648268r^{11}+1676277992835r^{10}+15583794209910r^9+92090095190235r^8+360297425137320r^7+940035462956685r}{729(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+}$

For $n=7$, using the above recursive equation gives

$$a_7 = \frac{80674338123r^{14}+4080569276151r^{13}+92307128293827r^{12}+1233512636444739r^{11}+10829721106}{}$$

Which for the root $r=0$ becomes

$$a_7 = -\frac{401483448544}{1336967775}$$

And the table now becomes

n	$a_{n,r}$
a_0	1
a_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$
a_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$
a_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$
a_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
a_5	$\frac{95127939r^{10}+2420949951r^9+26064871578r^8+154759665150r^7+552318920667r^6+1204450764687r^5+1536667458552r^4+964786860468r \cdots}{243(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
a_6	$\frac{2806539921r^{12}+103709648268r^{11}+1676277992835r^{10}+15583794209910r^9+92090095190235r^8+360297425137320r^7+940035462956685 \cdots}{729(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+ \cdots}$
a_7	$\frac{80674338123r^{14}+4080569276151r^{13}+92307128293827r^{12}+1233512636444739r^{11}+10829721106831365r^{10}+65685074939730909r^9+2814 \cdots}{2187(3r^2+31r+80) \cdots}$

Using the above table, then the solution $y_1(t)$ is

$$
\begin{aligned}
y_1(t) &= a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \ldots \\
&= 1 - \frac{4t}{3} - \frac{28t^2}{9} - \frac{3004t^3}{405} - \frac{285704t^4}{15795} - \frac{822592t^5}{18225} - \frac{4666732192t^6}{40514175} - \frac{4014834485 44t^7}{1336967775} + O(t^8)
\end{aligned}
$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
b_1 = \frac{63r^2 + 51r - 16}{9r^2 + 21r + 12}
$$

Substituting $n = 2$ in Eq. (2B) gives

$$
b_2 = \frac{2673r^4 + 10044r^3 + 9441r^2 + 438r - 1568}{81r^4 + 540r^3 + 1305r^2 + 1350r + 504}
$$

For $3 \leq n$ the recursive equation is

$$
\begin{aligned}
&-108b_{n-3}(n+r-3)(n-4+r) + 144b_{n-2}(n+r-2)(n+r-3) \\
&- 63b_{n-1}(n+r-1)(n+r-2) + 9b_n(n+r)(n+r-1) - 216b_{n-3}(n+r-3) \\
&+ 288b_{n-2}(n+r-2) - 114b_{n-1}(n+r-1) + 12(n+r)b_n + 16b_{n-1} = 0
\end{aligned} \tag{3}
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{108n^2b_{n-3} - 144n^2b_{n-2} + 63n^2b_{n-1} + 216nrb_{n-3} - 288nrb_{n-2} + 126nrb_{n-1} + 108r^2b_{n-3} - 144r^2b_{n-2} \cdots}{9n^2 + 18 \cdots} \tag{4}
$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_n = \frac{(108b_{n-3} - 144b_{n-2} + 63b_{n-1})\, n^2 + (-612b_{n-3} + 528b_{n-2} - 117b_{n-1})\, n + 840b_{n-3} - 448b_{n-2} + 28b_{n-}}{9n^2 - 3n} \tag{5}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -\frac{1}{3}$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$	$-\frac{13}{3}$
b_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$	$-\frac{251}{45}$

For $n = 3$, using the above recursive equation gives

$$b_3 = \frac{95499r^6 + 844911r^5 + 2671137r^4 + 3571317r^3 + 1572804r^2 - 419508r - 336448}{729r^6 + 9477r^5 + 49815r^4 + 135135r^3 + 198936r^2 + 150228r + 45360}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_3 = -\frac{7781}{810}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$	$-\frac{13}{3}$
b_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$	$-\frac{251}{45}$
b_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$	$-\frac{7781}{810}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{3103353r^8 + 49898592r^7 + 320994738r^6 + 1054759968r^5 + 1851078825r^4 + 1583317152r^3 + 348879}{81\,(3r^2 + 25r + 52)\,(27r^6 + 351r^5 + 1845r^4 + 5005r^3 + 7368r^2 + 5564r +}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_4 = -\frac{22151}{1215}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$	$-\frac{13}{3}$
b_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$	$-\frac{251}{45}$
b_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$	$-\frac{7781}{810}$
b_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$	$-\frac{2215}{121}$

For $n = 5$, using the above recursive equation gives

$$b_5 = \frac{95127939r^{10} + 2420949951r^9 + 26064871578r^8 + 154759665150r^7 + 552318920667r^6 + 12044507646}{243\left(3r^2 + 31r + 80\right)\left(3r^2 + 25r + 52\right)\left(27r^6 + 351r\right.}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_5 = -\frac{669229}{18225}$$

And the table now becomes

n	$b_{n,r}$
b_0	1
b_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$
b_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$
b_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$
b_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
b_5	$\frac{95127939r^{10}+2420949951r^9+26064871578r^8+154759665150r^7+552318920667r^6+1204450764687r^5+1536667458552r^4+964786860468r}{243(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$

For $n = 6$, using the above recursive equation gives

$$b_6 = \frac{2806539921r^{12} + 103709648268r^{11} + 1676277992835r^{10} + 15583794209910r^9 + 92090095190235r^8 +}{729\left(3r^2 + 31r + 80\right)}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_6 = -\frac{216463313}{2788425}$$

And the table now becomes

n	$b_{n,r}$
b_0	1
b_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$
b_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$
b_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$
b_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
b_5	$\frac{95127939r^{10}+2420949951r^9+26064871578r^8+154759665150r^7+552318920667r^6+1204450764687r^5+1536667458552r^4+964786860468r}{243(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
b_6	$\frac{2806539921r^{12}+103709648268r^{11}+1676277992835r^{10}+15583794209910r^9+92090095190235r^8+360297425137320r^7+940035462956685r}{729(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+}$

For $n = 7$, using the above recursive equation gives

$$b_7 = \frac{80674338123r^{14} + 4080569276151r^{13} + 92307128293827r^{12} + 1233512636444739r^{11} + 10829721106}{}$$

Which for the root $r = -\frac{1}{3}$ becomes

$$b_7 = -\frac{7179886604}{41826375}$$

And the table now becomes

n	$b_{n,r}$
b_0	1
b_1	$\frac{63r^2+51r-16}{9r^2+21r+12}$
b_2	$\frac{2673r^4+10044r^3+9441r^2+438r-1568}{81r^4+540r^3+1305r^2+1350r+504}$
b_3	$\frac{95499r^6+844911r^5+2671137r^4+3571317r^3+1572804r^2-419508r-336448}{729r^6+9477r^5+49815r^4+135135r^3+198936r^2+150228r+45360}$
b_4	$\frac{3103353r^8+49898592r^7+320994738r^6+1054759968r^5+1851078825r^4+1583317152r^3+348879276r^2-293260704r-127995392}{81(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
b_5	$\frac{95127939r^{10}+2420949951r^9+26064871578r^8+154759665150r^7+552318920667r^6+1204450764687r^5+1536667458552r^4+964786860468r}{243(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+5005r^3+7368r^2+5564r+1680)}$
b_6	$\frac{2806539921r^{12}+103709648268r^{11}+1676277992835r^{10}+15583794209910r^9+92090095190235r^8+360297425137320r^7+940035462956685r}{729(3r^2+31r+80)(3r^2+25r+52)(27r^6+351r^5+1845r^4+}$
b_7	$\frac{80674338123r^{14}+4080569276151r^{13}+92307128293827r^{12}+1233512636444739r^{11}+10829721106831365r^{10}+65685074939730909r^9+2814}{2187(3r^2+31r+80)}$

Using the above table, then the solution $y_2(t)$ is

$$y_2(t) = 1\left(b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots\right)$$
$$= \frac{1 - \frac{13t}{3} - \frac{251t^2}{45} - \frac{7781t^3}{810} - \frac{22151t^4}{1215} - \frac{669229t^5}{18225} - \frac{216463313t^6}{2788425} - \frac{7179886604t^7}{41826375} + O(t^8)}{t^{\frac{1}{3}}}$$

Therefore the homogeneous solution is

$$y_h(t) = c_1 y_1(t) + c_2 y_2(t)$$
$$= c_1\left(1 - \frac{4t}{3} - \frac{28t^2}{9} - \frac{3004t^3}{405} - \frac{285704t^4}{15795} - \frac{822592t^5}{18225} - \frac{4666732192t^6}{40514175} - \frac{401483448544t^7}{1336967775} + O(t^8)\right)$$
$$+ \frac{c_2\left(1 - \frac{13t}{3} - \frac{251t^2}{45} - \frac{7781t^3}{810} - \frac{22151t^4}{1215} - \frac{669229t^5}{18225} - \frac{216463313t^6}{2788425} - \frac{7179886604t^7}{41826375} + O(t^8)\right)}{t^{\frac{1}{3}}}$$

Hence the final solution is

$$y(t) = y_h$$
$$= c_1\left(1 - \frac{4t}{3} - \frac{28t^2}{9} - \frac{3004t^3}{405} - \frac{285704t^4}{15795} - \frac{822592t^5}{18225} - \frac{4666732192t^6}{40514175} - \frac{401483448544t^7}{1336967775} + O(t^8)\right)$$
$$+ \frac{c_2\left(1 - \frac{13t}{3} - \frac{251t^2}{45} - \frac{7781t^3}{810} - \frac{22151t^4}{1215} - \frac{669229t^5}{18225} - \frac{216463313t^6}{2788425} - \frac{7179886604t^7}{41826375} + O(t^8)\right)}{t^{\frac{1}{3}}}$$

Replacing t by $\frac{1}{x}$ gives

$$y = c_1\left(1 - \frac{4}{3x} - \frac{28}{9x^2} - \frac{3004}{405x^3} - \frac{285704}{15795x^4} - \frac{822592}{18225x^5} - \frac{4666732192}{40514175x^6} - \frac{401483448544}{1336967775x^7} + O\left(\frac{1}{x^8}\right)\right) + \frac{c_2(}{}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1\left(1 - \frac{4}{3x} - \frac{28}{9x^2} - \frac{3004}{405x^3} - \frac{285704}{15795x^4} - \frac{822592}{18225x^5} - \frac{4666732192}{40514175x^6} - \frac{401483448544}{1336967775x^7} + O\left(\frac{1}{x^8}\right)\right)$$
$$+ \frac{c_2\left(1 - \frac{13}{3x} - \frac{251}{45x^2} - \frac{7781}{810x^3} - \frac{22151}{1215x^4} - \frac{669229}{18225x^5} - \frac{216463313}{2788425x^6} - \frac{7179886604}{41826375x^7} + O\left(\frac{1}{x^8}\right)\right)}{\left(\frac{1}{x}\right)^{\frac{1}{3}}} \quad (1)$$

Verification of solutions

$$y = c_1 \left(1 - \frac{4}{3x} - \frac{28}{9x^2} - \frac{3004}{405x^3} - \frac{285704}{15795x^4} - \frac{822592}{18225x^5} - \frac{4666732192}{40514175x^6} - \frac{401483448544}{1336967775x^7} + O\left(\frac{1}{x^8}\right)\right) + \frac{c_2 \left(1 - \frac{13}{3x} - \frac{251}{45x^2} - \frac{7781}{810x^3} - \frac{22151}{1215x^4} - \frac{669229}{18225x^5} - \frac{216463313}{2788425x^6} - \frac{7179886604}{41826375x^7} + O\left(\frac{1}{x^8}\right)\right)}{\left(\frac{1}{x}\right)^{\frac{1}{3}}}$$

Verified OK.

23.2.1 Maple step by step solution

Let's solve

$9(-2+x)^2 (x-3) y'' + (6x^2 - 12x) y' + 16y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{16y}{9(-2+x)^2(x-3)} - \frac{2xy'}{3(x-3)(-2+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2xy'}{3(x-3)(-2+x)} + \frac{16y}{9(-2+x)^2(x-3)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{2x}{3(x-3)(-2+x)}, P_3(x) = \frac{16}{9(-2+x)^2(x-3)}\right]$

  ◦ $(-2+x) \cdot P_2(x)$ is analytic at $x = 2$

    $\left((-2+x) \cdot P_2(x)\right)\Big|_{x=2} = -\frac{4}{3}$

  ◦ $(-2+x)^2 \cdot P_3(x)$ is analytic at $x = 2$

    $\left((-2+x)^2 \cdot P_3(x)\right)\Big|_{x=2} = -\frac{16}{9}$

  ◦ $x = 2$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 2$

- Multiply by denominators

$$9(-2+x)^2(x-3)y''+6x(-2+x)y'+16y=0$$

- Change variables using $x=u+2$ so that the regular singular point is at $u=0$

$$(9u^3-9u^2)\left(\frac{d^2}{du^2}y(u)\right)+(6u^2+12u)\left(\frac{d}{du}y(u)\right)+16y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

   ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=1..2$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

   ◦ Shift index using $k->k+1-m$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

   ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=2..3$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

   ◦ Shift index using $k->k+2-m$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0(9r^2-21r-16)u^r+\left(\sum_{k=1}^{\infty}\left(-a_k(9k^2+18kr+9r^2-21k-21r-16)+3a_{k-1}(k+r-1)(3\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-9r^2+21r+16=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{\frac{7}{6}-\frac{\sqrt{113}}{6},\frac{7}{6}+\frac{\sqrt{113}}{6}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$9(k+r-1)\left(k-\frac{4}{3}+r\right)a_{k-1}-9a_k\left(k^2+\left(2r-\frac{7}{3}\right)k+r^2-\frac{7r}{3}-\frac{16}{9}\right)=0$$

- Shift index using $k->k+1$

$$9(k+r)\left(k-\frac{1}{3}+r\right)a_k-9a_{k+1}\left((k+1)^2+\left(2r-\frac{7}{3}\right)(k+1)+r^2-\frac{7r}{3}-\frac{16}{9}\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{3(k+r)(3k+3r-1)a_k}{9k^2+18kr+9r^2-3k-3r-28}$$

- Recursion relation for $r = \frac{7}{6} - \frac{\sqrt{113}}{6}$

$$a_{k+1} = \frac{3\left(k+\frac{7}{6}-\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}-\frac{\sqrt{113}}{2}\right)a_k}{9k^2+18k\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)^2-3k-\frac{63}{2}+\frac{\sqrt{113}}{2}}$$

- Solution for $r = \frac{7}{6} - \frac{\sqrt{113}}{6}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{7}{6}-\frac{\sqrt{113}}{6}}, a_{k+1} = \frac{3\left(k+\frac{7}{6}-\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}-\frac{\sqrt{113}}{2}\right)a_k}{9k^2+18k\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)^2-3k-\frac{63}{2}+\frac{\sqrt{113}}{2}}\right]$$

- Revert the change of variables $u = -2 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(-2+x)^{k+\frac{7}{6}-\frac{\sqrt{113}}{6}}, a_{k+1} = \frac{3\left(k+\frac{7}{6}-\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}-\frac{\sqrt{113}}{2}\right)a_k}{9k^2+18k\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)^2-3k-\frac{63}{2}+\frac{\sqrt{113}}{2}}\right]$$

- Recursion relation for $r = \frac{7}{6} + \frac{\sqrt{113}}{6}$

$$a_{k+1} = \frac{3\left(k+\frac{7}{6}+\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}+\frac{\sqrt{113}}{2}\right)a_k}{9k^2+18k\left(\frac{7}{6}+\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}+\frac{\sqrt{113}}{6}\right)^2-3k-\frac{63}{2}-\frac{\sqrt{113}}{2}}$$

- Solution for $r = \frac{7}{6} + \frac{\sqrt{113}}{6}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{7}{6}+\frac{\sqrt{113}}{6}}, a_{k+1} = \frac{3\left(k+\frac{7}{6}+\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}+\frac{\sqrt{113}}{2}\right)a_k}{9k^2+18k\left(\frac{7}{6}+\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}+\frac{\sqrt{113}}{6}\right)^2-3k-\frac{63}{2}-\frac{\sqrt{113}}{2}}\right]$$

- Revert the change of variables $u = -2 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(-2+x)^{k+\frac{7}{6}+\frac{\sqrt{113}}{6}}, a_{k+1} = \frac{3\left(k+\frac{7}{6}+\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}+\frac{\sqrt{113}}{2}\right)a_k}{9k^2+18k\left(\frac{7}{6}+\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}+\frac{\sqrt{113}}{6}\right)^2-3k-\frac{63}{2}-\frac{\sqrt{113}}{2}}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k(-2+x)^{k+\frac{7}{6}-\frac{\sqrt{113}}{6}}\right) + \left(\sum_{k=0}^{\infty} b_k(-2+x)^{k+\frac{7}{6}+\frac{\sqrt{113}}{6}}\right), a_{k+1} = \frac{3\left(k+\frac{7}{6}-\frac{\sqrt{113}}{6}\right)\left(3k+\frac{5}{2}-\right.}{9k^2+18k\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right)+9\left(\frac{7}{6}-\frac{\sqrt{113}}{6}\right.}\right.$$

Problem number: 1(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference not integer"**

Maple gives the following as the ode type

```
[_Gegenbauer]
```

$$\boxed{\left(-x^{2}+1\right) y''-2 x y'+p(p+1) y=0}$$

With the expansion point for the power series method at $x=\infty$.

Since expansion is around ∞, then the independent variable x is replaced by $\frac{1}{t}$ and the expansion is made around $t=0$ and after solving, the solution is changed back to x using $x=\frac{1}{t}$. Changing variables results in the new ode

$$-\left(-\frac{1}{t^{2}}+1\right)\left(-\left(\frac{d^{2}}{d t^{2}} y(t)\right) t^{2}-2 t\left(\frac{d}{d t} y(t)\right)\right) t^{2}+2 t\left(\frac{d}{d t} y(t)\right)+\left(p^{2}+p\right) y(t)=0$$

The transformed ODE is now solved. The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(t^{4}-t^{2}\right)\left(\frac{d^{2}}{d t^{2}} y(t)\right)+2\left(\frac{d}{d t} y(t)\right) t^{3}+\left(p^{2}+p\right) y(t)=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$\frac{d^{2}}{d t^{2}} y(t)+p(t) \frac{d}{d t} y(t)+q(t) y(t)=0$$

Where

$$p(t) = \frac{2t}{t^2 - 1}$$
$$q(t) = \frac{p(p+1)}{(t^2 - 1)\, t^2}$$

Table 519: Table $p(t), q(t)$ singularites.

$p(t) = \frac{2t}{t^2-1}$	
singularity	type
$t = -1$	"regular"
$t = 1$	"regular"

$q(t) = \frac{p(p+1)}{(t^2-1)t^2}$	
singularity	type
$t = -1$	"regular"
$t = 0$	"regular"
$t = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 1, 0, \infty]$

Irregular singular points : []

Since $t = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)(t^2 - 1)\, t^2 + 2\left(\frac{d}{dt}y(t)\right) t^3 + (p^2 + p)\, y(t) = 0$$

Let the solution be represented as Frobenius power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^{n+r}$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=0}^{\infty} (n+r)\, a_n t^{n+r-1}$$
$$\frac{d^2}{dt^2}y(t) = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n t^{n+r-2}$$

Substituting the above back into the ode gives

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty}(n+r)\,(n+r-1)\,a_n t^{n+r-2}\right)\left(t^2-1\right)t^2 \\
&+2\left(\sum_{n=0}^{\infty}(n+r)\,a_n t^{n+r-1}\right)t^3+\left(p^2+p\right)\left(\sum_{n=0}^{\infty}a_n t^{n+r}\right)=0
\end{aligned} \tag{1}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty}t^{n+r+2}a_n(n+r)\,(n+r-1)\right)+\sum_{n=0}^{\infty}\left(-t^{n+r}a_n(n+r)\,(n+r-1)\right) \\
&+\left(\sum_{n=0}^{\infty}2t^{n+r+2}a_n(n+r)\right)+\left(\sum_{n=0}^{\infty}\left(p^2+p\right)a_n t^{n+r}\right)=0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of t be $n+r$ in each summation term. Going over each summation term above with power of t in it which is not already t^{n+r} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty}t^{n+r+2}a_n(n+r)\,(n+r-1)&=\sum_{n=2}^{\infty}a_{n-2}(n+r-2)\,(n-3+r)\,t^{n+r} \\
\sum_{n=0}^{\infty}2t^{n+r+2}a_n(n+r)&=\sum_{n=2}^{\infty}2a_{n-2}(n+r-2)\,t^{n+r}
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of t are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty}a_{n-2}(n+r-2)\,(n-3+r)\,t^{n+r}\right)+\sum_{n=0}^{\infty}\left(-t^{n+r}a_n(n+r)\,(n+r-1)\right) \\
&+\left(\sum_{n=2}^{\infty}2a_{n-2}(n+r-2)\,t^{n+r}\right)+\left(\sum_{n=0}^{\infty}\left(p^2+p\right)a_n t^{n+r}\right)=0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
-t^{n+r}a_n(n+r)\,(n+r-1)+\left(p^2+p\right)a_n t^{n+r}=0
$$

When $n = 0$ the above becomes

$$-t^r a_0 r(-1+r) + \left(p^2+p\right) a_0 t^r = 0$$

Or

$$\left(-t^r r(-1+r) + \left(p^2+p\right) t^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(p^2 - r^2 + p + r\right) t^r = 0$$

Since the above is true for all t then the indicial equation becomes

$$p^2 - r^2 + p + r = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -p$$
$$r_2 = p + 1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(p^2 - r^2 + p + r\right) t^r = 0$$

Solving for r gives the roots of the indicial equation as Assuming the roots differ by non-integer Since $r_1 - r_2 = -2p - 1$ is not an integer, then we can construct two linearly independent solutions

$$y_1(t) = t^{r_1} \left(\sum_{n=0}^{\infty} a_n t^n\right)$$
$$y_2(t) = t^{r_2} \left(\sum_{n=0}^{\infty} b_n t^n\right)$$

Or

$$y_1(t) = \sum_{n=0}^{\infty} a_n t^{n-p}$$
$$y_2(t) = \sum_{n=0}^{\infty} b_n t^{n+p+1}$$

We start by finding $y_1(t)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_{n-2}(n+r-2)(n-3+r)-a_n(n+r)(n+r-1)+2a_{n-2}(n+r-2)+a_n p(p+1)=0 \quad (3)$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-2}(n^2+2nr+r^2-3n-3r+2)}{n^2+2nr-p^2+r^2-n-p-r} \tag{4}$$

Which for the root $r = -p$ becomes

$$a_n = \frac{a_{n-2}(n-1-p)(n-p-2)}{n(n-2p-1)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -p$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = -\frac{(1+r)r}{p^2-r^2+p-3r-2}$$

Which for the root $r = -p$ becomes

$$a_2 = -\frac{(-1+p)p}{4p-2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$-\frac{(-1+p)p}{4p-2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$-\frac{(-1+p)p}{4p-2}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(1+r)\, r(r+3)\, (r+2)}{(p+r+2)\, (p-1-r)\, (p+4+r)\, (p-3-r)}$$

Which for the root $r = -p$ becomes

$$a_4 = \frac{(-1+p)\, p(p-3)\, (p-2)}{32p^2 - 64p + 24}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$-\frac{(-1+p)p}{4p-2}$
a_3	0	0
a_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(-1+p)p(p-3)(p-2)}{32p^2-64p+24}$

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$-\frac{(-1+p)p}{4p-2}$
a_3	0	0
a_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(-1+p)p(p-3)(p-2)}{32p^2-64p+24}$
a_5	0	0

For $n = 6$, using the above recursive equation gives

$$a_6 = -\frac{(1+r)\, r(r+3)\,(r+2)\,(r+5)\,(4+r)}{(p+r+2)\,(p-1-r)\,(p+4+r)\,(p-3-r)\,(p+6+r)\,(p-5-r)}$$

Which for the root $r = -p$ becomes

$$a_6 = -\frac{(-1+p)\, p(p-3)\,(p-2)\,(p-5)\,(-4+p)}{384p^3-1728p^2+2208p-720}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$-\frac{(-1+p)p}{4p-2}$
a_3	0	0
a_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(-1+p)p(p-3)(p-2)}{32p^2-64p+24}$
a_5	0	0
a_6	$-\frac{(1+r)r(r+3)(r+2)(r+5)(4+r)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)(p+6+r)(p-5-r)}$	$-\frac{(-1+p)p(p-3)(p-2)(p-5)(-4+p)}{384p^3-1728p^2+2208p-720}$

For $n = 7$, using the above recursive equation gives

$$a_7 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$-\frac{(-1+p)p}{4p-2}$
a_3	0	0
a_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(-1+p)p(p-3)(p-2)}{32p^2-64p+24}$
a_5	0	0
a_6	$-\frac{(1+r)r(r+3)(r+2)(r+5)(4+r)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)(p+6+r)(p-5-r)}$	$-\frac{(-1+p)p(p-3)(p-2)(p-5)(-4+p)}{384p^3-1728p^2+2208p-720}$
a_7	0	0

Using the above table, then the solution $y_1(t)$ is

$$
\begin{aligned}
y_1(t) &= t^{-p}\left(a_0 + a_1 t + a_2 t^2 + a_3 t^3 + a_4 t^4 + a_5 t^5 + a_6 t^6 + a_7 t^7 + a_8 t^8 \dots\right) \\
&= t^{-p}\left(1 - \frac{(-1+p)\,p\,t^2}{4p-2} + \frac{(-1+p)\,p(p-3)\,(p-2)\,t^4}{32p^2-64p+24} - \frac{(-1+p)\,p(p-3)\,(p-2)\,(p-5)\,(-4+p)}{384p^3-1728p^2+2208p-720}\right.
\end{aligned}
$$

Now the second solution $y_2(t)$ is found. Eq (2B) derived above is now used to find all b_n coefficients. The case $n=0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$
b_1 = 0
$$

For $2 \leq n$ the recursive equation is

$$
b_{n-2}(n+r-2)\,(n-3+r) - b_n(n+r)\,(n+r-1) + 2b_{n-2}(n+r-2) + p(p+1)\,b_n = 0 \quad (3)
$$

Solving for b_n from recursive equation (4) gives

$$
b_n = \frac{b_{n-2}(n^2+2nr+r^2-3n-3r+2)}{n^2+2nr-p^2+r^2-n-p-r} \tag{4}
$$

Which for the root $r = p+1$ becomes

$$
b_n = \frac{b_{n-2}(n+p)\,(n+p-1)}{n\,(n+2p+1)} \tag{5}
$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = p+1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{(1+r)\,r}{p^2 - r^2 + p - 3r - 2}$$

Which for the root $r = p + 1$ becomes

$$b_2 = \frac{(p+2)\,(p+1)}{4p+6}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$\frac{(p+2)(p+1)}{4p+6}$

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$\frac{(p+2)(p+1)}{4p+6}$
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{(1+r)\,r(r+3)\,(r+2)}{(p+r+2)\,(p-1-r)\,(p+4+r)\,(p-3-r)}$$

Which for the root $r = p + 1$ becomes

$$b_4 = \frac{(p+1)(p+2)(p+3)(p+4)}{32p^2 + 128p + 120}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$\frac{(p+2)(p+1)}{4p+6}$
b_3	0	0
b_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(p+1)(p+2)(p+3)(p+4)}{32p^2+128p+120}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$\frac{(p+2)(p+1)}{4p+6}$
b_3	0	0
b_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(p+1)(p+2)(p+3)(p+4)}{32p^2+128p+120}$
b_5	0	0

For $n = 6$, using the above recursive equation gives

$$b_6 = -\frac{(1+r)\, r(r+3)(r+2)(r+5)(4+r)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)(p+6+r)(p-5-r)}$$

Which for the root $r = p + 1$ becomes

$$b_6 = \frac{(p+2)(p+1)(p+4)(p+3)(p+6)(5+p)}{384p^3 + 2880p^2 + 6816p + 5040}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$\frac{(p+2)(p+1)}{4p+6}$
b_3	0	0
b_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(p+1)(p+2)(p+3)(p+4)}{32p^2+128p+120}$
b_5	0	0
b_6	$-\frac{(1+r)r(r+3)(r+2)(r+5)(4+r)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)(p+6+r)(p-5-r)}$	$\frac{(p+2)(p+1)(p+4)(p+3)(p+6)(5+p)}{384p^3+2880p^2+6816p+5040}$

For $n = 7$, using the above recursive equation gives

$$b_7 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$-\frac{(1+r)r}{p^2-r^2+p-3r-2}$	$\frac{(p+2)(p+1)}{4p+6}$
b_3	0	0
b_4	$\frac{(1+r)r(r+3)(r+2)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)}$	$\frac{(p+1)(p+2)(p+3)(p+4)}{32p^2+128p+120}$
b_5	0	0
b_6	$-\frac{(1+r)r(r+3)(r+2)(r+5)(4+r)}{(p+r+2)(p-1-r)(p+4+r)(p-3-r)(p+6+r)(p-5-r)}$	$\frac{(p+2)(p+1)(p+4)(p+3)(p+6)(5+p)}{384p^3+2880p^2+6816p+5040}$
b_7	0	0

Using the above table, then the solution $y_2(t)$ is

$$\begin{aligned} y_2(t) &= t^{-p}\left(b_0 + b_1 t + b_2 t^2 + b_3 t^3 + b_4 t^4 + b_5 t^5 + b_6 t^6 + b_7 t^7 + b_8 t^8 \dots\right) \\ &= t^{p+1}\left(1 + \frac{(p+2)(p+1)t^2}{4p+6} + \frac{(p+1)(p+2)(p+3)(p+4)t^4}{32p^2+128p+120} + \frac{(p+2)(p+1)(p+4)(p+3)(p}{384p^3+2880p^2+6816p} \right. \end{aligned}$$

Therefore the homogeneous solution is

$$y_h(t) = c_1 y_1(t) + c_2 y_2(t)$$

$$
\begin{aligned}
&= c_1 t^{-p}\left(1-\frac{(-1+p)\,p\,t^2}{4p-2}+\frac{(-1+p)\,p(p-3)\,(p-2)\,t^4}{32p^2-64p+24} \right.\\
&\left. -\frac{(-1+p)\,p(p-3)\,(p-2)\,(p-5)\,(-4+p)\,t^6}{384p^3-1728p^2+2208p-720}+O(t^8)\right)\\
&+ c_2 t^{p+1}\left(1+\frac{(p+2)\,(p+1)\,t^2}{4p+6}+\frac{(p+1)\,(p+2)\,(p+3)\,(p+4)\,t^4}{32p^2+128p+120} \right.\\
&\left. +\frac{(p+2)\,(p+1)\,(p+4)\,(p+3)\,(p+6)\,(5+p)\,t^6}{384p^3+2880p^2+6816p+5040}+O(t^8)\right)
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y(t) &= y_h\\
&= c_1 t^{-p}\left(1-\frac{(-1+p)\,p\,t^2}{4p-2}+\frac{(-1+p)\,p(p-3)\,(p-2)\,t^4}{32p^2-64p+24} \right.\\
&\left. -\frac{(-1+p)\,p(p-3)\,(p-2)\,(p-5)\,(-4+p)\,t^6}{384p^3-1728p^2+2208p-720}+O(t^8)\right)\\
&+ c_2 t^{p+1}\left(1+\frac{(p+2)\,(p+1)\,t^2}{4p+6}+\frac{(p+1)\,(p+2)\,(p+3)\,(p+4)\,t^4}{32p^2+128p+120} \right.\\
&\left. +\frac{(p+2)\,(p+1)\,(p+4)\,(p+3)\,(p+6)\,(5+p)\,t^6}{384p^3+2880p^2+6816p+5040}+O(t^8)\right)
\end{aligned}
$$

Replacing t by $\frac{1}{x}$ gives

$$
y = c_1\left(\frac{1}{x}\right)^{-p}\left(1-\frac{(-1+p)\,p}{(4p-2)\,x^2}+\frac{(-1+p)\,p(p-3)\,(p-2)}{(32p^2-64p+24)\,x^4}-\frac{(-1+p)\,p(p-3)\,(p-2)\,(p-5)\,(-4+p)}{(384p^3-1728p^2+2208p-720)\,x^6}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1\left(\frac{1}{x}\right)^{-p}\left(1-\frac{(-1+p)\,p}{(4p-2)\,x^2}+\frac{(-1+p)\,p(p-3)\,(p-2)}{(32p^2-64p+24)\,x^4} \right.\\
&\left. -\frac{(-1+p)\,p(p-3)\,(p-2)\,(p-5)\,(-4+p)}{(384p^3-1728p^2+2208p-720)\,x^6}+O\left(\frac{1}{x^8}\right)\right)\\
&+ c_2\left(\frac{1}{x}\right)^{p+1}\left(1+\frac{(p+2)\,(p+1)}{(4p+6)\,x^2}+\frac{(p+1)\,(p+2)\,(p+3)\,(p+4)}{(32p^2+128p+120)\,x^4} \right.\\
&\left. +\frac{(p+2)\,(p+1)\,(p+4)\,(p+3)\,(p+6)\,(5+p)}{(384p^3+2880p^2+6816p+5040)\,x^6}+O\left(\frac{1}{x^8}\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1 \left(\frac{1}{x}\right)^{-p} \left(1 - \frac{(-1+p)\,p}{(4p-2)\,x^2} + \frac{(-1+p)\,p(p-3)\,(p-2)}{(32p^2-64p+24)\,x^4} - \frac{(-1+p)\,p(p-3)\,(p-2)\,(p-5)\,(-4+p)}{(384p^3-1728p^2+2208p-720)\,x^6} + O\left(\frac{1}{x^8}\right)\right) + c_2 \left(\frac{1}{x}\right)^{p+1} \left(1 + \frac{(p+2)\,(p+1)}{(4p+6)\,x^2} + \frac{(p+1)\,(p+2)\,(p+3)\,(p+4)}{(32p^2+128p+120)\,x^4} + \frac{(p+2)\,(p+1)\,(p+4)\,(p+3)\,(p+6)\,(5+p)}{(384p^3+2880p^2+6816p+5040)\,x^6} + O\left(\frac{1}{x^8}\right)\right)$$

Verified OK.

23.3.1 Maple step by step solution

Let's solve

$(-x^2+1)\,y'' - 2xy' + (p^2+p)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{p(p+1)y}{x^2-1} - \frac{2xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2xy'}{x^2-1} - \frac{p(p+1)y}{x^2-1} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{2x}{x^2-1}, P_3(x) = -\frac{p(p+1)}{x^2-1}\right]$

  ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1} = 1$

  ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

$x_0 = -1$

- Multiply by denominators

  $(x^2-1)\, y'' + 2xy' - p(p+1)\, y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u = 0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (2u-2)\left(\frac{d}{du}y(u)\right) + (-p^2-p)\, y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

  - Shift index using $k- > k+1-m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

  - Shift index using $k- > k+2-m$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r^2u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)^2 + a_k(r+1+p+k)\,(r-p+k)\right) u^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r^2 = 0$

- Values of r that satisfy the indicial equation

  $r = 0$

- Each term in the series must be 0, giving the recursion relation

  $-2a_{k+1}(k+1)^2 + a_k(1+p+k)\,(-p+k) = 0$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{a_k(1+p+k)(-p+k)}{2(k+1)^2}$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{a_k(1+p+k)(-p+k)}{2(k+1)^2}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(1+p+k)(-p+k)}{2(k+1)^2}\right]$$

- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+1} = \frac{a_k(1+p+k)(-p+k)}{2(k+1)^2}\right]$$

Section: Chapter 7. Laplace Transforms. Section 7.5 The Unit Step and Impulse Functions. Page 303
Problem number: 1(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + 5y' + 6y = 5\,\mathrm{e}^{3t}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

24.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$\begin{aligned} p(t) &= 5 \\ q(t) &= 6 \\ F &= 5\,\mathrm{e}^{3t} \end{aligned}$$

Hence the ode is

$$y'' + 5y' + 6y = 5\,e^{3t}$$

The domain of $p(t) = 5$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 6$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = 5\,e^{3t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(y') &= sY(s) - y(0)\\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + 5sY(s) - 5y(0) + 6Y(s) = \frac{5}{s-3} \tag{1}$$

But the initial conditions are

$$\begin{aligned}y(0) &= 0\\ y'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + 5sY(s) + 6Y(s) = \frac{5}{s-3}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{5}{(s-3)\,(s^2 + 5s + 6)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{5}{6\,(s+3)} - \frac{1}{s+2} + \frac{1}{6s-18}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{5}{6\,(s+3)}\right) = \frac{5\,\mathrm{e}^{-3t}}{6}$$
$$\mathcal{L}^{-1}\left(-\frac{1}{s+2}\right) = -\mathrm{e}^{-2t}$$
$$\mathcal{L}^{-1}\left(\frac{1}{6s-18}\right) = \frac{\mathrm{e}^{3t}}{6}$$

Adding the above results and simplifying gives

$$y = \cosh(3t) - \frac{2\sinh(3t)}{3} - \mathrm{e}^{-2t}$$

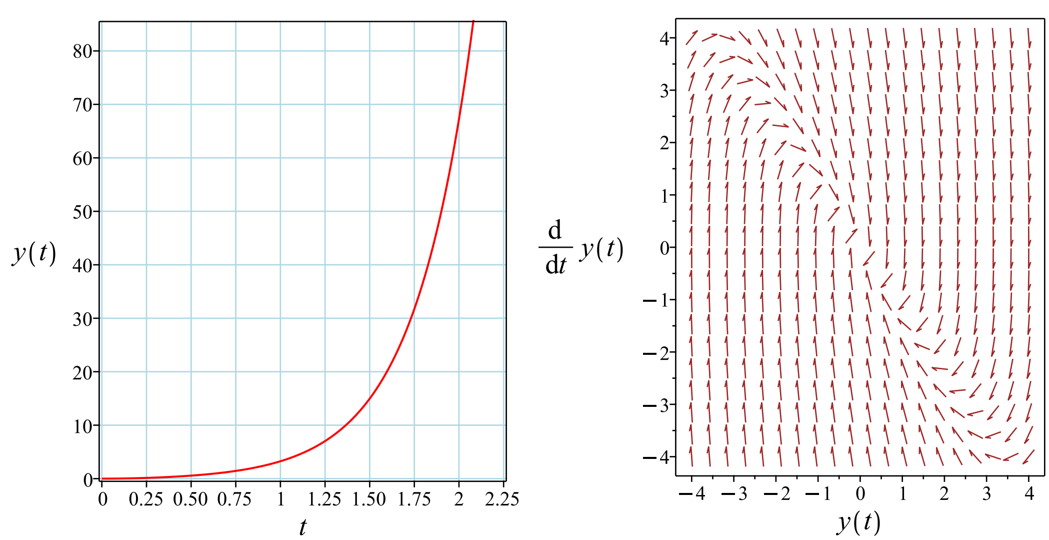
Simplifying the solution gives

$$y = \cosh(3t) - \frac{2\sinh(3t)}{3} - \mathrm{e}^{-2t}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \cosh(3t) - \frac{2\sinh(3t)}{3} - \mathrm{e}^{-2t} \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = \cosh(3t) - \frac{2\sinh(3t)}{3} - e^{-2t}$$

Verified OK.

24.1.2 Maple step by step solution

Let's solve

$\left[y'' + 5y' + 6y = 5\,e^{3t}, y(0) = 0, y'\Big|_{\{t=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r+3)(r+2) = 0$

- Roots of the characteristic polynomial

  $r = (-3, -2)$

- 1st solution of the homogeneous ODE

  $y_1(t) = e^{-3t}$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{-2t}$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{-3t} + c_2 e^{-2t} + y_p(t)$

□ Find a particular solution $y_p(t)$ of the ODE

  - Use variation of parameters to find y_p here $f(t)$ is the forcing function

    $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t)f(t)}{W(y_1(t),y_2(t))}dt\right) + y_2(t)\left(\int \frac{y_1(t)f(t)}{W(y_1(t),y_2(t))}dt\right), f(t) = 5\,e^{3t}\right]$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(t), y_2(t)) = \begin{bmatrix} e^{-3t} & e^{-2t} \\ -3\,e^{-3t} & -2\,e^{-2t} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(t), y_2(t)) = e^{-5t}$

- Substitute functions into equation for $y_p(t)$

  $y_p(t) = -5\,e^{-3t}\left(\int e^{6t}dt\right) + 5\,e^{-2t}\left(\int e^{5t}dt\right)$

- Compute integrals

  $y_p(t) = \frac{e^{3t}}{6}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{-3t} + c_2 e^{-2t} + \frac{e^{3t}}{6}$

☐ Check validity of solution $y = c_1 e^{-3t} + c_2 e^{-2t} + \frac{e^{3t}}{6}$

- Use initial condition $y(0) = 0$

  $0 = c_1 + c_2 + \frac{1}{6}$

- Compute derivative of the solution

  $y' = -3c_1 e^{-3t} - 2c_2 e^{-2t} + \frac{e^{3t}}{2}$

- Use the initial condition $y'\Big|_{\{t=0\}} = 0$

  $0 = -3c_1 - 2c_2 + \frac{1}{2}$

- Solve for c_1 and c_2

  $\left\{c_1 = \frac{5}{6}, c_2 = -1\right\}$

- Substitute constant values into general solution and simplify

  $y = \frac{(e^{6t} - 6\,e^{t} + 5)\,e^{-3t}}{6}$

- Solution to the IVP

  $y = \frac{(e^{6t} - 6\,e^{t} + 5)\,e^{-3t}}{6}$

Section: Chapter 7. Laplace Transforms. Section 7.5 The Unit Step and Impulse Functions. Page 303
Problem number: 1(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y' - 6y = t}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

24.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$\begin{aligned} p(t) &= 1 \\ q(t) &= -6 \\ F &= t \end{aligned}$$

Hence the ode is

$$y'' + y' - 6y = t$$

The domain of $p(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = -6$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = t$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(y') &= sY(s) - y(0)\\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + sY(s) - y(0) - 6Y(s) = \frac{1}{s^2} \tag{1}$$

But the initial conditions are

$$\begin{aligned}y(0) &= 0\\ y'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + sY(s) - 6Y(s) = \frac{1}{s^2}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{1}{s^2\,(s^2 + s - 6)}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{1}{36s} - \frac{1}{45(s+3)} + \frac{1}{20s-40} - \frac{1}{6s^2}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{1}{36s}\right) = -\frac{1}{36}$$
$$\mathcal{L}^{-1}\left(-\frac{1}{45(s+3)}\right) = -\frac{e^{-3t}}{45}$$
$$\mathcal{L}^{-1}\left(\frac{1}{20s-40}\right) = \frac{e^{2t}}{20}$$
$$\mathcal{L}^{-1}\left(-\frac{1}{6s^2}\right) = -\frac{t}{6}$$

Adding the above results and simplifying gives

$$y = \frac{e^{2t}}{20} - \frac{1}{36} - \frac{e^{-3t}}{45} - \frac{t}{6}$$

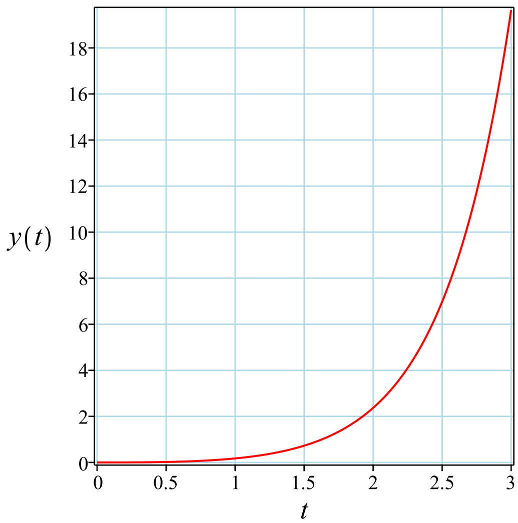
Simplifying the solution gives

$$y = \frac{(9\,e^{5t} - 30t\,e^{3t} - 5\,e^{3t} - 4)\,e^{-3t}}{180}$$

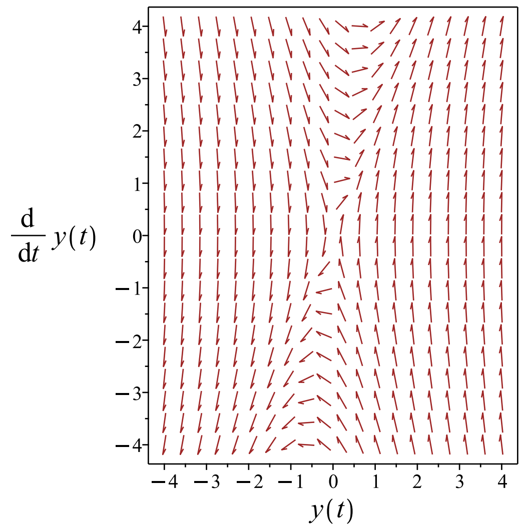
Summary

The solution(s) found are the following

$$y = \frac{(9\,e^{5t} - 30t\,e^{3t} - 5\,e^{3t} - 4)\,e^{-3t}}{180} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{(9\,e^{5t} - 30t\,e^{3t} - 5\,e^{3t} - 4)\,e^{-3t}}{180}$$

Verified OK.

24.2.2 Maple step by step solution

Let's solve

$$\left[y'' + y' - 6y = t, y(0) = 0, y'\Big|_{\{t=0\}} = 0\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r - 6 = 0$

- Factor the characteristic polynomial

  $(r+3)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (-3, 2)$

- 1st solution of the homogeneous ODE

$y_1(t) = \mathrm{e}^{-3t}$

- 2nd solution of the homogeneous ODE

  $y_2(t) = \mathrm{e}^{2t}$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-3t} + c_2 \mathrm{e}^{2t} + y_p(t)$

☐ Find a particular solution $y_p(t)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(t)$ is the forcing function

  $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t)f(t)}{W(y_1(t),y_2(t))}dt\right) + y_2(t)\left(\int \frac{y_1(t)f(t)}{W(y_1(t),y_2(t))}dt\right), f(t) = t\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(t), y_2(t)) = \begin{bmatrix} \mathrm{e}^{-3t} & \mathrm{e}^{2t} \\ -3\,\mathrm{e}^{-3t} & 2\,\mathrm{e}^{2t} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(t), y_2(t)) = 5\,\mathrm{e}^{-t}$

- ○ Substitute functions into equation for $y_p(t)$

  $y_p(t) = \frac{\left(\mathrm{e}^{5t}\left(\int t\,\mathrm{e}^{-2t}dt\right) - \left(\int t\,\mathrm{e}^{3t}dt\right)\right)\mathrm{e}^{-3t}}{5}$

- ○ Compute integrals

  $y_p(t) = -\frac{1}{36} - \frac{t}{6}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-3t} + c_2 \mathrm{e}^{2t} - \frac{1}{36} - \frac{t}{6}$

☐ Check validity of solution $y = c_1 \mathrm{e}^{-3t} + c_2 \mathrm{e}^{2t} - \frac{1}{36} - \frac{t}{6}$

- ○ Use initial condition $y(0) = 0$

  $0 = c_1 + c_2 - \frac{1}{36}$

- ○ Compute derivative of the solution

  $y' = -3c_1 \mathrm{e}^{-3t} + 2c_2 \mathrm{e}^{2t} - \frac{1}{6}$

- ○ Use the initial condition $y'\Big|_{\{t=0\}} = 0$

  $0 = -3c_1 + 2c_2 - \frac{1}{6}$

- Solve for c_1 and c_2

  $\left\{c_1 = -\frac{1}{45}, c_2 = \frac{1}{20}\right\}$

- Substitute constant values into general solution and simplify

  $y = \frac{(9\,e^{5t} - 30t\,e^{3t} - 5\,e^{3t} - 4)\,e^{-3t}}{180}$

- Solution to the IVP

  $y = \frac{(9\,e^{5t} - 30t\,e^{3t} - 5\,e^{3t} - 4)\,e^{-3t}}{180}$

Problem number: 1(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y = t^2}$$

With initial conditions

$$[y(0) = 0, y'(0) = 0]$$

24.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$\begin{aligned} p(t) &= 0 \\ q(t) &= -1 \\ F &= t^2 \end{aligned}$$

Hence the ode is

$$y'' - y = t^2$$

The domain of $p(t) = 0$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = t^2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(y') &= sY(s) - y(0)\\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) - Y(s) = \frac{2}{s^3} \tag{1}$$

But the initial conditions are

$$\begin{aligned}y(0) &= 0\\ y'(0) &= 0\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) - Y(s) = \frac{2}{s^3}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{2}{s^3\,(s^2 - 1)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{1}{s+1} + \frac{1}{s-1} - \frac{2}{s^3} - \frac{2}{s}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{1}{s+1}\right) = e^{-t}$$
$$\mathcal{L}^{-1}\left(\frac{1}{s-1}\right) = e^{t}$$
$$\mathcal{L}^{-1}\left(-\frac{2}{s^3}\right) = -t^2$$
$$\mathcal{L}^{-1}\left(-\frac{2}{s}\right) = -2$$

Adding the above results and simplifying gives

$$y = -2 - t^2 + 2\cosh(t)$$

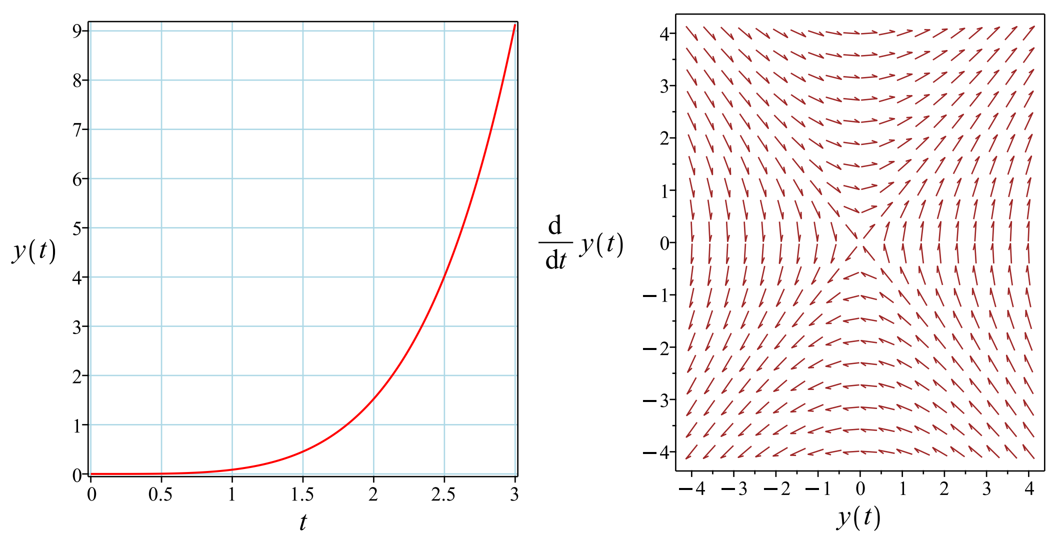
Simplifying the solution gives

$$y = -2 - t^2 + 2\cosh(t)$$

Summary

The solution(s) found are the following

$$y = -2 - t^2 + 2\cosh(t) \tag{1}$$



(a) Solution plot

(b) Slope field plot

Verification of solutions

$$y = -2 - t^2 + 2\cosh(t)$$

Verified OK.

24.3.2 Maple step by step solution

Let's solve

$\left[y'' - y = t^2, y(0) = 0, y'\Big|_{\{t=0\}} = 0\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(t) = e^{-t}$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{t}$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-t} c_1 + c_2 e^{t} + y_p(t)$

□ Find a particular solution $y_p(t)$ of the ODE

  - Use variation of parameters to find y_p here $f(t)$ is the forcing function

    $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t)f(t)}{W(y_1(t),y_2(t))}dt\right) + y_2(t)\left(\int \frac{y_1(t)f(t)}{W(y_1(t),y_2(t))}dt\right), f(t) = t^2\right]$

  - Wronskian of solutions of the homogeneous equation

$$W(y_1(t), y_2(t)) = \begin{bmatrix} e^{-t} & e^t \\ -e^{-t} & e^t \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(t), y_2(t)) = 2$

- Substitute functions into equation for $y_p(t)$

  $y_p(t) = -\frac{e^{-t}\left(\int e^t t^2 dt\right)}{2} + \frac{e^t\left(\int e^{-t} t^2 dt\right)}{2}$

- Compute integrals

  $y_p(t) = -t^2 - 2$

- Substitute particular solution into general solution to ODE

  $y = e^{-t}c_1 + c_2 e^t - t^2 - 2$

□ Check validity of solution $y = e^{-t}c_1 + c_2 e^t - t^2 - 2$

- Use initial condition $y(0) = 0$

  $0 = c_1 - 2 + c_2$

- Compute derivative of the solution

  $y' = -e^{-t}c_1 + c_2 e^t - 2t$

- Use the initial condition $y'\Big|_{\{t=0\}} = 0$

  $0 = -c_1 + c_2$

- Solve for c_1 and c_2

  $\{c_1 = 1, c_2 = 1\}$

- Substitute constant values into general solution and simplify

  $y = e^{-t} + e^t - t^2 - 2$

- Solution to the IVP

  $y = e^{-t} + e^t - t^2 - 2$

24.4 problem 7(a)

Internal problem ID [6502]
Internal file name [`OUTPUT/5750_Sunday_June_05_2022_03_52_42_PM_3334797/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 7. Laplace Transforms. Section 7.5 The Unit Step and Impulse Functions. Page 303
Problem number: 7(a).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{Li' + Ri = E_0 \operatorname{Heaviside}(t)}$$

With initial conditions

$$[i(0) = 0]$$

24.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$i' + p(t)i = q(t)$$

Where here

$$p(t) = \frac{R}{L}$$
$$q(t) = \frac{E_0 \operatorname{Heaviside}(t)}{L}$$

Hence the ode is

$$i' + \frac{Ri}{L} = \frac{E_0 \,\text{Heaviside}\,(t)}{L}$$

The domain of $p(t) = \frac{R}{L}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = \frac{E_0 \,\text{Heaviside}(t)}{L}$ is

$$\{t < 0 \lor 0 < t\}$$

But the point $t_0 = 0$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

24.4.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(i) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(i') = sY(s) - i(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$LY(s)\, s - Li(0) + RY(s) = \frac{E_0}{s} \tag{1}$$

Replacing initial condition gives

$$LY(s)\, s + RY(s) = \frac{E_0}{s}$$

Solving for $Y(s)$ gives

$$Y(s) = \frac{E_0}{s\,(Ls + R)}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{E_0}{R\left(s + \frac{R}{L}\right)} + \frac{E_0}{Rs}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(-\frac{E_0}{R\left(s+\frac{R}{L}\right)}\right) = -\frac{E_0 \mathrm{e}^{-\frac{Rt}{L}}}{R}$$
$$\mathcal{L}^{-1}\left(\frac{E_0}{Rs}\right) = \frac{E_0}{R}$$

Adding the above results and simplifying gives

$$i = \frac{E_0\left(1-\mathrm{e}^{-\frac{Rt}{L}}\right)}{R}$$

Summary

The solution(s) found are the following

$$i = \frac{E_0\left(1-\mathrm{e}^{-\frac{Rt}{L}}\right)}{R} \tag{1}$$

Verification of solutions

$$i = \frac{E_0\left(1-\mathrm{e}^{-\frac{Rt}{L}}\right)}{R}$$

Verified OK.

24.4.3 Maple step by step solution

Let's solve

$[Li' + Ri = E_0 Heaviside(t), i(0) = 0]$

- Highest derivative means the order of the ODE is 1

  i'

- Isolate the derivative

  $i' = -\frac{Ri}{L} + \frac{E_0 Heaviside(t)}{L}$

- Group terms with i on the lhs of the ODE and the rest on the rhs of the ODE

  $i' + \frac{Ri}{L} = \frac{E_0 Heaviside(t)}{L}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(i' + \frac{Ri}{L}\right) = \frac{\mu(t) E_0 Heaviside(t)}{L}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, i)$

$$\mu(t)\left(i'+\frac{Ri}{L}\right)=\mu'(t)\,i+\mu(t)\,i'$$

- Isolate $\mu'(t)$

$$\mu'(t)=\frac{\mu(t)R}{L}$$

- Solve to find the integrating factor

$$\mu(t)=\mathrm{e}^{\frac{Rt}{L}}$$

- Integrate both sides with respect to t

$$\int\left(\frac{d}{dt}(\mu(t)\,i)\right)dt=\int\frac{\mu(t)E_0\mathit{Heaviside}(t)}{L}dt+c_1$$

- Evaluate the integral on the lhs

$$\mu(t)\,i=\int\frac{\mu(t)E_0\mathit{Heaviside}(t)}{L}dt+c_1$$

- Solve for i

$$i=\frac{\int\frac{\mu(t)E_0\mathit{Heaviside}(t)}{L}dt+c_1}{\mu(t)}$$

- Substitute $\mu(t)=\mathrm{e}^{\frac{Rt}{L}}$

$$i=\frac{\int\frac{\mathrm{e}^{\frac{Rt}{L}}E_0\mathit{Heaviside}(t)}{L}dt+c_1}{\mathrm{e}^{\frac{Rt}{L}}}$$

- Evaluate the integrals on the rhs

$$i=\frac{\frac{E_0\left(\frac{L\,\mathrm{e}^{\frac{Rt}{L}}\mathit{Heaviside}(t)}{R}-\frac{\mathit{Heaviside}(t)L}{R}\right)}{L}+c_1}{\mathrm{e}^{\frac{Rt}{L}}}$$

- Simplify

$$i=\frac{E_0\mathit{Heaviside}(t)-E_0\mathit{Heaviside}(t)\mathrm{e}^{-\frac{Rt}{L}}+Rc_1\mathrm{e}^{-\frac{Rt}{L}}}{R}$$

- Use initial condition $i(0)=0$

$$0=c_1$$

- Solve for c_1

$$c_1=0$$

- Substitute $c_1=0$ into general solution and simplify

$$i=-\frac{E_0\mathit{Heaviside}(t)\left(\mathrm{e}^{-\frac{Rt}{L}}-1\right)}{R}$$

- Solution to the IVP

$$i=-\frac{E_0\mathit{Heaviside}(t)\left(\mathrm{e}^{-\frac{Rt}{L}}-1\right)}{R}$$

Section: Chapter 7. Laplace Transforms. Section 7.5 The Unit Step and Impulse Functions. Page 303
Problem number: 7(b).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "first__order__ode__lie__symmetry__lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{Li' + Ri = E_0\delta(t)}$$

With initial conditions

$$[i(0) = 0]$$

24.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$i' + p(t)i = q(t)$$

Where here

$$p(t) = \frac{R}{L}$$
$$q(t) = \frac{E_0\delta(t)}{L}$$

Hence the ode is

$$i' + \frac{Ri}{L} = \frac{E_0\delta(t)}{L}$$

The domain of $p(t) = \frac{R}{L}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = \frac{E_0\delta(t)}{L}$ is

$$\{t < 0 \lor 0 < t\}$$

But the point $t_0 = 0$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

24.5.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(i) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(i') = sY(s) - i(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$LY(s)\, s - Li(0) + RY(s) = E_0 \tag{1}$$

Replacing initial condition gives

$$LY(s)\, s + RY(s) = E_0$$

Solving for $Y(s)$ gives

$$Y(s) = \frac{E_0}{Ls + R}$$

Taking inverse Laplace transform gives

$$\mathcal{L}^{-1}\left(\frac{E_0}{Ls + R}\right) = \frac{E_0 \mathrm{e}^{-\frac{Rt}{L}}}{L}$$

Summary
The solution(s) found are the following

$$i = \frac{E_0 e^{-\frac{Rt}{L}}}{L} \tag{1}$$

Verification of solutions

$$i = \frac{E_0 e^{-\frac{Rt}{L}}}{L}$$

Verified OK.

24.5.3 Maple step by step solution

Let's solve

$[Li' + Ri = E_0 Dirac(t), i(0) = 0]$

- Highest derivative means the order of the ODE is 1

  i'

- Isolate the derivative

  $i' = -\frac{Ri}{L} + \frac{E_0 Dirac(t)}{L}$

- Group terms with i on the lhs of the ODE and the rest on the rhs of the ODE

  $i' + \frac{Ri}{L} = \frac{E_0 Dirac(t)}{L}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

  $\mu(t)\left(i' + \frac{Ri}{L}\right) = \frac{\mu(t) E_0 Dirac(t)}{L}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\, i)$

  $\mu(t)\left(i' + \frac{Ri}{L}\right) = \mu'(t)\, i + \mu(t)\, i'$

- Isolate $\mu'(t)$

  $\mu'(t) = \frac{\mu(t) R}{L}$

- Solve to find the integrating factor

  $\mu(t) = e^{\frac{Rt}{L}}$

- Integrate both sides with respect to t

  $\int \left(\frac{d}{dt}(\mu(t)\, i)\right) dt = \int \frac{\mu(t) E_0 Dirac(t)}{L} dt + c_1$

- Evaluate the integral on the lhs

  $\mu(t)\, i = \int \frac{\mu(t) E_0 Dirac(t)}{L} dt + c_1$

- Solve for i

$$i = \frac{\int \frac{\mu(t) E_0 \mathit{Dirac}(t)}{L} dt + c_1}{\mu(t)}$$

- Substitute $\mu(t) = e^{\frac{Rt}{L}}$

$$i = \frac{\int \frac{e^{\frac{Rt}{L}} E_0 \mathit{Dirac}(t)}{L} dt + c_1}{e^{\frac{Rt}{L}}}$$

- Evaluate the integrals on the rhs

$$i = \frac{\frac{E_0 \mathit{Heaviside}(t)}{L} + c_1}{e^{\frac{Rt}{L}}}$$

- Simplify

$$i = \frac{e^{-\frac{Rt}{L}} (E_0 \mathit{Heaviside}(t) + L c_1)}{L}$$

- Use initial condition $i(0) = 0$

$$0 = \frac{E_0 \mathit{undefined} + L c_1}{L}$$

- Solve for c_1

$$c_1 = -\frac{E_0 \mathit{undefined}}{L}$$

- Substitute $c_1 = -\frac{E_0 \mathit{undefined}}{L}$ into general solution and simplify

$$i = \frac{e^{-\frac{Rt}{L}} E_0 (\mathit{undefined} + \mathit{Heaviside}(t))}{L}$$

- Solution to the IVP

$$i = \frac{e^{-\frac{Rt}{L}} E_0 (\mathit{undefined} + \mathit{Heaviside}(t))}{L}$$

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_linear, `class A`]]
```

$$\boxed{Li' + Ri = E_0 \sin(\omega t)}$$

With initial conditions

$$[i(0) = 0]$$

24.6.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$i' + p(t)i = q(t)$$

Where here

$$p(t) = \frac{R}{L}$$
$$q(t) = \frac{E_0 \sin(\omega t)}{L}$$

Hence the ode is

$$i' + \frac{Ri}{L} = \frac{E_0 \sin(\omega t)}{L}$$

The domain of $p(t) = \frac{R}{L}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = \frac{E_0 \sin(\omega t)}{L}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

24.6.2 Solving as laplace ode

Solving using the Laplace transform method. Let

$$\mathcal{L}(i) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(i') = sY(s) - i(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$LY(s)\, s - Li(0) + RY(s) = \frac{E_0 \omega}{\omega^2 + s^2} \tag{1}$$

Replacing initial condition gives

$$LY(s)\, s + RY(s) = \frac{E_0 \omega}{\omega^2 + s^2}$$

Solving for $Y(s)$ gives

$$Y(s) = \frac{E_0 \omega}{(\omega^2 + s^2)(Ls + R)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{E_0 \omega L}{(\omega^2 L^2 + R^2)\left(s + \frac{R}{L}\right)} - \frac{\left(L\sqrt{-\omega^2} - R\right) E_0 \omega}{2(\omega^2 L^2 + R^2)\sqrt{-\omega^2}\,\left(s - \sqrt{-\omega^2}\right)} + \frac{\left(-L\sqrt{-\omega^2} - R\right) E_0 \omega}{2(\omega^2 L^2 + R^2)\sqrt{-\omega^2}\,\left(s + \sqrt{-\omega^2}\right)}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{E_0 \omega L}{(\omega^2 L^2 + R^2)\left(s+\frac{R}{L}\right)}\right) = \frac{E_0 \omega L\, e^{-\frac{Rt}{L}}}{\omega^2 L^2 + R^2}$$

$$\mathcal{L}^{-1}\left(-\frac{\left(L\sqrt{-\omega^2}-R\right)E_0 \omega}{2\left(\omega^2 L^2 + R^2\right)\sqrt{-\omega^2}\,\left(s-\sqrt{-\omega^2}\right)}\right) = \frac{E_0 e^{i\,\mathrm{csgn}(i\omega)\omega t}(-iR\ \mathrm{csgn}\left(i\omega\right) - L\omega)}{2\omega^2 L^2 + 2R^2}$$

$$\mathcal{L}^{-1}\left(\frac{\left(-L\sqrt{-\omega^2}-R\right)E_0 \omega}{2\left(\omega^2 L^2 + R^2\right)\sqrt{-\omega^2}\,\left(s+\sqrt{-\omega^2}\right)}\right) = \frac{E_0 e^{-i\,\mathrm{csgn}(i\omega)\omega t}(iR\ \mathrm{csgn}\left(i\omega\right) - L\omega)}{2\omega^2 L^2 + 2R^2}$$

Adding the above results and simplifying gives

$$i = \frac{E_0\left(R\sin\left(\omega t\right) + \left(-\cos\left(\omega t\right) + e^{-\frac{Rt}{L}}\right)\omega L\right)}{\omega^2 L^2 + R^2}$$

Summary

The solution(s) found are the following

$$i = \frac{E_0\left(R\sin\left(\omega t\right) + \left(-\cos\left(\omega t\right) + e^{-\frac{Rt}{L}}\right)\omega L\right)}{\omega^2 L^2 + R^2} \tag{1}$$

Verification of solutions

$$i = \frac{E_0\left(R\sin\left(\omega t\right) + \left(-\cos\left(\omega t\right) + e^{-\frac{Rt}{L}}\right)\omega L\right)}{\omega^2 L^2 + R^2}$$

Verified OK.

24.6.3 Maple step by step solution

Let's solve

$[Li' + Ri = E_0 \sin\left(\omega t\right), i(0) = 0]$

- Highest derivative means the order of the ODE is 1

  i'

- Isolate the derivative

  $i' = -\frac{Ri}{L} + \frac{E_0 \sin(\omega t)}{L}$

- Group terms with i on the lhs of the ODE and the rest on the rhs of the ODE

  $i' + \frac{Ri}{L} = \frac{E_0 \sin(\omega t)}{L}$

- The ODE is linear; multiply by an integrating factor $\mu(t)$

$$\mu(t)\left(i'+\frac{Ri}{L}\right)=\frac{\mu(t)E_0\sin(\omega t)}{L}$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dt}(\mu(t)\,i)$

$$\mu(t)\left(i'+\frac{Ri}{L}\right)=\mu'(t)\,i+\mu(t)\,i'$$

- Isolate $\mu'(t)$

$$\mu'(t)=\frac{\mu(t)R}{L}$$

- Solve to find the integrating factor

$$\mu(t)=\mathrm{e}^{\frac{Rt}{L}}$$

- Integrate both sides with respect to t

$$\int\left(\frac{d}{dt}(\mu(t)\,i)\right)dt=\int\frac{\mu(t)E_0\sin(\omega t)}{L}dt+c_1$$

- Evaluate the integral on the lhs

$$\mu(t)\,i=\int\frac{\mu(t)E_0\sin(\omega t)}{L}dt+c_1$$

- Solve for i

$$i=\frac{\int\frac{\mu(t)E_0\sin(\omega t)}{L}dt+c_1}{\mu(t)}$$

- Substitute $\mu(t)=\mathrm{e}^{\frac{Rt}{L}}$

$$i=\frac{\int\frac{\mathrm{e}^{\frac{Rt}{L}}E_0\sin(\omega t)}{L}dt+c_1}{\mathrm{e}^{\frac{Rt}{L}}}$$

- Evaluate the integrals on the rhs

$$i=\frac{\frac{E_0\left(-\frac{\omega\,\mathrm{e}^{\frac{Rt}{L}}\cos(\omega t)}{\omega^2+\frac{R^2}{L^2}}+\frac{R\,\mathrm{e}^{\frac{Rt}{L}}\sin(\omega t)}{L\left(\omega^2+\frac{R^2}{L^2}\right)}\right)}{L}+c_1}{\mathrm{e}^{\frac{Rt}{L}}}$$

- Simplify

$$i=\frac{c_1(\omega^2L^2+R^2)\mathrm{e}^{-\frac{Rt}{L}}-E_0(L\omega\cos(\omega t)-R\sin(\omega t))}{\omega^2L^2+R^2}$$

- Use initial condition $i(0)=0$

$$0=\frac{c_1(\omega^2L^2+R^2)-E_0\omega L}{\omega^2L^2+R^2}$$

- Solve for c_1

$$c_1=\frac{E_0\omega L}{\omega^2L^2+R^2}$$

- Substitute $c_1=\frac{E_0\omega L}{\omega^2L^2+R^2}$ into general solution and simplify

$$i=-\frac{E_0\left(L\omega\cos(\omega t)-\omega L\,\mathrm{e}^{-\frac{Rt}{L}}-R\sin(\omega t)\right)}{\omega^2L^2+R^2}$$

- Solution to the IVP

$$i = -\frac{E_0 \left(L\omega \cos(\omega t) - \omega L \,\mathrm{e}^{-\frac{Rt}{L}} - R\sin(\omega t)\right)}{\omega^2 L^2 + R^2}$$

Section: Chapter 7. Laplace Transforms. Section 7.5 Problesm for review and discovery. Section A, Drill exercises. Page 309
Problem number: 3(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 3y' - 5y = 1}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

25.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$p(t) = 3$$
$$q(t) = -5$$
$$F = 1$$

Hence the ode is

$$y'' + 3y' - 5y = 1$$

The domain of $p(t) = 3$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = -5$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(y') &= sY(s) - y(0)\\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + 3sY(s) - 3y(0) - 5Y(s) = \frac{1}{s} \tag{1}$$

But the initial conditions are

$$\begin{aligned}y(0) &= 0\\ y'(0) &= 1\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) - 1 + 3sY(s) - 5Y(s) = \frac{1}{s}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{1+s}{s\,(s^2 + 3s - 5)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{\frac{1}{10}+\frac{13\sqrt{29}}{290}}{s+\frac{3}{2}-\frac{\sqrt{29}}{2}} + \frac{\frac{1}{10}-\frac{13\sqrt{29}}{290}}{s+\frac{3}{2}+\frac{\sqrt{29}}{2}} - \frac{1}{5s}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{\frac{1}{10}+\frac{13\sqrt{29}}{290}}{s+\frac{3}{2}-\frac{\sqrt{29}}{2}}\right) = \frac{\left(29+13\sqrt{29}\right) e^{-\frac{3t}{2}+\frac{t\sqrt{29}}{2}}}{290}$$

$$\mathcal{L}^{-1}\left(\frac{\frac{1}{10}-\frac{13\sqrt{29}}{290}}{s+\frac{3}{2}+\frac{\sqrt{29}}{2}}\right) = \frac{e^{\frac{\left(-3-\sqrt{29}\right)\left(-\frac{3\left(3+\sqrt{29}\right)t}{2\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)}-\frac{\left(3+\sqrt{29}\right)t\sqrt{29}}{2\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)}\right)}{6+2\sqrt{29}}}\left(29-13\sqrt{29}\right)}{290}$$

$$\mathcal{L}^{-1}\left(-\frac{1}{5s}\right) = -\frac{1}{5}$$

Adding the above results and simplifying gives

$$y = -\frac{1}{5} + \frac{e^{-\frac{3t}{2}}\left(13\sqrt{29}\,\sinh\left(\frac{t\sqrt{29}}{2}\right)+29\cosh\left(\frac{t\sqrt{29}}{2}\right)\right)}{145}$$

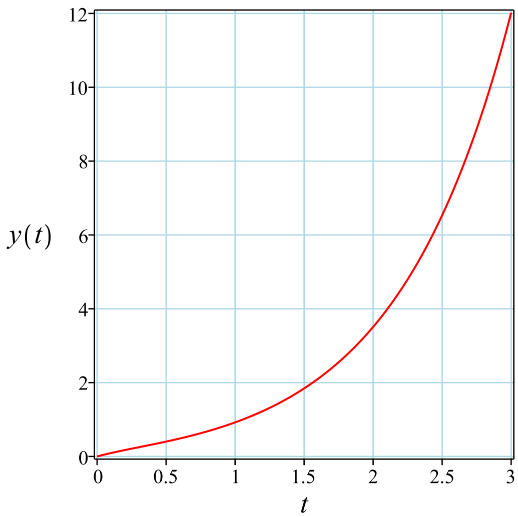
Simplifying the solution gives

$$y = \frac{13\sqrt{29}\,\sinh\left(\frac{t\sqrt{29}}{2}\right)e^{-\frac{3t}{2}}}{145} + \frac{\cosh\left(\frac{t\sqrt{29}}{2}\right)e^{-\frac{3t}{2}}}{5} - \frac{1}{5}$$

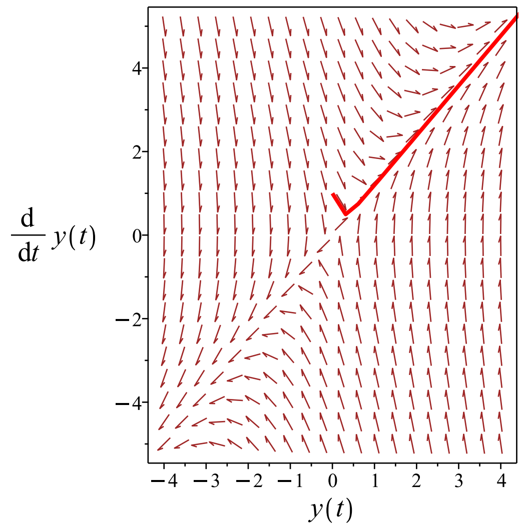
Summary

The solution(s) found are the following

$$y = \frac{13\sqrt{29}\,\sinh\left(\frac{t\sqrt{29}}{2}\right)e^{-\frac{3t}{2}}}{145} + \frac{\cosh\left(\frac{t\sqrt{29}}{2}\right)e^{-\frac{3t}{2}}}{5} - \frac{1}{5} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{13\sqrt{29}\,\sinh\left(\frac{t\sqrt{29}}{2}\right)\mathrm{e}^{-\frac{3t}{2}}}{145} + \frac{\cosh\left(\frac{t\sqrt{29}}{2}\right)\mathrm{e}^{-\frac{3t}{2}}}{5} - \frac{1}{5}$$

Verified OK.

25.1.2 Maple step by step solution

Let's solve

$\left[y'' + 3y' - 5y = 1, y(0) = 0, y'\Big|_{\{t=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r - 5 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-3)\pm\left(\sqrt{29}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{3}{2} - \frac{\sqrt{29}}{2}, -\frac{3}{2} + \frac{\sqrt{29}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(t) = e^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t}$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t}$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t} + c_2 e^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t} + y_p(t)$

☐ Find a particular solution $y_p(t)$ of the ODE

- Use variation of parameters to find y_p here $f(t)$ is the forcing function

  $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t)f(t)}{W(y_1(t),y_2(t))}dt\right) + y_2(t)\left(\int \frac{y_1(t)f(t)}{W(y_1(t),y_2(t))}dt\right), f(t) = 1\right]$

- Wronskian of solutions of the homogeneous equation

  $$W(y_1(t), y_2(t)) = \begin{bmatrix} e^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t} & e^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t} \\ \left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)e^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t} & \left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)e^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t} \end{bmatrix}$$

- Compute Wronskian

  $W(y_1(t), y_2(t)) = \sqrt{29}\, e^{-3t}$

- Substitute functions into equation for $y_p(t)$

  $$y_p(t) = -\frac{\sqrt{29}\left(e^{-\frac{(3+\sqrt{29})t}{2}}\left(\int e^{\frac{(3+\sqrt{29})t}{2}}dt\right) - e^{\frac{(-3+\sqrt{29})t}{2}}\left(\int e^{-\frac{(-3+\sqrt{29})t}{2}}dt\right)\right)}{29}$$

- Compute integrals

  $y_p(t) = -\frac{1}{5}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t} + c_2 e^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t} - \frac{1}{5}$

☐ Check validity of solution $y = c_1 e^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t} + c_2 e^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t} - \frac{1}{5}$

- Use initial condition $y(0) = 0$

  $0 = c_1 + c_2 - \frac{1}{5}$

- Compute derivative of the solution

$$y' = c_1\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)\mathrm{e}^{\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right)t} + c_2\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)\mathrm{e}^{\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)t}$$

- Use the initial condition $y'\Big|_{\{t=0\}} = 1$

$$1 = c_1\left(-\frac{3}{2}-\frac{\sqrt{29}}{2}\right) + c_2\left(-\frac{3}{2}+\frac{\sqrt{29}}{2}\right)$$

- Solve for c_1 and c_2

$$\left\{c_1 = \frac{1}{10}-\frac{13\sqrt{29}}{290}, c_2 = \frac{1}{10}+\frac{13\sqrt{29}}{290}\right\}$$

- Substitute constant values into general solution and simplify

$$y = \frac{\left(29+13\sqrt{29}\right)\mathrm{e}^{\frac{\left(-3+\sqrt{29}\right)t}{2}}}{290} - \frac{1}{5} + \frac{\left(29-13\sqrt{29}\right)\mathrm{e}^{-\frac{\left(3+\sqrt{29}\right)t}{2}}}{290}$$

- Solution to the IVP

$$y = \frac{\left(29+13\sqrt{29}\right)\mathrm{e}^{\frac{\left(-3+\sqrt{29}\right)t}{2}}}{290} - \frac{1}{5} + \frac{\left(29-13\sqrt{29}\right)\mathrm{e}^{-\frac{\left(3+\sqrt{29}\right)t}{2}}}{290}$$

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 3y' - 2y = -6\,\mathrm{e}^{\pi - t}}$$

With initial conditions

$$[y(\pi) = 1, y'(\pi) = 4]$$

25.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$\begin{aligned} p(t) &= 3 \\ q(t) &= -2 \\ F &= -6\,\mathrm{e}^{\pi - t} \end{aligned}$$

Hence the ode is

$$y'' + 3y' - 2y = -6\,\mathrm{e}^{\pi - t}$$

The domain of $p(t) = 3$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = \pi$ is inside this domain. The domain of $q(t) = -2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = \pi$ is also inside this domain. The domain of $F = -6\,\mathrm{e}^{\pi - t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = \pi$ is also inside this domain. Hence solution exists and is unique.

Since both initial conditions are not at zero, then let

$$\begin{aligned} y(0) &= c_1 \\ y'(0) &= c_2 \end{aligned}$$

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned} \mathcal{L}(y') &= sY(s) - y(0) \\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0) \end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + 3sY(s) - 3y(0) - 2Y(s) = -\frac{6\,\mathrm{e}^{\pi}}{s+1} \tag{1}$$

But the initial conditions are

$$\begin{aligned} y(0) &= c_1 \\ y'(0) &= c_2 \end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) - c_2 - sc_1 + 3sY(s) - 3c_1 - 2Y(s) = -\frac{6\,\mathrm{e}^{\pi}}{s+1}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = -\frac{-s^2 c_1 - 4 s c_1 - c_2 s + 6\,e^{\pi} - 3 c_1 - c_2}{(s+1)\left(s^2+3s-2\right)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{\left(-\frac{3\,e^{\pi}}{34}+\frac{3c_1}{17}+\frac{2c_2}{17}\right)\left(-\frac{3}{2}+\frac{\sqrt{17}}{2}\right)-\frac{15\,e^{\pi}}{17}+\frac{13c_1}{17}+\frac{3c_2}{17}}{s+\frac{3}{2}-\frac{\sqrt{17}}{2}}+\frac{\left(-\frac{3\,e^{\pi}}{34}+\frac{3c_1}{17}+\frac{2c_2}{17}\right)\left(-\frac{3}{2}-\frac{\sqrt{17}}{2}\right)-\frac{15\,e^{\pi}}{17}+\frac{1}{}}{s+\frac{3}{2}+\frac{\sqrt{17}}{2}}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{\left(-\frac{3\,e^{\pi}}{34}+\frac{3c_1}{17}+\frac{2c_2}{17}\right)\left(-\frac{3}{2}+\frac{\sqrt{17}}{2}\right)-\frac{15\,e^{\pi}}{17}+\frac{13c_1}{17}+\frac{3c_2}{17}}{s+\frac{3}{2}-\frac{\sqrt{17}}{2}}\right) = \frac{e^{-\frac{3t}{2}+\frac{t\sqrt{17}}{2}}\left(4c_2\sqrt{17}-3\,e^{\pi}\sqrt{17}-51\,e^{\pi}+2c\right.}{68}$$

$$\mathcal{L}^{-1}\left(\frac{\left(-\frac{3\,e^{\pi}}{34}+\frac{3c_1}{17}+\frac{2c_2}{17}\right)\left(-\frac{3}{2}-\frac{\sqrt{17}}{2}\right)-\frac{15\,e^{\pi}}{17}+\frac{13c_1}{17}+\frac{3c_2}{17}}{s+\frac{3}{2}+\frac{\sqrt{17}}{2}}\right) = \frac{e^{\frac{\left(-3-\sqrt{17}\right)\left(-\frac{3\left(3+\sqrt{17}\right)t}{2\left(-\frac{3}{2}-\frac{\sqrt{17}}{2}\right)}-\frac{\left(3+\sqrt{17}\right)t\sqrt{17}}{2\left(-\frac{3}{2}-\frac{\sqrt{17}}{2}\right)}\right)}{6+2\sqrt{17}}}\left(-4c_2\sqrt{}\right.}{6}$$

$$\mathcal{L}^{-1}\left(\frac{3\,e^{\pi}}{2\,(s+1)}\right) = \frac{3\,e^{\pi-t}}{2}$$

Adding the above results and simplifying gives

$$y = \frac{3\,e^{\pi-t}}{2}+\frac{\left(17\cosh\left(\frac{t\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+2c_1\right)+\sqrt{17}\,\sinh\left(\frac{t\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+6c_1+4c_2\right)\right)e^{-\frac{3t}{2}}}{34}$$

Since both initial conditions given are not at zero, then we need to setup two equations to solve for c_1, c_1. At $t = \pi$ the first equation becomes, using the above solution

$$1 = \frac{3}{2}+\frac{\left(17\cosh\left(\frac{\pi\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+2c_1\right)+\sqrt{17}\,\sinh\left(\frac{\pi\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+6c_1+4c_2\right)\right)e^{-\frac{3\pi}{2}}}{34}$$

And taking derivative of the solution and evaluating at $t = \pi$ gives the second equation as

$$4 = -\frac{3}{2}+\frac{\left(\frac{17\sqrt{17}\,\sinh\left(\frac{\pi\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+2c_1\right)}{2}+\frac{17\cosh\left(\frac{\pi\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+6c_1+4c_2\right)}{2}\right)e^{-\frac{3\pi}{2}}}{34}-\frac{3\left(17\cosh\left(\frac{\pi\sqrt{17}}{2}\right)\left(-3\,e^{\pi}+2c_1\right.\right.}{}$$

Solving gives

$$c_1 = \frac{e^{\frac{3\pi}{2}}\left(51\,e^{\pi}\sinh\left(\frac{\pi\sqrt{17}}{2}\right)^2 e^{-\frac{3\pi}{2}} - 51\,e^{\pi}e^{-\frac{3\pi}{2}}\cosh\left(\frac{\pi\sqrt{17}}{2}\right)^2 + 19\sqrt{17}\,\sinh\left(\frac{\pi\sqrt{17}}{2}\right) + 17\cosh\left(\frac{\pi\sqrt{17}}{2}\right)\right)}{34\sinh\left(\frac{\pi\sqrt{17}}{2}\right)^2 - 34\cosh\left(\frac{\pi\sqrt{17}}{2}\right)^2}$$

$$c_2 = -\frac{\left(51\,e^{\pi}\sinh\left(\frac{\pi\sqrt{17}}{2}\right)^2 e^{-\frac{3\pi}{2}} - 51\,e^{\pi}e^{-\frac{3\pi}{2}}\cosh\left(\frac{\pi\sqrt{17}}{2}\right)^2 + 37\sqrt{17}\,\sinh\left(\frac{\pi\sqrt{17}}{2}\right) + 187\cosh\left(\frac{\pi\sqrt{17}}{2}\right)\right)e^{\frac{3\pi}{2}}}{2\left(17\sinh\left(\frac{\pi\sqrt{17}}{2}\right)^2 - 17\cosh\left(\frac{\pi\sqrt{17}}{2}\right)^2\right)}$$

Subtituting these in the solution obtained above gives

$$y = \frac{3\,e^{\pi-t}}{2} + \frac{\left(17\cosh\left(\frac{t\sqrt{17}}{2}\right)\left(-3\,e^{\pi} + \frac{e^{\frac{3\pi}{2}}\left(51\,e^{\pi}\sinh\left(\frac{\pi\sqrt{17}}{2}\right)^2 e^{-\frac{3\pi}{2}} - 51\,e^{\pi}e^{-\frac{3\pi}{2}}\cosh\left(\frac{\pi\sqrt{17}}{2}\right)^2 + 19\sqrt{17}\,\sinh\left(\frac{\pi\sqrt{17}}{2}\right) + 17\cosh\right.}{17\sinh\left(\frac{\pi\sqrt{17}}{2}\right)^2 - 17\cosh\left(\frac{\pi\sqrt{17}}{2}\right)^2}\right.}{}$$

$$= -\frac{19\left(-\frac{51\,e^{-\frac{\pi}{2}-t}}{19} + e^{-\frac{3t}{2}}\left(\left(\left(-\sqrt{17}\,\sinh\left(\frac{t\sqrt{17}}{2}\right) + \frac{17\cosh\left(\frac{t\sqrt{17}}{2}\right)}{19}\right)\cosh\left(\frac{\pi\sqrt{17}}{2}\right) + \sinh\left(\frac{\pi\sqrt{17}}{2}\right)\left(\sqrt{17}\,\cosh\right.\right.\right.\right.}{34}$$

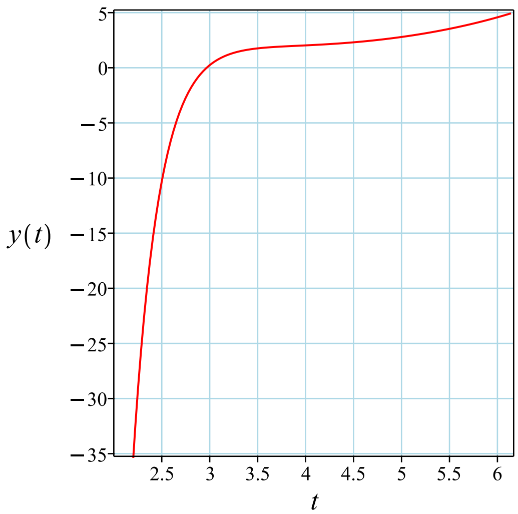
Simplifying the solution gives

$$y = -\frac{19\left(-\frac{51\,e^{-\frac{\pi}{2}-t}}{19} + e^{-\frac{3t}{2}}\left(\left(\left(-\sqrt{17}\,\sinh\left(\frac{t\sqrt{17}}{2}\right) + \frac{17\cosh\left(\frac{t\sqrt{17}}{2}\right)}{19}\right)\cosh\left(\frac{\pi\sqrt{17}}{2}\right) + \sinh\left(\frac{\pi\sqrt{17}}{2}\right)\left(\sqrt{17}\,\cosh\left(\right.\right.\right.\right.\right.}{34}$$

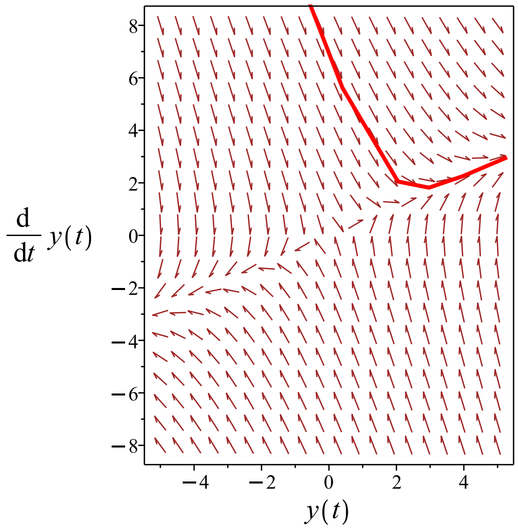
Summary

The solution(s) found are the following

$$y = -\frac{19\left(-\frac{51\,e^{-\frac{\pi}{2}-t}}{19} + e^{-\frac{3t}{2}}\left(\left(\left(-\sqrt{17}\,\sinh\left(\frac{t\sqrt{17}}{2}\right) + \frac{17\cosh\left(\frac{t\sqrt{17}}{2}\right)}{19}\right)\cosh\left(\frac{\pi\sqrt{17}}{2}\right) + \sinh\left(\frac{\pi\sqrt{17}}{2}\right)\left(\sqrt{17}\,\cosh\left(\right.\right.\right.\right.\right.}{34} \quad (1)$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$y =$

$$-\frac{19\left(-\frac{51\,e^{-\frac{\pi}{2}-t}}{19}+e^{-\frac{3t}{2}}\left(\left(\left(-\sqrt{17}\,\sinh\left(\frac{t\sqrt{17}}{2}\right)+\frac{17\cosh\left(\frac{t\sqrt{17}}{2}\right)}{19}\right)\cosh\left(\frac{\pi\sqrt{17}}{2}\right)+\sinh\left(\frac{\pi\sqrt{17}}{2}\right)\left(\sqrt{17}\,\cosh\left(\right.\right.\right.\right.}{34}$$

Verified OK.

Problem number: 3(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{y'' + 2y' - y = t\,\mathrm{e}^{-t}}$$

With initial conditions

$$[y(0) = 0, y'(0) = 1]$$

25.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$\begin{aligned} p(t) &= 2 \\ q(t) &= -1 \\ F &= t\,\mathrm{e}^{-t} \end{aligned}$$

Hence the ode is

$$y'' + 2y' - y = t\,\mathrm{e}^{-t}$$

The domain of $p(t) = 2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = t\,\mathrm{e}^{-t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(y') &= sY(s) - y(0)\\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + 2sY(s) - 2y(0) - Y(s) = \frac{1}{(s+1)^2} \tag{1}$$

But the initial conditions are

$$\begin{aligned}y(0) &= 0\\ y'(0) &= 1\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) - 1 + 2sY(s) - Y(s) = \frac{1}{(s+1)^2}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{s^2 + 2s + 2}{(s+1)^2\,(s^2 + 2s - 1)}$$

Applying partial fractions decomposition results in

$$Y(s) = -\frac{1}{2\left(s+1\right)^{2}}+\frac{3\sqrt{2}}{8\left(s-\sqrt{2}+1\right)}-\frac{3\sqrt{2}}{8\left(s+1+\sqrt{2}\right)}$$

The inverse Laplace of each term above is now found, which gives

$$\begin{aligned}
\mathcal{L}^{-1}\left(-\frac{1}{2\left(s+1\right)^{2}}\right) &= -\frac{t\,\mathrm{e}^{-t}}{2} \\
\mathcal{L}^{-1}\left(\frac{3\sqrt{2}}{8\left(s-\sqrt{2}+1\right)}\right) &= \frac{3\sqrt{2}\,\mathrm{e}^{t\sqrt{2}-t}}{8} \\
\mathcal{L}^{-1}\left(-\frac{3\sqrt{2}}{8\left(s+1+\sqrt{2}\right)}\right) &= -\frac{3\sqrt{2}\,\mathrm{e}^{\frac{\left(-1-\sqrt{2}\right)\left(-\frac{t\sqrt{2}\,\left(1+\sqrt{2}\right)}{-1-\sqrt{2}}-\frac{t\left(1+\sqrt{2}\right)}{-1-\sqrt{2}}\right)}{1+\sqrt{2}}}}{8}
\end{aligned}$$

Adding the above results and simplifying gives

$$y = \frac{\mathrm{e}^{-t}\left(3\sqrt{2}\,\sinh\left(t\sqrt{2}\right)-2t\right)}{4}$$

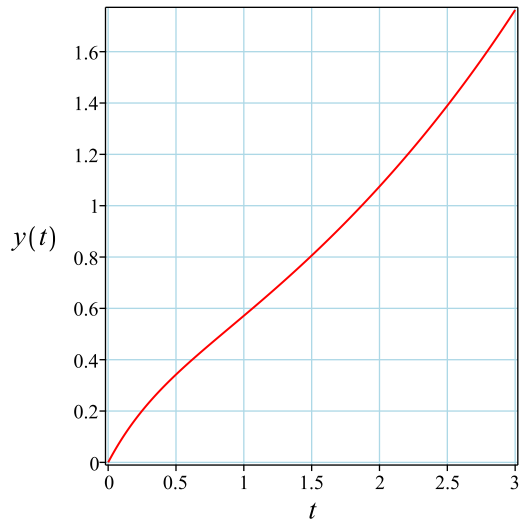
Simplifying the solution gives

$$y = \frac{\mathrm{e}^{-t}\left(3\sqrt{2}\,\sinh\left(t\sqrt{2}\right)-2t\right)}{4}$$

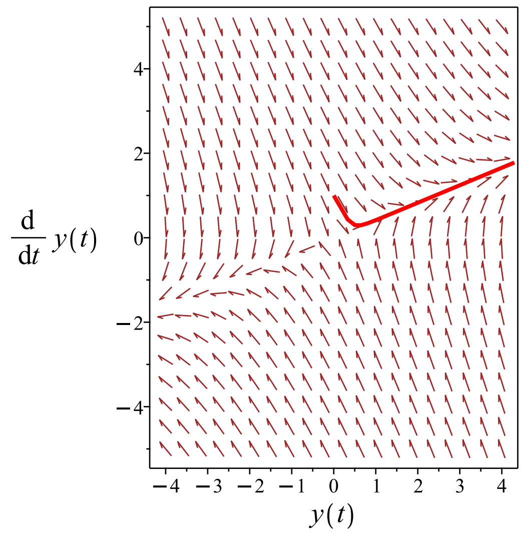
Summary

The solution(s) found are the following

$$y = \frac{\mathrm{e}^{-t}\left(3\sqrt{2}\,\sinh\left(t\sqrt{2}\right)-2t\right)}{4} \tag{1}$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{e^{-t}\left(3\sqrt{2}\,\sinh\left(t\sqrt{2}\right) - 2t\right)}{4}$$

Verified OK.

25.3.2 Maple step by step solution

Let's solve

$$\left[y'' + 2y' - y = t\,e^{-t}, y(0) = 0, y'\Big|_{\{t=0\}} = 1\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r - 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm\left(\sqrt{8}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-1-\sqrt{2}, \sqrt{2}-1\right)$

- 1st solution of the homogeneous ODE

  $y_1(t) = \mathrm{e}^{\left(-1-\sqrt{2}\right)t}$
- 2nd solution of the homogeneous ODE

  $y_2(t) = \mathrm{e}^{\left(\sqrt{2}-1\right)t}$
- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$
- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{\left(-1-\sqrt{2}\right)t} + c_2 \mathrm{e}^{\left(\sqrt{2}-1\right)t} + y_p(t)$

☐ Find a particular solution $y_p(t)$ of the ODE

- Use variation of parameters to find y_p here $f(t)$ is the forcing function

  $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t)f(t)}{W(y_1(t),y_2(t))}dt\right) + y_2(t)\left(\int \frac{y_1(t)f(t)}{W(y_1(t),y_2(t))}dt\right), f(t) = t\,\mathrm{e}^{-t}\right]$
- Wronskian of solutions of the homogeneous equation

  $W(y_1(t), y_2(t)) = \begin{bmatrix} \mathrm{e}^{\left(-1-\sqrt{2}\right)t} & \mathrm{e}^{\left(\sqrt{2}-1\right)t} \\ \left(-1-\sqrt{2}\right)\mathrm{e}^{\left(-1-\sqrt{2}\right)t} & \left(\sqrt{2}-1\right)\mathrm{e}^{\left(\sqrt{2}-1\right)t} \end{bmatrix}$
- Compute Wronskian

  $W(y_1(t), y_2(t)) = 2\sqrt{2}\,\mathrm{e}^{-2t}$
- Substitute functions into equation for $y_p(t)$

  $y_p(t) = -\frac{\sqrt{2}\left(\mathrm{e}^{-t\left(1+\sqrt{2}\right)}\left(\int t\,\mathrm{e}^{t\sqrt{2}}dt\right) - \mathrm{e}^{\left(\sqrt{2}-1\right)t}\left(\int t\,\mathrm{e}^{-t\sqrt{2}}dt\right)\right)}{4}$
- Compute integrals

  $y_p(t) = -\frac{t\,\mathrm{e}^{-t}}{2}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{\left(-1-\sqrt{2}\right)t} + c_2 \mathrm{e}^{\left(\sqrt{2}-1\right)t} - \frac{t\,\mathrm{e}^{-t}}{2}$

☐ Check validity of solution $y = c_1 \mathrm{e}^{\left(-1-\sqrt{2}\right)t} + c_2 \mathrm{e}^{\left(\sqrt{2}-1\right)t} - \frac{t\mathrm{e}^{-t}}{2}$

- Use initial condition $y(0) = 0$

  $0 = c_1 + c_2$
- Compute derivative of the solution

  $y' = c_1\left(-1-\sqrt{2}\right)\mathrm{e}^{\left(-1-\sqrt{2}\right)t} + c_2\left(\sqrt{2}-1\right)\mathrm{e}^{\left(\sqrt{2}-1\right)t} - \frac{\mathrm{e}^{-t}}{2} + \frac{t\,\mathrm{e}^{-t}}{2}$

- Use the initial condition $y'\Big|_{\{t=0\}} = 1$

  $1 = c_1\left(-1-\sqrt{2}\right) + c_2\left(\sqrt{2}-1\right) - \frac{1}{2}$

- Solve for c_1 and c_2

  $\left\{c_1 = -\frac{3\sqrt{2}}{8}, c_2 = \frac{3\sqrt{2}}{8}\right\}$

- Substitute constant values into general solution and simplify

  $y = -\frac{3\sqrt{2}\,\mathrm{e}^{-t\left(1+\sqrt{2}\right)}}{8} + \frac{3\sqrt{2}\,\mathrm{e}^{\left(\sqrt{2}-1\right)t}}{8} - \frac{t\,\mathrm{e}^{-t}}{2}$

- Solution to the IVP

  $y = -\frac{3\sqrt{2}\,\mathrm{e}^{-t\left(1+\sqrt{2}\right)}}{8} + \frac{3\sqrt{2}\,\mathrm{e}^{\left(\sqrt{2}-1\right)t}}{8} - \frac{t\,\mathrm{e}^{-t}}{2}$

Problem number: 3(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - y' + y = 3\,\mathrm{e}^{-t}}$$

With initial conditions

$$[y(0) = 3, y'(0) = 2]$$

25.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(t)y' + q(t)y = F$$

Where here

$$\begin{aligned}
p(t) &= -1 \\
q(t) &= 1 \\
F &= 3\,\mathrm{e}^{-t}
\end{aligned}$$

Hence the ode is

$$y'' - y' + y = 3\,\mathrm{e}^{-t}$$

The domain of $p(t) = -1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 1$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = 3\,\mathrm{e}^{-t}$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned}\mathcal{L}(y') &= sY(s) - y(0)\\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0)\end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) - sY(s) + y(0) + Y(s) = \frac{3}{s+1} \tag{1}$$

But the initial conditions are

$$\begin{aligned}y(0) &= 3\\ y'(0) &= 2\end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2Y(s) + 1 - 3s - sY(s) + Y(s) = \frac{3}{s+1}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{3s^2 + 2s + 2}{(s+1)\,(s^2 - s + 1)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{1-\frac{2i\sqrt{3}}{3}}{s-\frac{1}{2}-\frac{i\sqrt{3}}{2}} + \frac{1+\frac{2i\sqrt{3}}{3}}{s-\frac{1}{2}+\frac{i\sqrt{3}}{2}} + \frac{1}{s+1}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{1-\frac{2i\sqrt{3}}{3}}{s-\frac{1}{2}-\frac{i\sqrt{3}}{2}}\right) = \frac{\left(3-2i\sqrt{3}\right)\mathrm{e}^{\frac{\left(1+i\sqrt{3}\right)t}{2}}}{3}$$
$$\mathcal{L}^{-1}\left(\frac{1+\frac{2i\sqrt{3}}{3}}{s-\frac{1}{2}+\frac{i\sqrt{3}}{2}}\right) = \frac{\left(2i\sqrt{3}+3\right)\mathrm{e}^{\frac{\left(1-i\sqrt{3}\right)t}{2}}}{3}$$
$$\mathcal{L}^{-1}\left(\frac{1}{s+1}\right) = \mathrm{e}^{-t}$$

Adding the above results and simplifying gives

$$y = \mathrm{e}^{-t} + \frac{2\,\mathrm{e}^{\frac{t}{2}}\left(2\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right) + 3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3}$$

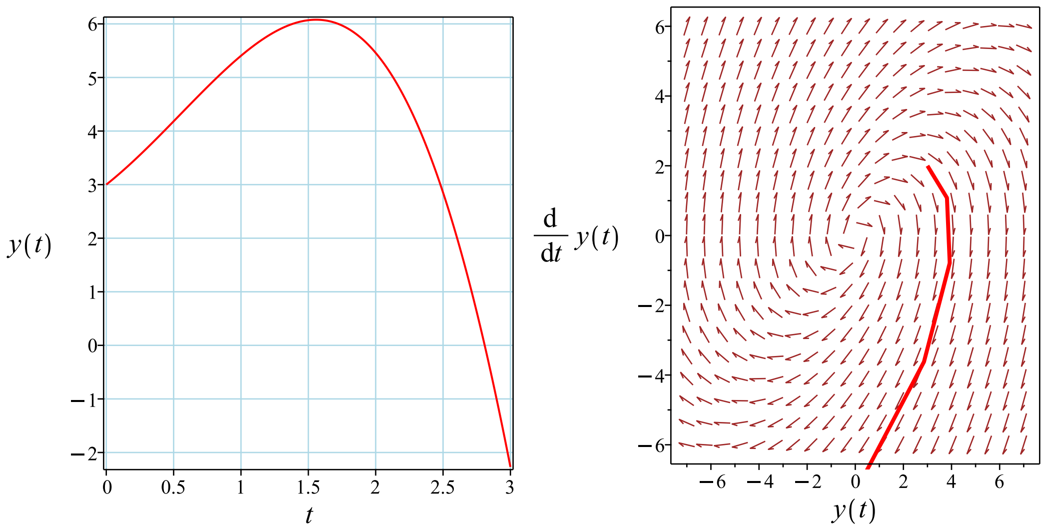
Simplifying the solution gives

$$y = \frac{\left(4\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}} + 6\cos\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}} + 3\right)\mathrm{e}^{-t}}{3}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(4\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}} + 6\cos\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}} + 3\right)\mathrm{e}^{-t}}{3} \tag{1}$$



(a) Solution plot

(b) Slope field plot

<u>Verification of solutions</u>

$$y = \frac{\left(4\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{3t}{2}} + 6\cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{3t}{2}} + 3\right) e^{-t}}{3}$$

Verified OK.

25.4.2 Maple step by step solution

Let's solve

$\left[y'' - y' + y = 3\,e^{-t}, y(0) = 3, y'\Big|_{\{t=0\}} = 2\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - r + 1 = 0$

- Use quadratic formula to solve for r

  $r = \frac{1 \pm (\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(\frac{1}{2} - \frac{I\sqrt{3}}{2}, \frac{1}{2} + \frac{I\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(t) = \cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}}$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}} + c_2 e^{\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right) + y_p(t)$

☐ Find a particular solution $y_p(t)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(t)$ is the forcing function

  $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t) f(t)}{W(y_1(t),y_2(t))} dt\right) + y_2(t)\left(\int \frac{y_1(t) f(t)}{W(y_1(t),y_2(t))} dt\right), f(t) = 3\,e^{-t}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(t)\,, y_2(t)) = \begin{bmatrix} \cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}} & e^{\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right) \\ -\frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}}}{2} + \frac{\cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}}}{2} & \frac{e^{\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} + \frac{e^{\frac{t}{2}} \sqrt{3}\,\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(t)\,, y_2(t)) = \frac{\sqrt{3}\,e^{t}}{2}$

  ◦ Substitute functions into equation for $y_p(t)$

  $y_p(t) = -2\sqrt{3}\,e^{\frac{t}{2}}\left(\cos\left(\frac{\sqrt{3}\,t}{2}\right)\left(\int e^{-\frac{3t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right) dt\right) - \sin\left(\frac{\sqrt{3}\,t}{2}\right)\left(\int e^{-\frac{3t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right) dt\right)\right)$

  ◦ Compute integrals

  $y_p(t) = e^{-t}$

- Substitute particular solution into general solution to ODE

  $y = c_1 \cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}} + c_2 e^{\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right) + e^{-t}$

☐ Check validity of solution $y = c_1 \cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{\frac{t}{2}} + c_2 e^{\frac{t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right) + e^{-t}$

  ◦ Use initial condition $y(0) = 3$

  $3 = c_1 + 1$

  ◦ Compute derivative of the solution

$$y' = -\frac{c_1\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{t}{2}}}{2}+\frac{c_1\cos\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{t}{2}}}{2}+\frac{c_2\mathrm{e}^{\frac{t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2}+\frac{c_2\mathrm{e}^{\frac{t}{2}}\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2}-\mathrm{e}^{-t}$$

- Use the initial condition $y'\Big|_{\{t=0\}}=2$

  $2=-1+\frac{c_1}{2}+\frac{c_2\sqrt{3}}{2}$

- Solve for c_1 and c_2

  $\left\{c_1=2, c_2=\frac{4\sqrt{3}}{3}\right\}$

- Substitute constant values into general solution and simplify

  $y=\frac{\left(4\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}}+6\cos\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}}+3\right)\mathrm{e}^{-t}}{3}$

- Solution to the IVP

  $y=\frac{\left(4\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}}+6\cos\left(\frac{\sqrt{3}\,t}{2}\right)\mathrm{e}^{\frac{3t}{2}}+3\right)\mathrm{e}^{-t}}{3}$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 7. Laplace Transforms. Section 7.5 Problesm for review and discovery. Section A, Drill exercises. Page 309
Problem number: 4(a).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 5y' + 4y = 0}$$

Since no initial conditions are explicitly given, then let

$$y(0) = c_1$$
$$y'(0) = c_2$$

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(y') = sY(s) - y(0)$$
$$\mathcal{L}(y'') = s^2Y(s) - y'(0) - sy(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) - 5sY(s) + 5y(0) + 4Y(s) = 0 \tag{1}$$

But the initial conditions are

$$\begin{aligned} y(0) &= c_1 \\ y'(0) &= c_2 \end{aligned}$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2 Y(s) - c_2 - s c_1 - 5 s Y(s) + 5 c_1 + 4 Y(s) = 0$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{s c_1 - 5 c_1 + c_2}{s^2 - 5 s + 4}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{\frac{4c_1}{3} - \frac{c_2}{3}}{s - 1} + \frac{-\frac{c_1}{3} + \frac{c_2}{3}}{s - 4}$$

The inverse Laplace of each term above is now found, which gives

$$\begin{aligned} \mathcal{L}^{-1}\left(\frac{\frac{4c_1}{3} - \frac{c_2}{3}}{s - 1}\right) &= \frac{(4 c_1 - c_2)\,\mathrm{e}^{t}}{3} \\ \mathcal{L}^{-1}\left(\frac{-\frac{c_1}{3} + \frac{c_2}{3}}{s - 4}\right) &= \frac{\mathrm{e}^{4t}(-c_1 + c_2)}{3} \end{aligned}$$

Adding the above results and simplifying gives

$$y = \frac{\mathrm{e}^{\frac{5t}{2}}\left(3 c_1 \cosh\left(\frac{3t}{2}\right) + \sinh\left(\frac{3t}{2}\right)(-5 c_1 + 2 c_2)\right)}{3}$$

Simplifying the solution gives

$$y = \frac{\mathrm{e}^{\frac{5t}{2}}(-5 c_1 + 2 c_2)\sinh\left(\frac{3t}{2}\right)}{3} + \mathrm{e}^{\frac{5t}{2}} c_1 \cosh\left(\frac{3t}{2}\right)$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{\mathrm{e}^{\frac{5t}{2}}(-5 c_1 + 2 c_2)\sinh\left(\frac{3t}{2}\right)}{3} + \mathrm{e}^{\frac{5t}{2}} c_1 \cosh\left(\frac{3t}{2}\right) \tag{1}$$

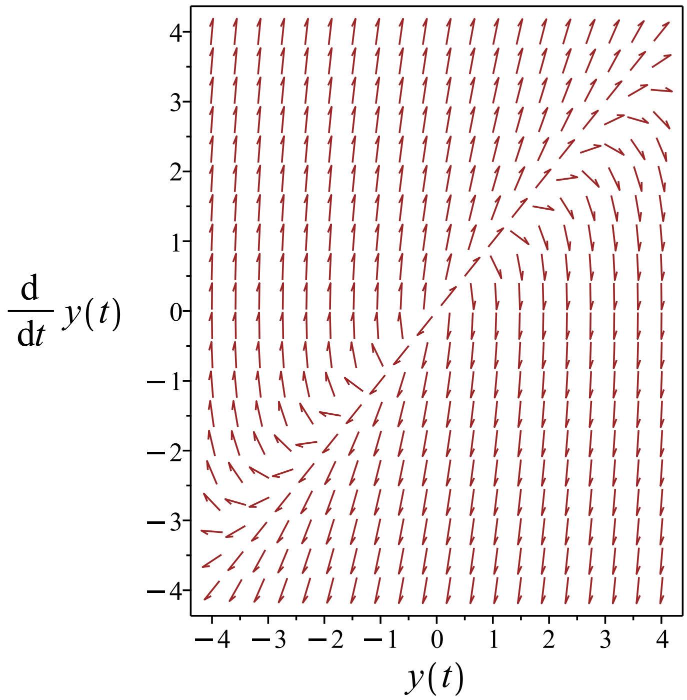

Figure 481: Slope field plot

Verification of solutions

$$y = \frac{e^{\frac{5t}{2}}(-5c_1 + 2c_2)\sinh\left(\frac{3t}{2}\right)}{3} + e^{\frac{5t}{2}} c_1 \cosh\left(\frac{3t}{2}\right)$$

Verified OK.

25.5.1 Maple step by step solution

Let's solve

25.6 problem 4(b)

Internal problem ID [6510]
Internal file name [`OUTPUT/5758_Sunday_June_05_2022_03_53_01_PM_80445232/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 7. Laplace Transforms. Section 7.5 Problesm for review and discovery. Section A, Drill exercises. Page 309
Problem number: 4(b).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + 3y' + 3y = 2}$$

Since no initial conditions are explicitly given, then let

$$y(0) = c_1$$
$$y'(0) = c_2$$

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\mathcal{L}(y') = sY(s) - y(0)$$
$$\mathcal{L}(y'') = s^2Y(s) - y'(0) - sy(0)$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + 3sY(s) - 3y(0) + 3Y(s) = \frac{2}{s} \tag{1}$$

But the initial conditions are

$$
\begin{aligned}
y(0) &= c_1 \\
y'(0) &= c_2
\end{aligned}
$$

Substituting these initial conditions in above in Eq (1) gives

$$
s^2 Y(s) - c_2 - s c_1 + 3 s Y(s) - 3 c_1 + 3 Y(s) = \frac{2}{s}
$$

Solving the above equation for $Y(s)$ results in

$$
Y(s) = \frac{c_1 s^2 + 3 s c_1 + c_2 s + 2}{s\left(s^2 + 3s + 3\right)}
$$

Applying partial fractions decomposition results in

$$
Y(s) = \frac{2}{3s} + \frac{\left(-c_1 - \frac{2c_2}{3} + \frac{2}{3}\right)\left(-\frac{3}{2} + \frac{i\sqrt{3}}{2}\right) - c_1 - c_2 + \frac{2}{3}}{s + \frac{3}{2} - \frac{i\sqrt{3}}{2}} + \frac{\left(-c_1 - \frac{2c_2}{3} + \frac{2}{3}\right)\left(-\frac{3}{2} - \frac{i\sqrt{3}}{2}\right) - c_1 - c_2 + \frac{2}{3}}{s + \frac{3}{2} + \frac{i\sqrt{3}}{2}}
$$

The inverse Laplace of each term above is now found, which gives

$$
\mathcal{L}^{-1}\left(\frac{2}{3s}\right) = \frac{2}{3}
$$

$$
\mathcal{L}^{-1}\left(\frac{\left(-c_1 - \frac{2c_2}{3} + \frac{2}{3}\right)\left(-\frac{3}{2} + \frac{i\sqrt{3}}{2}\right) - c_1 - c_2 + \frac{2}{3}}{s + \frac{3}{2} - \frac{i\sqrt{3}}{2}}\right) = \frac{e^{-\frac{\left(-i\sqrt{3}+3\right)\left(-\frac{t\sqrt{3}}{2\left(-\frac{3}{2}+\frac{i\sqrt{3}}{2}\right)} + \frac{it}{-3+i\sqrt{3}}\right)\sqrt{3}}{2}} \left(-2 - 2ic_2\sqrt{3} + 2\right.}{6}
$$

$$
\mathcal{L}^{-1}\left(\frac{\left(-c_1 - \frac{2c_2}{3} + \frac{2}{3}\right)\left(-\frac{3}{2} - \frac{i\sqrt{3}}{2}\right) - c_1 - c_2 + \frac{2}{3}}{s + \frac{3}{2} + \frac{i\sqrt{3}}{2}}\right) = \frac{e^{-\frac{\left(i\sqrt{3}+3\right)\left(-\frac{t\sqrt{3}}{2\left(-\frac{3}{2}-\frac{i\sqrt{3}}{2}\right)} - \frac{it}{2\left(-\frac{3}{2}-\frac{i\sqrt{3}}{2}\right)}\right)\sqrt{3}}{2}} \left(-2 + 2ic_2\sqrt{3} -\right.}{6}
$$

Adding the above results and simplifying gives

$$
y = \frac{2}{3} + \frac{\left(\cos\left(\frac{\sqrt{3}\,t}{2}\right)(-2 + 3c_1) + \sin\left(\frac{\sqrt{3}\,t}{2}\right)\sqrt{3}\,(3c_1 + 2c_2 - 2)\right) e^{-\frac{3t}{2}}}{3}
$$

Simplifying the solution gives

$$
y = \sqrt{3}\, e^{-\frac{3t}{2}}\left(c_1 + \frac{2c_2}{3} - \frac{2}{3}\right)\sin\left(\frac{\sqrt{3}\,t}{2}\right) + \frac{2}{3} + \frac{e^{-\frac{3t}{2}}(-2 + 3c_1)\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{3}
$$

Summary

The solution(s) found are the following

$$y=\sqrt{3}\,\mathrm{e}^{-\frac{3t}{2}}\left(c_1+\frac{2c_2}{3}-\frac{2}{3}\right)\sin\left(\frac{\sqrt{3}\,t}{2}\right)+\frac{2}{3}+\frac{\mathrm{e}^{-\frac{3t}{2}}(-2+3c_1)\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \tag{1}$$

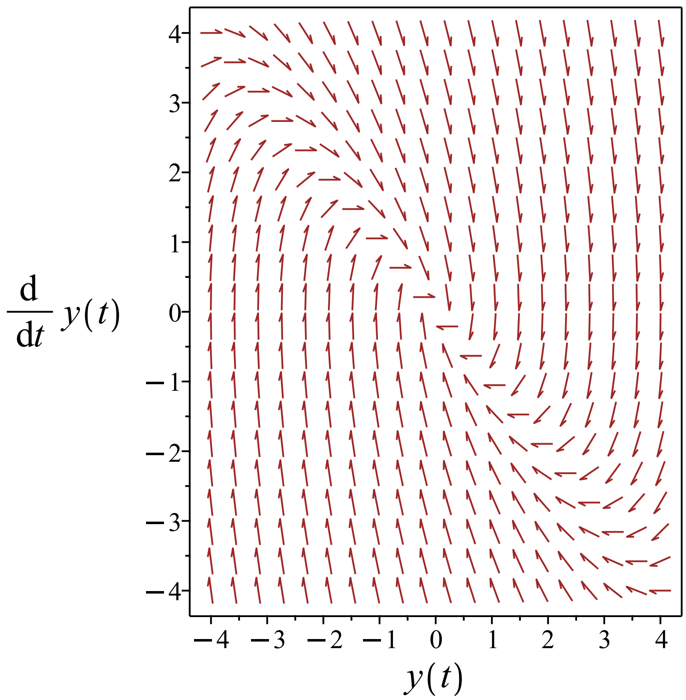

Figure 482: Slope field plot

Verification of solutions

$$y=\sqrt{3}\,\mathrm{e}^{-\frac{3t}{2}}\left(c_1+\frac{2c_2}{3}-\frac{2}{3}\right)\sin\left(\frac{\sqrt{3}\,t}{2}\right)+\frac{2}{3}+\frac{\mathrm{e}^{-\frac{3t}{2}}(-2+3c_1)\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{3}$$

Verified OK.

25.6.1 Maple step by step solution

Let's solve

$y'' + 3y' + 3y = 2$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 3r + 3 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-3)\pm(\sqrt{-3})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{3}{2} - \frac{I\sqrt{3}}{2}, -\frac{3}{2} + \frac{I\sqrt{3}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(t) = e^{-\frac{3t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{-\frac{3t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos\left(\frac{\sqrt{3}\,t}{2}\right) e^{-\frac{3t}{2}} c_1 + \sin\left(\frac{\sqrt{3}\,t}{2}\right) e^{-\frac{3t}{2}} c_2 + y_p(t)$

□ Find a particular solution $y_p(t)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(t)$ is the forcing function

  $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t) f(t)}{W(y_1(t), y_2(t))} dt\right) + y_2(t)\left(\int \frac{y_1(t) f(t)}{W(y_1(t), y_2(t))} dt\right), f(t) = 2\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(t), y_2(t)) = \begin{bmatrix} e^{-\frac{3t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right) & e^{-\frac{3t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right) \\ -\frac{3 e^{-\frac{3t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} - \frac{\sqrt{3}\, e^{-\frac{3t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} & -\frac{3 e^{-\frac{3t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} + \frac{\sqrt{3}\, e^{-\frac{3t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} \end{bmatrix}$

- ○ Compute Wronskian

$W(y_1(t), y_2(t)) = \frac{\sqrt{3}\,e^{-3t}}{2}$

- Substitute functions into equation for $y_p(t)$

  $y_p(t) = -\frac{4\sqrt{3}\,e^{-\frac{3t}{2}}\left(\cos\left(\frac{\sqrt{3}\,t}{2}\right)\left(\int \sin\left(\frac{\sqrt{3}\,t}{2}\right)e^{\frac{3t}{2}}dt\right)-\sin\left(\frac{\sqrt{3}\,t}{2}\right)\left(\int \cos\left(\frac{\sqrt{3}\,t}{2}\right)e^{\frac{3t}{2}}dt\right)\right)}{3}$

- Compute integrals

  $y_p(t) = \frac{2}{3}$

- Substitute particular solution into general solution to ODE

  $y = \cos\left(\frac{\sqrt{3}\,t}{2}\right)e^{-\frac{3t}{2}}c_1 + \sin\left(\frac{\sqrt{3}\,t}{2}\right)e^{-\frac{3t}{2}}c_2 + \frac{2}{3}$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 7. Laplace Transforms. Section 7.5 Problesm for review and discovery. Section A, Drill exercises. Page 309
Problem number: 4(c).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + y' + 2y = t}$$

Since no initial conditions are explicitly given, then let

$$\begin{aligned} y(0) &= c_1 \\ y'(0) &= c_2 \end{aligned}$$

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned} \mathcal{L}(y') &= sY(s) - y(0) \\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0) \end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) + sY(s) - y(0) + 2Y(s) = \frac{1}{s^2} \tag{1}$$

But the initial conditions are

$$
\begin{aligned}
y(0) &= c_1 \\
y'(0) &= c_2
\end{aligned}
$$

Substituting these initial conditions in above in Eq (1) gives

$$
s^2 Y(s) - c_2 - s c_1 + s Y(s) - c_1 + 2Y(s) = \frac{1}{s^2}
$$

Solving the above equation for $Y(s)$ results in

$$
Y(s) = \frac{c_1 s^3 + c_1 s^2 + c_2 s^2 + 1}{s^2 \left(s^2 + s + 2\right)}
$$

Applying partial fractions decomposition results in

$$
Y(s) = \frac{\left(-\frac{c_1}{7} - \frac{2c_2}{7} + \frac{3}{28}\right)\left(-\frac{1}{2} + \frac{i\sqrt{7}}{2}\right) + \frac{3c_1}{7} - \frac{c_2}{7} + \frac{5}{28}}{s + \frac{1}{2} - \frac{i\sqrt{7}}{2}} + \frac{\left(-\frac{c_1}{7} - \frac{2c_2}{7} + \frac{3}{28}\right)\left(-\frac{1}{2} - \frac{i\sqrt{7}}{2}\right) + \frac{3c_1}{7} - \frac{c_2}{7} + \frac{5}{28}}{s + \frac{1}{2} + \frac{i\sqrt{7}}{2}} - \frac{1}{4\cdots}
$$

The inverse Laplace of each term above is now found, which gives

$$
\mathcal{L}^{-1}\left(\frac{\left(-\frac{c_1}{7} - \frac{2c_2}{7} + \frac{3}{28}\right)\left(-\frac{1}{2} + \frac{i\sqrt{7}}{2}\right) + \frac{3c_1}{7} - \frac{c_2}{7} + \frac{5}{28}}{s + \frac{1}{2} - \frac{i\sqrt{7}}{2}}\right) = \frac{e^{-\frac{\left(1 - i\sqrt{7}\right)\left(-\frac{t}{2\left(-\frac{1}{2} + \frac{i\sqrt{7}}{2}\right)} + \frac{i\sqrt{7}\, t}{-1 + i\sqrt{7}}\right)}{2}} \left(7 - 8ic_2\sqrt{7} + 3i\sqrt{\cdots}\right.}{56}
$$

$$
\mathcal{L}^{-1}\left(\frac{\left(-\frac{c_1}{7} - \frac{2c_2}{7} + \frac{3}{28}\right)\left(-\frac{1}{2} - \frac{i\sqrt{7}}{2}\right) + \frac{3c_1}{7} - \frac{c_2}{7} + \frac{5}{28}}{s + \frac{1}{2} + \frac{i\sqrt{7}}{2}}\right) = \frac{e^{-\frac{\left(1 + i\sqrt{7}\right)\left(-\frac{t}{2\left(-\frac{1}{2} - \frac{i\sqrt{7}}{2}\right)} - \frac{i\sqrt{7}\, t}{2\left(-\frac{1}{2} - \frac{i\sqrt{7}}{2}\right)}\right)}{2}} \left(7 + 8ic_2\sqrt{7} - \cdots\right.}{56}
$$

$$
\begin{aligned}
\mathcal{L}^{-1}\left(-\frac{1}{4s}\right) &= -\frac{1}{4} \\
\mathcal{L}^{-1}\left(\frac{1}{2s^2}\right) &= \frac{t}{2}
\end{aligned}
$$

Adding the above results and simplifying gives

$$
y = -\frac{1}{4} + \frac{t}{2} + \frac{\left(7\cos\left(\frac{\sqrt{7}\, t}{2}\right)(1 + 4c_1) + \sin\left(\frac{\sqrt{7}\, t}{2}\right)\sqrt{7}\,(4c_1 + 8c_2 - 3)\right) e^{-\frac{t}{2}}}{28}
$$

Simplifying the solution gives

$$
y = -\frac{1}{4} + \frac{\sqrt{7}\, e^{-\frac{t}{2}}\left(c_1 + 2c_2 - \frac{3}{4}\right)\sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} + \frac{(1 + 4c_1)\, e^{-\frac{t}{2}}\cos\left(\frac{\sqrt{7}\, t}{2}\right)}{4} + \frac{t}{2}
$$

Summary

The solution(s) found are the following

$$y = -\frac{1}{4}+\frac{\sqrt{7}\,\mathrm{e}^{-\frac{t}{2}} \left(c_1 +2 c_2 -\frac{3}{4}\right) \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7}+\frac{\left(1+4 c_1 \right) \mathrm{e}^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\, t}{2}\right)}{4}+\frac{t}{2} \tag{1}$$

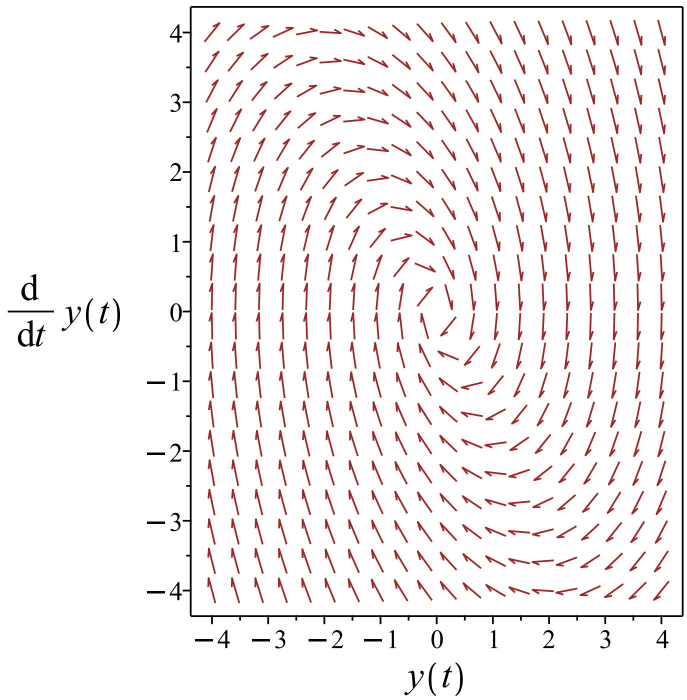

Figure 483: Slope field plot

Verification of solutions

$$y = -\frac{1}{4}+\frac{\sqrt{7}\,\mathrm{e}^{-\frac{t}{2}} \left(c_1 +2 c_2 -\frac{3}{4}\right) \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7}+\frac{\left(1+4 c_1 \right) \mathrm{e}^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\, t}{2}\right)}{4}+\frac{t}{2}$$

Verified OK.

25.7.1 Maple step by step solution

Let's solve

$y'' + y' + 2y = t$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-1) \pm (\sqrt{-7})}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{1}{2} - \frac{I\sqrt{7}}{2}, -\frac{1}{2} + \frac{I\sqrt{7}}{2}\right)$

- 1st solution of the homogeneous ODE

  $y_1(t) = e^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\,t}{2}\right)$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{-\frac{t}{2}} \sin\left(\frac{\sqrt{7}\,t}{2}\right)$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = e^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\,t}{2}\right) c_1 + e^{-\frac{t}{2}} \sin\left(\frac{\sqrt{7}\,t}{2}\right) c_2 + y_p(t)$

☐ Find a particular solution $y_p(t)$ of the ODE

  - Use variation of parameters to find y_p here $f(t)$ is the forcing function

    $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t) f(t)}{W(y_1(t), y_2(t))} dt\right) + y_2(t)\left(\int \frac{y_1(t) f(t)}{W(y_1(t), y_2(t))} dt\right), f(t) = t\right]$

  - Wronskian of solutions of the homogeneous equation

    $$W(y_1(t), y_2(t)) = \begin{bmatrix} e^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\,t}{2}\right) & e^{-\frac{t}{2}} \sin\left(\frac{\sqrt{7}\,t}{2}\right) \\ -\frac{e^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} - \frac{\sqrt{7}\,e^{-\frac{t}{2}} \sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2} & -\frac{e^{-\frac{t}{2}} \sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{e^{-\frac{t}{2}} \sqrt{7} \cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} \end{bmatrix}$$

  - Compute Wronskian

    $W(y_1(t), y_2(t)) = \frac{\sqrt{7}\,e^{-t}}{2}$

  - Substitute functions into equation for $y_p(t)$

    $y_p(t) = -\frac{2\sqrt{7}\,e^{-\frac{t}{2}}\left(\cos\left(\frac{\sqrt{7}\,t}{2}\right)\left(\int t\,e^{\frac{t}{2}} \sin\left(\frac{\sqrt{7}\,t}{2}\right) dt\right) - \sin\left(\frac{\sqrt{7}\,t}{2}\right)\left(\int t\,e^{\frac{t}{2}} \cos\left(\frac{\sqrt{7}\,t}{2}\right) dt\right)\right)}{7}$

  - Compute integrals

    $y_p(t) = \frac{t}{2} - \frac{1}{4}$

- Substitute particular solution into general solution to ODE

$$y = e^{-\frac{t}{2}} \cos\left(\frac{\sqrt{7}\, t}{2}\right) c_1 + e^{-\frac{t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right) c_2 + \frac{t}{2} - \frac{1}{4}$$

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 7. Laplace Transforms. Section 7.5 Problesm for review and discovery. Section A, Drill exercises. Page 309
Problem number: 4(d).
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 7y' + 12y = t\,e^{2t}}$$

Since no initial conditions are explicitly given, then let

$$\begin{aligned} y(0) &= c_1 \\ y'(0) &= c_2 \end{aligned}$$

Solving using the Laplace transform method. Let

$$\mathcal{L}(y) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$\begin{aligned} \mathcal{L}(y') &= sY(s) - y(0) \\ \mathcal{L}(y'') &= s^2Y(s) - y'(0) - sy(0) \end{aligned}$$

The given ode now becomes an algebraic equation in the Laplace domain

$$s^2Y(s) - y'(0) - sy(0) - 7sY(s) + 7y(0) + 12Y(s) = \frac{1}{(s-2)^2} \tag{1}$$

But the initial conditions are

$$y(0) = c_1$$
$$y'(0) = c_2$$

Substituting these initial conditions in above in Eq (1) gives

$$s^2 Y(s) - c_2 - s c_1 - 7 s Y(s) + 7 c_1 + 12 Y(s) = \frac{1}{(s-2)^2}$$

Solving the above equation for $Y(s)$ results in

$$Y(s) = \frac{c_1 s^3 - 11 c_1 s^2 + c_2 s^2 + 32 s c_1 - 4 c_2 s - 28 c_1 + 4 c_2 + 1}{(s-2)^2 (s^2 - 7s + 12)}$$

Applying partial fractions decomposition results in

$$Y(s) = \frac{-3c_1 + c_2 + \frac{1}{4}}{s-4} + \frac{1}{2(s-2)^2} + \frac{3}{4(s-2)} + \frac{4c_1 - c_2 - 1}{s-3}$$

The inverse Laplace of each term above is now found, which gives

$$\mathcal{L}^{-1}\left(\frac{-3c_1 + c_2 + \frac{1}{4}}{s-4}\right) = \frac{e^{4t}(-12c_1 + 4c_2 + 1)}{4}$$
$$\mathcal{L}^{-1}\left(\frac{1}{2(s-2)^2}\right) = \frac{t\, e^{2t}}{2}$$
$$\mathcal{L}^{-1}\left(\frac{3}{4(s-2)}\right) = \frac{3\, e^{2t}}{4}$$
$$\mathcal{L}^{-1}\left(\frac{4c_1 - c_2 - 1}{s-3}\right) = (4c_1 - c_2 - 1)\, e^{3t}$$

Adding the above results and simplifying gives

$$y = \frac{e^{2t}(2t+3)}{4} + (4c_1 - c_2 - 1)\, e^{3t} + \frac{e^{4t}(-12c_1 + 4c_2 + 1)}{4}$$

Simplifying the solution gives

$$y = \frac{e^{2t}(2t+3)}{4} + (4c_1 - c_2 - 1)\, e^{3t} + \frac{e^{4t}(-12c_1 + 4c_2 + 1)}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{2t}(2t+3)}{4} + (4c_1 - c_2 - 1)\, e^{3t} + \frac{e^{4t}(-12c_1 + 4c_2 + 1)}{4} \tag{1}$$

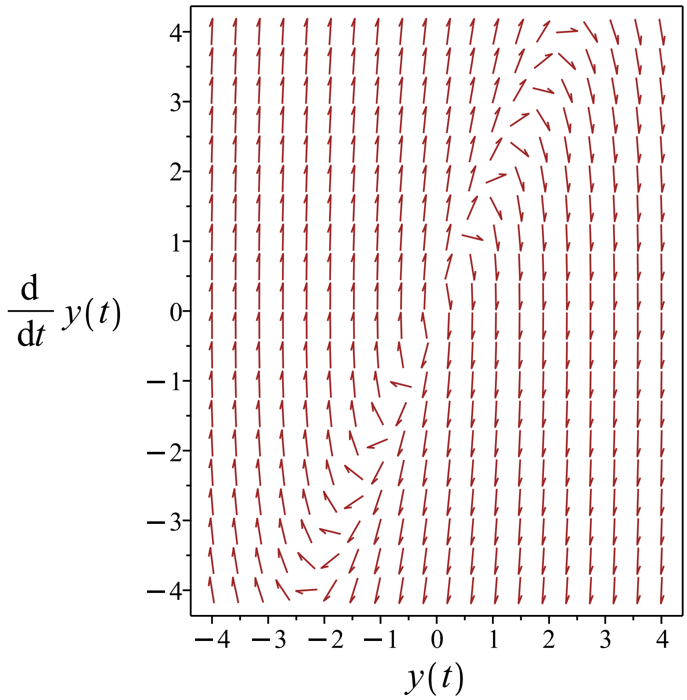

Figure 484: Slope field plot

Verification of solutions

$$y = \frac{e^{2t}(2t+3)}{4} + (4c_1 - c_2 - 1)\,e^{3t} + \frac{e^{4t}(-12c_1 + 4c_2 + 1)}{4}$$

Verified OK.

25.8.1 Maple step by step solution

Let's solve

$y'' - 7y' + 12y = t\,e^{2t}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 7r + 12 = 0$

- Factor the characteristic polynomial

  $(r-3)(r-4) = 0$

- Roots of the characteristic polynomial

$r = (3, 4)$

- 1st solution of the homogeneous ODE

  $y_1(t) = e^{3t}$

- 2nd solution of the homogeneous ODE

  $y_2(t) = e^{4t}$

- General solution of the ODE

  $y = c_1 y_1(t) + c_2 y_2(t) + y_p(t)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^{3t} + c_2 e^{4t} + y_p(t)$

☐ Find a particular solution $y_p(t)$ of the ODE

  - Use variation of parameters to find y_p here $f(t)$ is the forcing function

    $\left[y_p(t) = -y_1(t)\left(\int \frac{y_2(t)f(t)}{W(y_1(t),y_2(t))}dt\right) + y_2(t)\left(\int \frac{y_1(t)f(t)}{W(y_1(t),y_2(t))}dt\right), f(t) = t\,e^{2t}\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(t), y_2(t)) = \begin{bmatrix} e^{3t} & e^{4t} \\ 3\,e^{3t} & 4\,e^{4t} \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(t), y_2(t)) = e^{7t}$

  - Substitute functions into equation for $y_p(t)$

    $y_p(t) = -e^{3t}\left(\int t\,e^{-t}dt\right) + e^{4t}\left(\int t\,e^{-2t}dt\right)$

  - Compute integrals

    $y_p(t) = \frac{e^{2t}(2t+3)}{4}$

- Substitute particular solution into general solution to ODE

  $y = c_1 e^{3t} + c_2 e^{4t} + \frac{e^{2t}(2t+3)}{4}$

Internal file name [`OUTPUT/5761_Sunday_June_05_2022_03_53_07_PM_95044538/index.tex`]

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 7. Laplace Transforms. Section 7.5 Problesm for review and discovery. Section B, Challenge Problems. Page 310
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_laplace", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$
i'' + 2i' + 3i = \begin{cases} 30 & 0 < t < 2\pi \\ 0 & 2\pi \leq t \leq 5\pi \\ 10 & 5\pi < t < \infty \end{cases}
$$

With initial conditions

$$
[i(0) = 8, i'(0) = 0]
$$

26.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$
i'' + p(t)i' + q(t)i = F
$$

Where here

$$p(t) = 2$$
$$q(t) = 3$$
$$F = \begin{cases} 0 & t \leq 0 \\ 30 & t < 2\pi \\ 0 & t \leq 5\pi \\ 10 & 5\pi < t \end{cases}$$

Hence the ode is

$$i'' + 2i' + 3i = \begin{cases} 0 & t \leq 0 \\ 30 & t < 2\pi \\ 0 & t \leq 5\pi \\ 10 & 5\pi < t \end{cases}$$

The domain of $p(t) = 2$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is inside this domain. The domain of $q(t) = 3$ is

$$\{-\infty < t < \infty\}$$

And the point $t_0 = 0$ is also inside this domain. The domain of $F = \begin{cases} 0 & t \leq 0 \\ 30 & t < 2\pi \\ 0 & t \leq 5\pi \\ 10 & 5\pi < t \end{cases}$ is

$$\{0 \leq t \leq 2\pi, 2\pi \leq t \leq 5\pi, 5\pi \leq t \leq \infty, -\infty \leq t \leq 0\}$$

And the point $t_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving using the Laplace transform method. Let

$$\mathcal{L}(i) = Y(s)$$

Taking the Laplace transform of the ode and using the relations that

$$
\begin{aligned}
\mathcal{L}(i') &= sY(s) - i(0) \\
\mathcal{L}(i'') &= s^2 Y(s) - i'(0) - si(0)
\end{aligned}
$$

The given ode now becomes an algebraic equation in the Laplace domain

$$
s^2 Y(s) - i'(0) - si(0) + 2sY(s) - 2i(0) + 3Y(s) = \frac{30 - 30\,\mathrm{e}^{-2\pi s} + 10\,\mathrm{e}^{-5\pi s}}{s} \tag{1}
$$

But the initial conditions are

$$
\begin{aligned}
i(0) &= 8 \\
i'(0) &= 0
\end{aligned}
$$

Substituting these initial conditions in above in Eq (1) gives

$$
s^2 Y(s) - 16 - 8s + 2sY(s) + 3Y(s) = \frac{30 - 30\,\mathrm{e}^{-2\pi s} + 10\,\mathrm{e}^{-5\pi s}}{s}
$$

Solving the above equation for $Y(s)$ results in

$$
Y(s) = -\frac{2(-4s^2 + 15\,\mathrm{e}^{-2\pi s} - 5\,\mathrm{e}^{-5\pi s} - 8s - 15)}{s\,(s^2 + 2s + 3)}
$$

Taking the inverse Laplace transform gives

$$
\begin{aligned}
i &= \mathcal{L}^{-1}(Y(s)) \\
&= \mathcal{L}^{-1}\left(-\frac{2(-4s^2 + 15\,\mathrm{e}^{-2\pi s} - 5\,\mathrm{e}^{-5\pi s} - 8s - 15)}{s\,(s^2 + 2s + 3)}\right) \\
&= 10 - \mathrm{e}^{-t}\left(\sqrt{2}\,\sin\left(t\sqrt{2}\right) + 2\cos\left(t\sqrt{2}\right)\right) + \frac{5\left(i\sqrt{2} + 2\right)\left(4 - 2i\sqrt{2} - 3\,\mathrm{e}^{-\left(i\sqrt{2}+1\right)(t-5\pi)} - \left(1 - 2i\sqrt{2}\right)\mathrm{e}\right.}{18}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
i = {} & 10 - \mathrm{e}^{-t}\left(\sqrt{2}\,\sin\left(t\sqrt{2}\right) + 2\cos\left(t\sqrt{2}\right)\right) \\
& + \frac{5\left(i\sqrt{2} + 2\right)\left(4 - 2i\sqrt{2} - 3\,\mathrm{e}^{-\left(i\sqrt{2}+1\right)(t-5\pi)} - \left(1 - 2i\sqrt{2}\right)\mathrm{e}^{-\left(-i\sqrt{2}+1\right)(t-5\pi)}\right)\operatorname{Heaviside}(t - 5\pi)}{18} \\
& + \frac{5\left(i\sqrt{2} + 2\right)\left(-4 + 2i\sqrt{2} + 3\,\mathrm{e}^{-\left(i\sqrt{2}+1\right)(t-2\pi)} + \left(1 - 2i\sqrt{2}\right)\mathrm{e}^{-\left(-i\sqrt{2}+1\right)(t-2\pi)}\right)\operatorname{Heaviside}(t - 2\pi)}{6}
\end{aligned}
$$

Simplifying the solution gives

$$
\begin{aligned}
i = 10 &+ \frac{5\,\mathrm{Heaviside}\left(t-2\pi\right) \mathrm{e}^{-\left(i\sqrt{2}+1\right)\left(t-2\pi\right)} \left(i\sqrt{2}+2\right)}{2} \\
&- \frac{5\,\mathrm{Heaviside}\left(t-5\pi\right) \mathrm{e}^{-\left(i\sqrt{2}+1\right)\left(t-5\pi\right)} \left(i\sqrt{2}+2\right)}{6} \\
&+ \frac{5\left(-i\sqrt{2}+2\right) \mathrm{Heaviside}\left(t-2\pi\right) \mathrm{e}^{\left(i\sqrt{2}-1\right)\left(t-2\pi\right)}}{2} \\
&+ \frac{5\left(i\sqrt{2}-2\right) \mathrm{Heaviside}\left(t-5\pi\right) \mathrm{e}^{\left(i\sqrt{2}-1\right)\left(t-5\pi\right)}}{6} - \mathrm{e}^{-t}\sqrt{2}\,\sin\left(t\sqrt{2}\right) \\
&- 2\,\mathrm{e}^{-t}\cos\left(t\sqrt{2}\right) + \frac{10\,\mathrm{Heaviside}\left(t-5\pi\right)}{3} - 10\,\mathrm{Heaviside}\left(t-2\pi\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
i = 10 &+ \frac{5\,\mathrm{Heaviside}\left(t-2\pi\right) \mathrm{e}^{-\left(i\sqrt{2}+1\right)\left(t-2\pi\right)} \left(i\sqrt{2}+2\right)}{2} \\
&- \frac{5\,\mathrm{Heaviside}\left(t-5\pi\right) \mathrm{e}^{-\left(i\sqrt{2}+1\right)\left(t-5\pi\right)} \left(i\sqrt{2}+2\right)}{6} \\
&+ \frac{5\left(-i\sqrt{2}+2\right) \mathrm{Heaviside}\left(t-2\pi\right) \mathrm{e}^{\left(i\sqrt{2}-1\right)\left(t-2\pi\right)}}{2} \\
&+ \frac{5\left(i\sqrt{2}-2\right) \mathrm{Heaviside}\left(t-5\pi\right) \mathrm{e}^{\left(i\sqrt{2}-1\right)\left(t-5\pi\right)}}{6} - \mathrm{e}^{-t}\sqrt{2}\,\sin\left(t\sqrt{2}\right) \\
&- 2\,\mathrm{e}^{-t}\cos\left(t\sqrt{2}\right) + \frac{10\,\mathrm{Heaviside}\left(t-5\pi\right)}{3} - 10\,\mathrm{Heaviside}\left(t-2\pi\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
i = 10 &+ \frac{5\,\mathrm{Heaviside}\,(t-2\pi)\,\mathrm{e}^{-\left(i\sqrt{2}+1\right)(t-2\pi)}\left(i\sqrt{2}+2\right)}{2} \\
&- \frac{5\,\mathrm{Heaviside}\,(t-5\pi)\,\mathrm{e}^{-\left(i\sqrt{2}+1\right)(t-5\pi)}\left(i\sqrt{2}+2\right)}{6} \\
&+ \frac{5\left(-i\sqrt{2}+2\right)\mathrm{Heaviside}\,(t-2\pi)\,\mathrm{e}^{\left(i\sqrt{2}-1\right)(t-2\pi)}}{2} \\
&+ \frac{5\left(i\sqrt{2}-2\right)\mathrm{Heaviside}\,(t-5\pi)\,\mathrm{e}^{\left(i\sqrt{2}-1\right)(t-5\pi)}}{6} - \mathrm{e}^{-t}\sqrt{2}\,\sin\left(t\sqrt{2}\right) \\
&- 2\,\mathrm{e}^{-t}\cos\left(t\sqrt{2}\right) + \frac{10\,\mathrm{Heaviside}\,(t-5\pi)}{3} - 10\,\mathrm{Heaviside}\,(t-2\pi)
\end{aligned}
$$

Verified OK.

26.1.2 Maple step by step solution

Let's solve

$$
\left[i'' + 2i' + 3i = \left\{\begin{array}{cc} 0 & t \le 0 \\ 30 & t < 2\pi \\ 0 & t \le 5\pi \\ 10 & 5\pi < t \end{array}\right., i(0) = 8, i'\Big|_{\{t=0\}} = 0\right]
$$

- Highest derivative means the order of the ODE is 2

  i''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 2r + 3 = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-2)\pm\left(\sqrt{-8}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-1 - \mathrm{I}\sqrt{2}, \mathrm{I}\sqrt{2} - 1\right)$

- 1st solution of the homogeneous ODE

  $i_1(t) = \mathrm{e}^{-t}\cos\left(t\sqrt{2}\right)$

- 2nd solution of the homogeneous ODE

  $i_2(t) = \mathrm{e}^{-t}\sin\left(t\sqrt{2}\right)$

- General solution of the ODE

  $i = c_1 i_1(t) + c_2 i_2(t) + i_p(t)$

- Substitute in solutions of the homogeneous ODE

  $i = c_1 \mathrm{e}^{-t} \cos\left(t\sqrt{2}\right) + c_2 \mathrm{e}^{-t} \sin\left(t\sqrt{2}\right) + i_p(t)$

☐ Find a particular solution $i_p(t)$ of the ODE

  - Use variation of parameters to find i_p here $f(t)$ is the forcing function

    $$\left[i_p(t) = -i_1(t)\left(\int \frac{i_2(t) f(t)}{W(i_1(t), i_2(t))} dt\right) + i_2(t)\left(\int \frac{i_1(t) f(t)}{W(i_1(t), i_2(t))} dt\right), f(t) = \begin{cases} 0 & t \leq 0 \\ 30 & t < 2\pi \\ 0 & t \leq 5\pi \\ 10 & 5\pi < t \end{cases}\right]$$

  - Wronskian of solutions of the homogeneous equation

    $$W(i_1(t), i_2(t)) = \begin{bmatrix} \mathrm{e}^{-t}\cos\left(t\sqrt{2}\right) & \mathrm{e}^{-t}\sin\left(t\sqrt{2}\right) \\ -\mathrm{e}^{-t}\cos\left(t\sqrt{2}\right) - \mathrm{e}^{-t}\sqrt{2}\sin\left(t\sqrt{2}\right) & -\mathrm{e}^{-t}\sin\left(t\sqrt{2}\right) + \mathrm{e}^{-t}\sqrt{2}\cos\left(t\sqrt{2}\right) \end{bmatrix}$$

  - Compute Wronskian

    $W(i_1(t), i_2(t)) = \sqrt{2}\,\mathrm{e}^{-2t}$

  - Substitute functions into equation for $i_p(t)$

    $$i_p(t) = \frac{\sqrt{2}\,\mathrm{e}^{-t}\left(-\cos\left(t\sqrt{2}\right)\left(\int \mathrm{e}^{t}\sin\left(t\sqrt{2}\right)\left(\begin{cases} 0 & t \leq 0 \\ 30 & t < 2\pi \\ 0 & t \leq 5\pi \\ 10 & 5\pi < t \end{cases}\right) dt\right) + \sin\left(t\sqrt{2}\right)\left(\int \mathrm{e}^{t}\cos\left(t\sqrt{2}\right)\left(\begin{cases} 0 & t \leq 0 \\ 30 & t < 2\pi \\ 0 & t \leq 5\pi \\ 10 & 5\pi < t \end{cases}\right) dt\right)\right)}{2}$$

  - Compute integrals

    $$i_p(t) = 5\left(\begin{cases} \\ \sqrt{2}\left(\mathrm{e}^{2\pi}\left(\sqrt{2}\sin\left(t\sqrt{2}\right) - \cos\left(t\right.\right.\right. \\ \frac{2}{3} + \left(\left(\sqrt{2}\sin\left(t\sqrt{2}\right) + 2\cos\left(t\sqrt{2}\right)\right)\cos\left(2\pi\sqrt{2}\right) - \sin\left(2\pi\sqrt{2}\right)\left(\sqrt{2}\cos\left(t\sqrt{2}\right) - 2\,\mathrm{si}\right.\right. \end{cases}\right.$$

- Substitute particular solution into general solution to ODE

$$i = c_1 \mathrm{e}^{-t} \cos\left(t\sqrt{2}\right) + c_2 \mathrm{e}^{-t} \sin\left(t\sqrt{2}\right) + 5 \left(\left\{ \begin{array}{l} \\ \frac{2}{3} + \left(\left(\sqrt{2}\sin\left(t\sqrt{2}\right) + 2\cos\left(t\sqrt{2}\right)\right)\cos\left(2\pi\sqrt{2}\right) - \end{array}\right.\right.$$

☐ Check validity of solution $i = c_1 \mathrm{e}^{-t} \cos\left(t\sqrt{2}\right) + c_2 \mathrm{e}^{-t} \sin\left(t\sqrt{2}\right) + 5 \left(\left\{ \begin{array}{l} \\ \frac{2}{3} + \left(\left(\sqrt{2}\sin\left(t\sqrt{2}\right) + \right.\right. \end{array}\right.\right.$

- Use initial condition $i(0) = 8$

  $8 = c_1$

- Compute derivative of the solution

$$i' = -c_1 \mathrm{e}^{-t} \cos\left(t\sqrt{2}\right) - c_1 \mathrm{e}^{-t} \sqrt{2}\sin\left(t\sqrt{2}\right) - c_2 \mathrm{e}^{-t} \sin\left(t\sqrt{2}\right) + c_2 \mathrm{e}^{-t}\sqrt{2}\cos\left(t\sqrt{2}\right) + 5 \left(\left\{ \begin{array}{l} \\ \left(\left(2\right.\right. \end{array}\right.\right.$$

- Use the initial condition $i'\Big|_{\{t=0\}} = 0$

  $0 = -c_1 + c_2\sqrt{2}$

- Solve for c_1 and c_2

  $\left\{c_1 = 8, c_2 = 4\sqrt{2}\right\}$

- Substitute constant values into general solution and simplify

$$i = 8\,\mathrm{e}^{-t} \cos\left(t\sqrt{2}\right) + 4\,\mathrm{e}^{-t}\sqrt{2}\sin\left(t\sqrt{2}\right) + 5 \left(\left\{ \begin{array}{l} \\ \frac{2}{3} + \left(\left(\sqrt{2}\sin\left(t\sqrt{2}\right) + 2\cos\left(t\sqrt{2}\right)\right)\cos\left(2\pi\sqrt{2}\right) \end{array}\right.\right.$$

- Solution to the IVP

$$i = 8\,e^{-t}\cos\left(t\sqrt{2}\right) + 4\,e^{-t}\sqrt{2}\,\sin\left(t\sqrt{2}\right) + 5\left(\left\{\begin{array}{l} \\ \\ \frac{2}{3} + \left(\left(\sqrt{2}\,\sin\left(t\sqrt{2}\right) + 2\cos\left(t\sqrt{2}\right)\right)\cos\left(2\pi\sqrt{2}\right)\right.\end{array}\right.\right.$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + 3y(t) \\
y'(t) &= 3x(t) + y(t)
\end{aligned}
$$

27.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{-2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^{-2t}}{2}+\frac{e^{4t}}{2} & \frac{e^{4t}}{2}-\frac{e^{-2t}}{2} \\ \frac{e^{4t}}{2}-\frac{e^{-2t}}{2} & \frac{e^{-2t}}{2}+\frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{e^{-2t}}{2}+\frac{e^{4t}}{2}\right)c_1+\left(\frac{e^{4t}}{2}-\frac{e^{-2t}}{2}\right)c_2 \\ \left(\frac{e^{4t}}{2}-\frac{e^{-2t}}{2}\right)c_1+\left(\frac{e^{-2t}}{2}+\frac{e^{4t}}{2}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(-c_2+c_1)e^{-2t}}{2}+\frac{e^{4t}(c_1+c_2)}{2} \\ \frac{(c_2-c_1)e^{-2t}}{2}+\frac{e^{4t}(c_1+c_2)}{2} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 3 \\ 3 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda - 8 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 4$$
$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & 3 & 0 \\ 3 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & 3 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & 3 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 3 & 0 \\ 3 & -3 & 0 \end{array} \right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 3 & 0 \\ 0 & 0 & 0 \end{array} \right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
4	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
-2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 4 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{4t}$$
$$= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{4t}$$

Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-2t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-2t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{4t} \\ \mathrm{e}^{4t} \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{-2t} \\ \mathrm{e}^{-2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 \mathrm{e}^{4t} - c_2 \mathrm{e}^{-2t} \\ c_1 \mathrm{e}^{4t} + c_2 \mathrm{e}^{-2t} \end{bmatrix}$$

The following is the phase plot of the system.

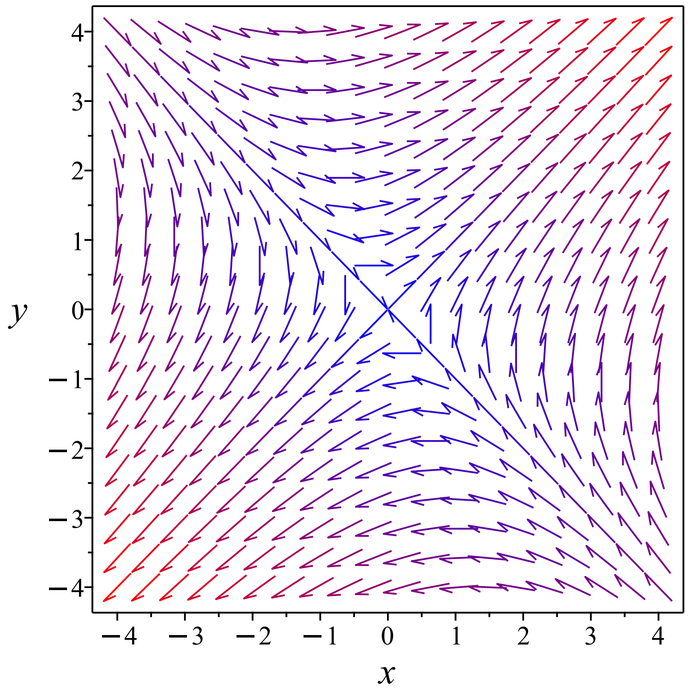

Figure 485: Phase plot

27.1.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + 3y(t), y'(t) = 3x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[-2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[-2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{x}_1 = \mathrm{e}^{-2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

  $$\left[4, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{x}_2 = \mathrm{e}^{4t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

  $\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$

- Substitute solutions into the general solution

  $$\vec{x} = c_1 \mathrm{e}^{-2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{4t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{-2t} + c_2 e^{4t} \\ c_1 e^{-2t} + c_2 e^{4t} \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = -c_1 e^{-2t} + c_2 e^{4t}, y(t) = c_1 e^{-2t} + c_2 e^{4t}\}$

✓ Solution by Maple

Problem number: 2(c).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + 3y(t) \\
y'(t) &= 3x(t) + y(t)
\end{aligned}
$$

With initial conditions

$$[x(0) = 5, y(0) = 1]$$

27.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} & \frac{e^{4t}}{2} - \frac{e^{-2t}}{2} \\ \frac{e^{4t}}{2} - \frac{e^{-2t}}{2} & \frac{e^{-2t}}{2} + \frac{e^{4t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{x}_0 \\
&= \begin{bmatrix} \frac{e^{-2t}}{2}+\frac{e^{4t}}{2} & \frac{e^{4t}}{2}-\frac{e^{-2t}}{2} \\ \frac{e^{4t}}{2}-\frac{e^{-2t}}{2} & \frac{e^{-2t}}{2}+\frac{e^{4t}}{2} \end{bmatrix} \begin{bmatrix} 5 \\ 1 \end{bmatrix} \\
&= \begin{bmatrix} 2\,e^{-2t}+3\,e^{4t} \\ 3\,e^{4t}-2\,e^{-2t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 3 \\ 3 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda - 8 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 4$$
$$\lambda_2 = -2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-2	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 3 & 3 \\ 3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & 3 & 0 \\ 3 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & 3 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 3 \\ 3 & 1 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & 3 \\ 3 & -3 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 3 & 0 \\ 3 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
4	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$
-2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 4 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{4t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{4t} \end{aligned}$$

Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-2t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-2t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{4t} \\ \mathrm{e}^{4t} \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{-2t} \\ \mathrm{e}^{-2t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 \mathrm{e}^{4t} - c_2 \mathrm{e}^{-2t} \\ c_1 \mathrm{e}^{4t} + c_2 \mathrm{e}^{-2t} \end{bmatrix}$$

Since initial conditions are given, the solution above needs to be updated by solving for the constants of integrations using the given initial conditions

$$\begin{bmatrix} x(0) = 5 \\ y(0) = 1 \end{bmatrix} \tag{1}$$

Substituting initial conditions into the above solution at $t = 0$ gives

$$\begin{bmatrix} 5 \\ 1 \end{bmatrix} = \begin{bmatrix} c_1 - c_2 \\ c_1 + c_2 \end{bmatrix}$$

Solving for the constants of integrations gives

$$\begin{bmatrix} c_1 = 3 \\ c_2 = -2 \end{bmatrix}$$

Substituting these constants back in original solution in Eq. (1) gives

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 2\,\mathrm{e}^{-2t} + 3\,\mathrm{e}^{4t} \\ 3\,\mathrm{e}^{4t} - 2\,\mathrm{e}^{-2t} \end{bmatrix}$$

The following is the phase plot of the system.

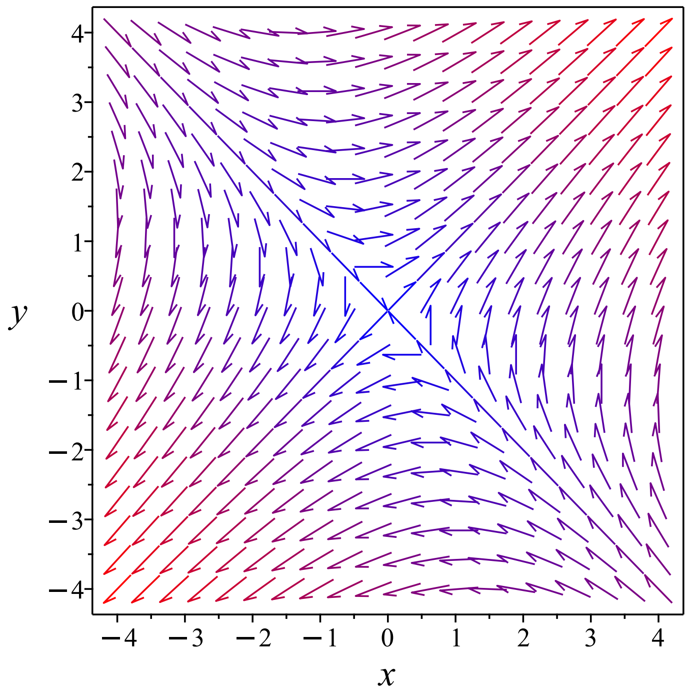

Figure 486: Phase plot

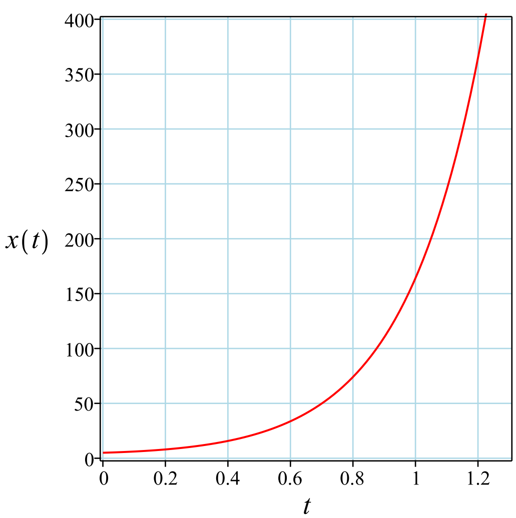
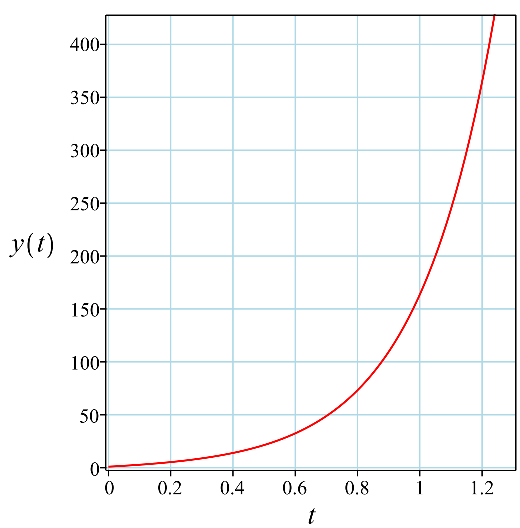
The following are plots of each solution.





✓ Solution by Maple

Time used: 0.016 (sec). Leaf size: 34

```
dsolve([diff(x(t),t) = x(t)+3*y(t), diff(y(t),t) = 3*x(t)+y(t), x(0) = 5, y(0) = 1], singsol
```

$$x(t) = 2\,e^{-2t} + 3\,e^{4t}$$
$$y(t) = -2\,e^{-2t} + 3\,e^{4t}$$

✓ Solution by Mathematica

Time used: 0.004 (sec). Leaf size: 38

```

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + 2y(t) \\
y'(t) &= 3x(t) + 2y(t)
\end{aligned}
$$

27.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{3\,e^{-t}}{5} + \frac{2\,e^{4t}}{5} & \frac{2\,e^{4t}}{5} - \frac{2\,e^{-t}}{5} \\ \frac{3\,e^{4t}}{5} - \frac{3\,e^{-t}}{5} & \frac{2\,e^{-t}}{5} + \frac{3\,e^{4t}}{5} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{3\,e^{-t}}{5}+\frac{2\,e^{4t}}{5} & \frac{2\,e^{4t}}{5}-\frac{2\,e^{-t}}{5} \\ \frac{3\,e^{4t}}{5}-\frac{3\,e^{-t}}{5} & \frac{2\,e^{-t}}{5}+\frac{3\,e^{4t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{3\,e^{-t}}{5}+\frac{2\,e^{4t}}{5}\right)c_1+\left(\frac{2\,e^{4t}}{5}-\frac{2\,e^{-t}}{5}\right)c_2 \\ \left(\frac{3\,e^{4t}}{5}-\frac{3\,e^{-t}}{5}\right)c_1+\left(\frac{2\,e^{-t}}{5}+\frac{3\,e^{4t}}{5}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(3c_1-2c_2)e^{-t}}{5}+\frac{2\,e^{4t}(c_1+c_2)}{5} \\ \frac{(-3c_1+2c_2)e^{-t}}{5}+\frac{3\,e^{4t}(c_1+c_2)}{5} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 2 \\ 3 & 2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 3\lambda - 4 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 4$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 2 \\ 3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 2 & 0 \\ 3 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & 2 \\ 3 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 2 & 0 \\ 3 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{2t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
4	1	1	No	$\begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 4 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{4t} \\
&= \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix} e^{4t}
\end{aligned}
$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{-t} \\
&= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{2\,\mathrm{e}^{4t}}{3} \\ \mathrm{e}^{4t} \end{bmatrix} + c_2 \begin{bmatrix} -\mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{2c_1 \mathrm{e}^{4t}}{3} - c_2 \mathrm{e}^{-t} \\ c_1 \mathrm{e}^{4t} + c_2 \mathrm{e}^{-t} \end{bmatrix}
$$

The following is the phase plot of the system.

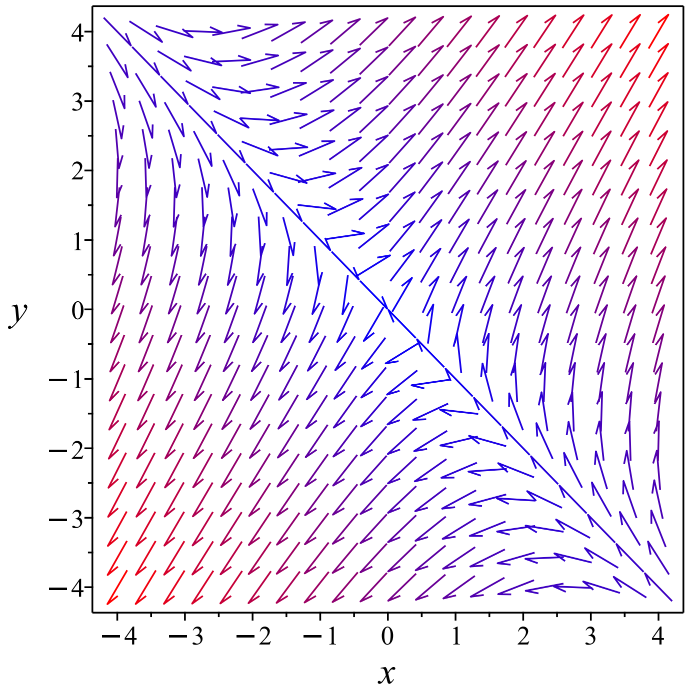

Figure 487: Phase plot

27.3.3 Maple step by step solution

Let's solve

$$[x'(t) = x(t) + 2y(t), y'(t) = 3x(t) + 2y(t)]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[-1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\overrightarrow{x}_1 = e^{-t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

  $$\left[4, \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\overrightarrow{x}_2 = e^{4t} \cdot \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

  $\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2$

- Substitute solutions into the general solution

  $$\overrightarrow{x} = e^{-t} c_1 \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + c_2 e^{4t} \cdot \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -e^{-t}c_1 + \frac{2c_2 e^{4t}}{3} \\ e^{-t}c_1 + c_2 e^{4t} \end{bmatrix}$$

- Solution to the system of ODEs

  $\left\{x(t) = -e^{-t}c_1 + \frac{2c_2 e^{4t}}{3}, y(t) = e^{-t}c_1 + c_2 e^{4t}\right\}$

✓ Solution by Maple

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 10. Systems of First-Order Equations. Section 10.2 Linear Systems. Page 380
Problem number: 3(c).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + 2y(t) + t - 1 \\
y'(t) &= 3x(t) + 2y(t) - 5t - 2
\end{aligned}
$$

27.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix}
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{3\,e^{-t}}{5} + \frac{2\,e^{4t}}{5} & \frac{2\,e^{4t}}{5} - \frac{2\,e^{-t}}{5} \\ \frac{3\,e^{4t}}{5} - \frac{3\,e^{-t}}{5} & \frac{2\,e^{-t}}{5} + \frac{3\,e^{4t}}{5} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{3\,e^{-t}}{5} + \frac{2\,e^{4t}}{5} & \frac{2\,e^{4t}}{5} - \frac{2\,e^{-t}}{5} \\ \frac{3\,e^{4t}}{5} - \frac{3\,e^{-t}}{5} & \frac{2\,e^{-t}}{5} + \frac{3\,e^{4t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{3\,e^{-t}}{5} + \frac{2\,e^{4t}}{5}\right) c_1 + \left(\frac{2\,e^{4t}}{5} - \frac{2\,e^{-t}}{5}\right) c_2 \\ \left(\frac{3\,e^{4t}}{5} - \frac{3\,e^{-t}}{5}\right) c_1 + \left(\frac{2\,e^{-t}}{5} + \frac{3\,e^{4t}}{5}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(3c_1-2c_2)\,e^{-t}}{5} + \frac{2\,e^{4t}(c_1+c_2)}{5} \\ \frac{(-3c_1+2c_2)\,e^{-t}}{5} + \frac{3\,e^{4t}(c_1+c_2)}{5} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \frac{(3\,e^{5t}+2)\,e^{-4t}}{5} & -\frac{2(e^{5t}-1)\,e^{-4t}}{5} \\ -\frac{3(e^{5t}-1)\,e^{-4t}}{5} & \frac{(2\,e^{5t}+3)\,e^{-4t}}{5} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{3\,e^{-t}}{5} + \frac{2\,e^{4t}}{5} & \frac{2\,e^{4t}}{5} - \frac{2\,e^{-t}}{5} \\ \frac{3\,e^{4t}}{5} - \frac{3\,e^{-t}}{5} & \frac{2\,e^{-t}}{5} + \frac{3\,e^{4t}}{5} \end{bmatrix} \int \begin{bmatrix} \frac{(3\,e^{5t}+2)\,e^{-4t}}{5} & -\frac{2(e^{5t}-1)\,e^{-4t}}{5} \\ -\frac{3(e^{5t}-1)\,e^{-4t}}{5} & \frac{(2\,e^{5t}+3)\,e^{-4t}}{5} \end{bmatrix} \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{3\,e^{-t}}{5} + \frac{2\,e^{4t}}{5} & \frac{2\,e^{4t}}{5} - \frac{2\,e^{-t}}{5} \\ \frac{3\,e^{4t}}{5} - \frac{3\,e^{-t}}{5} & \frac{2\,e^{-t}}{5} + \frac{3\,e^{4t}}{5} \end{bmatrix} \begin{bmatrix} \frac{(13\,e^{5t}t-12\,e^{5t}+2t+2)\,e^{-4t}}{5} \\ -\frac{(13\,e^{5t}t-12\,e^{5t}-3t-3)\,e^{-4t}}{5} \end{bmatrix} \\
&= \begin{bmatrix} 3t-2 \\ 3-2t \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(3c_1-2c_2)e^{-t}}{5} + \frac{(2c_1+2c_2)e^{4t}}{5} + 3t - 2 \\ \frac{(-3c_1+2c_2)e^{-t}}{5} + \frac{(3c_1+3c_2)e^{4t}}{5} - 2t + 3 \end{bmatrix}$$

27.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 2 \\ 3 & 2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 3\lambda - 4 = 0$$

The roots of the above are the eigenvalues.

$$
\begin{aligned}
\lambda_1 &= -1 \\
\lambda_2 &= 4
\end{aligned}
$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$
\begin{aligned}
\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix} \\
\begin{bmatrix} 2 & 2 \\ 3 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} &= \begin{bmatrix} 0 \\ 0 \end{bmatrix}
\end{aligned}
$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$
\left[\begin{array}{cc|c} 2 & 2 & 0 \\ 3 & 3 & 0 \end{array}\right]
$$

$$
R_2 = R_2 - \frac{3R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]
$$

Therefore the system in Echelon form is

$$
\begin{bmatrix} 2 & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}
$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} - (4) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & 2 \\ 3 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 2 & 0 \\ 3 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -3 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{2t}{3}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{2t}{3} \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 3 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
4	1	1	No	$\begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{-t}$$
$$= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{-t}$$

Since eigenvalue 4 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{4t}$$
$$= \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix} e^{4t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{2\,\mathrm{e}^{4t}}{3} \\ \mathrm{e}^{4t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\mathrm{e}^{-t} & \frac{2\,\mathrm{e}^{4t}}{3} \\ \mathrm{e}^{-t} & \mathrm{e}^{4t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{3\,\mathrm{e}^{t}}{5} & \frac{2\,\mathrm{e}^{t}}{5} \\ \frac{3\,\mathrm{e}^{-4t}}{5} & \frac{3\,\mathrm{e}^{-4t}}{5} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -e^{-t} & \frac{2e^{4t}}{3} \\ e^{-t} & e^{4t} \end{bmatrix} \int \begin{bmatrix} -\frac{3e^{t}}{5} & \frac{2e^{t}}{5} \\ \frac{3e^{-4t}}{5} & \frac{3e^{-4t}}{5} \end{bmatrix} \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix} dt$$

$$= \begin{bmatrix} -e^{-t} & \frac{2e^{4t}}{3} \\ e^{-t} & e^{4t} \end{bmatrix} \int \begin{bmatrix} -\frac{e^{t}(13t+1)}{5} \\ -\frac{3e^{-4t}(4t+3)}{5} \end{bmatrix} dt$$

$$= \begin{bmatrix} -e^{-t} & \frac{2e^{4t}}{3} \\ e^{-t} & e^{4t} \end{bmatrix} \begin{bmatrix} -\frac{e^{t}(13t-12)}{5} \\ \frac{3e^{-4t}(t+1)}{5} \end{bmatrix}$$

$$= \begin{bmatrix} 3t-2 \\ 3-2t \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{-t} \\ c_1 e^{-t} \end{bmatrix} + \begin{bmatrix} \frac{2c_2 e^{4t}}{3} \\ c_2 e^{4t} \end{bmatrix} + \begin{bmatrix} 3t-2 \\ 3-2t \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 e^{-t} + \frac{2c_2 e^{4t}}{3} + 3t - 2 \\ c_1 e^{-t} + c_2 e^{4t} + 3 - 2t \end{bmatrix}$$

27.4.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + 2y(t) + t - 1, y'(t) = 3x(t) + 2y(t) - 5t - 2]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} t-1 \\ -5t-2 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 2 \\ 3 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[4, \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[4, \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{4t} \cdot \begin{bmatrix} \frac{2}{3} \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \vec{x}_p(t)$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$\phi(t) = \begin{bmatrix} -\mathrm{e}^{-t} & \frac{2\,\mathrm{e}^{4t}}{3} \\ \mathrm{e}^{-t} & \mathrm{e}^{4t} \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$\Phi(t) = \begin{bmatrix} -\mathrm{e}^{-t} & \frac{2\,\mathrm{e}^{4t}}{3} \\ \mathrm{e}^{-t} & \mathrm{e}^{4t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -1 & \frac{2}{3} \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

$\Phi(t) = \begin{bmatrix} \frac{3\,\mathrm{e}^{-t}}{5} + \frac{2\,\mathrm{e}^{4t}}{5} & \frac{2\,\mathrm{e}^{4t}}{5} - \frac{2\,\mathrm{e}^{-t}}{5} \\ \frac{3\,\mathrm{e}^{4t}}{5} - \frac{3\,\mathrm{e}^{-t}}{5} & \frac{2\,\mathrm{e}^{-t}}{5} + \frac{3\,\mathrm{e}^{4t}}{5} \end{bmatrix}$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

$\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$

- Take the derivative of the particular solution

$\vec{x}_p'(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

$\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

$A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$

- Cancel like terms

$\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

  $$\vec{x}_p(t) = \begin{bmatrix} 3t + \frac{12\,e^{-t}}{5} - 2 - \frac{2\,e^{4t}}{5} \\ -\frac{3\,e^{4t}}{5} - 2t + 3 - \frac{12\,e^{-t}}{5} \end{bmatrix}$$

- Plug particular solution back into general solution

  $$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \begin{bmatrix} 3t + \frac{12\,e^{-t}}{5} - 2 - \frac{2\,e^{4t}}{5} \\ -\frac{3\,e^{4t}}{5} - 2t + 3 - \frac{12\,e^{-t}}{5} \end{bmatrix}$$

- Substitute in vector of dependent variables

  $$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(-15c_1+36)e^{-t}}{15} + \frac{(10c_2-6)e^{4t}}{15} + 3t - 2 \\ \frac{(-12+5c_1)e^{-t}}{5} + \frac{(-3+5c_2)e^{4t}}{5} - 2t + 3 \end{bmatrix}$$

- Solution to the system of ODEs

  $$\left\{x(t) = \frac{(-15c_1+36)e^{-t}}{15} + \frac{(10c_2-6)e^{4t}}{15} + 3t - 2, y(t) = \frac{(-12+5c_1)e^{-t}}{5} + \frac{(-3+5c_2)e^{4t}}{5} - 2t + 3\right\}$$

✓ Solution by Maple

27.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} e^{t} & t\,e^{t} \\ 0 & e^{t} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \mathrm{e}^{t} & t\,\mathrm{e}^{t} \\ 0 & \mathrm{e}^{t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \mathrm{e}^{t} c_1 + t\,\mathrm{e}^{t} c_2 \\ \mathrm{e}^{t} c_2 \end{bmatrix} \\
&= \begin{bmatrix} \mathrm{e}^{t} (c_2 t + c_1) \\ \mathrm{e}^{t} c_2 \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 \\ 0 & 1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(1-\lambda)(1-\lambda)=0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A-\lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}1 & 1\\ 0 & 1\end{bmatrix} - (1)\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$
$$\begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c}0 & 1 & 0\\ 0 & 0 & 0\end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix}0 & 1\\ 0 & 0\end{bmatrix}\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix}t\\ 0\end{bmatrix} = \begin{bmatrix}t\\ 0\end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	2	1	Yes	$\begin{bmatrix} 1 \\ 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 1 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

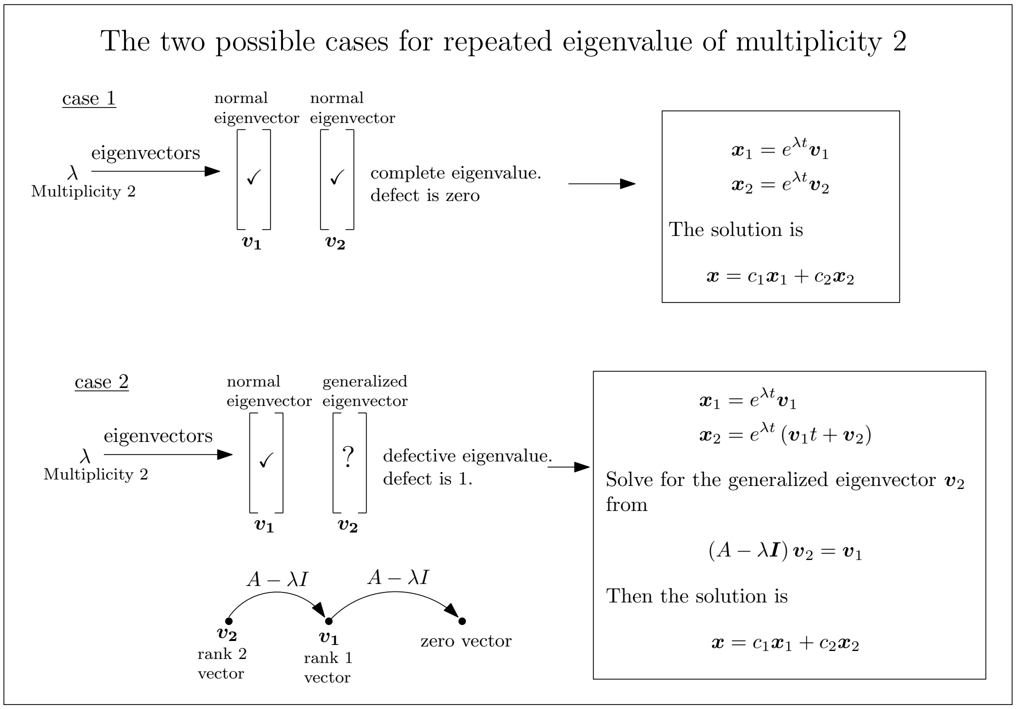

Figure 488: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\,\vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} 1 & 1 \\ 0 & 1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue 1. Therefore the two basis solution associated with this eigenvalue are

$$\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\
&= \begin{bmatrix} 1 \\ 0 \end{bmatrix} \mathrm{e}^{t} \\
&= \begin{bmatrix} \mathrm{e}^{t} \\ 0 \end{bmatrix}
\end{aligned}$$

And

$$\begin{aligned}
\vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t} \\
&= \left(\begin{bmatrix} 1 \\ 0 \end{bmatrix} t + \begin{bmatrix} 1 \\ 1 \end{bmatrix} \right) \mathrm{e}^{t} \\
&= \begin{bmatrix} \mathrm{e}^{t}(t+1) \\ \mathrm{e}^{t} \end{bmatrix}
\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \mathrm{e}^{t} \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{t}(t+1) \\ \mathrm{e}^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \mathrm{e}^{t}(c_2 t + c_1 + c_2) \\ c_2 \mathrm{e}^{t} \end{bmatrix}$$

The following is the phase plot of the system.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = x(t)$$
$$y'(t) = y(t)$$

27.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{t} & 0 \\ 0 & e^{t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \mathrm{e}^t & 0 \\ 0 & \mathrm{e}^t \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \mathrm{e}^t c_1 \\ \mathrm{e}^t c_2 \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

27.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det{(A - \lambda I)} = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 0 \\ 0 & 1-\lambda \end{bmatrix}\right) = 0$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$(1-\lambda)(1-\lambda) = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & 0 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1, v_2\}$ and there are no leading variables. Let $v_1 = t$. Let $v_2 = s$. Since there are two free Variable, we have found two eigenvectors associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ s \end{bmatrix} = \begin{bmatrix} t \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ s \end{bmatrix}$$

$$= t\begin{bmatrix} 1 \\ 0 \end{bmatrix} + s\begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

By letting $t = 1$ and $s = 1$ then the above becomes

$$\begin{bmatrix} t \\ s \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix} + \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Hence the two eigenvectors associated with this eigenvalue are

$$\left(\begin{bmatrix} 1 \\ 0 \end{bmatrix}, \begin{bmatrix} 0 \\ 1 \end{bmatrix} \right)$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	2	2	No	$\begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 1 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

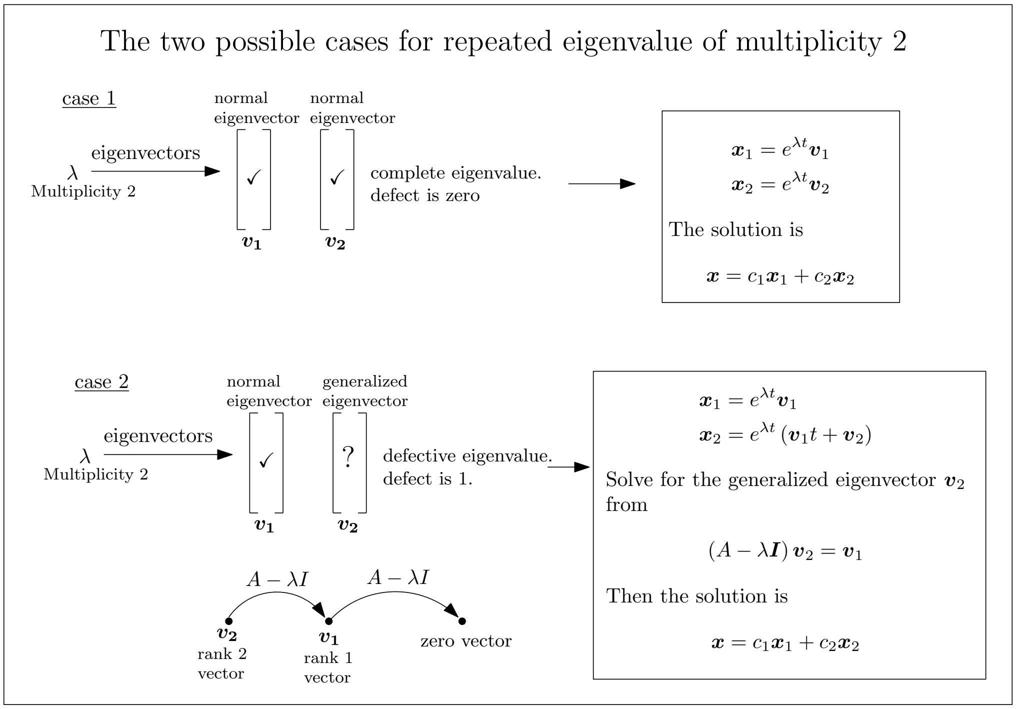

Figure 490: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2 which is the same as its geometric multiplicity 2, then it is complete eigenvalue and this falls into case 1 shown above. Hence the corresponding eigenvector basis are

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^t \\
&= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^t
\end{aligned}
$$

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^t \\
&= \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^t
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 0 \\ e^t \end{bmatrix} + c_2 \begin{bmatrix} e^t \\ 0 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_2 e^t \\ c_1 e^t \end{bmatrix}$$

The following is the phase plot of the system.

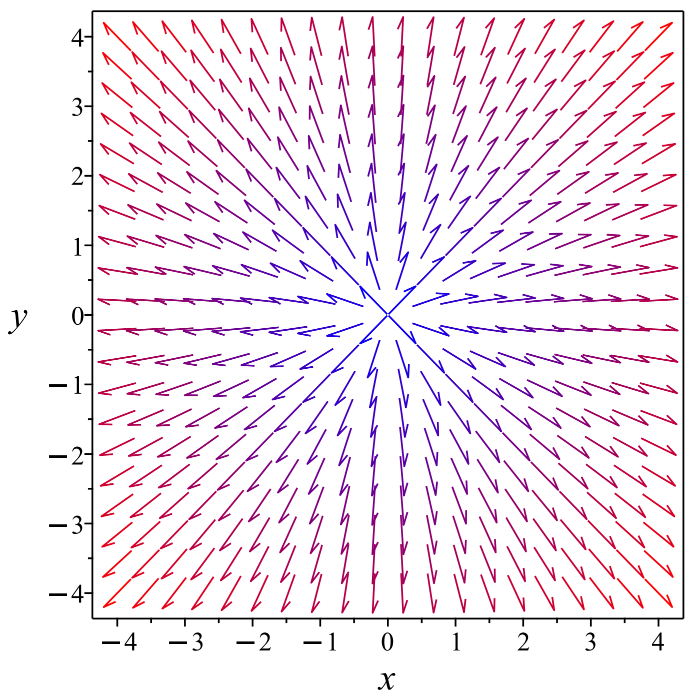

Figure 491: Phase plot

27.6.3 Maple step by step solution

Let's solve

$[x'(t) = x(t), y'(t) = y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[1, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 1

$$\vec{x}_1(t) = e^t \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, and

$$\vec{x}_2(t) = e^{\lambda t}\left(t\vec{v} + \vec{p}\right)$$

- Note that the t multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\vec{x}_2(t)$ into the homogeneous system

$$\lambda e^{\lambda t}\left(t\vec{v}+\vec{p}\right)+e^{\lambda t}\vec{v}=\left(e^{\lambda t}A\right)\cdot\left(t\vec{v}+\vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda e^{\lambda t}\left(t\vec{v}+\vec{p}\right)+e^{\lambda t}\vec{v}=e^{\lambda t}\left(\lambda t\vec{v}+A\cdot\vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p}+\vec{v}=A\cdot\vec{p}$$

- Make use of the identity matrix I

$$(\lambda\cdot I)\cdot\vec{p}+\vec{v}=A\cdot\vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{x}_2(t)$ to be a solution to the homogeneous system

$$(A-\lambda\cdot I)\cdot\vec{p}=\vec{v}$$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}-1\cdot\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right)\cdot\vec{p}=\begin{bmatrix}0\\ 1\end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p}=\begin{bmatrix}0\\ 0\end{bmatrix}$$

- Second solution from eigenvalue 1

$$\vec{x}_2(t)=e^{t}\cdot\left(t\cdot\begin{bmatrix}0\\ 1\end{bmatrix}+\begin{bmatrix}0\\ 0\end{bmatrix}\right)$$

- General solution to the system of ODEs

$$\vec{x}=c_1\vec{x}_1(t)+c_2\vec{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x}=c_1e^{t}\cdot\begin{bmatrix}0\\ 1\end{bmatrix}+c_2e^{t}\cdot\left(t\cdot\begin{bmatrix}0\\ 1\end{bmatrix}+\begin{bmatrix}0\\ 0\end{bmatrix}\right)$$

- Substitute in vector of dependent variables

$$\begin{bmatrix}x(t)\\ y(t)\end{bmatrix}=\begin{bmatrix}0\\ e^{t}(tc_2+c_1)\end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = 0, y(t) = e^t(tc_2 + c_1)\}$$

Problem number: 1(a).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -3x(t) + 4y(t)$$
$$y'(t) = -2x(t) + 3y(t)$$

28.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} 2\,\mathrm{e}^{-t} - \mathrm{e}^{t} & 2\,\mathrm{e}^{t} - 2\,\mathrm{e}^{-t} \\ -\mathrm{e}^{t} + \mathrm{e}^{-t} & -\mathrm{e}^{-t} + 2\,\mathrm{e}^{t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} 2\,e^{-t}-e^{t} & 2\,e^{t}-2\,e^{-t} \\ -e^{t}+e^{-t} & -e^{-t}+2\,e^{t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} (2\,e^{-t}-e^{t})\,c_1+(2\,e^{t}-2\,e^{-t})\,c_2 \\ (-e^{t}+e^{-t})\,c_1+(-e^{-t}+2\,e^{t})\,c_2 \end{bmatrix} \\
&= \begin{bmatrix} (2c_1-2c_2)\,e^{-t}-e^{t}(-2c_2+c_1) \\ (-c_2+c_1)\,e^{-t}-e^{t}(-2c_2+c_1) \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A-\lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} - \lambda\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -3-\lambda & 4 \\ -2 & 3-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -2 & 4 \\ -2 & 4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 4 & 0 \\ -2 & 4 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = t \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -4 & 4 \\ -2 & 2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -4 & 4 & 0 \\ -2 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} -4 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -4 & 4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} 2 \\ 1 \end{bmatrix}$
1	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the

corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} 2 \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{t} \\ &= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 2\,\mathrm{e}^{-t} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 2c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{t} \\ c_1 \mathrm{e}^{-t} + c_2 \mathrm{e}^{t} \end{bmatrix}$$

The following is the phase plot of the system.

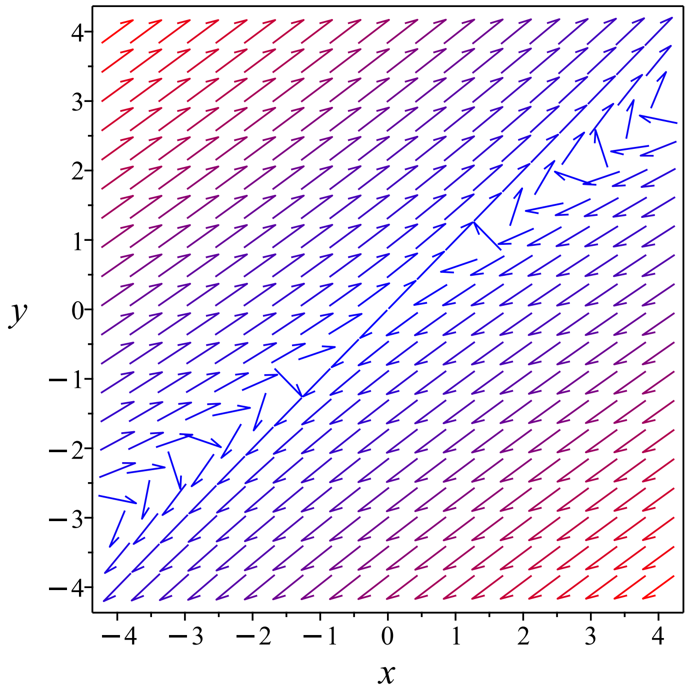

Figure 492: Phase plot

28.1.3 Maple step by step solution

Let's solve

$$[x'(t) = -3x(t) + 4y(t), y'(t) = -2x(t) + 3y(t)]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -3 & 4 \\ -2 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = e^{-t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_2 = e^{t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2$$

- Substitute solutions into the general solution

$$\overrightarrow{x} = e^{-t} c_1 \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix} + c_2 e^{t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} 2\,\mathrm{e}^{-t}c_1 + c_2\mathrm{e}^t \\ \mathrm{e}^{-t}c_1 + c_2\mathrm{e}^t \end{bmatrix}$$

- Solution to the system of ODEs

  $\{x(t) = 2\,\mathrm{e}^{-t}c_1 + c_2\mathrm{e}^t, y(t) = \mathrm{e}^{-t}c_1 + c_2\mathrm{e}^t\}$

✓ Solution by Maple

Time used: 0.016 (sec). Leaf size: 31

```
dsolve([diff(x(t),t)=-3*x(t)+4*y(t),diff(y(t),t)=-2*x(t)+3*y(t)],singsol=all)
```

$$x(t) = c_1\mathrm{e}^t + c_2\mathrm{e}^{-t}$$
$$y(t) = c_1\mathrm{e}^t + \frac{c_2\mathrm{e}^{-t}}{2}$$

✓ Solution by Mathematica

Time used: 0.006 (sec). Leaf size: 67

```

Problem number: 1(b).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 4x(t) - 2y(t)$$
$$y'(t) = 5x(t) + 2y(t)$$

28.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$\begin{aligned} e^{At} &= \begin{bmatrix} e^{3t}\cos(3t) + \frac{e^{3t}\sin(3t)}{3} & -\frac{2\,e^{3t}\sin(3t)}{3} \\ \frac{5\,e^{3t}\sin(3t)}{3} & e^{3t}\cos(3t) - \frac{e^{3t}\sin(3t)}{3} \end{bmatrix} \\ &= \begin{bmatrix} \frac{e^{3t}(3\cos(3t)+\sin(3t))}{3} & -\frac{2\,e^{3t}\sin(3t)}{3} \\ \frac{5\,e^{3t}\sin(3t)}{3} & \frac{e^{3t}(3\cos(3t)-\sin(3t))}{3} \end{bmatrix} \end{aligned}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^{3t}(3\cos(3t)+\sin(3t))}{3} & -\frac{2\,e^{3t}\sin(3t)}{3} \\ \frac{5\,e^{3t}\sin(3t)}{3} & \frac{e^{3t}(3\cos(3t)-\sin(3t))}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{e^{3t}(3\cos(3t)+\sin(3t))c_1}{3} - \frac{2\,e^{3t}\sin(3t)c_2}{3} \\ \frac{5\,e^{3t}\sin(3t)c_1}{3} + \frac{e^{3t}(3\cos(3t)-\sin(3t))c_2}{3} \end{bmatrix} \\
&= \begin{bmatrix} \frac{e^{3t}(-2c_2+c_1)\sin(3t)}{3} + e^{3t}\cos(3t)\,c_1 \\ \frac{e^{3t}(5c_1-c_2)\sin(3t)}{3} + e^{3t}\cos(3t)\,c_2 \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} 4-\lambda & -2 \\ 5 & 2-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$\lambda^2 - 6\lambda + 18 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3 + 3i$$
$$\lambda_2 = 3 - 3i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$3 - 3i$	1	complex eigenvalue
$3 + 3i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 3 - 3i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} - (3 - 3i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 + 3i & -2 \\ 5 & -1 + 3i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 + 3i & -2 & 0 \\ 5 & -1 + 3i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(-\frac{1}{2} + \frac{3i}{2}\right) R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 + 3i & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 + 3i & -2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = \left(\frac{1}{5} - \frac{3i}{5}\right) t\}$

Hence the solution is

$$\begin{bmatrix} \left(\frac{1}{5} - \frac{3\,\mathrm{I}}{5}\right) t \\ t \end{bmatrix} = \begin{bmatrix} \left(\frac{1}{5} - \frac{3i}{5}\right) t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(\frac{1}{5} - \frac{3\,\mathrm{I}}{5}\right) t \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{5} - \frac{3i}{5} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(\frac{1}{5} - \frac{3\,\mathrm{I}}{5}\right) t \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{5} - \frac{3i}{5} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(\frac{1}{5} - \frac{3\,\mathrm{I}}{5}\right) t \\ t \end{bmatrix} = \begin{bmatrix} 1 - 3i \\ 5 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3 + 3i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} - (3 + 3i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 1 - 3i & -2 \\ 5 & -1 - 3i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 - 3i & -2 & 0 \\ 5 & -1 - 3i & 0 \end{array}\right]$$

$$R_2 = R_2 + \left(-\frac{1}{2} - \frac{3i}{2}\right) R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 - 3i & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1-3i & -2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(\frac{1}{5} + \frac{3i}{5}\right)t\right\}$

Hence the solution is

$$\begin{bmatrix} \left(\frac{1}{5} + \frac{3\,\mathrm{I}}{5}\right)t \\ t \end{bmatrix} = \begin{bmatrix} \left(\frac{1}{5} + \frac{3i}{5}\right)t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(\frac{1}{5} + \frac{3\,\mathrm{I}}{5}\right)t \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{5} + \frac{3i}{5} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(\frac{1}{5} + \frac{3\,\mathrm{I}}{5}\right)t \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{5} + \frac{3i}{5} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(\frac{1}{5} + \frac{3\,\mathrm{I}}{5}\right)t \\ t \end{bmatrix} = \begin{bmatrix} 1+3i \\ 5 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity algebraic m	multiplicity geometric k	defective?	eigenvectors
$3+3i$	1	1	No	$\begin{bmatrix} \frac{1}{5}+\frac{3i}{5} \\ 1 \end{bmatrix}$
$3-3i$	1	1	No	$\begin{bmatrix} \frac{1}{5}-\frac{3i}{5} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \left(\frac{1}{5}+\frac{3i}{5}\right) e^{(3+3i)t} \\ e^{(3+3i)t} \end{bmatrix} + c_2 \begin{bmatrix} \left(\frac{1}{5}-\frac{3i}{5}\right) e^{(3-3i)t} \\ e^{(3-3i)t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \left(\frac{1}{5}+\frac{3i}{5}\right) c_1 e^{(3+3i)t} + \left(\frac{1}{5}-\frac{3i}{5}\right) c_2 e^{(3-3i)t} \\ c_1 e^{(3+3i)t} + c_2 e^{(3-3i)t} \end{bmatrix}$$

The following is the phase plot of the system.

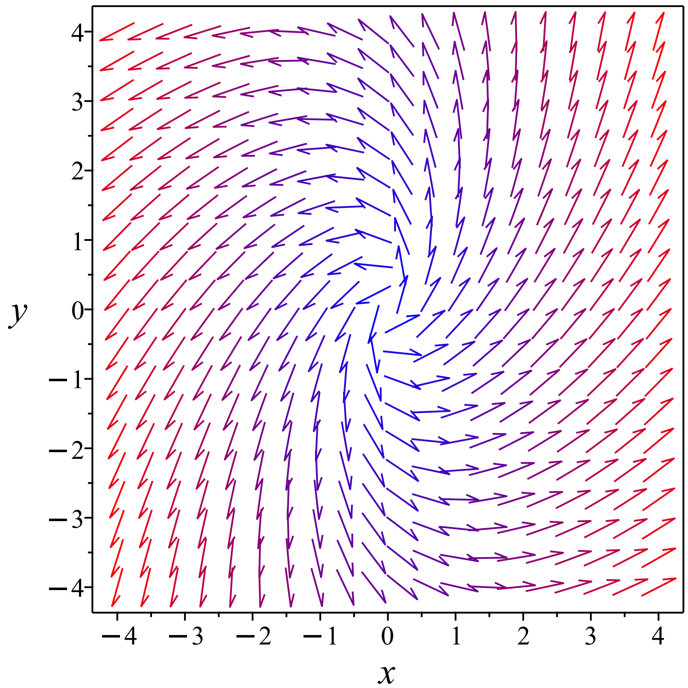

Figure 493: Phase plot

28.2.3 Maple step by step solution

Let's solve

$[x'(t) = 4x(t) - 2y(t), y'(t) = 5x(t) + 2y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 4 & -2 \\ 5 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[3-3\,\mathrm{I}, \begin{bmatrix} \frac{1}{5}-\frac{3\,\mathrm{I}}{5} \\ 1 \end{bmatrix}\right], \left[3+3\,\mathrm{I}, \begin{bmatrix} \frac{1}{5}+\frac{3\,\mathrm{I}}{5} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[3-3\,\mathrm{I}, \begin{bmatrix} \frac{1}{5}-\frac{3\,\mathrm{I}}{5} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{(3-3\,\mathrm{I})t} \cdot \begin{bmatrix} \frac{1}{5}-\frac{3\,\mathrm{I}}{5} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of sin and cos

$$\mathrm{e}^{3t} \cdot (\cos(3t) - \mathrm{I}\sin(3t)) \cdot \begin{bmatrix} \frac{1}{5}-\frac{3\,\mathrm{I}}{5} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\mathrm{e}^{3t} \cdot \begin{bmatrix} \left(\frac{1}{5}-\frac{3\,\mathrm{I}}{5}\right)(\cos(3t) - \mathrm{I}\sin(3t)) \\ \cos(3t) - \mathrm{I}\sin(3t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\overrightarrow{x}_1(t) = \mathrm{e}^{3t} \cdot \begin{bmatrix} \frac{\cos(3t)}{5} - \frac{3\sin(3t)}{5} \\ \cos(3t) \end{bmatrix}, \overrightarrow{x}_2(t) = \mathrm{e}^{3t} \cdot \begin{bmatrix} -\frac{\sin(3t)}{5} - \frac{3\cos(3t)}{5} \\ -\sin(3t) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1\overrightarrow{x}_1(t) + c_2\overrightarrow{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^{3t} \cdot \begin{bmatrix} \frac{\cos(3t)}{5} - \frac{3\sin(3t)}{5} \\ \cos(3t) \end{bmatrix} + e^{3t} c_2 \cdot \begin{bmatrix} -\frac{\sin(3t)}{5} - \frac{3\cos(3t)}{5} \\ -\sin(3t) \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{\left((c_1 - 3c_2)\cos(3t) - 3\left(c_1 + \frac{c_2}{3}\right)\sin(3t)\right)e^{3t}}{5} \\ e^{3t}(c_1 \cos(3t) - c_2 \sin(3t)) \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{\left((c_1 - 3c_2)\cos(3t) - 3\left(c_1 + \frac{c_2}{3}\right)\sin(3t)\right)e^{3t}}{5}, y(t) = e^{3t}(c_1 \cos(3t) - c_2 \sin(3t))\right\}$$

✓ Solution by Maple

Section: Chapter 10. Systems of First-Order Equations. Section 10.3 Homogeneous Linear Systems with Constant Coefficients. Page 387
Problem number: 1(c).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 5x(t) + 4y(t)$$
$$y'(t) = -x(t) + y(t)$$

28.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} (2t+1)\,e^{3t} & 4t\,e^{3t} \\ -t\,e^{3t} & e^{3t}(1-2t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} (2t+1)\,\mathrm{e}^{3t} & 4t\,\mathrm{e}^{3t} \\ -t\,\mathrm{e}^{3t} & \mathrm{e}^{3t}(1-2t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} (2t+1)\,\mathrm{e}^{3t}c_1 + 4t\,\mathrm{e}^{3t}c_2 \\ -t\,\mathrm{e}^{3t}c_1 + \mathrm{e}^{3t}(1-2t)\,c_2 \end{bmatrix} \\
&= \begin{bmatrix} \mathrm{e}^{3t}(2tc_1 + 4c_2t + c_1) \\ \mathrm{e}^{3t}(-tc_1 - 2c_2t + c_2) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & 4 \\ -1 & 1-\lambda \end{bmatrix} \right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 6\lambda + 9 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} - (3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 4 & 0 \\ -1 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 2 & 4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -2t\}$

Hence the solution is

$$\begin{bmatrix} -2t \\ t \end{bmatrix} = \begin{bmatrix} -2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -2t \\ t \end{bmatrix} = t \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -2t \\ t \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	2	1	Yes	$\begin{bmatrix} -2 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 3 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

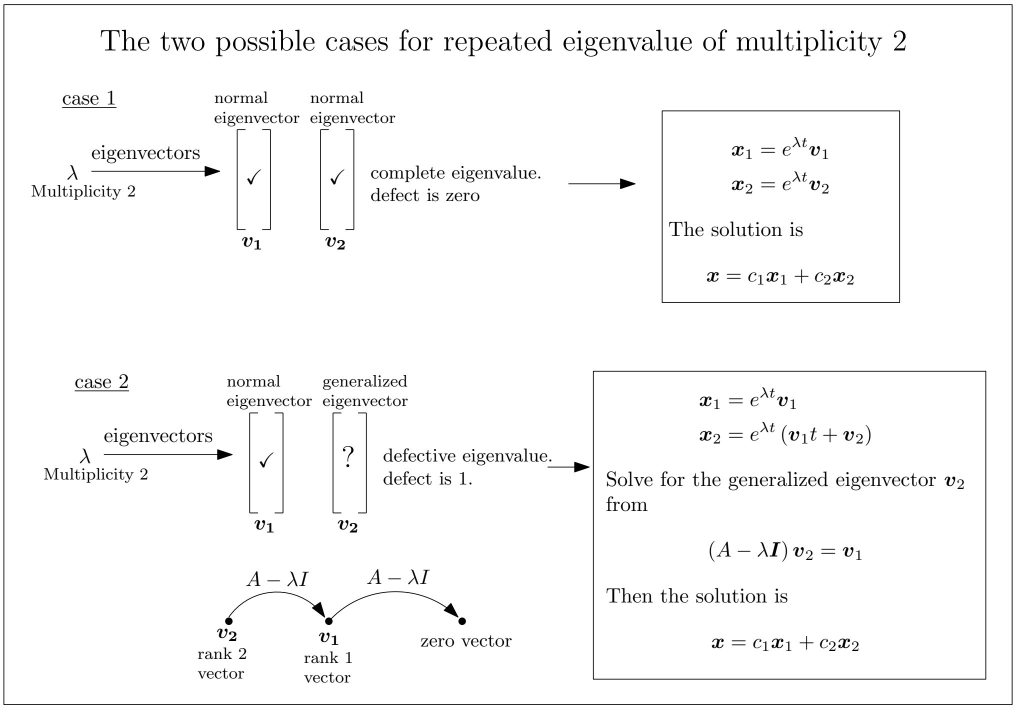

Figure 494: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\, \vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 4 \\ -1 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} -3 \\ 1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue 3. Therefore the two basis solution associated with this eigenvalue are

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\
&= \begin{bmatrix} -2 \\ 1 \end{bmatrix} \mathrm{e}^{3t} \\
&= \begin{bmatrix} -2\,\mathrm{e}^{3t} \\ \mathrm{e}^{3t} \end{bmatrix}
\end{aligned}
$$

And

$$
\begin{aligned}
\vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t} \\
&= \left(\begin{bmatrix} -2 \\ 1 \end{bmatrix} t + \begin{bmatrix} -3 \\ 1 \end{bmatrix} \right) \mathrm{e}^{3t} \\
&= \begin{bmatrix} \mathrm{e}^{3t}(-2t-3) \\ \mathrm{e}^{3t}(t+1) \end{bmatrix}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -2\,\mathrm{e}^{3t} \\ \mathrm{e}^{3t} \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{3t}(-2t-3) \\ \mathrm{e}^{3t}(t+1) \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \mathrm{e}^{3t}(-2c_2 t - 2c_1 - 3c_2) \\ \mathrm{e}^{3t}(c_2 t + c_1 + c_2) \end{bmatrix}
$$

The following is the phase plot of the system.

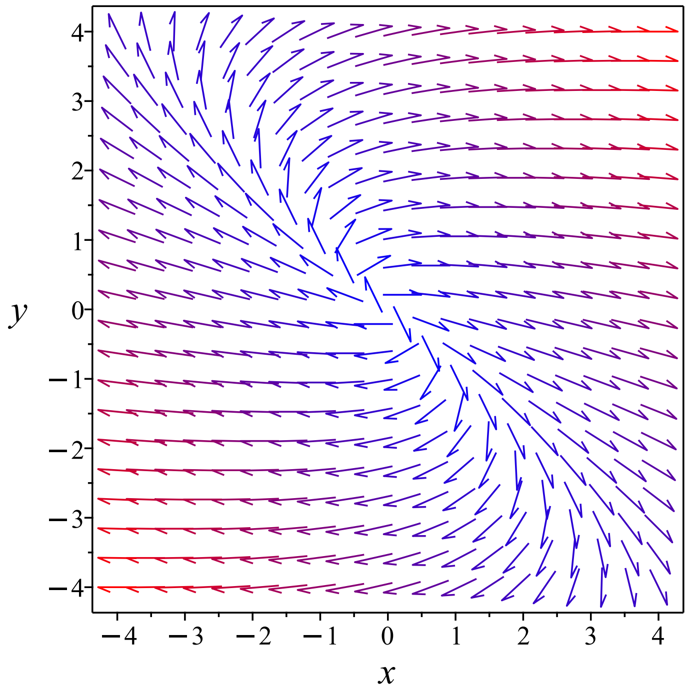

Figure 495: Phase plot

28.3.3 Maple step by step solution

Let's solve

$[x'(t) = 5x(t) + 4y(t), y'(t) = -x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 5 & 4 \\ -1 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[3, \begin{bmatrix} -2 \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

  $$\left[3, \begin{bmatrix} -2 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 3

  $$\overrightarrow{x}_1(t) = e^{3t} \cdot \begin{bmatrix} -2 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 3$ is the eigenvalue, and

  $\overrightarrow{x}_2(t) = e^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right)$

- Note that the t multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\overrightarrow{x}_2(t)$ into the homogeneous system

  $\lambda e^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda t}\overrightarrow{v} = \left(e^{\lambda t} A\right) \cdot \left(t\overrightarrow{v} + \overrightarrow{p}\right)$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

  $\lambda e^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda t}\overrightarrow{v} = e^{\lambda t}\left(\lambda t\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$

- Simplify equation

  $\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Make use of the identity matrix I

  $(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{x}_2(t)$ to be a solution to the homogeneous system

  $(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue 3

$$\left(\left[\begin{array}{cc} 5 & 4 \\ -1 & 1 \end{array}\right]-3\cdot\left[\begin{array}{cc} 1 & 0 \\ 0 & 1 \end{array}\right]\right)\cdot\overrightarrow{p}=\left[\begin{array}{c} -2 \\ 1 \end{array}\right]$$

- Choice of $\overrightarrow{p}$

$$\overrightarrow{p}=\left[\begin{array}{c} -1 \\ 0 \end{array}\right]$$

- Second solution from eigenvalue 3

$$\overrightarrow{x}_2(t)=\mathrm{e}^{3t}\cdot\left(t\cdot\left[\begin{array}{c} -2 \\ 1 \end{array}\right]+\left[\begin{array}{c} -1 \\ 0 \end{array}\right]\right)$$

- General solution to the system of ODEs

$$\overrightarrow{x}=c_1\overrightarrow{x}_1(t)+c_2\overrightarrow{x}_2(t)$$

- Substitute solutions into the general solution

$$\overrightarrow{x}=c_1\mathrm{e}^{3t}\cdot\left[\begin{array}{c} -2 \\ 1 \end{array}\right]+\mathrm{e}^{3t}c_2\cdot\left(t\cdot\left[\begin{array}{c} -2 \\ 1 \end{array}\right]+\left[\begin{array}{c} -1 \\ 0 \end{array}\right]\right)$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right]=\left[\begin{array}{c} \mathrm{e}^{3t}(-2tc_2-2c_1-c_2) \\ \mathrm{e}^{3t}(tc_2+c_1) \end{array}\right]$$

- Solution to the system of ODEs

$$\{x(t)=\mathrm{e}^{3t}(-2tc_2-2c_1-c_2)\,, y(t)=\mathrm{e}^{3t}(tc_2+c_1)\}$$

✓ Solution by Maple

Problem number: 1(d).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 4x(t) - 3y(t) \\
y'(t) &= 8x(t) - 6y(t)
\end{aligned}
$$

28.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} -2\,\mathrm{e}^{-2t} + 3 & -\frac{3}{2} + \frac{3\,\mathrm{e}^{-2t}}{2} \\ 4 - 4\,\mathrm{e}^{-2t} & 3\,\mathrm{e}^{-2t} - 2 \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} -2\,\mathrm{e}^{-2t}+3 & -\frac{3}{2}+\frac{3\,\mathrm{e}^{-2t}}{2} \\ 4-4\,\mathrm{e}^{-2t} & 3\,\mathrm{e}^{-2t}-2 \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(-2\,\mathrm{e}^{-2t}+3\right)c_1 + \left(-\frac{3}{2}+\frac{3\,\mathrm{e}^{-2t}}{2}\right)c_2 \\ \left(4-4\,\mathrm{e}^{-2t}\right)c_1 + \left(3\,\mathrm{e}^{-2t}-2\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(-4c_1+3c_2)\mathrm{e}^{-2t}}{2} + 3c_1 - \frac{3c_2}{2} \\ \left(-4c_1+3c_2\right)\mathrm{e}^{-2t} + 4c_1 - 2c_2 \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 4-\lambda & -3 \\ 8 & -6-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 2\lambda = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -2$$
$$\lambda_2 = 0$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
0	1	real eigenvalue
-2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} - (-2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 6 & -3 \\ 8 & -4 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 6 & -3 & 0 \\ 8 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{4R_1}{3} \Longrightarrow \left[\begin{array}{cc|c} 6 & -3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 6 & -3 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 0$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} - (0) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & -3 & 0 \\ 8 & -6 & 0 \end{array}\right]$$

$$R_2 = R_2 - 2R_1 \Longrightarrow \left[\begin{array}{cc|c} 4 & -3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & -3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{3t}{4}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{3t}{4} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{3t}{4} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{3t}{4} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{3t}{4} \\ t \end{bmatrix} = \begin{bmatrix} 3 \\ 4 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
-2	1	1	No	$\begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$
0	1	1	No	$\begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{-2t} \\ &= \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} e^{-2t} \end{aligned}$$

Since eigenvalue 0 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_2(t) &= \vec{v}_2 e^{0} \\ &= \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix} e^{0} \end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{\mathrm{e}^{-2t}}{2} \\ \mathrm{e}^{-2t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 \mathrm{e}^{-2t}}{2} + \frac{3c_2}{4} \\ c_1 \mathrm{e}^{-2t} + c_2 \end{bmatrix}$$

The following is the phase plot of the system.

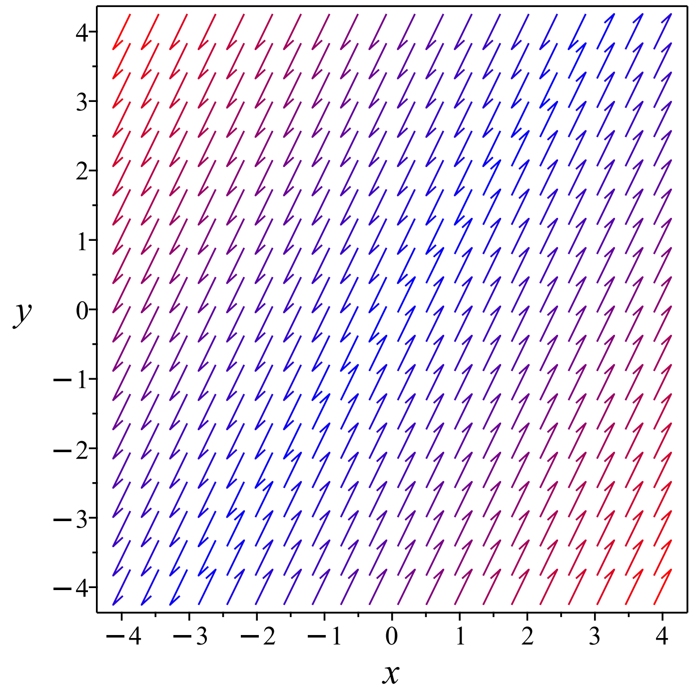

Figure 496: Phase plot

28.4.3 Maple step by step solution

Let's solve

$[x'(t) = 4x(t) - 3y(t), y'(t) = 8x(t) - 6y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 4 & -3 \\ 8 & -6 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-2, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[0, \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-2, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = \mathrm{e}^{-2t} \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[0, \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_2 = \begin{bmatrix} \frac{3}{4} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2$$

- Substitute solutions into the general solution

$$\overrightarrow{x} = c_1 \mathrm{e}^{-2t} \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} + \begin{bmatrix} \frac{3c_2}{4} \\ c_2 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 \mathrm{e}^{-2t}}{2} + \frac{3c_2}{4} \\ c_1 \mathrm{e}^{-2t} + c_2 \end{bmatrix}$$

- Solution to the system of ODEs
  $\left\{x(t) = \frac{c_1 \mathrm{e}^{-2t}}{2} + \frac{3c_2}{4}, y(t) = c_1 \mathrm{e}^{-2t} + c_2\right\}$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 2x(t)$$
$$y'(t) = 3y(t)$$

28.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \mathrm{e}^{2t} & 0 \\ 0 & \mathrm{e}^{3t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{2t} & 0 \\ 0 & e^{3t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^{2t}c_1 \\ e^{3t}c_2 \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} 2-\lambda & 0 \\ 0 & 3-\lambda \end{bmatrix}\right) = 0
$$

Since the matrix A is triangular matrix, then the determinant is the product of the elements along the diagonal. Therefore the above becomes

$$
(2-\lambda)(3-\lambda) = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
2	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} - (2)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 0 & 0 \\ 0 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 0 & 0 & 0 \\ 0 & 1 & 0 \end{array}\right]$$

Since the current pivot $A(1,2)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{cc|c} 0 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 0 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_1\}$ and the leading variables are $\{v_2\}$. Let $v_1 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_2 = 0\}$

Hence the solution is

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = t \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ 0 \end{bmatrix} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 0 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 0 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 0\}$

Hence the solution is

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = t \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 0 \\ t \end{bmatrix} = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} 1 \\ 0 \end{bmatrix}$
3	1	1	No	$\begin{bmatrix} 0 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned} \vec{x}_1(t) &= \vec{v}_1 e^{2t} \\ &= \begin{bmatrix} 1 \\ 0 \end{bmatrix} e^{2t} \end{aligned}$$

Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{3t}$$
$$= \begin{bmatrix} 0 \\ 1 \end{bmatrix} e^{3t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} e^{2t} \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} 0 \\ e^{3t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{2t} \\ c_2 e^{3t} \end{bmatrix}$$

The following is the phase plot of the system.

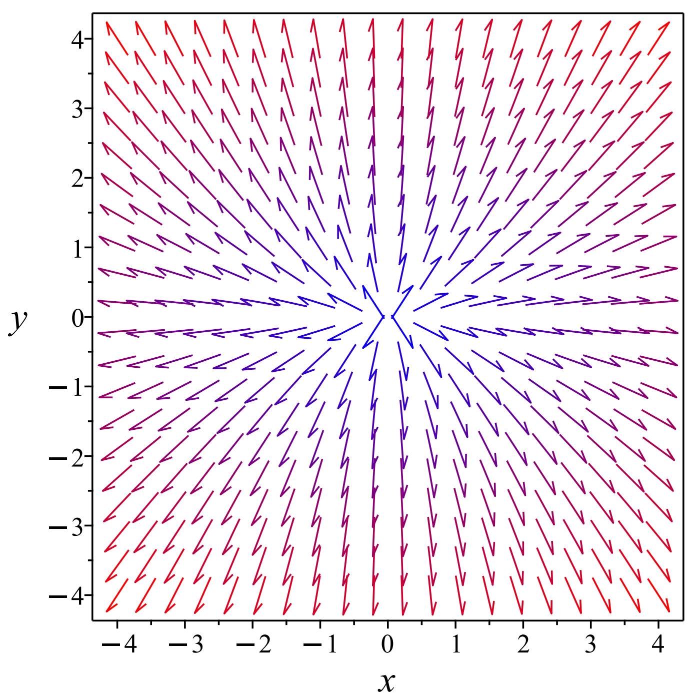

Figure 497: Phase plot

28.5.3 Maple step by step solution

Let's solve

$[x'(t) = 2x(t), y'(t) = 3y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 2 & 0 \\ 0 & 3 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[2, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right], \left[3, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{2t} \cdot \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} 0 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{3t} \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^{2t} \cdot \begin{bmatrix} 1 \\ 0 \end{bmatrix} + e^{3t} c_2 \cdot \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} c_1 e^{2t} \\ e^{3t} c_2 \end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = c_1 e^{2t}, y(t) = e^{3t} c_2\}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -4x(t) - y(t)$$
$$y'(t) = x(t) - 2y(t)$$

28.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{-3t}(-t+1) & -t\,e^{-3t} \\ t\,e^{-3t} & e^{-3t}(t+1) \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{-3t}(-t+1) & -t\,e^{-3t} \\ t\,e^{-3t} & e^{-3t}(t+1) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^{-3t}(-t+1)\,c_1 - t\,e^{-3t}c_2 \\ t\,e^{-3t}c_1 + e^{-3t}(t+1)\,c_2 \end{bmatrix} \\
&= \begin{bmatrix} -e^{-3t}(c_1(t-1)+c_2t) \\ e^{-3t}(tc_1+c_2t+c_2) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -4-\lambda & -1 \\ 1 & -2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 6\lambda + 9 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} - (-3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -1 & -1 \\ 1 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & -1 & 0 \\ 1 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & -1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & -1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-3	2	1	Yes	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue -3 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

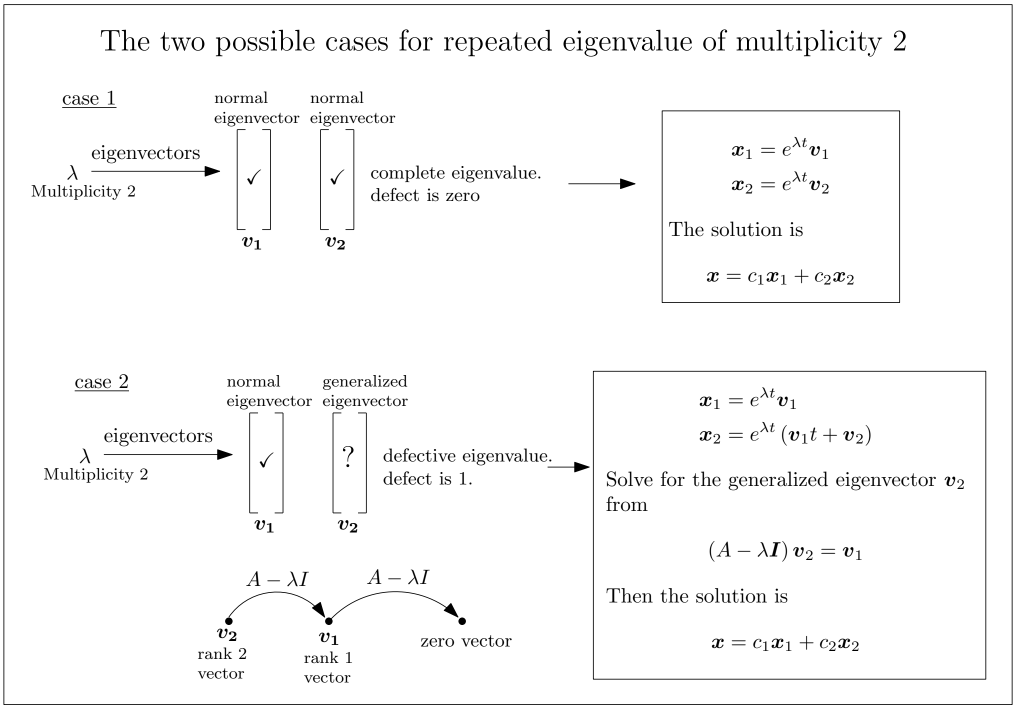

Figure 498: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\, \vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} - (-3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$
$$\begin{bmatrix} -1 & -1 \\ 1 & 1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} 0 \\ 1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue -3. Therefore the two basis solution associated with this eigenvalue are

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{\lambda t}\\ &= \begin{bmatrix}-1\\ 1\end{bmatrix} \mathrm{e}^{-3t}\\ &= \begin{bmatrix}-\mathrm{e}^{-3t}\\ \mathrm{e}^{-3t}\end{bmatrix}\end{aligned}$$

And

$$\begin{aligned}\vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t}\\ &= \left(\begin{bmatrix}-1\\ 1\end{bmatrix} t + \begin{bmatrix}0\\ 1\end{bmatrix}\right) \mathrm{e}^{-3t}\\ &= \begin{bmatrix}-t\,\mathrm{e}^{-3t}\\ \mathrm{e}^{-3t}(t+1)\end{bmatrix}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix}x(t)\\ y(t)\end{bmatrix} = c_1 \begin{bmatrix}-\mathrm{e}^{-3t}\\ \mathrm{e}^{-3t}\end{bmatrix} + c_2 \begin{bmatrix}-t\,\mathrm{e}^{-3t}\\ \mathrm{e}^{-3t}(t+1)\end{bmatrix}$$

Which becomes

$$\begin{bmatrix}x(t)\\ y(t)\end{bmatrix} = \begin{bmatrix}\mathrm{e}^{-3t}(-t c_2 - c_1)\\ \mathrm{e}^{-3t}(t c_2 + c_1 + c_2)\end{bmatrix}$$

The following is the phase plot of the system.

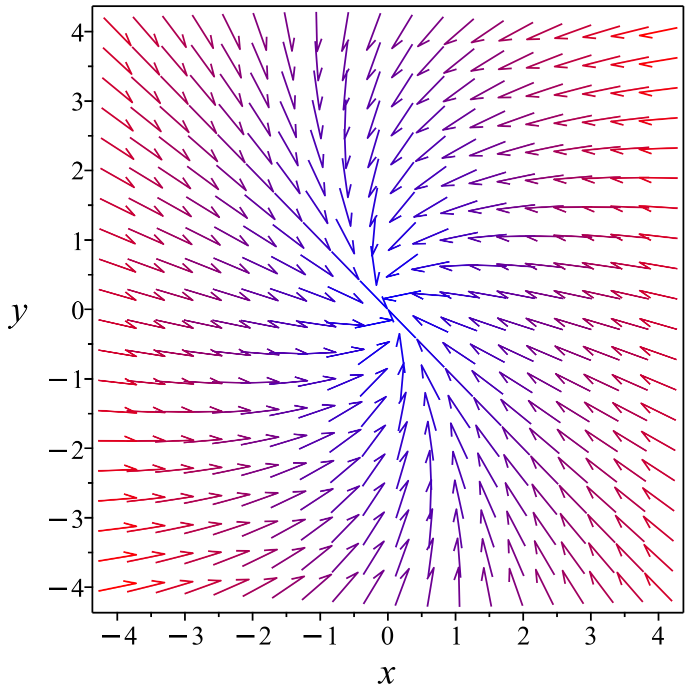

Figure 499: Phase plot

28.6.3 Maple step by step solution

Let's solve

$[x'(t) = -4x(t) - y(t), y'(t) = x(t) - 2y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[-3, \begin{bmatrix} 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

$$\left[-3, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue -3

$$\vec{x}_1(t) = \mathrm{e}^{-3t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\vec{p}$ is to be solved for, $\lambda = -3$ is the eigenvalue, an

$$\vec{x}_2(t) = \mathrm{e}^{\lambda t}\left(t\vec{v} + \vec{p}\right)$$

- Note that the t multiplying $\vec{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\vec{x}_2(t)$ into the homogeneous system

$$\lambda \mathrm{e}^{\lambda t}\left(t\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda t}\vec{v} = \left(\mathrm{e}^{\lambda t} A\right) \cdot \left(t\vec{v} + \vec{p}\right)$$

- Use the fact that $\vec{v}$ is an eigenvector of A

$$\lambda \mathrm{e}^{\lambda t}\left(t\vec{v} + \vec{p}\right) + \mathrm{e}^{\lambda t}\vec{v} = \mathrm{e}^{\lambda t}\left(\lambda t\vec{v} + A \cdot \vec{p}\right)$$

- Simplify equation

$$\lambda\vec{p} + \vec{v} = A \cdot \vec{p}$$

- Make use of the identity matrix I

$$(\lambda \cdot I) \cdot \vec{p} + \vec{v} = A \cdot \vec{p}$$

- Condition $\vec{p}$ must meet for $\vec{x}_2(t)$ to be a solution to the homogeneous system

$$(A - \lambda \cdot I) \cdot \vec{p} = \vec{v}$$

- Choose $\overrightarrow{p}$ to use in the second solution to the homogeneous system from eigenvalue -3

$$\left(\begin{bmatrix} -4 & -1 \\ 1 & -2 \end{bmatrix} - (-3) \cdot \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) \cdot \overrightarrow{p} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Choice of $\overrightarrow{p}$

$$\overrightarrow{p} = \begin{bmatrix} 1 \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue -3

$$\overrightarrow{x}_2(t) = e^{-3t} \cdot \left(t \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right)$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1 \overrightarrow{x}_1(t) + c_2 \overrightarrow{x}_2(t)$$

- Substitute solutions into the general solution

$$\overrightarrow{x} = c_1 e^{-3t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + c_2 e^{-3t} \cdot \left(t \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} 1 \\ 0 \end{bmatrix}\right)$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -e^{-3t}((t-1)\, c_2 + c_1) \\ e^{-3t}(tc_2 + c_1) \end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = -e^{-3t}((t-1)\, c_2 + c_1)\, , y(t) = e^{-3t}(tc_2 + c_1)\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 7x(t) + 6y(t) \\
y'(t) &= 2x(t) + 6y(t)
\end{aligned}
$$

28.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{3\,e^{3t}}{7} + \frac{4\,e^{10t}}{7} & \frac{6\,e^{10t}}{7} - \frac{6\,e^{3t}}{7} \\ \frac{2\,e^{10t}}{7} - \frac{2\,e^{3t}}{7} & \frac{4\,e^{3t}}{7} + \frac{3\,e^{10t}}{7} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{3\,e^{3t}}{7}+\frac{4\,e^{10t}}{7} & \frac{6\,e^{10t}}{7}-\frac{6\,e^{3t}}{7} \\ \frac{2\,e^{10t}}{7}-\frac{2\,e^{3t}}{7} & \frac{4\,e^{3t}}{7}+\frac{3\,e^{10t}}{7} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{3\,e^{3t}}{7}+\frac{4\,e^{10t}}{7}\right)c_1+\left(\frac{6\,e^{10t}}{7}-\frac{6\,e^{3t}}{7}\right)c_2 \\ \left(\frac{2\,e^{10t}}{7}-\frac{2\,e^{3t}}{7}\right)c_1+\left(\frac{4\,e^{3t}}{7}+\frac{3\,e^{10t}}{7}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(4c_1+6c_2)e^{10t}}{7}+\frac{3\,e^{3t}(-2c_2+c_1)}{7} \\ \frac{(2c_1+3c_2)e^{10t}}{7}-\frac{2\,e^{3t}(-2c_2+c_1)}{7} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det\left(A-\lambda I\right)=0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} 7-\lambda & 6 \\ 2 & 6-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$\lambda^2 - 13\lambda + 30 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3$$
$$\lambda_2 = 10$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
3	1	real eigenvalue
10	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} - (3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & 6 \\ 2 & 3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & 6 & 0 \\ 2 & 3 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 4 & 6 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 6 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{3t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{3t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -3 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 10$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} - (10) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3 & 6 \\ 2 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3 & 6 & 0 \\ 2 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{2R_1}{3} \Longrightarrow \left[\begin{array}{cc|c} -3 & 6 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3 & 6 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = t \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
3	1	1	No	$\begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$
10	1	1	No	$\begin{bmatrix} 2 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{3t} \\
&= \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix} e^{3t}
\end{aligned}
$$

Since eigenvalue 10 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{10t} \\
&= \begin{bmatrix} 2 \\ 1 \end{bmatrix} e^{10t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{3\,\mathrm{e}^{3t}}{2} \\ \mathrm{e}^{3t} \end{bmatrix} + c_2 \begin{bmatrix} 2\,\mathrm{e}^{10t} \\ \mathrm{e}^{10t} \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{3c_1\mathrm{e}^{3t}}{2} + 2c_2\mathrm{e}^{10t} \\ c_1\mathrm{e}^{3t} + c_2\mathrm{e}^{10t} \end{bmatrix}
$$

The following is the phase plot of the system.

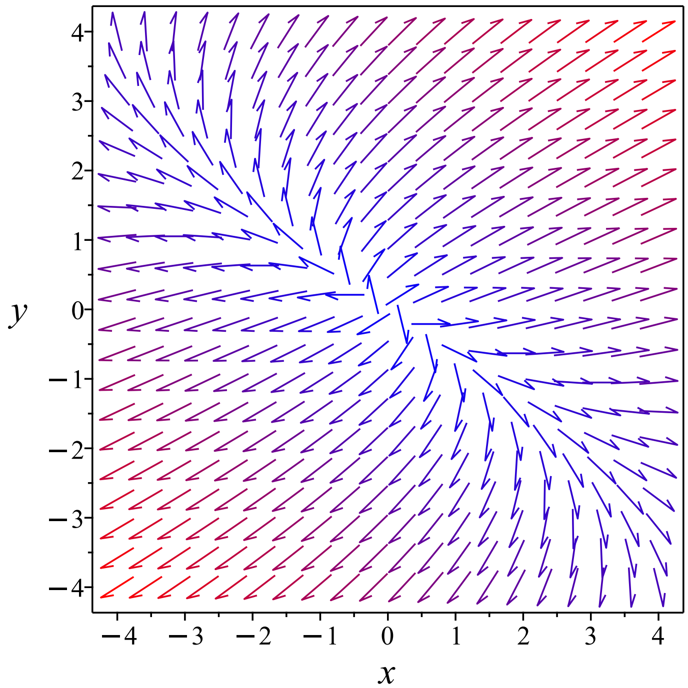

Figure 500: Phase plot

28.7.3 Maple step by step solution

Let's solve

$[x'(t) = 7x(t) + 6y(t), y'(t) = 2x(t) + 6y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 7 & 6 \\ 2 & 6 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[3, \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}\right], \left[10, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_1 = \mathrm{e}^{3t} \cdot \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[10, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\overrightarrow{x}_2 = \mathrm{e}^{10t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2$$

- Substitute solutions into the general solution

$$\overrightarrow{x} = c_1 \mathrm{e}^{3t} \cdot \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{10t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{3c_1 e^{3t}}{2} + 2c_2 e^{10t} \\ c_1 e^{3t} + c_2 e^{10t} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{3c_1 e^{3t}}{2} + 2c_2 e^{10t}, y(t) = c_1 e^{3t} + c_2 e^{10t}\right\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = x(t) - 2y(t)$$
$$y'(t) = 4x(t) + 5y(t)$$

28.8.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{3t}\cos(2t) - e^{3t}\sin(2t) & -e^{3t}\sin(2t) \\ 2\,e^{3t}\sin(2t) & e^{3t}\cos(2t) + e^{3t}\sin(2t) \end{bmatrix}$$
$$= \begin{bmatrix} e^{3t}(\cos(2t) - \sin(2t)) & -e^{3t}\sin(2t) \\ 2\,e^{3t}\sin(2t) & e^{3t}(\cos(2t) + \sin(2t)) \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^{3t}(\cos(2t) - \sin(2t)) & -e^{3t}\sin(2t) \\ 2e^{3t}\sin(2t) & e^{3t}(\cos(2t) + \sin(2t)) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^{3t}(\cos(2t) - \sin(2t))\, c_1 - e^{3t}\sin(2t)\, c_2 \\ 2e^{3t}\sin(2t)\, c_1 + e^{3t}(\cos(2t) + \sin(2t))\, c_2 \end{bmatrix} \\
&= \begin{bmatrix} ((-c_1 - c_2)\sin(2t) + c_1\cos(2t))\, e^{3t} \\ e^{3t}(2c_1 + c_2)\sin(2t) + e^{3t}\cos(2t)\, c_2 \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

28.8.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & -2 \\ 4 & 5-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 6\lambda + 13 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 3 + 2i$$
$$\lambda_2 = 3 - 2i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$3 - 2i$	1	complex eigenvalue
$3 + 2i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 3 - 2i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} - (3 - 2i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -2 + 2i & -2 \\ 4 & 2 + 2i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 + 2i & -2 & 0 \\ 4 & 2 + 2i & 0 \end{array}\right]$$

$$R_2 = R_2 + (1 + i)\, R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 + 2i & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 + 2i & -2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = \left(-\frac{1}{2} - \frac{i}{2}\right) t\}$

Hence the solution is

$$\begin{bmatrix} \left(-\frac{1}{2} - \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2} - \frac{i}{2}\right) t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(-\frac{1}{2} - \frac{I}{2}\right) t \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} - \frac{i}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(-\frac{1}{2} - \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} - \frac{i}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(-\frac{1}{2} - \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -1 - i \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3 + 2i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} - (3 + 2i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 - 2i & -2 \\ 4 & 2 - 2i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 - 2i & -2 & 0 \\ 4 & 2 - 2i & 0 \end{array}\right]$$

$$R_2 = R_2 + (1 - i) R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 - 2i & -2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2-2i & -2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \left(-\frac{1}{2} + \frac{i}{2}\right) t\right\}$

Hence the solution is

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} \left(-\frac{1}{2} + \frac{i}{2}\right) t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} + \frac{i}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} + \frac{i}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \left(-\frac{1}{2} + \frac{I}{2}\right) t \\ t \end{bmatrix} = \begin{bmatrix} -1+i \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
$3+2i$	1	1	No	$\left[\begin{array}{c} -\frac{1}{2}+\frac{i}{2} \\ 1 \end{array}\right]$
$3-2i$	1	1	No	$\left[\begin{array}{c} -\frac{1}{2}-\frac{i}{2} \\ 1 \end{array}\right]$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = c_1\left[\begin{array}{c} \left(-\frac{1}{2}+\frac{i}{2}\right) \mathrm{e}^{(3+2i)t} \\ \mathrm{e}^{(3+2i)t} \end{array}\right] + c_2\left[\begin{array}{c} \left(-\frac{1}{2}-\frac{i}{2}\right) \mathrm{e}^{(3-2i)t} \\ \mathrm{e}^{(3-2i)t} \end{array}\right]$$

Which becomes

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \left(-\frac{1}{2}+\frac{i}{2}\right) c_1\mathrm{e}^{(3+2i)t} + \left(-\frac{1}{2}-\frac{i}{2}\right) c_2\mathrm{e}^{(3-2i)t} \\ c_1\mathrm{e}^{(3+2i)t} + c_2\mathrm{e}^{(3-2i)t} \end{array}\right]$$

The following is the phase plot of the system.

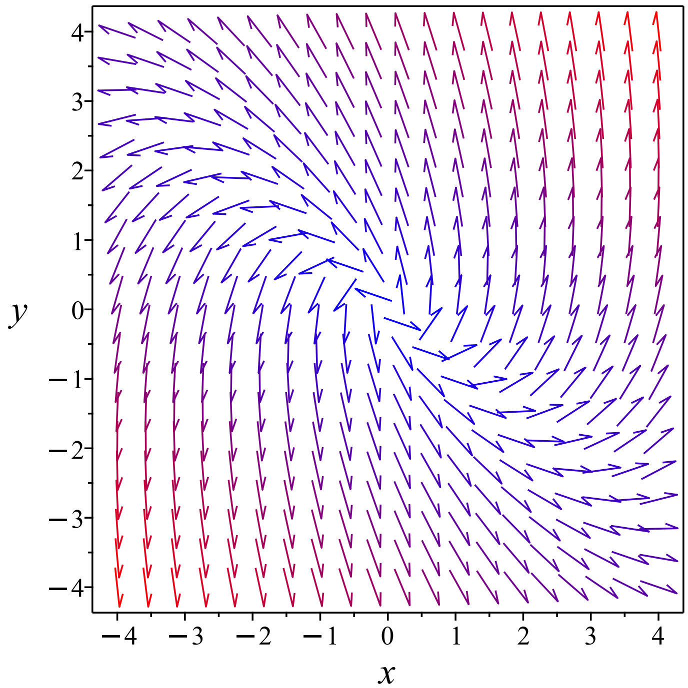

Figure 501: Phase plot

28.8.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) - 2y(t), y'(t) = 4x(t) + 5y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & -2 \\ 4 & 5 \end{bmatrix}$$

- Rewrite the system as

$$\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[3-2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right], \left[3+2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{2}+\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[3-2\,\mathrm{I}, \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{(3-2\,\mathrm{I})t} \cdot \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{3t} \cdot \left(\cos(2t) - \mathrm{I}\sin(2t)\right) \cdot \begin{bmatrix} -\frac{1}{2}-\frac{\mathrm{I}}{2} \\ 1 \end{bmatrix}$$

- Simplify expression

$$\mathrm{e}^{3t} \cdot \begin{bmatrix} \left(-\frac{1}{2}-\frac{\mathrm{I}}{2}\right)\left(\cos(2t) - \mathrm{I}\sin(2t)\right) \\ \cos(2t) - \mathrm{I}\sin(2t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\overrightarrow{x}_1(t) = \mathrm{e}^{3t} \cdot \begin{bmatrix} -\frac{\cos(2t)}{2} - \frac{\sin(2t)}{2} \\ \cos(2t) \end{bmatrix}, \overrightarrow{x}_2(t) = \mathrm{e}^{3t} \cdot \begin{bmatrix} \frac{\sin(2t)}{2} - \frac{\cos(2t)}{2} \\ -\sin(2t) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\overrightarrow{x} = c_1\overrightarrow{x}_1(t) + c_2\overrightarrow{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^{3t} \cdot \begin{bmatrix} -\frac{\cos(2t)}{2} - \frac{\sin(2t)}{2} \\ \cos(2t) \end{bmatrix} + e^{3t} c_2 \cdot \begin{bmatrix} \frac{\sin(2t)}{2} - \frac{\cos(2t)}{2} \\ -\sin(2t) \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{((c_1+c_2)\cos(2t)+\sin(2t)(c_1-c_2))e^{3t}}{2} \\ e^{3t}(c_1 \cos(2t) - c_2 \sin(2t)) \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{((c_1+c_2)\cos(2t)+\sin(2t)(c_1-c_2))e^{3t}}{2}, y(t) = e^{3t}(c_1 \cos(2t) - c_2 \sin(2t))\right\}$$

Problem number: 5(b).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + y(t) - 5t + 2\\
y'(t) &= 4x(t) - 2y(t) - 8t - 8
\end{aligned}
$$

28.9.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{(4\,e^{5t}+1)e^{-3t}}{5} & \frac{(e^{5t}-1)e^{-3t}}{5} \\ \frac{4(e^{5t}-1)e^{-3t}}{5} & \frac{(e^{5t}+4)e^{-3t}}{5} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{(4\,e^{5t}+1)e^{-3t}}{5} & \frac{(e^{5t}-1)e^{-3t}}{5} \\ \frac{4(e^{5t}-1)e^{-3t}}{5} & \frac{(e^{5t}+4)e^{-3t}}{5} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(4\,e^{5t}+1)e^{-3t}c_1}{5} + \frac{(e^{5t}-1)e^{-3t}c_2}{5} \\ \frac{4(e^{5t}-1)e^{-3t}c_1}{5} + \frac{(e^{5t}+4)e^{-3t}c_2}{5} \end{bmatrix} \\
&= \begin{bmatrix} \frac{e^{-3t}((4c_1+c_2)e^{5t}-c_2+c_1)}{5} \\ \frac{4((c_1+\frac{c_2}{4})e^{5t}+c_2-c_1)e^{-3t}}{5} \end{bmatrix}
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$\begin{aligned}
e^{-At} &= (e^{At})^{-1} \\
&= \begin{bmatrix} \frac{(e^{5t}+4)e^{-2t}}{5} & -\frac{(e^{5t}-1)e^{-2t}}{5} \\ -\frac{4(e^{5t}-1)e^{-2t}}{5} & \frac{(4\,e^{5t}+1)e^{-2t}}{5} \end{bmatrix}
\end{aligned}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{(4\,e^{5t}+1)e^{-3t}}{5} & \frac{(e^{5t}-1)e^{-3t}}{5} \\ \frac{4(e^{5t}-1)e^{-3t}}{5} & \frac{(e^{5t}+4)e^{-3t}}{5} \end{bmatrix} \int \begin{bmatrix} \frac{(e^{5t}+4)e^{-2t}}{5} & -\frac{(e^{5t}-1)e^{-2t}}{5} \\ -\frac{4(e^{5t}-1)e^{-2t}}{5} & \frac{(4\,e^{5t}+1)e^{-2t}}{5} \end{bmatrix} \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{(4\,e^{5t}+1)e^{-3t}}{5} & \frac{(e^{5t}-1)e^{-3t}}{5} \\ \frac{4(e^{5t}-1)e^{-3t}}{5} & \frac{(e^{5t}+4)e^{-3t}}{5} \end{bmatrix} \begin{bmatrix} \frac{((t+3)e^{5t}+14t+7)e^{-2t}}{5} \\ -\frac{(4\,e^{5t}t+12\,e^{5t}-14t-7)e^{-2t}}{5} \end{bmatrix} \\
&= \begin{bmatrix} 2+3t \\ 2t-1 \end{bmatrix}
\end{aligned}$$

Hence the complete solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$
$$= \begin{bmatrix} \frac{(4\,e^{5t}c_1+e^{5t}c_2+15t\,e^{3t}+10\,e^{3t}+c_1-c_2)e^{-3t}}{5} \\ \frac{(4\,e^{5t}c_1+e^{5t}c_2+10t\,e^{3t}-5\,e^{3t}-4c_1+4c_2)e^{-3t}}{5} \end{bmatrix}$$

28.9.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 \\ 4 & -2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + \lambda - 6 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -3$$
$$\lambda_2 = 2$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-3	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} - (-3)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 4 & 1 \\ 4 & 1 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 4 & 1 & 0 \\ 4 & 1 & 0 \end{array}\right]$$

$$R_2 = R_2 - R_1 \Longrightarrow \left[\begin{array}{cc|c} 4 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{4}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{4} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 4 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -1 & 1 \\ 4 & -4 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -1 & 1 & 0 \\ 4 & -4 & 0 \end{array}\right]$$

$$R_2 = R_2 + 4R_1 \Longrightarrow \left[\begin{array}{cc|c} -1 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -1 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = t\}$

Hence the solution is

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} t \\ t \end{bmatrix} = t \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} t \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-3	1	1	No	$\begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$
2	1	1	No	$\begin{bmatrix} 1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -3 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{-3t}$$
$$= \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix} e^{-3t}$$

Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{2t}$$
$$= \begin{bmatrix} 1 \\ 1 \end{bmatrix} e^{2t}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{e^{-3t}}{4} \\ e^{-3t} \end{bmatrix} + c_2 \begin{bmatrix} e^{2t} \\ e^{2t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} -\frac{e^{-3t}}{4} & e^{2t} \\ e^{-3t} & e^{2t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t) \, dt$$

But

$$\Phi^{-1} = \begin{bmatrix} -\frac{4 e^{3t}}{5} & \frac{4 e^{3t}}{5} \\ \frac{4 e^{-2t}}{5} & \frac{e^{-2t}}{5} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} -\frac{e^{-3t}}{4} & e^{2t} \\ e^{-3t} & e^{2t} \end{bmatrix} \int \begin{bmatrix} -\frac{4\,e^{3t}}{5} & \frac{4\,e^{3t}}{5} \\ \frac{4\,e^{-2t}}{5} & \frac{e^{-2t}}{5} \end{bmatrix} \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix} dt$$

$$= \begin{bmatrix} -\frac{e^{-3t}}{4} & e^{2t} \\ e^{-3t} & e^{2t} \end{bmatrix} \int \begin{bmatrix} 4\,e^{3t}\left(-2-\frac{3t}{5}\right) \\ -\frac{28t\,e^{-2t}}{5} \end{bmatrix} dt$$

$$= \begin{bmatrix} -\frac{e^{-3t}}{4} & e^{2t} \\ e^{-3t} & e^{2t} \end{bmatrix} \begin{bmatrix} -\frac{4\,e^{3t}(t+3)}{5} \\ \frac{7(2t+1)e^{-2t}}{5} \end{bmatrix}$$

$$= \begin{bmatrix} 2+3t \\ 2t-1 \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{-3t}}{4} \\ c_1 e^{-3t} \end{bmatrix} + \begin{bmatrix} c_2 e^{2t} \\ c_2 e^{2t} \end{bmatrix} + \begin{bmatrix} 2+3t \\ 2t-1 \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(4c_2 e^{5t}+12t\,e^{3t}+8\,e^{3t}-c_1)e^{-3t}}{4} \\ (c_2 e^{5t}+2t\,e^{3t}-e^{3t}+c_1)\,e^{-3t} \end{bmatrix}$$

28.9.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + y(t) - 5t + 2, y'(t) = 4x(t) - 2y(t) - 8t - 8]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} -5t+2 \\ -8t-8 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 1 \\ 4 & -2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-3, \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-3, \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = e^{-3t} \cdot \begin{bmatrix} -\frac{1}{4} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[2, \begin{bmatrix} 1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = e^{2t} \cdot \begin{bmatrix} 1 \\ 1 \end{bmatrix}$$

- General solution of the system of ODEs can be written in terms of the particular solution $\overrightarrow{x}_p($

  $\overrightarrow{x}(t) = c_1\overrightarrow{x}_1 + c_2\overrightarrow{x}_2 + \overrightarrow{x}_p(t)$

□ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

  $\phi(t) = \begin{bmatrix} -\frac{e^{-3t}}{4} & e^{2t} \\ e^{-3t} & e^{2t} \end{bmatrix}$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

  $\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$

- Substitute the value of $\phi(t)$ and $\phi(0)$

  $\Phi(t) = \begin{bmatrix} -\frac{e^{-3t}}{4} & e^{2t} \\ e^{-3t} & e^{2t} \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{1}{4} & 1 \\ 1 & 1 \end{bmatrix}}$

- Evaluate and simplify to get the fundamental matrix

  $\Phi(t) = \begin{bmatrix} \frac{(4\,e^{5t}+1)e^{-3t}}{5} & \frac{(e^{5t}-1)e^{-3t}}{5} \\ \frac{4(e^{5t}-1)e^{-3t}}{5} & \frac{(e^{5t}+4)e^{-3t}}{5} \end{bmatrix}$

□ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t) = \Phi(t) \cdot \overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}_p'(t) = \Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \Phi(t) \cdot \overrightarrow{v}'(t) = A \cdot \Phi(t) \cdot \overrightarrow{v}(t) + \overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t) \cdot \overrightarrow{v}'(t) = \overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

$\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$

- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$

- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \begin{bmatrix} \frac{(-7\,e^{5t}+15t\,e^{3t}+10\,e^{3t}-3)e^{-3t}}{5} \\ \frac{(-7\,e^{5t}+10t\,e^{3t}-5\,e^{3t}+12)e^{-3t}}{5} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \begin{bmatrix} \frac{(-7\,e^{5t}+15t\,e^{3t}+10\,e^{3t}-3)e^{-3t}}{5} \\ \frac{(-7\,e^{5t}+10t\,e^{3t}-5\,e^{3t}+12)e^{-3t}}{5} \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(20c_2 e^{5t}-28\,e^{5t}+60t\,e^{3t}+40\,e^{3t}-5c_1-12)e^{-3t}}{20} \\ \frac{(5c_2 e^{5t}-7\,e^{5t}+10t\,e^{3t}-5\,e^{3t}+5c_1+12)e^{-3t}}{5} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{(20c_2 e^{5t}-28\,e^{5t}+60t\,e^{3t}+40\,e^{3t}-5c_1-12)e^{-3t}}{20}, y(t) = \frac{(5c_2 e^{5t}-7\,e^{5t}+10t\,e^{3t}-5\,e^{3t}+5c_1+12)e^{-3t}}{5}\right\}$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 3x(t) - 4y(t)$$
$$y'(t) = 4x(t) - 7y(t)$$

29.1.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{(4\,e^{6t}-1)\,e^{-5t}}{3} & -\frac{2(e^{6t}-1)\,e^{-5t}}{3} \\ \frac{2(e^{6t}-1)\,e^{-5t}}{3} & -\frac{(e^{6t}-4)\,e^{-5t}}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{(4\,e^{6t}-1)\,e^{-5t}}{3} & -\frac{2(e^{6t}-1)\,e^{-5t}}{3} \\ \frac{2(e^{6t}-1)\,e^{-5t}}{3} & -\frac{(e^{6t}-4)\,e^{-5t}}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(4\,e^{6t}-1)\,e^{-5t}c_1}{3} - \frac{2(e^{6t}-1)\,e^{-5t}c_2}{3} \\ \frac{2(e^{6t}-1)\,e^{-5t}c_1}{3} - \frac{(e^{6t}-4)\,e^{-5t}c_2}{3} \end{bmatrix} \\
&= \begin{bmatrix} \frac{e^{-5t}(2(-c_2+2c_1)\,e^{6t}+2c_2-c_1)}{3} \\ \frac{2\,e^{-5t}((c_1-\frac{c_2}{2})\,e^{6t}+2c_2-c_1)}{3} \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.1.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & -4 \\ 4 & -7-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 4\lambda - 5 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = -5$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue
-5	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -5$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} - (-5)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 8 & -4 \\ 4 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 8 & -4 & 0 \\ 4 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} 8 & -4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 8 & -4 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 & -4 \\ 4 & -8 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & -4 & 0 \\ 4 & -8 & 0 \end{array}\right]$$

$$R_2 = R_2 - 2R_1 \Longrightarrow \left[\begin{array}{cc|c} 2 & -4 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & -4 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = 2t\}$

Hence the solution is

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = t \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} 2t \\ t \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	1	1	No	$\begin{bmatrix} 2 \\ 1 \end{bmatrix}$
-5	1	1	No	$\begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{t} \\
&= \begin{bmatrix} 2 \\ 1 \end{bmatrix} e^{t}
\end{aligned}
$$

Since eigenvalue -5 is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{-5t} \\
&= \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} e^{-5t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} 2\,\mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{\mathrm{e}^{-5t}}{2} \\ \mathrm{e}^{-5t} \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(4c_1 \mathrm{e}^{6t} + c_2)\mathrm{e}^{-5t}}{2} \\ (c_1 \mathrm{e}^{6t} + c_2)\,\mathrm{e}^{-5t} \end{bmatrix}
$$

The following is the phase plot of the system.

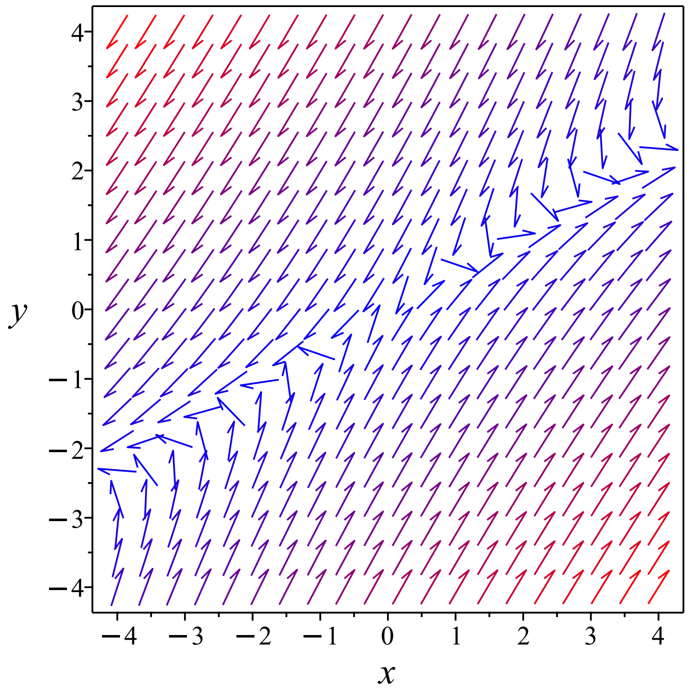

Figure 502: Phase plot

29.1.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t) - 4y(t), y'(t) = 4x(t) - 7y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & -4 \\ 4 & -7 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-5, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-5, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-5t} \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \begin{bmatrix} 2 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 \mathrm{e}^{-5t} \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{t} \cdot \begin{bmatrix} 2 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{(4c_2 e^{6t}+c_1)e^{-5t}}{2} \\ (c_2 e^{6t} + c_1)\, e^{-5t} \end{bmatrix}$$

- Solution to the system of ODEs
  $\left\{x(t) = \frac{(4c_2 e^{6t}+c_1)e^{-5t}}{2}, y(t) = (c_2 e^{6t} + c_1)\, e^{-5t}\right\}$

✓ Solution by Maple

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = x(t) + y(t)$$
$$y'(t) = 4x(t) + y(t)$$

29.2.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{e^{-t}}{2} + \frac{e^{3t}}{2} & \frac{e^{3t}}{4} - \frac{e^{-t}}{4} \\ e^{3t} - e^{-t} & \frac{e^{-t}}{2} + \frac{e^{3t}}{2} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{e^{-t}}{2}+\frac{e^{3t}}{2} & \frac{e^{3t}}{4}-\frac{e^{-t}}{4} \\ e^{3t}-e^{-t} & \frac{e^{-t}}{2}+\frac{e^{3t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{e^{-t}}{2}+\frac{e^{3t}}{2}\right)c_1+\left(\frac{e^{3t}}{4}-\frac{e^{-t}}{4}\right)c_2 \\ \left(e^{3t}-e^{-t}\right)c_1+\left(\frac{e^{-t}}{2}+\frac{e^{3t}}{2}\right)c_2 \end{bmatrix} \\
&= \begin{bmatrix} \frac{(-c_2+2c_1)e^{-t}}{4}+\frac{(c_1+\frac{c_2}{2})e^{3t}}{2} \\ \frac{(c_2-2c_1)e^{-t}}{2}+\left(c_1+\frac{c_2}{2}\right)e^{3t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.2.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A-\lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 \\ 4 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda - 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 1 \\ 4 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 1 & 0 \\ 4 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - 2R_1 \Longrightarrow \left[\begin{array}{cc|c} 2 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} - (3) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & 1 \\ 4 & -2 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & 1 & 0 \\ 4 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + 2R_1 \Longrightarrow \left[\begin{array}{cc|c} -2 & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = \frac{t}{2}\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 1 \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
-1	1	1	No	$\begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$
3	1	1	No	$\begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^{-t} \\ &= \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{3t} \\ &= \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix} e^{3t}\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{e^{-t}}{2} \\ e^{-t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{e^{3t}}{2} \\ e^{3t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{c_1 e^{-t}}{2} + \frac{c_2 e^{3t}}{2} \\ c_1 e^{-t} + c_2 e^{3t} \end{bmatrix}$$

The following is the phase plot of the system.

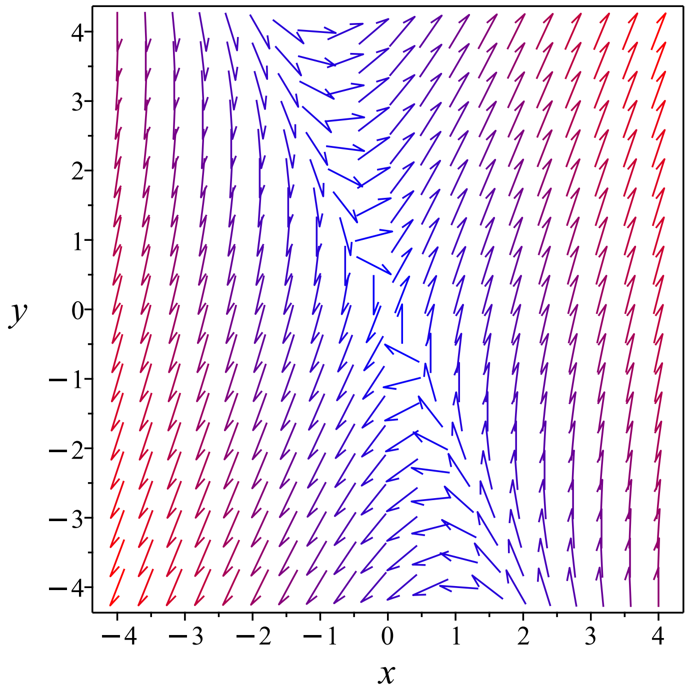

Figure 503: Phase plot

29.2.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + y(t), y'(t) = 4x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 1 \\ 4 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[3, \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{3t} \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$$

- Substitute solutions into the general solution

$$\vec{x} = \mathrm{e}^{-t} c_1 \cdot \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix} + \mathrm{e}^{3t} c_2 \cdot \begin{bmatrix} \frac{1}{2} \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{e^{-t}c_1}{2} + \frac{e^{3t}c_2}{2} \\ e^{-t}c_1 + e^{3t}c_2 \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{e^{-t}c_1}{2} + \frac{e^{3t}c_2}{2}, y(t) = e^{-t}c_1 + e^{3t}c_2\right\}$$

✓ Solution by Maple

Book: Differential Equations: Theory, Technique, and Practice by George Simmons, Steven Krantz. McGraw-Hill NY. 2007. 1st Edition.
Section: Chapter 10. Systems of First-Order Equations. Section A. Drill exercises. Page 400
Problem number: 2(c).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -3x(t) + \sqrt{2}\, y(t) \\
y'(t) &= \sqrt{2}\, x(t) - 2y(t)
\end{aligned}
$$

29.3.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -3 & \sqrt{2} \\ \sqrt{2} & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{2\,\mathrm{e}^{-4t}}{3} + \frac{\mathrm{e}^{-t}}{3} & -\frac{\sqrt{2}\,(-\mathrm{e}^{-t}+\mathrm{e}^{-4t})}{3} \\ -\frac{\sqrt{2}\,(-\mathrm{e}^{-t}+\mathrm{e}^{-4t})}{3} & \frac{\mathrm{e}^{-4t}}{3} + \frac{2\,\mathrm{e}^{-t}}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{2\,e^{-4t}}{3}+\frac{e^{-t}}{3} & -\frac{\sqrt{2}\,(-e^{-t}+e^{-4t})}{3} \\ -\frac{\sqrt{2}\,(-e^{-t}+e^{-4t})}{3} & \frac{e^{-4t}}{3}+\frac{2\,e^{-t}}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{2\,e^{-4t}}{3}+\frac{e^{-t}}{3}\right)c_1 - \frac{\sqrt{2}\,(-e^{-t}+e^{-4t})\,c_2}{3} \\ -\frac{\sqrt{2}\,(-e^{-t}+e^{-4t})\,c_1}{3} + \left(\frac{e^{-4t}}{3}+\frac{2\,e^{-t}}{3}\right)c_2 \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.3.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -3 & \sqrt{2} \\ \sqrt{2} & -2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det(A - \lambda I) = 0
$$

Expanding gives

$$
\det\left(\begin{bmatrix} -3 & \sqrt{2} \\ \sqrt{2} & -2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0
$$

Therefore

$$
\det\left(\begin{bmatrix} -3-\lambda & \sqrt{2} \\ \sqrt{2} & -2-\lambda \end{bmatrix}\right) = 0
$$

Which gives the characteristic equation

$$
\lambda^2 + 5\lambda + 4 = 0
$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -1$$
$$\lambda_2 = -4$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
-4	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -4$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -3 & \sqrt{2} \\ \sqrt{2} & -2 \end{bmatrix} - (-4)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 1 & \sqrt{2} \\ \sqrt{2} & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 1 & \sqrt{2} & 0 \\ \sqrt{2} & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 - \sqrt{2}\, R_1 \Longrightarrow \left[\begin{array}{cc|c} 1 & \sqrt{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 1 & \sqrt{2} \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -\sqrt{2}\, t\}$

Hence the solution is

$$\begin{bmatrix} -\sqrt{2}\,t \\ t \end{bmatrix} = \begin{bmatrix} -\sqrt{2}\,t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\sqrt{2}\,t \\ t \end{bmatrix} = t \begin{bmatrix} -\sqrt{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\sqrt{2}\,t \\ t \end{bmatrix} = \begin{bmatrix} -\sqrt{2} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -3 & \sqrt{2} \\ \sqrt{2} & -2 \end{bmatrix} - (-1) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2 & \sqrt{2} \\ \sqrt{2} & -1 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2 & \sqrt{2} & 0 \\ \sqrt{2} & -1 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{\sqrt{2}\,R_1}{2} \Longrightarrow \left[\begin{array}{cc|c} -2 & \sqrt{2} & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & \sqrt{2} \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{\sqrt{2}\,t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{\sqrt{2}\,t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{\sqrt{2}\,t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{\sqrt{2}\,t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{\sqrt{2}}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{\sqrt{2}\,t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{\sqrt{2}}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{\sqrt{2}\,t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \sqrt{2} \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
-1	1	1	No	$\begin{bmatrix} \frac{\sqrt{2}}{2} \\ 1 \end{bmatrix}$
-4	1	1	No	$\begin{bmatrix} -\sqrt{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue -1 is real and distinct then the

corresponding eigenvector solution is

$$\vec{x}_1(t) = \vec{v}_1 e^{-t} = \begin{bmatrix} \frac{\sqrt{2}}{2} \\ 1 \end{bmatrix} e^{-t}$$

Since eigenvalue -4 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_2(t) = \vec{v}_2 e^{-4t} = \begin{bmatrix} -\sqrt{2} \\ 1 \end{bmatrix} e^{-4t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{\sqrt{2}\,\mathrm{e}^{-t}}{2} \\ \mathrm{e}^{-t} \end{bmatrix} + c_2 \begin{bmatrix} -\sqrt{2}\,\mathrm{e}^{-4t} \\ \mathrm{e}^{-4t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{\sqrt{2}\,\mathrm{e}^{-t}(-2c_2\mathrm{e}^{-3t}+c_1)}{2} \\ c_1\mathrm{e}^{-t} + c_2\mathrm{e}^{-4t} \end{bmatrix}$$

The following is the phase plot of the system.

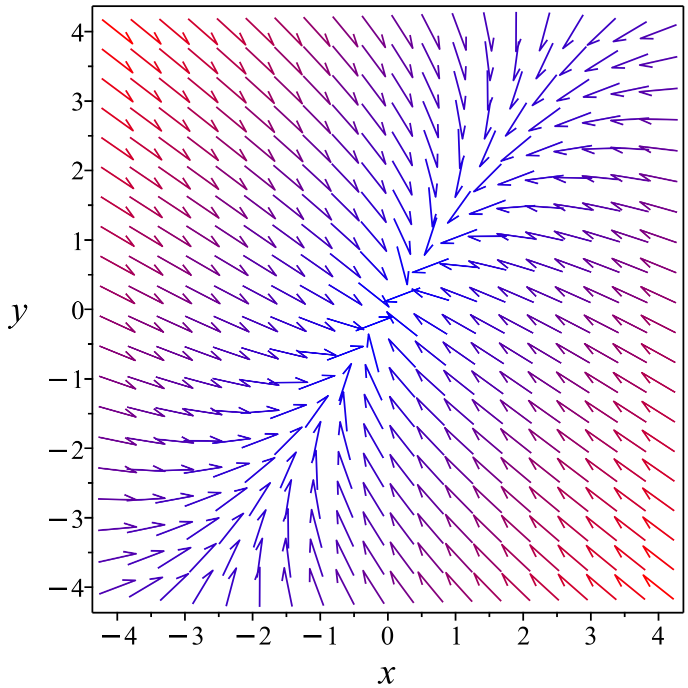

Figure 504: Phase plot

✓ Solution by Maple

Time used: 0.031 (sec). Leaf size: 41

```
dsolve([diff(x(t),t)=-3*x(t)+sqrt(2)*y(t),diff(y(t),t)=sqrt(2)*x(t)-2*y(t)],singsol=all)
```

$$x(t) = e^{-4t}c_1 + c_2e^{-t}$$
$$y(t) = \frac{(-e^{-4t}c_1 + 2c_2e^{-t})\sqrt{2}}{2}$$

✓ Solution by Mathematica

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 5x(t) + 3y(t)$$
$$y'(t) = -6x(t) - 4y(t)$$

29.4.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} -\mathrm{e}^{-t} + 2\,\mathrm{e}^{2t} & \mathrm{e}^{2t} - \mathrm{e}^{-t} \\ -2\,\mathrm{e}^{2t} + 2\,\mathrm{e}^{-t} & 2\,\mathrm{e}^{-t} - \mathrm{e}^{2t} \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} -\mathrm{e}^{-t} + 2\,\mathrm{e}^{2t} & \mathrm{e}^{2t} - \mathrm{e}^{-t} \\ -2\,\mathrm{e}^{2t} + 2\,\mathrm{e}^{-t} & 2\,\mathrm{e}^{-t} - \mathrm{e}^{2t} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(-\mathrm{e}^{-t} + 2\,\mathrm{e}^{2t}\right) c_1 + \left(\mathrm{e}^{2t} - \mathrm{e}^{-t}\right) c_2 \\ \left(-2\,\mathrm{e}^{2t} + 2\,\mathrm{e}^{-t}\right) c_1 + \left(2\,\mathrm{e}^{-t} - \mathrm{e}^{2t}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} \left(-c_1 - c_2\right) \mathrm{e}^{-t} + 2\left(c_1 + \frac{c_2}{2}\right) \mathrm{e}^{2t} \\ \left(2c_1 + 2c_2\right) \mathrm{e}^{-t} - 2\left(c_1 + \frac{c_2}{2}\right) \mathrm{e}^{2t} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.4.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 5-\lambda & 3 \\ -6 & -4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - \lambda - 2 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2$$
$$\lambda_2 = -1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
2	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 6 & 3 \\ -6 & -3 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 6 & 3 & 0 \\ -6 & -3 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} 6 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 6 & 3 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} - (2) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 3 & 3 \\ -6 & -6 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 3 & 3 & 0 \\ -6 & -6 & 0 \end{array}\right]$$

$$R_2 = R_2 + 2R_1 \Longrightarrow \left[\begin{array}{cc|c} 3 & 3 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 3 & 3 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
2	1	1	No	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 2 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{2t} \\
&= \begin{bmatrix} -1 \\ 1 \end{bmatrix} e^{2t}
\end{aligned}$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{-t} \\
&= \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix} e^{-t}
\end{aligned}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{2t} \\ \mathrm{e}^{2t} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{\mathrm{e}^{-t}}{2} \\ \mathrm{e}^{-t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_1 \mathrm{e}^{2t} - \frac{c_2 \mathrm{e}^{-t}}{2} \\ c_1 \mathrm{e}^{2t} + c_2 \mathrm{e}^{-t} \end{bmatrix}$$

The following is the phase plot of the system.

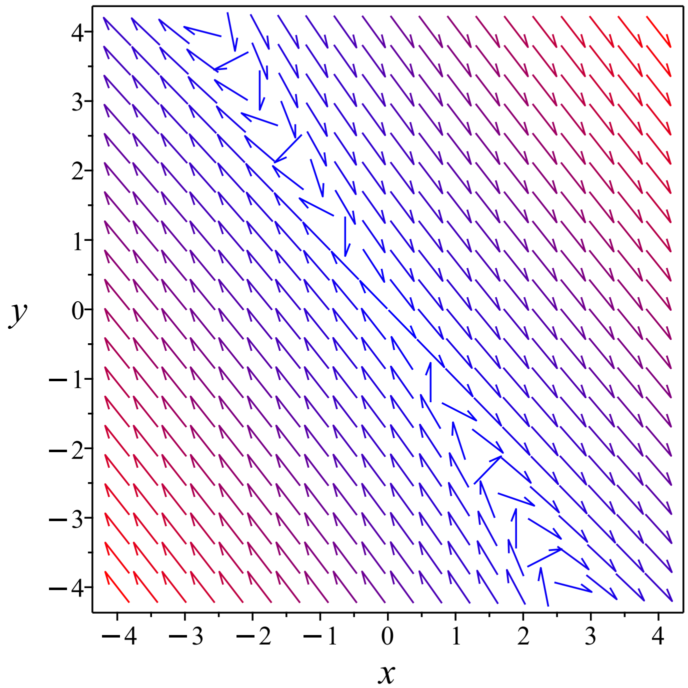

Figure 505: Phase plot

29.4.3 Maple step by step solution

Let's solve

$$[x'(t) = 5x(t) + 3y(t), y'(t) = -6x(t) - 4y(t)]$$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 5 & 3 \\ -6 & -4 \end{bmatrix}$$

- Rewrite the system as

  $\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[-1, \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}\right], \left[2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

  $$\left[-1, \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

  $$\left[2, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

  $$\vec{x}_2 = \mathrm{e}^{2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs

  $\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2$

- Substitute solutions into the general solution

  $$\vec{x} = \mathrm{e}^{-t} c_1 \cdot \begin{bmatrix} -\frac{1}{2} \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{2t} \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -\frac{e^{-t}c_1}{2} - c_2e^{2t} \\ e^{-t}c_1 + c_2e^{2t} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{e^{-t}c_1}{2} - c_2e^{2t}, y(t) = e^{-t}c_1 + c_2e^{2t}\right\}$$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 3x(t) + 2y(t)$$
$$y'(t) = -2x(t) - y(t)$$

29.5.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \mathrm{e}^{t}(2t+1) & 2t\,\mathrm{e}^{t} \\ -2t\,\mathrm{e}^{t} & \mathrm{e}^{t}(1-2t) \end{bmatrix}$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^t(2t+1) & 2t\,e^t \\ -2t\,e^t & e^t(1-2t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^t(2t+1)\,c_1 + 2t\,e^t c_2 \\ -2t\,e^t c_1 + e^t(1-2t)\,c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^t(2tc_1 + 2c_2t + c_1) \\ (c_2(1-2t) - 2tc_1)\,e^t \end{bmatrix}
\end{aligned}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.5.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & 2 \\ -2 & -1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
1	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 2 \\ -2 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2 & 2 & 0 \\ -2 & -2 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{cc|c} 2 & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -t \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
1	2	1	Yes	$\begin{bmatrix} -1 \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. eigenvalue 1 is real and repated eigenvalue of multiplicity 2.There are two possible cases that can happen. This is illustrated in this diagram

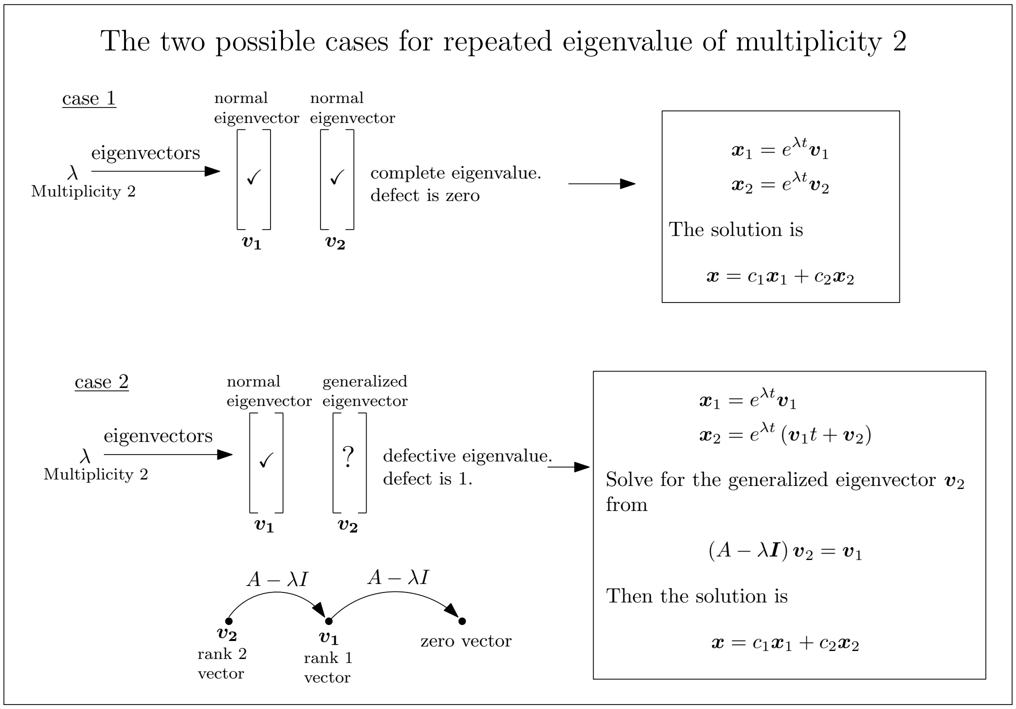

Figure 506: Possible case for repeated λ of multiplicity 2

This eigenvalue has algebraic multiplicity of 2, and geometric multiplicity 1, therefore this is defective eigenvalue. The defect is 1. This falls into case 2 shown above. We need to generate the missing additonal generalized eigevector $\vec{v}_2$ by solving

$$(A - \lambda I)\,\vec{v}_2 = \vec{v}_1$$

Where $\vec{v}_1$ is the normal (rank 1) eigenvector found above. Hence we need to solve

$$\left(\begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} - (1)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$
$$\begin{bmatrix} 2 & 2 \\ -2 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

Solving for $\vec{v}_2$ gives

$$\vec{v}_2 = \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix}$$

We have found two generalized eigenvectors for eigenvalue 1. Therefore the two basis solution associated with this eigenvalue are

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\lambda t} \\
&= \begin{bmatrix} -1 \\ 1 \end{bmatrix} \mathrm{e}^{t} \\
&= \begin{bmatrix} -\mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix}
\end{aligned}
$$

And

$$
\begin{aligned}
\vec{x}_2(t) &= (\vec{v}_1 t + \vec{v}_2)\, e^{\lambda t} \\
&= \left(\begin{bmatrix} -1 \\ 1 \end{bmatrix} t + \begin{bmatrix} -\frac{3}{2} \\ 1 \end{bmatrix} \right) \mathrm{e}^{t} \\
&= \begin{bmatrix} -\frac{\mathrm{e}^{t}(2t+3)}{2} \\ \mathrm{e}^{t}(t+1) \end{bmatrix}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{t} \\ \mathrm{e}^{t} \end{bmatrix} + c_2 \begin{bmatrix} \mathrm{e}^{t}\left(-t - \frac{3}{2}\right) \\ \mathrm{e}^{t}(t+1) \end{bmatrix}
$$

Which becomes

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \mathrm{e}^{t}\left(-c_1 - c_2 t - \frac{3}{2} c_2\right) \\ \mathrm{e}^{t}(c_2 t + c_1 + c_2) \end{bmatrix}
$$

The following is the phase plot of the system.

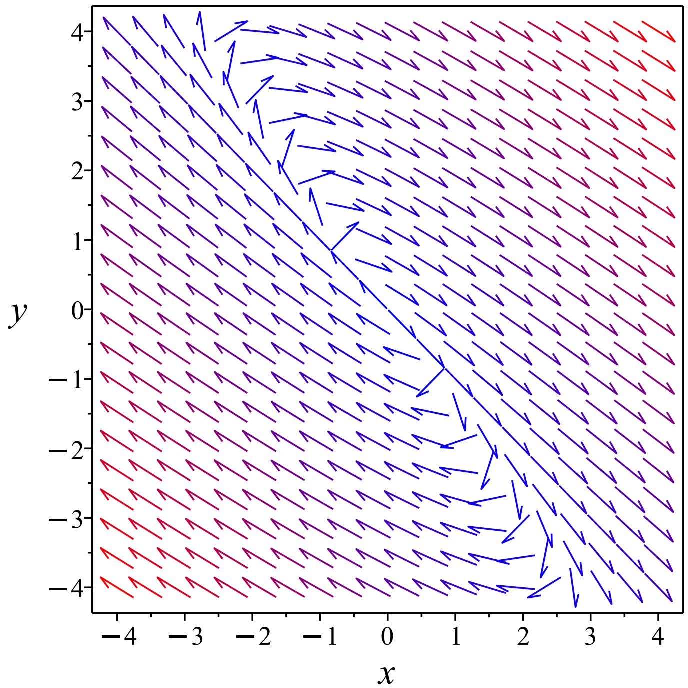

Figure 507: Phase plot

29.5.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t) + 2y(t), y'(t) = -2x(t) - y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} 0 \\ 0 \end{bmatrix}\right]\right]$$

- Consider eigenpair, with eigenvalue of algebraic multiplicity 2

  $$\left[1, \begin{bmatrix} -1 \\ 1 \end{bmatrix}\right]$$

- First solution from eigenvalue 1

  $$\overrightarrow{x}_1(t) = e^t \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Form of the 2nd homogeneous solution where $\overrightarrow{p}$ is to be solved for, $\lambda = 1$ is the eigenvalue, and

  $\overrightarrow{x}_2(t) = e^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right)$

- Note that the t multiplying $\overrightarrow{v}$ makes this solution linearly independent to the 1st solution obtai
- Substitute $\overrightarrow{x}_2(t)$ into the homogeneous system

  $\lambda e^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda t}\overrightarrow{v} = \left(e^{\lambda t}A\right) \cdot \left(t\overrightarrow{v} + \overrightarrow{p}\right)$

- Use the fact that $\overrightarrow{v}$ is an eigenvector of A

  $\lambda e^{\lambda t}\left(t\overrightarrow{v} + \overrightarrow{p}\right) + e^{\lambda t}\overrightarrow{v} = e^{\lambda t}\left(\lambda t\overrightarrow{v} + A \cdot \overrightarrow{p}\right)$

- Simplify equation

  $\lambda\overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Make use of the identity matrix I

  $(\lambda \cdot I) \cdot \overrightarrow{p} + \overrightarrow{v} = A \cdot \overrightarrow{p}$

- Condition $\overrightarrow{p}$ must meet for $\overrightarrow{x}_2(t)$ to be a solution to the homogeneous system

  $(A - \lambda \cdot I) \cdot \overrightarrow{p} = \overrightarrow{v}$

- Choose $\vec{p}$ to use in the second solution to the homogeneous system from eigenvalue 1

$$\left(\begin{bmatrix} 3 & 2 \\ -2 & -1 \end{bmatrix} - 1 \cdot \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) \cdot \vec{p} = \begin{bmatrix} -1 \\ 1 \end{bmatrix}$$

- Choice of $\vec{p}$

$$\vec{p} = \begin{bmatrix} -\frac{1}{2} \\ 0 \end{bmatrix}$$

- Second solution from eigenvalue 1

$$\vec{x}_2(t) = \mathrm{e}^t \cdot \left(t \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -\frac{1}{2} \\ 0 \end{bmatrix}\right)$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 \mathrm{e}^t \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + c_2 \mathrm{e}^t \cdot \left(t \cdot \begin{bmatrix} -1 \\ 1 \end{bmatrix} + \begin{bmatrix} -\frac{1}{2} \\ 0 \end{bmatrix}\right)$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \mathrm{e}^t\left(-c_1 - tc_2 - \frac{1}{2}c_2\right) \\ \mathrm{e}^t(tc_2 + c_1) \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \mathrm{e}^t\left(-c_1 - tc_2 - \frac{1}{2}c_2\right), y(t) = \mathrm{e}^t(tc_2 + c_1)\right\}$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + y(t) \\
y'(t) &= -x(t) + y(t)
\end{aligned}
$$

29.6.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t)
$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \mathrm{e}^{t}\cos(t) & \sin(t)\,\mathrm{e}^{t} \\ -\sin(t)\,\mathrm{e}^{t} & \mathrm{e}^{t}\cos(t) \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^t \cos(t) & \sin(t) e^t \\ -\sin(t) e^t & e^t \cos(t) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^t \cos(t) c_1 + \sin(t) e^t c_2 \\ -\sin(t) e^t c_1 + e^t \cos(t) c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^t (\cos(t) c_1 + \sin(t) c_2) \\ e^t (-\sin(t) c_1 + \cos(t) c_2) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.6.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 1 \\ -1 & 1-\lambda \end{bmatrix} \right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda + 2 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1 + i$$
$$\lambda_2 = 1 - i$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$1+i$	1	complex eigenvalue
$1-i$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1 - i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} - (1-i)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} i & 1 \\ -1 & i \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} i & 1 & 0 \\ -1 & i & 0 \end{array}\right]$$

$$R_2 = -iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} i & 1 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = it\}$

Hence the solution is

$$\begin{bmatrix} \mathrm{I}t \\ t \end{bmatrix} = \begin{bmatrix} it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \mathrm{I}t \\ t \end{bmatrix} = t \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \mathrm{I}t \\ t \end{bmatrix} = \begin{bmatrix} i \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1 + i$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} - (1+i) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -i & 1 \\ -1 & -i \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -i & 1 & 0 \\ -1 & -i & 0 \end{array}\right]$$

$$R_2 = iR_1 + R_2 \Longrightarrow \left[\begin{array}{cc|c} -i & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -i & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -it\}$

Hence the solution is

$$\begin{bmatrix} \text{-I}\,t \\ t \end{bmatrix} = \begin{bmatrix} -it \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \text{-I}\,t \\ t \end{bmatrix} = t \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \text{-I}\,t \\ t \end{bmatrix} = \begin{bmatrix} -i \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$1 + i$	1	1	No	$\begin{bmatrix} -i \\ 1 \end{bmatrix}$
$1 - i$	1	1	No	$\begin{bmatrix} i \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -i\mathrm{e}^{(1+i)t} \\ \mathrm{e}^{(1+i)t} \end{bmatrix} + c_2 \begin{bmatrix} i\mathrm{e}^{(1-i)t} \\ \mathrm{e}^{(1-i)t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} i\left(c_2\mathrm{e}^{(1-i)t} - c_1\mathrm{e}^{(1+i)t}\right) \\ c_1\mathrm{e}^{(1+i)t} + c_2\mathrm{e}^{(1-i)t} \end{bmatrix}$$

The following is the phase plot of the system.

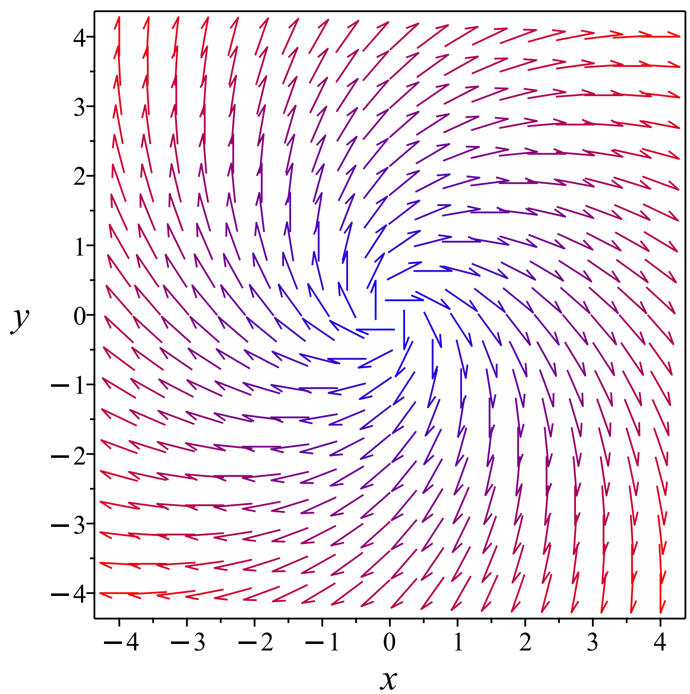

Figure 508: Phase plot

29.6.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + y(t)\,, y'(t) = -x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1 - \mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right], \left[1 + \mathrm{I}, \begin{bmatrix} -\mathrm{I} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[1 - \mathrm{I}, \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

$$\mathrm{e}^{(1-\mathrm{I})t} \cdot \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$\mathrm{e}^{t} \cdot (\cos(t) - \mathrm{I}\sin(t)) \cdot \begin{bmatrix} \mathrm{I} \\ 1 \end{bmatrix}$$

- Simplify expression

$$e^t \cdot \begin{bmatrix} I(\cos(t) - I\sin(t)) \\ \cos(t) - I\sin(t) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = e^t \cdot \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix}, \vec{x}_2(t) = e^t \cdot \begin{bmatrix} \cos(t) \\ -\sin(t) \end{bmatrix}\right]$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)$$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^t \cdot \begin{bmatrix} \sin(t) \\ \cos(t) \end{bmatrix} + c_2 e^t \cdot \begin{bmatrix} \cos(t) \\ -\sin(t) \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} e^t(c_1 \sin(t) + c_2 \cos(t)) \\ e^t(c_1 \cos(t) - c_2 \sin(t)) \end{bmatrix}$$

- Solution to the system of ODEs

$$\{x(t) = e^t(c_1 \sin(t) + c_2 \cos(t)), y(t) = e^t(c_1 \cos(t) - c_2 \sin(t))\}$$

✓ Solution by Maple

Problem number: 3(c).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = 3x(t) - 5y(t)$$
$$y'(t) = -x(t) + 2y(t)$$

29.7.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} \frac{\left(-\sqrt{21}+21\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} + \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(\sqrt{21}+21\right)}{42} & \frac{5\left(-e^{\frac{\left(5+\sqrt{21}\right)t}{2}}+e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}\right)\sqrt{21}}{21} \\ \frac{\left(-e^{\frac{\left(5+\sqrt{21}\right)t}{2}}+e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}\right)\sqrt{21}}{21} & \frac{\left(\sqrt{21}+21\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} - \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(\sqrt{21}-21\right)}{42} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = e^{At}\vec{c}$$

$$= \begin{bmatrix} \frac{\left(-\sqrt{21}+21\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} + \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(\sqrt{21}+21\right)}{42} & \frac{5\left(-e^{\frac{\left(5+\sqrt{21}\right)t}{2}}+e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}\right)\sqrt{21}}{21} \\ \frac{\left(-e^{\frac{\left(5+\sqrt{21}\right)t}{2}}+e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}\right)\sqrt{21}}{21} & \frac{\left(\sqrt{21}+21\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} - \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(\sqrt{21}-21\right)}{42} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}$$

$$= \begin{bmatrix} \left(\frac{\left(-\sqrt{21}+21\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} + \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(\sqrt{21}+21\right)}{42}\right)c_1 + \frac{5\left(-e^{\frac{\left(5+\sqrt{21}\right)t}{2}}+e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}\right)\sqrt{21}\,c_2}{21} \\ \frac{\left(-e^{\frac{\left(5+\sqrt{21}\right)t}{2}}+e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}\right)\sqrt{21}\,c_1}{21} + \left(\frac{\left(\sqrt{21}+21\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} - \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(\sqrt{21}-21\right)}{42}\right)c_2 \end{bmatrix}$$

$$= \begin{bmatrix} \frac{\left((-c_1+10c_2)\sqrt{21}+21c_1\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} + \frac{\left((c_1-10c_2)\sqrt{21}+21c_1\right)e^{\frac{\left(5+\sqrt{21}\right)t}{2}}}{42} \\ \frac{\left((2c_1+c_2)\sqrt{21}+21c_2\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{42} - \frac{\left((c_1+\frac{c_2}{2})\sqrt{21}-\frac{21c_2}{2}\right)e^{\frac{\left(5+\sqrt{21}\right)t}{2}}}{21} \end{bmatrix}$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.7.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & -5 \\ -1 & 2-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 5\lambda + 1 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = \frac{5}{2} + \frac{\sqrt{21}}{2}$$
$$\lambda_2 = \frac{5}{2} - \frac{\sqrt{21}}{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$\frac{5}{2} + \frac{\sqrt{21}}{2}$	1	real eigenvalue
$\frac{5}{2} - \frac{\sqrt{21}}{2}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = \frac{5}{2} - \frac{\sqrt{21}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} - \left(\frac{5}{2} - \frac{\sqrt{21}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} \frac{1}{2} + \frac{\sqrt{21}}{2} & -5 \\ -1 & -\frac{1}{2} + \frac{\sqrt{21}}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{1}{2} + \frac{\sqrt{21}}{2} & -5 & 0 \\ -1 & -\frac{1}{2} + \frac{\sqrt{21}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{\frac{1}{2}+\frac{\sqrt{21}}{2}} \Longrightarrow \left[\begin{array}{cc|c} \frac{1}{2}+\frac{\sqrt{21}}{2} & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{1}{2}+\frac{\sqrt{21}}{2} & -5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{10t}{1+\sqrt{21}}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{10t}{1+\sqrt{21}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{10t}{1+\sqrt{21}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{10t}{1+\sqrt{21}} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{10}{1+\sqrt{21}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{10t}{1+\sqrt{21}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{10}{1+\sqrt{21}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{10t}{1+\sqrt{21}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{10}{1+\sqrt{21}} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = \frac{5}{2} + \frac{\sqrt{21}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} - \left(\frac{5}{2} + \frac{\sqrt{21}}{2}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \frac{1}{2}-\frac{\sqrt{21}}{2} & -5 \\ -1 & -\frac{1}{2}-\frac{\sqrt{21}}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{1}{2}-\frac{\sqrt{21}}{2} & -5 & 0 \\ -1 & -\frac{1}{2}-\frac{\sqrt{21}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{\frac{1}{2}-\frac{\sqrt{21}}{2}} \Longrightarrow \left[\begin{array}{cc|c} \frac{1}{2}-\frac{\sqrt{21}}{2} & -5 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{1}{2}-\frac{\sqrt{21}}{2} & -5 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{10t}{-1+\sqrt{21}}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{10t}{-1+\sqrt{21}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10t}{-1+\sqrt{21}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{10t}{-1+\sqrt{21}} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{10}{-1+\sqrt{21}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{10t}{-1+\sqrt{21}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10}{-1+\sqrt{21}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{10t}{-1+\sqrt{21}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{10}{-1+\sqrt{21}} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
$\frac{5}{2}+\frac{\sqrt{21}}{2}$	1	1	No	$\begin{bmatrix} -\frac{5}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}$
$\frac{5}{2}-\frac{\sqrt{21}}{2}$	1	1	No	$\begin{bmatrix} -\frac{5}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $\frac{5}{2}+\frac{\sqrt{21}}{2}$ is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t} \\
&= \begin{bmatrix} -\frac{5}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix} e^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t}
\end{aligned}
$$

Since eigenvalue $\frac{5}{2}-\frac{\sqrt{21}}{2}$ is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t} \\
&= \begin{bmatrix} -\frac{5}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix} e^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t}
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} -\frac{5\,\mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t}}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ \mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t} \end{bmatrix} + c_2 \begin{bmatrix} -\frac{5\,\mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t}}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ \mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t} \end{bmatrix}
$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_2\left(-1+\sqrt{21}\right)e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{2} - \frac{e^{\frac{\left(5+\sqrt{21}\right)t}{2}} c_1\left(1+\sqrt{21}\right)}{2} \\ c_1 e^{\frac{\left(5+\sqrt{21}\right)t}{2}} + c_2 e^{-\frac{\left(-5+\sqrt{21}\right)t}{2}} \end{bmatrix}$$

The following is the phase plot of the system.

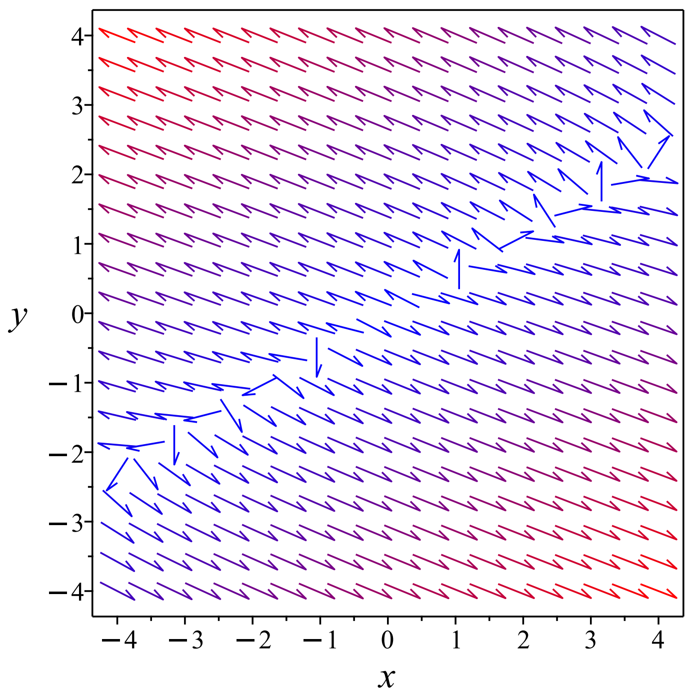

Figure 509: Phase plot

29.7.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t) - 5y(t), y'(t) = -x(t) + 2y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & -5 \\ -1 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t)$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[\frac{5}{2} - \frac{\sqrt{21}}{2}, \begin{bmatrix} -\frac{5}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}\right], \left[\frac{5}{2} + \frac{\sqrt{21}}{2}, \begin{bmatrix} -\frac{5}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[\frac{5}{2} - \frac{\sqrt{21}}{2}, \begin{bmatrix} -\frac{5}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t} \cdot \begin{bmatrix} -\frac{5}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[\frac{5}{2} + \frac{\sqrt{21}}{2}, \begin{bmatrix} -\frac{5}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t} \cdot \begin{bmatrix} -\frac{5}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}$$

- General solution to the system of ODEs
  $\overrightarrow{x} = c_1 \overrightarrow{x}_1 + c_2 \overrightarrow{x}_2$
- Substitute solutions into the general solution

$$\overrightarrow{x} = c_1 \mathrm{e}^{\left(\frac{5}{2}-\frac{\sqrt{21}}{2}\right)t} \cdot \begin{bmatrix} -\frac{5}{-\frac{1}{2}-\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix} + c_2 \mathrm{e}^{\left(\frac{5}{2}+\frac{\sqrt{21}}{2}\right)t} \cdot \begin{bmatrix} -\frac{5}{-\frac{1}{2}+\frac{\sqrt{21}}{2}} \\ 1 \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1\left(-1+\sqrt{21}\right)\mathrm{e}^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{2} - \frac{c_2 \mathrm{e}^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(1+\sqrt{21}\right)}{2} \\ c_1 \mathrm{e}^{-\frac{\left(-5+\sqrt{21}\right)t}{2}} + c_2 \mathrm{e}^{\frac{\left(5+\sqrt{21}\right)t}{2}} \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{c_1\left(-1+\sqrt{21}\right)\mathrm{e}^{-\frac{\left(-5+\sqrt{21}\right)t}{2}}}{2} - \frac{c_2 \mathrm{e}^{\frac{\left(5+\sqrt{21}\right)t}{2}}\left(1+\sqrt{21}\right)}{2}, y(t) = c_1 \mathrm{e}^{-\frac{\left(-5+\sqrt{21}\right)t}{2}} + c_2 \mathrm{e}^{\frac{\left(5+\sqrt{21}\right)t}{2}}\right\}$$

✓ Solution by Maple

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= x(t) + 2y(t) \\
y'(t) &= -4x(t) + y(t)
\end{aligned}
$$

29.8.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^t \cos\left(2t\sqrt{2}\right) & \frac{e^t \sin\left(2t\sqrt{2}\right)\sqrt{2}}{2} \\ -e^t \sin\left(2t\sqrt{2}\right)\sqrt{2} & e^t \cos\left(2t\sqrt{2}\right) \end{bmatrix}$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} e^t \cos\left(2t\sqrt{2}\right) & \frac{e^t \sin\left(2t\sqrt{2}\right)\sqrt{2}}{2} \\ -e^t \sin\left(2t\sqrt{2}\right)\sqrt{2} & e^t \cos\left(2t\sqrt{2}\right) \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^t \cos\left(2t\sqrt{2}\right) c_1 + \frac{e^t \sin\left(2t\sqrt{2}\right)\sqrt{2}\, c_2}{2} \\ -e^t \sin\left(2t\sqrt{2}\right)\sqrt{2}\, c_1 + e^t \cos\left(2t\sqrt{2}\right) c_2 \end{bmatrix} \\
&= \begin{bmatrix} e^t \cos\left(2t\sqrt{2}\right) c_1 + \frac{e^t \sin\left(2t\sqrt{2}\right)\sqrt{2}\, c_2}{2} \\ e^t\left(-\sin\left(2t\sqrt{2}\right)\sqrt{2}\, c_1 + \cos\left(2t\sqrt{2}\right) c_2\right) \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.8.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 1-\lambda & 2 \\ -4 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda + 9 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 2i\sqrt{2} + 1$$
$$\lambda_2 = 1 - 2i\sqrt{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$1 - 2i\sqrt{2}$	1	complex eigenvalue
$2i\sqrt{2} + 1$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1 - 2i\sqrt{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} - \left(1 - 2i\sqrt{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} 2i\sqrt{2} & 2 \\ -4 & 2i\sqrt{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} 2i\sqrt{2} & 2 & 0 \\ -4 & 2i\sqrt{2} & 0 \end{array}\right]$$

$$R_2 = R_2 - i\sqrt{2}\,R_1 \Longrightarrow \left[\begin{array}{cc|c} 2i\sqrt{2} & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2i\sqrt{2} & 2 \\ 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{it\sqrt{2}}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{it\sqrt{2}}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{i\sqrt{2}}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{i\sqrt{2}}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = \begin{bmatrix} i\sqrt{2} \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 2i\sqrt{2} + 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} - \left(2i\sqrt{2} + 1\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -2i\sqrt{2} & 2 \\ -4 & -2i\sqrt{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -2i\sqrt{2} & 2 & 0 \\ -4 & -2i\sqrt{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + i\sqrt{2}\, R_1 \Longrightarrow \left[\begin{array}{cc|c} -2i\sqrt{2} & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2i\sqrt{2} & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{it\sqrt{2}}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{it\sqrt{2}}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{i\sqrt{2}}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{i\sqrt{2}}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{\mathrm{I}}{2}t\sqrt{2} \\ t \end{bmatrix} = \begin{bmatrix} -i\sqrt{2} \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity: algebraic m	multiplicity: geometric k	defective?	eigenvectors
$2i\sqrt{2}+1$	1	1	No	$\left[\begin{array}{c} -\frac{i\sqrt{2}}{2} \\ 1 \end{array}\right]$
$1-2i\sqrt{2}$	1	1	No	$\left[\begin{array}{c} \frac{i\sqrt{2}}{2} \\ 1 \end{array}\right]$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = c_1 \left[\begin{array}{c} -\frac{i\,\mathrm{e}^{\left(2i\sqrt{2}+1\right)t}\sqrt{2}}{2} \\ \mathrm{e}^{\left(2i\sqrt{2}+1\right)t} \end{array}\right] + c_2 \left[\begin{array}{c} \frac{i\,\mathrm{e}^{\left(1-2i\sqrt{2}\right)t}\sqrt{2}}{2} \\ \mathrm{e}^{\left(1-2i\sqrt{2}\right)t} \end{array}\right]$$

Which becomes

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} -\frac{i\sqrt{2}\left(c_1\mathrm{e}^{2i\sqrt{2}\,t+t}-c_2\mathrm{e}^{-2i\sqrt{2}\,t+t}\right)}{2} \\ c_1\mathrm{e}^{2i\sqrt{2}\,t+t} + c_2\mathrm{e}^{-2i\sqrt{2}\,t+t} \end{array}\right]$$

The following is the phase plot of the system.

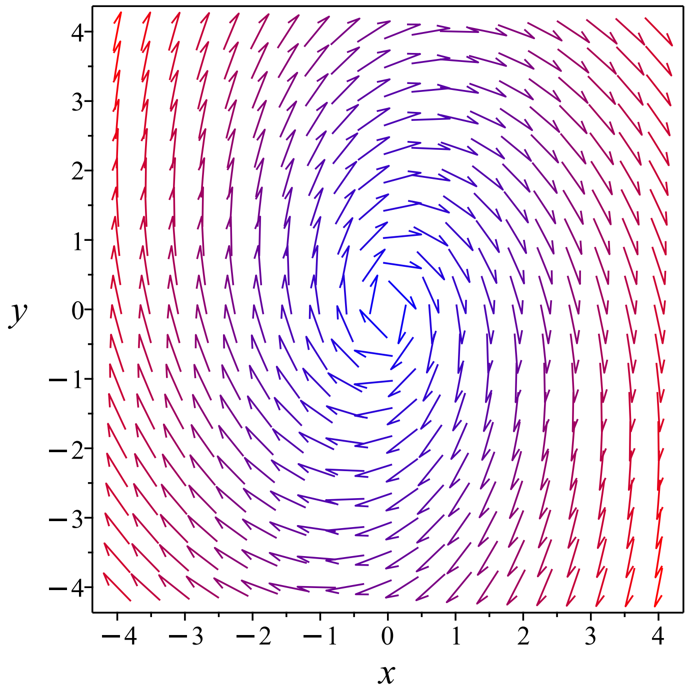

Figure 510: Phase plot

29.8.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + 2y(t), y'(t) = -4x(t) + y(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 2 \\ -4 & 1 \end{bmatrix}$$

- Rewrite the system as

  $\overrightarrow{x}'(t) = A \cdot \overrightarrow{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

  $$\left[\left[1 - 2\,\mathrm{I}\sqrt{2}, \begin{bmatrix} \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}\right], \left[2\,\mathrm{I}\sqrt{2} + 1, \begin{bmatrix} -\frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

  $$\left[1 - 2\,\mathrm{I}\sqrt{2}, \begin{bmatrix} \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}\right]$$

- Solution from eigenpair

  $$\mathrm{e}^{\left(1-2\,\mathrm{I}\sqrt{2}\right)t} \cdot \begin{bmatrix} \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

  $$\mathrm{e}^{t} \cdot \left(\cos\left(2t\sqrt{2}\right) - \mathrm{I}\sin\left(2t\sqrt{2}\right)\right) \cdot \begin{bmatrix} \frac{\mathrm{I}}{2}\sqrt{2} \\ 1 \end{bmatrix}$$

- Simplify expression

  $$\mathrm{e}^{t} \cdot \begin{bmatrix} \frac{\mathrm{I}}{2}\left(\cos\left(2t\sqrt{2}\right) - \mathrm{I}\sin\left(2t\sqrt{2}\right)\right)\sqrt{2} \\ \cos\left(2t\sqrt{2}\right) - \mathrm{I}\sin\left(2t\sqrt{2}\right) \end{bmatrix}$$

- Both real and imaginary parts are solutions to the homogeneous system

  $$\left[\overrightarrow{x}_{1}(t) = \mathrm{e}^{t} \cdot \begin{bmatrix} \frac{\sqrt{2}\sin\left(2t\sqrt{2}\right)}{2} \\ \cos\left(2t\sqrt{2}\right) \end{bmatrix}, \overrightarrow{x}_{2}(t) = \mathrm{e}^{t} \cdot \begin{bmatrix} \frac{\sqrt{2}\cos\left(2t\sqrt{2}\right)}{2} \\ -\sin\left(2t\sqrt{2}\right) \end{bmatrix}\right]$$

- General solution to the system of ODEs

  $\overrightarrow{x} = c_{1}\overrightarrow{x}_{1}(t) + c_{2}\overrightarrow{x}_{2}(t)$

- Substitute solutions into the general solution

$$\vec{x} = c_1 e^t \cdot \begin{bmatrix} \frac{\sqrt{2}\sin\left(2t\sqrt{2}\right)}{2} \\ \cos\left(2t\sqrt{2}\right) \end{bmatrix} + c_2 e^t \cdot \begin{bmatrix} \frac{\sqrt{2}\cos\left(2t\sqrt{2}\right)}{2} \\ -\sin\left(2t\sqrt{2}\right) \end{bmatrix}$$

- Substitute in vector of dependent variables

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{e^t\sqrt{2}\left(c_1\sin\left(2t\sqrt{2}\right)+c_2\cos\left(2t\sqrt{2}\right)\right)}{2} \\ e^t\left(c_1\cos\left(2t\sqrt{2}\right) - c_2\sin\left(2t\sqrt{2}\right)\right) \end{bmatrix}$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{e^t\sqrt{2}\left(c_1\sin\left(2t\sqrt{2}\right)+c_2\cos\left(2t\sqrt{2}\right)\right)}{2}, y(t) = e^t\left(c_1\cos\left(2t\sqrt{2}\right) - c_2\sin\left(2t\sqrt{2}\right)\right)\right\}$$

✓ Solution by Maple

Problem number: 3(e).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= 3x(t) + 2y(t) + z(t) \\
y'(t) &= -2x(t) - y(t) + 3z(t) \\
z'(t) &= x(t) + y(t) + z(t)
\end{aligned}
$$

29.9.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$
\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}
$$

For the above matrix A, the matrix exponential can be found to be

$$
e^{At} = \begin{bmatrix} \frac{5\,e^{3t}}{8} + \frac{3\,e^{t}}{4} - \frac{3\,e^{-t}}{8} & \frac{5\,e^{3t}}{8} - \frac{3\,e^{-t}}{8} - \frac{e^{t}}{4} & \frac{5\,e^{3t}}{4} - 2\,e^{t} + \frac{3\,e^{-t}}{4} \\ -\frac{e^{3t}}{8} + \frac{7\,e^{-t}}{8} - \frac{3\,e^{t}}{4} & \frac{7\,e^{-t}}{8} - \frac{e^{3t}}{8} + \frac{e^{t}}{4} & -\frac{e^{3t}}{4} + 2\,e^{t} - \frac{7\,e^{-t}}{4} \\ \frac{e^{3t}}{4} - \frac{e^{-t}}{4} & \frac{e^{3t}}{4} - \frac{e^{-t}}{4} & \frac{e^{-t}}{2} + \frac{e^{3t}}{2} \end{bmatrix}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} \frac{5\,\mathrm{e}^{3t}}{8}+\frac{3\,\mathrm{e}^{t}}{4}-\frac{3\,\mathrm{e}^{-t}}{8} & \frac{5\,\mathrm{e}^{3t}}{8}-\frac{3\,\mathrm{e}^{-t}}{8}-\frac{\mathrm{e}^{t}}{4} & \frac{5\,\mathrm{e}^{3t}}{4}-2\,\mathrm{e}^{t}+\frac{3\,\mathrm{e}^{-t}}{4} \\ -\frac{\mathrm{e}^{3t}}{8}+\frac{7\,\mathrm{e}^{-t}}{8}-\frac{3\,\mathrm{e}^{t}}{4} & \frac{7\,\mathrm{e}^{-t}}{8}-\frac{\mathrm{e}^{3t}}{8}+\frac{\mathrm{e}^{t}}{4} & -\frac{\mathrm{e}^{3t}}{4}+2\,\mathrm{e}^{t}-\frac{7\,\mathrm{e}^{-t}}{4} \\ \frac{\mathrm{e}^{3t}}{4}-\frac{\mathrm{e}^{-t}}{4} & \frac{\mathrm{e}^{3t}}{4}-\frac{\mathrm{e}^{-t}}{4} & \frac{\mathrm{e}^{-t}}{2}+\frac{\mathrm{e}^{3t}}{2} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \begin{bmatrix} \left(\frac{5\,\mathrm{e}^{3t}}{8}+\frac{3\,\mathrm{e}^{t}}{4}-\frac{3\,\mathrm{e}^{-t}}{8}\right)c_1+\left(\frac{5\,\mathrm{e}^{3t}}{8}-\frac{3\,\mathrm{e}^{-t}}{8}-\frac{\mathrm{e}^{t}}{4}\right)c_2+\left(\frac{5\,\mathrm{e}^{3t}}{4}-2\,\mathrm{e}^{t}+\frac{3\,\mathrm{e}^{-t}}{4}\right)c_3 \\ \left(-\frac{\mathrm{e}^{3t}}{8}+\frac{7\,\mathrm{e}^{-t}}{8}-\frac{3\,\mathrm{e}^{t}}{4}\right)c_1+\left(\frac{7\,\mathrm{e}^{-t}}{8}-\frac{\mathrm{e}^{3t}}{8}+\frac{\mathrm{e}^{t}}{4}\right)c_2+\left(-\frac{\mathrm{e}^{3t}}{4}+2\,\mathrm{e}^{t}-\frac{7\,\mathrm{e}^{-t}}{4}\right)c_3 \\ \left(\frac{\mathrm{e}^{3t}}{4}-\frac{\mathrm{e}^{-t}}{4}\right)c_1+\left(\frac{\mathrm{e}^{3t}}{4}-\frac{\mathrm{e}^{-t}}{4}\right)c_2+\left(\frac{\mathrm{e}^{-t}}{2}+\frac{\mathrm{e}^{3t}}{2}\right)c_3 \end{bmatrix} \\
&= \begin{bmatrix} \frac{3(-c_1-c_2+2c_3)\mathrm{e}^{-t}}{8}+\frac{5(c_1+c_2+2c_3)\mathrm{e}^{3t}}{8}+\frac{3\left(c_1-\frac{c_2}{3}-\frac{8c_3}{3}\right)\mathrm{e}^{t}}{4} \\ \frac{7(c_1+c_2-2c_3)\mathrm{e}^{-t}}{8}+\frac{(-c_1-c_2-2c_3)\mathrm{e}^{3t}}{8}-\frac{3\left(c_1-\frac{c_2}{3}-\frac{8c_3}{3}\right)\mathrm{e}^{t}}{4} \\ \frac{(-c_1-c_2+2c_3)\mathrm{e}^{-t}}{4}+\frac{(c_1+c_2+2c_3)\mathrm{e}^{3t}}{4} \end{bmatrix}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.9.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} 3-\lambda & 2 & 1 \\ -2 & -1-\lambda & 3 \\ 1 & 1 & 1-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^3 - 3\lambda^2 - \lambda + 3 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$
$$\lambda_3 = 3$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
-1	1	real eigenvalue
1	1	real eigenvalue
3	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} - (-1)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 4 & 2 & 1 \\ -2 & 0 & 3 \\ 1 & 1 & 2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 4 & 2 & 1 & 0 \\ -2 & 0 & 3 & 0 \\ 1 & 1 & 2 & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 4 & 2 & 1 & 0 \\ 0 & 1 & \frac{7}{2} & 0 \\ 1 & 1 & 2 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{R_1}{4} \Longrightarrow \left[\begin{array}{ccc|c} 4 & 2 & 1 & 0 \\ 0 & 1 & \frac{7}{2} & 0 \\ 0 & \frac{1}{2} & \frac{7}{4} & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{R_2}{2} \Longrightarrow \left[\begin{array}{ccc|c} 4 & 2 & 1 & 0 \\ 0 & 1 & \frac{7}{2} & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 4 & 2 & 1 \\ 0 & 1 & \frac{7}{2} \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{3t}{2}, v_2 = -\frac{7t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{3t}{2} \\ -\frac{7t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3t}{2} \\ -\frac{7t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{3t}{2} \\ -\frac{7t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{3t}{2} \\ -\frac{7t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{3t}{2} \\ -\frac{7t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 3 \\ -7 \\ 2 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} - (1) \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 2 & 2 & 1 \\ -2 & -2 & 3 \\ 1 & 1 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 2 & 2 & 1 & 0 \\ -2 & -2 & 3 & 0 \\ 1 & 1 & 0 & 0 \end{array}\right]$$

$$R_2 = R_2 + R_1 \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & 1 & 0 \\ 0 & 0 & 4 & 0 \\ 1 & 1 & 0 & 0 \end{array}\right]$$

$$R_3 = R_3 - \frac{R_1}{2} \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & 1 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & -\frac{1}{2} & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{R_2}{8} \Longrightarrow \left[\begin{array}{ccc|c} 2 & 2 & 1 & 0 \\ 0 & 0 & 4 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} 2 & 2 & 1 \\ 0 & 0 & 4 \\ 0 & 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1, v_3\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\{v_1 = -t, v_3 = 0\}$

Hence the solution is

$$\begin{bmatrix} -t \\ t \\ 0 \end{bmatrix} = \begin{bmatrix} -t \\ t \\ 0 \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -t \\ t \\ 0 \end{bmatrix} = t \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -t \\ t \\ 0 \end{bmatrix} = \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$$

Considering the eigenvalue $\lambda_3 = 3$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} - (3)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} 0 & 2 & 1 \\ -2 & -4 & 3 \\ 1 & 1 & -2 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{ccc|c} 0 & 2 & 1 & 0 \\ -2 & -4 & 3 & 0 \\ 1 & 1 & -2 & 0 \end{array}\right]$$

Since the current pivot $A(1,1)$ is zero, then the current pivot row is replaced with a row with a non-zero pivot. Swapping row 1 and row 2 gives

$$\left[\begin{array}{ccc|c} -2 & -4 & 3 & 0 \\ 0 & 2 & 1 & 0 \\ 1 & 1 & -2 & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{R_1}{2} \implies \left[\begin{array}{ccc|c} -2 & -4 & 3 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & -1 & -\frac{1}{2} & 0 \end{array}\right]$$

$$R_3 = R_3 + \frac{R_2}{2} \implies \left[\begin{array}{ccc|c} -2 & -4 & 3 & 0 \\ 0 & 2 & 1 & 0 \\ 0 & 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -2 & -4 & 3 \\ 0 & 2 & 1 \\ 0 & 0 & 0 \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \\ v_3 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{5t}{2}, v_2 = -\frac{t}{2}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{5t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{5t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{5t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{5t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{5t}{2} \\ -\frac{t}{2} \\ t \end{bmatrix} = \begin{bmatrix} 5 \\ -1 \\ 2 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
1	1	1	No	$\begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}$
-1	1	1	No	$\begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix}$
3	1	1	No	$\begin{bmatrix} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue 1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_1(t) &= \vec{v}_1 e^t \\ &= \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix} e^t\end{aligned}$$

Since eigenvalue -1 is real and distinct then the corresponding eigenvector solution is

$$\begin{aligned}\vec{x}_2(t) &= \vec{v}_2 e^{-t} \\ &= \begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix} e^{-t}\end{aligned}$$

Since eigenvalue 3 is real and distinct then the corresponding eigenvector solution is

$$\vec{x}_3(t) = \vec{v}_3 e^{3t}$$
$$= \begin{bmatrix} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix} e^{3t}$$

Therefore the final solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = c_1 \begin{bmatrix} -\mathrm{e}^{t} \\ \mathrm{e}^{t} \\ 0 \end{bmatrix} + c_2 \begin{bmatrix} \frac{3\,\mathrm{e}^{-t}}{2} \\ -\frac{7\,\mathrm{e}^{-t}}{2} \\ \mathrm{e}^{-t} \end{bmatrix} + c_3 \begin{bmatrix} \frac{5\,\mathrm{e}^{3t}}{2} \\ -\frac{\mathrm{e}^{3t}}{2} \\ \mathrm{e}^{3t} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix} = \begin{bmatrix} -c_1\mathrm{e}^{t} + \frac{3c_2\mathrm{e}^{-t}}{2} + \frac{5c_3\mathrm{e}^{3t}}{2} \\ c_1\mathrm{e}^{t} - \frac{7c_2\mathrm{e}^{-t}}{2} - \frac{c_3\mathrm{e}^{3t}}{2} \\ c_2\mathrm{e}^{-t} + c_3\mathrm{e}^{3t} \end{bmatrix}$$

29.9.3 Maple step by step solution

Let's solve

$[x'(t) = 3x(t) + 2y(t) + z(t)\,, y'(t) = -2x(t) - y(t) + 3z(t)\,, z'(t) = x(t) + y(t) + z(t)]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 0 \\ 0 \\ 0 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix} \cdot \vec{x}(t)$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 3 & 2 & 1 \\ -2 & -1 & 3 \\ 1 & 1 & 1 \end{bmatrix}$$

- Rewrite the system as

$\vec{x}'(t) = A \cdot \vec{x}(t)$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-1, \begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix}\right], \left[1, \begin{bmatrix} -1 \\ 1 \\ 0 \end{bmatrix}\right], \left[3, \begin{bmatrix} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{bmatrix}\right]\right]$$

- Consider eigenpair

$$\left[-1, \begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix}\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{-t} \cdot \begin{bmatrix} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{bmatrix}$$

- Consider eigenpair

$$\left[1, \left[\begin{array}{c} -1 \\ 1 \\ 0 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{t} \cdot \left[\begin{array}{c} -1 \\ 1 \\ 0 \end{array}\right]$$

- Consider eigenpair

$$\left[3, \left[\begin{array}{c} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_3 = \mathrm{e}^{3t} \cdot \left[\begin{array}{c} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- General solution to the system of ODEs

$$\vec{x} = c_1 \vec{x}_1 + c_2 \vec{x}_2 + c_3 \vec{x}_3$$

- Substitute solutions into the general solution

$$\vec{x} = \mathrm{e}^{-t} c_1 \cdot \left[\begin{array}{c} \frac{3}{2} \\ -\frac{7}{2} \\ 1 \end{array}\right] + c_2 \mathrm{e}^{t} \cdot \left[\begin{array}{c} -1 \\ 1 \\ 0 \end{array}\right] + c_3 \mathrm{e}^{3t} \cdot \left[\begin{array}{c} \frac{5}{2} \\ -\frac{1}{2} \\ 1 \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \\ z(t) \end{array}\right] = \left[\begin{array}{c} \frac{3\,\mathrm{e}^{-t} c_1}{2} - c_2 \mathrm{e}^{t} + \frac{5 c_3 \mathrm{e}^{3t}}{2} \\ -\frac{7\,\mathrm{e}^{-t} c_1}{2} + c_2 \mathrm{e}^{t} - \frac{c_3 \mathrm{e}^{3t}}{2} \\ \mathrm{e}^{-t} c_1 + c_3 \mathrm{e}^{3t} \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{3\,\mathrm{e}^{-t} c_1}{2} - c_2 \mathrm{e}^{t} + \frac{5 c_3 \mathrm{e}^{3t}}{2}, y(t) = -\frac{7\,\mathrm{e}^{-t} c_1}{2} + c_2 \mathrm{e}^{t} - \frac{c_3 \mathrm{e}^{3t}}{2}, z(t) = \mathrm{e}^{-t} c_1 + c_3 \mathrm{e}^{3t}\right\}$$

Section: Chapter 10. Systems of First-Order Equations. Section A. Drill exercises. Page 400
Problem number: 3(f).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -x(t) + y(t) - z(t) \\
y'(t) &= 2x(t) - y(t) - 4z(t) \\
z'(t) &= 3x(t) - y(t) + z(t)
\end{aligned}
$$

29.10.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} -1 & 1 & -1 \\ 2 & -1 & -4 \\ 3 & -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

For the above matrix A, the matrix exponential can be found to be

$$
\begin{aligned}
e^{At} &= \text{Expression too large to display} \\
&= \text{Expression too large to display}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \text{Expression too large to display} \begin{bmatrix} c_1 \\ c_2 \\ c_3 \end{bmatrix} \\
&= \text{Expression too large to display} \\
&= \text{Expression too large to display}
\end{aligned}
$$

Since no forcing function is given, then the final solution is $\vec{x}_h(t)$ above.

29.10.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \\ z'(t) \end{bmatrix} = \begin{bmatrix} -1 & 1 & -1 \\ 2 & -1 & -4 \\ 3 & -1 & 1 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \\ z(t) \end{bmatrix}$$

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -1 & 1 & -1 \\ 2 & -1 & -4 \\ 3 & -1 & 1 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix} \right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -1-\lambda & 1 & -1 \\ 2 & -1-\lambda & -4 \\ 3 & -1 & 1-\lambda \end{bmatrix} \right) = 0$$

Which gives the characteristic equation

$$\lambda^3+\lambda^2-4\lambda+10=0$$

The roots of the above are the eigenvalues.

$$\lambda_1=-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}$$

$$\lambda_2=\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}+\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$$

$$\lambda_3=\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}-\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type o
$\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}-\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$	1	comple
$-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}$	1	real ei
$\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}+\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$	1	comple

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1=-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 1 & -1 \\ 2 & -1 & -4 \\ 3 & -1 & 1 \end{bmatrix} - \left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3} - \frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} - \frac{1}{3}\right)\begin{bmatrix} 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{bmatrix}\right) [$$

$$\begin{bmatrix} \frac{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} - 2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + 13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & 1 & -1 \\ 2 & \frac{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} - 2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + 13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & -4 \\ 3 & -1 & \frac{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} + 4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + 13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} \end{bmatrix} [$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\begin{bmatrix} -\frac{2}{3} + \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3} + \frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & 1 & -1 \\ 2 & -\frac{2}{3} + \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3} + \frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & -4 \\ 3 & -1 & \frac{4}{3} + \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3} + \frac{}{3\left(154+3\right.} \end{bmatrix}$$

$$R_2 = R_2 - \frac{2R_1}{-\frac{2}{3} + \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3} + \frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}} \Longrightarrow \begin{bmatrix} \frac{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} - 2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + 13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & \\ 0 & \frac{\sqrt{2391}\left(154+3\sqrt{2391}\right.}{\left(154+3\sqrt{23\right.}} \\ 3 & \end{bmatrix}$$

$$R_3 = R_3 - \frac{9\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} R_1}{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} - 2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + 13} \Longrightarrow \begin{bmatrix} \frac{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & \\ 0 & \frac{\sqrt{2391}\,(1}{} \\ 0 & \end{bmatrix}$$

$$R_3 = R_3 - \frac{\left(-\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} - 7\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} - 13\right)\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} R_2}{\sqrt{2391}\,\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + 4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} - 4\sqrt{2391} + 34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} - 149} \Longrightarrow$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} & 1 & \\ 0 & \frac{\sqrt{2391}\,\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149}{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)} & \frac{-4\left(154+\right.}{\left(154+3\right.} \\ 0 & 0 & \end{bmatrix}$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{ v_1 = \frac{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t\left(\sqrt{2391}\,\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+18\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-16\sqrt{2391}-18(\right.}{\left(\sqrt{2391}\,\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149\right)\left(\left(154+3\right.\right.} \right.$

Hence the solution is

$$\left[\begin{array}{c} \frac{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+18\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-16\sqrt{2391}-18\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-765\right)}{\left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149\right)\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)} \\ -\frac{2t\left(7\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-26\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-6\sqrt{2391}-308\right)}{\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149} \\ t \end{array}\right] =$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\left[\begin{array}{c} \frac{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+18\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-16\sqrt{2391}-18\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-765\right)}{\left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149\right)\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)} \\ -\frac{2t\left(7\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-26\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-6\sqrt{2391}-308\right)}{\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149} \\ t \end{array}\right] = t$$

Let $t = 1$ the eigenvector becomes

$$\left[\begin{array}{c} \frac{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+18\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-16\sqrt{2391}-18\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-765\right)}{\left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149\right)\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)} \\ -\frac{2t\left(7\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-26\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-6\sqrt{2391}-308\right)}{\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149} \\ t \end{array}\right] =$$

Which is normalized to

$$\left[\begin{array}{c} \frac{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+18\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-16\sqrt{2391}-18\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-765\right)}{\left(\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149\right)\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-2\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)} \\ -\frac{2t\left(7\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-26\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-6\sqrt{2391}-308\right)}{\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+4\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-4\sqrt{2391}+34\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149} \\ t \end{array}\right] =$$

Considering the eigenvalue $\lambda_2 = \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}-\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\left[\begin{array}{ccc} -1 & 1 & -1 \\ 2 & -1 & -4 \\ 3 & -1 & 1 \end{array}\right] - \left(\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}-\frac{i\sqrt{3}\left(\right.}{}\right.\right.$$

$$\left[\begin{array}{cc} -\frac{\left(1+i\sqrt{3}\right)\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}}-13i\sqrt{3}+4\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}}+13}{6\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}}} & 1 \\ 2 & -\frac{\left(1+i\sqrt{3}\right)\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}}-13i\sqrt{3}+4\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}}+13}{6\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}}} \\ 3 & -1 \end{array}\right.$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc} -\frac{2}{3}-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}-\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2} & \\ 2 & -\frac{2}{3}-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}-\frac{1}{6\left(154+3\right.} \\ 3 & \end{array}\right.$$

$$R_2 = R_2 - \frac{2R_1}{-\frac{2}{3} - \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6} - \frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} + \frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3} + \frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}} \Longrightarrow \left[-\frac{\left(1+i\sqrt{3}\right)\left(154 \cdots\right.}{\cdots} \right.$$

$$R_3 = R_3 + \frac{18\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}} R_1}{\left(1+i\sqrt{3}\right)\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}} - 13i\sqrt{3} + 4\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}} + 13} \Longrightarrow \left[-\frac{\left(1+i\sqrt{3}\right)\left(154+3 \cdots\right.}{\cdots} \right.$$

$$R_3 = R_3 - \frac{\left(-i\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}}\sqrt{3} - \left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}} + 13i\sqrt{3} + 14\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}} \cdots\right.}{\left(i\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}}\sqrt{3} + \left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}} - 13i\sqrt{3} + 4\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}} + 13\right)\left(\left(\cdots\right.\right.}$$

Therefore the system in Echelon form is

$$\left[\begin{array}{cc} -\frac{\left(1+i\sqrt{3}\right)\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}} - 13i\sqrt{3} + 4\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}} + 13}{6\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}}} & 1 \\ 0 & \frac{\left(-34i\sqrt{3} - 3i\sqrt{797} + \sqrt{2391} + 34\right)\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} - 149i\sqrt{3} - 12i\sqrt{797} \cdots}{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\left(13 + 4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} + i\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}} \cdots\right.\right.} \\ 0 & 0 \end{array}\right.$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation

$$\left\{ v_1 = -\frac{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(48i\sqrt{797}-18i\sqrt{3}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+3i\sqrt{797}\cdots\right.}{\left(i\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}\sqrt{3}+\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-13i\sqrt{3}+4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)\left(3i\sqrt{797}\left(154\cdots\right.\right.} \right.$$

Hence the solution is

Expression too large to display

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\left[\begin{array}{c} -\frac{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(48\,\mathrm{I}\sqrt{797}-18\,\mathrm{I}\sqrt{3}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+3\,\mathrm{I}\sqrt{797}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-\sqrt{2391}\left(154+3\sqrt{2391}\cdots\right.\right.}{\left(\mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}\sqrt{3}+\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-13\,\mathrm{I}\sqrt{3}+4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+13\right)\left(3\,\mathrm{I}\sqrt{797}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+34\,\mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{3}-\sqrt{2}\cdots\right.} \\ -\frac{4t\left(9\,\mathrm{I}\sqrt{797}-13\,\mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{3}+154\,\mathrm{I}\sqrt{3}+7\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}+\cdots\right.}{3\,\mathrm{I}\sqrt{797}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+34\,\mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{3}-\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+149\,\mathrm{I}\sqrt{3}+12\,\mathrm{I}\cdots} \\ t \end{array}\right.$$

Let $t = 1$ the eigenvector becomes

Expression too large to display

Which is normalized to

Expression too large to display

Considering the eigenvalue $\lambda_3 = \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}+\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -1 & 1 & -1 \\ 2 & -1 & -4 \\ 3 & -1 & 1 \end{bmatrix} - \left(\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6} + \frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} - \frac{1}{3} + \frac{i\sqrt{3}\left(-\frac{(15\cdots}{\cdots}\right.}{\cdots}\right.\right.$$

$$\begin{bmatrix} \frac{\left(i\sqrt{3}-1\right)\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}}-13i\sqrt{3}-4\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}}-13}{6\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}}} & 1 & \cdots \\ 2 & \frac{\left(i\sqrt{3}-1\right)\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{2}{3}}-13i\sqrt{3}-4\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}}-13}{6\left(154+3\sqrt{3}\sqrt{797}\right)^{\frac{1}{3}}} & \cdots \\ 3 & -1 & \frac{(i\sqrt{\cdots}}{\cdots} \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\begin{bmatrix} -\frac{2}{3} - \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6} - \frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2} & \cdots \\ 2 & -\frac{2}{3} - \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6} - \frac{1\cdots}{6\left(154+3\cdots\right.} \\ 3 & \cdots \end{bmatrix}$$

$$R_2 = R_2 - \frac{2R_1}{-\frac{2}{3} - \frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6} - \frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}} - \frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}} \Longrightarrow \begin{bmatrix} \frac{\left(i\sqrt{3}-1\right)\left(154+3\cdots\right.}{\cdots} & \cdots \\ \cdots \end{bmatrix}$$

$$R_3 = R_3 - \frac{18\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}} R_1}{\left(i\sqrt{3}-1\right)\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}} - 13i\sqrt{3} - 4\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}} - 13} \Longrightarrow \left[\frac{\left(i\sqrt{3}-1\right)\left(154+3\sqrt{3} \cdots\right.}{\cdots}\right.$$

$$R_3 = R_3 - \frac{\left(-i\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}}\sqrt{3} + \left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}} + 13i\sqrt{3} - 14\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}} + \cdots\right.}{\left(i\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}}\sqrt{3} - \left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}} - 13i\sqrt{3} - 4\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}} - 13\right)\left(-\cdots\right.}$$

Therefore the system in Echelon form is

$$\left[\begin{array}{cc} \frac{\left(i\sqrt{3}-1\right)\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{2}{3}}-13i\sqrt{3}-4\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}}-13}{6\left(154+3\sqrt{3}\,\sqrt{797}\right)^{\frac{1}{3}}} & 1 \cdots \\ 0 & \frac{-\left(34i\sqrt{3}+3i\sqrt{797}+\sqrt{2391}+34\right)\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-149i\sqrt{3}-12i\sqrt{797}+4\cdots}{\left(-13-4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+i\left(\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-13\right)\sqrt{3}-\left(154+3\cdots\right)\right.} \cdots \\ 0 & 0 \cdots \end{array}\right.$$

The free variables are $\{v_3\}$ and the leading variables are $\{v_1, v_2\}$. Let $v_3 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t\left(18i\sqrt{3}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-3i\sqrt{797}\left(154+3\sqrt{2\cdots}\right.\right.}{\left(i\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}\sqrt{3}-\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-13i\sqrt{3}-4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-13\right)\left(-34i\sqrt{3}\left(154+3\cdots\right.\right.}\right.$

Hence the solution is

Expression too large to display

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\left[\begin{array}{c} \frac{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}} t \left(18 \mathrm{I} \sqrt{3}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-3 \mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{797}-\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+36\left(154+ \right.\right.}{\left(\mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}\sqrt{3}-\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-13 \mathrm{I}\sqrt{3}-4\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}-13\right)\left(-34 \mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{3}-3 \mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{797}-\sqrt{23}\right.} \\ -\frac{4t\left(13 \mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{3}+7\left(154+3\sqrt{2391}\right)^{\frac{2}{3}}-154 \mathrm{I}\sqrt{3}-9 \mathrm{I}\sqrt{797}+3\right.}{-34 \mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{3}-3 \mathrm{I}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}\sqrt{797}-\sqrt{2391}\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}+8\left(154+3\sqrt{2391}\right.} \\ t \end{array}\right.$$

Let $t = 1$ the eigenvector becomes

Expression too large to display

Which is normalized to

Expression too large to display

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		de
	algebraic m	geometric k	
$-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}$	1	1	
$\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}+\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$	1	1	
$\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{6}+\frac{13}{6\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}-\frac{i\sqrt{3}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}+\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}\right)}{2}$	1	1	

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}$ is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)t} \\
&= \left[\begin{array}{c}
-\frac{7\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{14}{3}\right)}{\left(-\frac{7\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{91}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{2}{3}+\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)^2\right)\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right.} \cdots} \\
\frac{\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)^2-32}{-\frac{7\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{91}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{2}{3}+\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)^2} \\
1
\end{array}\right.
\end{aligned}
$$

Therefore the final solution is

$$
\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + c_3\vec{x}_3(t)
$$

Which is written as

$$
\left[\begin{array}{c} x(t) \\ y(t) \\ z(t) \end{array}\right] = c_1 \left[\begin{array}{c}
-\frac{7\,e^{\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)t}\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{14}{3}\right)}{\left(-\frac{7\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{91}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{2}{3}+\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)^2\right)\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{}{3(15} \cdots} \\
\frac{e^{\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)t}\left(\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)^2-32\right)}{-\frac{7\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{91}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}+\frac{2}{3}+\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)^2} \\
e^{\left(-\frac{\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}{3}-\frac{13}{3\left(154+3\sqrt{2391}\right)^{\frac{1}{3}}}-\frac{1}{3}\right)t}
\end{array}\right.
$$

Problem number: 4(a).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = x(t) + 2y(t) - 4t + 1$$
$$y'(t) = -x(t) + 2y(t) + 3t + 4$$

29.11.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} 1-4t \\ 3t+4 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$
\begin{aligned}
e^{At} &= \begin{bmatrix} e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right)-\frac{\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} & \frac{4\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} \\ -\frac{2\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} & e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right)+\frac{\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} \end{bmatrix} \\
&= \begin{bmatrix} -\frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)-7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)}{7} & \frac{4\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} \\ -\frac{2\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} & \frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)+7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)}{7} \end{bmatrix}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \begin{bmatrix} -\frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)-7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)}{7} & \frac{4\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} \\ -\frac{2\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} & \frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)+7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)}{7} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix} \\
&= \begin{bmatrix} -\frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)-7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)c_1}{7}+\frac{4\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)c_2}{7} \\ -\frac{2\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)c_1}{7}+\frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)+7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)c_2}{7} \end{bmatrix} \\
&= \begin{bmatrix} -\frac{\left(\sqrt{7}\,(c_1-4c_2)\sin\left(\frac{\sqrt{7}\,t}{2}\right)-7\cos\left(\frac{\sqrt{7}\,t}{2}\right)c_1\right)e^{\frac{3t}{2}}}{7} \\ -\frac{2\left(\sqrt{7}\,\left(c_1-\frac{c_2}{2}\right)\sin\left(\frac{\sqrt{7}\,t}{2}\right)-\frac{7\cos\left(\frac{\sqrt{7}\,t}{2}\right)c_2}{2}\right)e^{\frac{3t}{2}}}{7} \end{bmatrix}
\end{aligned}
$$

The particular solution given by

$$
\vec{x}_p(t) = e^{At}\int e^{-At}\vec{G}(t)\,dt
$$

But

$$
\begin{aligned}
e^{-At} &= \left(e^{At}\right)^{-1} \\
&= \begin{bmatrix} \frac{\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)+7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)e^{-\frac{3t}{2}}}{7} & -\frac{4\sqrt{7}\,e^{-\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} \\ \frac{2\sqrt{7}\,e^{-\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} & -\frac{\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)-7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)e^{-\frac{3t}{2}}}{7} \end{bmatrix}
\end{aligned}
$$

Hence

$$
\vec{x}_p(t) = \left[\begin{array}{cc} -\frac{e^{\frac{3t}{2}} \left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, t}{2}\right)-7 \cos\left(\frac{\sqrt{7}\, t}{2}\right)\right)}{7} & \frac{4 \sqrt{7}\, e^{\frac{3t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} \\ -\frac{2 \sqrt{7}\, e^{\frac{3t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} & \frac{e^{\frac{3t}{2}} \left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, t}{2}\right)+7 \cos\left(\frac{\sqrt{7}\, t}{2}\right)\right)}{7} \end{array}\right] \int \left[\begin{array}{cc} \frac{\left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, t}{2}\right)+7 \cos\left(\frac{\sqrt{7}\, t}{2}\right)\right) e^{-\frac{3t}{2}}}{7} & \\ \frac{2 \sqrt{7}\, e^{-\frac{3t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} & -\frac{(\cdots}{} \end{array}\right.
$$

$$
= \left[\begin{array}{cc} -\frac{e^{\frac{3t}{2}} \left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, t}{2}\right)-7 \cos\left(\frac{\sqrt{7}\, t}{2}\right)\right)}{7} & \frac{4 \sqrt{7}\, e^{\frac{3t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} \\ -\frac{2 \sqrt{7}\, e^{\frac{3t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} & \frac{e^{\frac{3t}{2}} \left(\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, t}{2}\right)+7 \cos\left(\frac{\sqrt{7}\, t}{2}\right)\right)}{7} \end{array}\right] \left[\begin{array}{c} \frac{5\left(\left(\frac{49t}{5}+\frac{35}{4}\right) \cos\left(\frac{\sqrt{7}\, t}{2}\right)+\sqrt{7}\, \sin\left(\frac{\sqrt{7}\, t}{2}\right)\left(t+\cdots\right.}{14} \\ \frac{e^{-\frac{3t}{2}} (28t-35) \cos\left(\frac{\sqrt{7}\, t}{2}\right)}{112} + \frac{27\, e^{-\frac{3t}{2}} \left(t+\frac{35}{36}\right)\sqrt{\cdots}}{28} \end{array}\right.
$$

$$
= \left[\begin{array}{c} \frac{7t}{2}+\frac{25}{8} \\ \frac{t}{4}-\frac{5}{16} \end{array}\right]
$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \left[\begin{array}{c} -\frac{e^{\frac{3t}{2}} \sqrt{7}\, (c_1-4c_2) \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} + e^{\frac{3t}{2}} \cos\left(\frac{\sqrt{7}\, t}{2}\right) c_1 + \frac{7t}{2} + \frac{25}{8} \\ -\frac{2\sqrt{7}\, \left(c_1-\frac{c_2}{2}\right) e^{\frac{3t}{2}} \sin\left(\frac{\sqrt{7}\, t}{2}\right)}{7} + e^{\frac{3t}{2}} \cos\left(\frac{\sqrt{7}\, t}{2}\right) c_2 + \frac{t}{4} - \frac{5}{16} \end{array}\right]
\end{aligned}
$$

29.11.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\, \vec{x}(t) + \vec{G}(t)
$$

Or

$$
\left[\begin{array}{c} x'(t) \\ y'(t) \end{array}\right] = \left[\begin{array}{cc} 1 & 2 \\ -1 & 2 \end{array}\right] \left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] + \left[\begin{array}{c} 1-4t \\ 3t+4 \end{array}\right]
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\, \vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\, \vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$
\det\left(A - \lambda I\right) = 0
$$

Expanding gives

$$\det\left(\begin{bmatrix}1 & 2\\ -1 & 2\end{bmatrix} - \lambda\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix}1-\lambda & 2\\ -1 & 2-\lambda\end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 3\lambda + 4 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = \frac{3}{2} + \frac{i\sqrt{7}}{2}$$
$$\lambda_2 = \frac{3}{2} - \frac{i\sqrt{7}}{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$\frac{3}{2} + \frac{i\sqrt{7}}{2}$	1	complex eigenvalue
$\frac{3}{2} - \frac{i\sqrt{7}}{2}$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = \frac{3}{2} - \frac{i\sqrt{7}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix}1 & 2\\ -1 & 2\end{bmatrix} - \left(\frac{3}{2} - \frac{i\sqrt{7}}{2}\right)\begin{bmatrix}1 & 0\\ 0 & 1\end{bmatrix}\right)\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$
$$\begin{bmatrix}-\frac{1}{2} + \frac{i\sqrt{7}}{2} & 2\\ -1 & \frac{i\sqrt{7}}{2} + \frac{1}{2}\end{bmatrix}\begin{bmatrix}v_1\\ v_2\end{bmatrix} = \begin{bmatrix}0\\ 0\end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c}-\frac{1}{2} + \frac{i\sqrt{7}}{2} & 2 & 0\\ -1 & \frac{i\sqrt{7}}{2} + \frac{1}{2} & 0\end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{-\frac{1}{2} + \frac{i\sqrt{7}}{2}} \Longrightarrow \left[\begin{array}{cc|c} -\frac{1}{2} + \frac{i\sqrt{7}}{2} & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{1}{2} + \frac{i\sqrt{7}}{2} & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{4t}{-1+i\sqrt{7}}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{4t}{-1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{4t}{-1+i\sqrt{7}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{4t}{-1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{4}{-1+i\sqrt{7}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{4t}{-1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{4}{-1+i\sqrt{7}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{4t}{-1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{4}{-1+i\sqrt{7}} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = \frac{3}{2} + \frac{i\sqrt{7}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} - \left(\frac{3}{2} + \frac{i\sqrt{7}}{2}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -\frac{1}{2} - \frac{i\sqrt{7}}{2} & 2 \\ -1 & \frac{1}{2} - \frac{i\sqrt{7}}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -\frac{1}{2}-\frac{i\sqrt{7}}{2} & 2 & 0 \\ -1 & \frac{1}{2}-\frac{i\sqrt{7}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{-\frac{1}{2}-\frac{i\sqrt{7}}{2}} \Longrightarrow \left[\begin{array}{cc|c} -\frac{1}{2}-\frac{i\sqrt{7}}{2} & 2 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -\frac{1}{2}-\frac{i\sqrt{7}}{2} & 2 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{4t}{1+i\sqrt{7}}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{4t}{1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{4t}{1+i\sqrt{7}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{4t}{1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{4}{1+i\sqrt{7}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{4t}{1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{4}{1+i\sqrt{7}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{4t}{1+\mathrm{I}\sqrt{7}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{4}{1+i\sqrt{7}} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m-k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
$\frac{3}{2}+\frac{i\sqrt{7}}{2}$	1	1	No	$\begin{bmatrix} \frac{2}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} \\ 1 \end{bmatrix}$
$\frac{3}{2}-\frac{i\sqrt{7}}{2}$	1	1	No	$\begin{bmatrix} \frac{2}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ 1 \end{bmatrix}$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$\vec{x}_h(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t)$$

Which is written as

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = c_1 \begin{bmatrix} \frac{2\,e^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t}}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} \\ e^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix} + c_2 \begin{bmatrix} \frac{2\,e^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ e^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix}$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$\Phi = \begin{bmatrix} \vec{x}_1 & \vec{x}_2 & \cdots \end{bmatrix}$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \frac{2\,e^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t}}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} & \frac{2\,e^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ e^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t} & e^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{i\sqrt{7}\, \mathrm{e}^{-\frac{(3+i\sqrt{7})t}{2}}}{7} & -\frac{\sqrt{7}\, \mathrm{e}^{-\frac{(3+i\sqrt{7})t}{2}} (i-\sqrt{7})}{14} \\ -\frac{i\sqrt{7}\, \mathrm{e}^{\frac{(i\sqrt{7}-3)t}{2}}}{7} & \frac{\sqrt{7}\, \mathrm{e}^{\frac{(i\sqrt{7}-3)t}{2}} (i+\sqrt{7})}{14} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} \frac{2\, \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t}}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} & \frac{2\, \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t} & \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix} \int \begin{bmatrix} \frac{i\sqrt{7}\, \mathrm{e}^{-\frac{(3+i\sqrt{7})t}{2}}}{7} & -\frac{\sqrt{7}\, \mathrm{e}^{-\frac{(3+i\sqrt{7})t}{2}} (i-\sqrt{7})}{14} \\ -\frac{i\sqrt{7}\, \mathrm{e}^{\frac{(i\sqrt{7}-3)t}{2}}}{7} & \frac{\sqrt{7}\, \mathrm{e}^{\frac{(i\sqrt{7}-3)t}{2}} (i+\sqrt{7})}{14} \end{bmatrix} \begin{bmatrix} 1-4t \\ 3t+4 \end{bmatrix} dt$$

$$= \begin{bmatrix} \frac{2\, \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t}}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} & \frac{2\, \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t} & \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix} \int \begin{bmatrix} \frac{\mathrm{e}^{-\frac{(3+i\sqrt{7})t}{2}} \left(28+i(-2-11t)\sqrt{7}+21t\right)}{14} \\ \frac{\mathrm{e}^{\frac{(i\sqrt{7}-3)t}{2}} \left(28+i(11t+2)\sqrt{7}+21t\right)}{14} \end{bmatrix} dt$$

$$= \begin{bmatrix} \frac{2\, \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t}}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} & \frac{2\, \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t} & \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix} \begin{bmatrix} \frac{\sqrt{7}\, \mathrm{e}^{-\frac{(3+i\sqrt{7})t}{2}} \left(92\sqrt{7}\, t+65\sqrt{7}+276it+315i\right)\left(11t+3i\sqrt{7}\, t+2+4i\sqrt{7}\right)}{2128i\sqrt{7}+10304t+5936} \\ \frac{\left(92i\sqrt{7}\, t+65i\sqrt{7}+276t+315\right)\sqrt{7}\, \mathrm{e}^{\frac{(i\sqrt{7}-3)t}{2}} \left(11it+3\sqrt{7}\, t+2i+4\sqrt{7}\right)}{2128i\sqrt{7}-10304t-5936} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{1288t^3+2634t^2+2137t+725}{368t^2+424t+232} \\ \frac{184t^3-18t^2-149t-145}{736t^2+848t+464} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{2c_1 \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t}}{\frac{i\sqrt{7}}{2}+\frac{1}{2}} \\ c_1 \mathrm{e}^{\left(\frac{3}{2}+\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix} + \begin{bmatrix} \frac{2c_2 \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t}}{\frac{1}{2}-\frac{i\sqrt{7}}{2}} \\ c_2 \mathrm{e}^{\left(\frac{3}{2}-\frac{i\sqrt{7}}{2}\right)t} \end{bmatrix} + \begin{bmatrix} \frac{1288t^3+2634t^2+2137t+725}{368t^2+424t+232} \\ \frac{184t^3-18t^2-149t-145}{736t^2+848t+464} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{25}{8} + \frac{c_1 \left(1-i\sqrt{7}\right) \mathrm{e}^{\frac{(3+i\sqrt{7})t}{2}}}{2} + \frac{c_2 \left(1+i\sqrt{7}\right) \mathrm{e}^{-\frac{(i\sqrt{7}-3)t}{2}}}{2} + \frac{7t}{2} \\ c_1 \mathrm{e}^{\frac{(3+i\sqrt{7})t}{2}} + c_2 \mathrm{e}^{-\frac{(i\sqrt{7}-3)t}{2}} + \frac{t}{4} - \frac{5}{16} \end{bmatrix}$$

29.11.3 Maple step by step solution

Let's solve

$[x'(t) = x(t) + 2y(t) - 4t + 1, y'(t) = -x(t) + 2y(t) + 3t + 4]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 1-4t \\ 3t+4 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} 1-4t \\ 3t+4 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} 1-4t \\ 3t+4 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} 1 & 2 \\ -1 & 2 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[\frac{3}{2} - \frac{I\sqrt{7}}{2}, \begin{bmatrix} \frac{2}{\frac{1}{2} - \frac{I\sqrt{7}}{2}} \\ 1 \end{bmatrix}\right], \left[\frac{3}{2} + \frac{I\sqrt{7}}{2}, \begin{bmatrix} \frac{2}{\frac{I\sqrt{7}}{2} + \frac{1}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[\frac{3}{2}-\frac{I\sqrt{7}}{2}, \left[\begin{array}{c} \frac{2}{\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ 1 \end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(\frac{3}{2}-\frac{I\sqrt{7}}{2}\right)t} \cdot \left[\begin{array}{c} \frac{2}{\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ 1 \end{array}\right]$$

- Use Euler identity to write solution in terms of sin and cos

$$e^{\frac{3t}{2}} \cdot \left(\cos\left(\frac{\sqrt{7}\,t}{2}\right) - I\sin\left(\frac{\sqrt{7}\,t}{2}\right)\right) \cdot \left[\begin{array}{c} \frac{2}{\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ 1 \end{array}\right]$$

- Simplify expression

$$e^{\frac{3t}{2}} \cdot \left[\begin{array}{c} \frac{2\left(\cos\left(\frac{\sqrt{7}\,t}{2}\right)-I\sin\left(\frac{\sqrt{7}\,t}{2}\right)\right)}{\frac{1}{2}-\frac{I\sqrt{7}}{2}} \\ \cos\left(\frac{\sqrt{7}\,t}{2}\right) - I\sin\left(\frac{\sqrt{7}\,t}{2}\right) \end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = e^{\frac{3t}{2}} \cdot \left[\begin{array}{c} \frac{\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2} \\ \cos\left(\frac{\sqrt{7}\,t}{2}\right) \end{array}\right], \vec{x}_2(t) = e^{\frac{3t}{2}} \cdot \left[\begin{array}{c} \frac{\sqrt{7}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2} \\ -\sin\left(\frac{\sqrt{7}\,t}{2}\right) \end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$$

☐ Fundamental matrix

  ◦ Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syste

$$\phi(t) = \left[\begin{array}{cc} e^{\frac{3t}{2}}\left(\frac{\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2}\right) & e^{\frac{3t}{2}}\left(\frac{\sqrt{7}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2}\right) \\ e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right) & -e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right) \end{array}\right]$$

  ◦ The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$$

  ◦ Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} e^{\frac{3t}{2}}\left(\frac{\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2}\right) & e^{\frac{3t}{2}}\left(\frac{\sqrt{7}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} - \frac{\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2}\right) \\ e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right) & -e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} \frac{1}{2} & \frac{\sqrt{7}}{2} \\ 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \frac{e^{\frac{3t}{2}}\left(\sqrt{7}\cos\left(\frac{\sqrt{7}\,t}{2}\right) - \sin\left(\frac{\sqrt{7}\,t}{2}\right)\right)\sqrt{7}}{7} & \frac{4\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} \\ -\frac{2\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{7} & \frac{e^{\frac{3t}{2}}\left(\sqrt{7}\sin\left(\frac{\sqrt{7}\,t}{2}\right) + 7\cos\left(\frac{\sqrt{7}\,t}{2}\right)\right)}{7} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$
- Take the derivative of the particular solution

  $\vec{x}'_p(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- Cancel like terms

  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$
- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds$
- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\, ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \left[\begin{array}{c} \frac{5\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{8} - \frac{25\,e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{8} + \frac{7t}{2} + \frac{25}{8} \\ \frac{15\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{16} + \frac{5\,e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{16} + \frac{t}{4} - \frac{5}{16} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \left[\begin{array}{c} \frac{5\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{8} - \frac{25\,e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{8} + \frac{7t}{2} + \frac{25}{8} \\ \frac{15\sqrt{7}\,e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{16} + \frac{5\,e^{\frac{3t}{2}}\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{16} + \frac{t}{4} - \frac{5}{16} \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{e^{\frac{3t}{2}}\left(\sqrt{7}\,c_2+c_1-\frac{25}{4}\right)\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{\left(\left(c_1+\frac{5}{4}\right)\sqrt{7}-c_2\right)e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{7t}{2} + \frac{25}{8} \\ \frac{e^{\frac{3t}{2}}(16c_1+5)\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{16} - e^{\frac{3t}{2}}\left(c_2 - \frac{15\sqrt{7}}{16}\right)\sin\left(\frac{\sqrt{7}\,t}{2}\right) + \frac{t}{4} - \frac{5}{16} \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{e^{\frac{3t}{2}}\left(\sqrt{7}\,c_2+c_1-\frac{25}{4}\right)\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{\left(\left(c_1+\frac{5}{4}\right)\sqrt{7}-c_2\right)e^{\frac{3t}{2}}\sin\left(\frac{\sqrt{7}\,t}{2}\right)}{2} + \frac{7t}{2} + \frac{25}{8}, y(t) = \frac{e^{\frac{3t}{2}}(16c_1+5)\cos\left(\frac{\sqrt{7}\,t}{2}\right)}{16} -\right.$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$x'(t) = -2x(t) + y(t) - t + 3$$
$$y'(t) = x(t) + 4y(t) + t - 2$$

29.12.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t+3 \\ -2+t \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \left[\begin{array}{cc} \frac{\left(3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{\left(-3\sqrt{10}+10\right) e^{\left(1+\sqrt{10}\right) t}}{20} & -\frac{\left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right) \sqrt{10}}{20} \\ -\frac{\left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right) \sqrt{10}}{20} & \frac{\left(-3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{e^{\left(1+\sqrt{10}\right) t} \left(3\sqrt{10}+10\right)}{20} \end{array}\right]$$

Therefore the homogeneous solution is

$$\begin{aligned}
\vec{x}_h(t) &= e^{At}\vec{c} \\
&= \left[\begin{array}{cc} \frac{\left(3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{\left(-3\sqrt{10}+10\right) e^{\left(1+\sqrt{10}\right) t}}{20} & -\frac{\left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right) \sqrt{10}}{20} \\ -\frac{\left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right) \sqrt{10}}{20} & \frac{\left(-3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{e^{\left(1+\sqrt{10}\right) t} \left(3\sqrt{10}+10\right)}{20} \end{array}\right] \left[\begin{array}{c} c_1 \\ c_2 \end{array}\right] \\
&= \left[\begin{array}{c} \left(\frac{\left(3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{\left(-3\sqrt{10}+10\right) e^{\left(1+\sqrt{10}\right) t}}{20}\right) c_1 -\frac{\left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right) \sqrt{10}\, c_2}{20} \\ -\frac{\left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right) \sqrt{10}\, c_1}{20}+\left(\frac{\left(-3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{e^{\left(1+\sqrt{10}\right) t} \left(3\sqrt{10}+10\right)}{20}\right) c_2 \end{array}\right] \\
&= \left[\begin{array}{c} \frac{\left(\left(3 c_1-c_2\right) \sqrt{10}+10 c_1\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}-\frac{3 \left(\left(c_1-\frac{c_2}{3}\right) \sqrt{10}-\frac{10 c_1}{3}\right) e^{\left(1+\sqrt{10}\right) t}}{20} \\ \frac{\left(\left(-c_1-3 c_2\right) \sqrt{10}+10 c_2\right) e^{-\left(-1+\sqrt{10}\right) t}}{20}+\frac{\left(\left(c_1+3 c_2\right) \sqrt{10}+10 c_2\right) e^{\left(1+\sqrt{10}\right) t}}{20} \end{array}\right]
\end{aligned}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At} \vec{G}(t) \, dt$$

But

$$\begin{aligned}
e^{-At} &= \left(e^{At}\right)^{-1} \\
&= \left[\begin{array}{cc} -\frac{e^{-2t} \left(3\sqrt{10}\, e^{-\left(-1+\sqrt{10}\right) t}-3\sqrt{10}\, e^{\left(1+\sqrt{10}\right) t}-10\, e^{-\left(-1+\sqrt{10}\right) t}-10\, e^{\left(1+\sqrt{10}\right) t}\right)}{20} & \frac{\sqrt{10}\, e^{-2t} \left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right.}\cdots\right.}{20} \\ \frac{\sqrt{10}\, e^{-2t} \left(-e^{\left(1+\sqrt{10}\right) t}+e^{-\left(-1+\sqrt{10}\right) t}\right)}{20} & \frac{e^{-2t} \left(\left(3\sqrt{10}+10\right) e^{-\left(-1+\sqrt{10}\right) t}-3\, e^{\left(1+\sqrt{10}\right) t}\cdots\right.}{20} \end{array}\right.
\end{aligned}$$

Hence

$$
\begin{aligned}
\vec{x}_p(t) &= \left[\begin{array}{cc} \frac{(3\sqrt{10}+10)e^{-(-1+\sqrt{10})t}}{20} + \frac{(-3\sqrt{10}+10)e^{(1+\sqrt{10})t}}{20} & -\frac{\left(-e^{(1+\sqrt{10})t}+e^{-(-1+\sqrt{10})t}\right)\sqrt{10}}{20} \\ -\frac{\left(-e^{(1+\sqrt{10})t}+e^{-(-1+\sqrt{10})t}\right)\sqrt{10}}{20} & \frac{(-3\sqrt{10}+10)e^{-(-1+\sqrt{10})t}}{20} + \frac{e^{(1+\sqrt{10})t}(3\sqrt{10}+10)}{20} \end{array}\right] \int \left[\begin{array}{c} e \cdots \\ \cdots \end{array}\right. \\
&= \left[\begin{array}{cc} \frac{(3\sqrt{10}+10)e^{-(-1+\sqrt{10})t}}{20} + \frac{(-3\sqrt{10}+10)e^{(1+\sqrt{10})t}}{20} & -\frac{\left(-e^{(1+\sqrt{10})t}+e^{-(-1+\sqrt{10})t}\right)\sqrt{10}}{20} \\ -\frac{\left(-e^{(1+\sqrt{10})t}+e^{-(-1+\sqrt{10})t}\right)\sqrt{10}}{20} & \frac{(-3\sqrt{10}+10)e^{-(-1+\sqrt{10})t}}{20} + \frac{e^{(1+\sqrt{10})t}(3\sqrt{10}+10)}{20} \end{array}\right] \left[\begin{array}{c} ((126t \cdots \\ ((-7 \cdots \end{array}\right. \\
&= \left[\begin{array}{c} -\frac{5t}{9} + \frac{145}{81} \\ -\frac{t}{9} + \frac{2}{81} \end{array}\right]
\end{aligned}
$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \left[\begin{array}{c} \frac{145}{81} + \frac{\left((3c_1-c_2)\sqrt{10}+10c_1\right)e^{-(-1+\sqrt{10})t}}{20} + \frac{\left((-3c_1+c_2)\sqrt{10}+10c_1\right)e^{(1+\sqrt{10})t}}{20} - \frac{5t}{9} \\ \frac{\left((-c_1-3c_2)\sqrt{10}+10c_2\right)e^{-(-1+\sqrt{10})t}}{20} + \frac{\left((c_1+3c_2)\sqrt{10}+10c_2\right)e^{(1+\sqrt{10})t}}{20} - \frac{t}{9} + \frac{2}{81} \end{array}\right]
\end{aligned}
$$

29.12.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$
\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)
$$

Or

$$
\left[\begin{array}{c} x'(t) \\ y'(t) \end{array}\right] = \left[\begin{array}{cc} -2 & 1 \\ 1 & 4 \end{array}\right] \left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] + \left[\begin{array}{c} -t+3 \\ -2+t \end{array}\right]
$$

Since the system is nonhomogeneous, then the solution is given by

$$
\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)
$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det(A - \lambda I) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -2-\lambda & 1 \\ 1 & 4-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 - 2\lambda - 9 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = 1 + \sqrt{10}$$
$$\lambda_2 = 1 - \sqrt{10}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$1 - \sqrt{10}$	1	real eigenvalue
$1 + \sqrt{10}$	1	real eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = 1 - \sqrt{10}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix} - \left(1 - \sqrt{10}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} -3+\sqrt{10} & 1 \\ 1 & 3+\sqrt{10} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3+\sqrt{10} & 1 & 0 \\ 1 & 3+\sqrt{10} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{-3+\sqrt{10}} \Longrightarrow \left[\begin{array}{cc|c} -3+\sqrt{10} & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3+\sqrt{10} & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{t}{-3+\sqrt{10}}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{t}{-3+\sqrt{10}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{t}{-3+\sqrt{10}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{t}{-3+\sqrt{10}} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{1}{-3+\sqrt{10}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{t}{-3+\sqrt{10}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{1}{-3+\sqrt{10}} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = 1 + \sqrt{10}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix} - \left(1+\sqrt{10}\right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} -3-\sqrt{10} & 1 \\ 1 & 3-\sqrt{10} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} -3-\sqrt{10} & 1 & 0 \\ 1 & 3-\sqrt{10} & 0 \end{array}\right]$$

$$R_2 = R_2 - \frac{R_1}{-3-\sqrt{10}} \Longrightarrow \left[\begin{array}{cc|c} -3-\sqrt{10} & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} -3-\sqrt{10} & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{t}{3+\sqrt{10}}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{t}{3+\sqrt{10}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{t}{3+\sqrt{10}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{t}{3+\sqrt{10}} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{1}{3+\sqrt{10}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{t}{3+\sqrt{10}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{3+\sqrt{10}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{t}{3+\sqrt{10}} \\ t \end{bmatrix} = \begin{bmatrix} \frac{1}{3+\sqrt{10}} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m - k$ generalized eigenvectors for this eigenvalue.

eigenvalue	multiplicity		defective?	eigenvectors
	algebraic m	geometric k		
$1+\sqrt{10}$	1	1	No	$\left[\begin{array}{c} \frac{1}{3+\sqrt{10}} \\ 1 \end{array}\right]$
$1-\sqrt{10}$	1	1	No	$\left[\begin{array}{c} \frac{1}{3-\sqrt{10}} \\ 1 \end{array}\right]$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Since eigenvalue $1+\sqrt{10}$ is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_1(t) &= \vec{v}_1 e^{\left(1+\sqrt{10}\right)t} \\
&= \left[\begin{array}{c} \frac{1}{3+\sqrt{10}} \\ 1 \end{array}\right] e^{\left(1+\sqrt{10}\right)t}
\end{aligned}
$$

Since eigenvalue $1-\sqrt{10}$ is real and distinct then the corresponding eigenvector solution is

$$
\begin{aligned}
\vec{x}_2(t) &= \vec{v}_2 e^{\left(1-\sqrt{10}\right)t} \\
&= \left[\begin{array}{c} \frac{1}{3-\sqrt{10}} \\ 1 \end{array}\right] e^{\left(1-\sqrt{10}\right)t}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = c_1 \left[\begin{array}{c} \frac{e^{\left(1+\sqrt{10}\right)t}}{3+\sqrt{10}} \\ e^{\left(1+\sqrt{10}\right)t} \end{array}\right] + c_2 \left[\begin{array}{c} \frac{e^{\left(1-\sqrt{10}\right)t}}{3-\sqrt{10}} \\ e^{\left(1-\sqrt{10}\right)t} \end{array}\right]
$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$
\Phi = \left[\begin{array}{ccc} \vec{x}_1 & \vec{x}_2 & \cdots \end{array}\right]
$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$\Phi(t) = \begin{bmatrix} \frac{e^{(1+\sqrt{10})t}}{3+\sqrt{10}} & \frac{e^{(1-\sqrt{10})t}}{3-\sqrt{10}} \\ e^{(1+\sqrt{10})t} & e^{(1-\sqrt{10})t} \end{bmatrix}$$

The particular solution is then given by

$$\vec{x}_p(t) = \Phi \int \Phi^{-1}\vec{G}(t)\,dt$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{\sqrt{10}\,e^{-(1+\sqrt{10})t}}{20} & \frac{\sqrt{10}\left(3+\sqrt{10}\right)e^{-(1+\sqrt{10})t}}{20} \\ -\frac{\sqrt{10}\,e^{(-1+\sqrt{10})t}}{20} & \frac{e^{(-1+\sqrt{10})t}\sqrt{10}\left(-3+\sqrt{10}\right)}{20} \end{bmatrix}$$

Hence

$$\vec{x}_p(t) = \begin{bmatrix} \frac{e^{(1+\sqrt{10})t}}{3+\sqrt{10}} & \frac{e^{(1-\sqrt{10})t}}{3-\sqrt{10}} \\ e^{(1+\sqrt{10})t} & e^{(1-\sqrt{10})t} \end{bmatrix} \int \begin{bmatrix} \frac{\sqrt{10}\,e^{-(1+\sqrt{10})t}}{20} & \frac{\sqrt{10}\left(3+\sqrt{10}\right)e^{-(1+\sqrt{10})t}}{20} \\ -\frac{\sqrt{10}\,e^{(-1+\sqrt{10})t}}{20} & \frac{e^{(-1+\sqrt{10})t}\sqrt{10}\left(-3+\sqrt{10}\right)}{20} \end{bmatrix} \begin{bmatrix} -t+3 \\ -2+t \end{bmatrix} dt$$

$$= \begin{bmatrix} \frac{e^{(1+\sqrt{10})t}}{3+\sqrt{10}} & \frac{e^{(1-\sqrt{10})t}}{3-\sqrt{10}} \\ e^{(1+\sqrt{10})t} & e^{(1-\sqrt{10})t} \end{bmatrix} \int \begin{bmatrix} \frac{\left((2t-3)\sqrt{10}+10t-20\right)e^{-(1+\sqrt{10})t}}{20} \\ \frac{\left((3-2t)\sqrt{10}+10t-20\right)e^{(-1+\sqrt{10})t}}{20} \end{bmatrix} dt$$

$$= \begin{bmatrix} \frac{e^{(1+\sqrt{10})t}}{3+\sqrt{10}} & \frac{e^{(1-\sqrt{10})t}}{3-\sqrt{10}} \\ e^{(1+\sqrt{10})t} & e^{(1-\sqrt{10})t} \end{bmatrix} \begin{bmatrix} -\frac{\left(18t\sqrt{10}-49\sqrt{10}-18t+94\right)\sqrt{10}\,e^{-(1+\sqrt{10})t}\left(t\sqrt{10}-2\sqrt{10}+2t-3\right)}{540\left(6t-14+\sqrt{10}\right)} \\ \frac{\left(18t\sqrt{10}-49\sqrt{10}+18t-94\right)\sqrt{10}\,e^{(-1+\sqrt{10})t}\left(t\sqrt{10}-2\sqrt{10}-2t+3\right)}{3240t-7560-540\sqrt{10}} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{-540t^3+4260t^2-10910t+8990}{-270+27(6t-14)^2} \\ \frac{-108t^3+528t^2-670t+124}{-270+27(6t-14)^2} \end{bmatrix}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^{(1+\sqrt{10})t}}{3+\sqrt{10}} \\ c_1 e^{(1+\sqrt{10})t} \end{bmatrix} + \begin{bmatrix} \frac{c_2 e^{(1-\sqrt{10})t}}{3-\sqrt{10}} \\ c_2 e^{(1-\sqrt{10})t} \end{bmatrix} + \begin{bmatrix} \frac{-540t^3+4260t^2-10910t+8990}{-270+27(6t-14)^2} \\ \frac{-108t^3+528t^2-670t+124}{-270+27(6t-14)^2} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} -c_2(3+\sqrt{10})\,e^{-(-1+\sqrt{10})t} + c_1(-3+\sqrt{10})\,e^{(1+\sqrt{10})t} - \frac{5t}{9} + \frac{145}{81} \\ c_1 e^{(1+\sqrt{10})t} + c_2 e^{-(-1+\sqrt{10})t} - \frac{t}{9} + \frac{2}{81} \end{bmatrix}$$

29.12.3 Maple step by step solution

Let's solve

$[x'(t) = -2x(t) + y(t) - t + 3, y'(t) = x(t) + 4y(t) + t - 2]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t+3 \\ -2+t \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t+3 \\ -2+t \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} -t+3 \\ -2+t \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -2 & 1 \\ 1 & 4 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[1-\sqrt{10}, \left[\begin{array}{c}\frac{1}{3-\sqrt{10}} \\ 1\end{array}\right]\right], \left[1+\sqrt{10}, \left[\begin{array}{c}\frac{1}{3+\sqrt{10}} \\ 1\end{array}\right]\right]\right]$$

- Consider eigenpair

$$\left[1-\sqrt{10}, \left[\begin{array}{c}\frac{1}{3-\sqrt{10}} \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_1 = \mathrm{e}^{\left(1-\sqrt{10}\right)t} \cdot \left[\begin{array}{c}\frac{1}{3-\sqrt{10}} \\ 1\end{array}\right]$$

- Consider eigenpair

$$\left[1+\sqrt{10}, \left[\begin{array}{c}\frac{1}{3+\sqrt{10}} \\ 1\end{array}\right]\right]$$

- Solution to homogeneous system from eigenpair

$$\vec{x}_2 = \mathrm{e}^{\left(1+\sqrt{10}\right)t} \cdot \left[\begin{array}{c}\frac{1}{3+\sqrt{10}} \\ 1\end{array}\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1\vec{x}_1 + c_2\vec{x}_2 + \vec{x}_p(t)$$

☐ Fundamental matrix

- Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \left[\begin{array}{cc}\frac{\mathrm{e}^{\left(1-\sqrt{10}\right)t}}{3-\sqrt{10}} & \frac{\mathrm{e}^{\left(1+\sqrt{10}\right)t}}{3+\sqrt{10}} \\ \mathrm{e}^{\left(1-\sqrt{10}\right)t} & \mathrm{e}^{\left(1+\sqrt{10}\right)t}\end{array}\right]$$

- The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$$

- Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \left[\begin{array}{cc}\frac{\mathrm{e}^{\left(1-\sqrt{10}\right)t}}{3-\sqrt{10}} & \frac{\mathrm{e}^{\left(1+\sqrt{10}\right)t}}{3+\sqrt{10}} \\ \mathrm{e}^{\left(1-\sqrt{10}\right)t} & \mathrm{e}^{\left(1+\sqrt{10}\right)t}\end{array}\right] \cdot \frac{1}{\left[\begin{array}{cc}\frac{1}{3-\sqrt{10}} & \frac{1}{3+\sqrt{10}} \\ 1 & 1\end{array}\right]}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t)=\begin{bmatrix} \frac{\left(\left(3+\sqrt{10}\right)e^{-\left(-1+\sqrt{10}\right)t}+e^{\left(1+\sqrt{10}\right)t}\left(-3+\sqrt{10}\right)\right)\sqrt{10}}{20} & -\frac{\left(-e^{\left(1+\sqrt{10}\right)t}+e^{-\left(-1+\sqrt{10}\right)t}\right)\sqrt{10}}{20} \\ -\frac{\left(-e^{\left(1+\sqrt{10}\right)t}+e^{-\left(-1+\sqrt{10}\right)t}\right)\sqrt{10}}{20} & \frac{\left(-3\sqrt{10}+10\right)e^{-\left(-1+\sqrt{10}\right)t}}{20}+\frac{e^{\left(1+\sqrt{10}\right)t}\left(3\sqrt{10}+10\right)}{20} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\overrightarrow{v}(t)$ and solve for $\overrightarrow{v}(t)$

  $\overrightarrow{x}_p(t)=\Phi(t)\cdot\overrightarrow{v}(t)$

- Take the derivative of the particular solution

  $\overrightarrow{x}'_p(t)=\Phi'(t)\cdot\overrightarrow{v}(t)+\Phi(t)\cdot\overrightarrow{v}'(t)$

- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t)\cdot\overrightarrow{v}(t)+\Phi(t)\cdot\overrightarrow{v}'(t)=A\cdot\Phi(t)\cdot\overrightarrow{v}(t)+\overrightarrow{f}(t)$

- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A\cdot\Phi(t)\cdot\overrightarrow{v}(t)+\Phi(t)\cdot\overrightarrow{v}'(t)=A\cdot\Phi(t)\cdot\overrightarrow{v}(t)+\overrightarrow{f}(t)$

- Cancel like terms

  $\Phi(t)\cdot\overrightarrow{v}'(t)=\overrightarrow{f}(t)$

- Multiply by the inverse of the fundamental matrix

  $\overrightarrow{v}'(t)=\frac{1}{\Phi(t)}\cdot\overrightarrow{f}(t)$

- Integrate to solve for $\overrightarrow{v}(t)$

  $\overrightarrow{v}(t)=\int_0^t\frac{1}{\Phi(s)}\cdot\overrightarrow{f}(s)\,ds$

- Plug $\overrightarrow{v}(t)$ into the equation for the particular solution

  $\overrightarrow{x}_p(t)=\Phi(t)\cdot\left(\int_0^t\frac{1}{\Phi(s)}\cdot\overrightarrow{f}(s)\,ds\right)$

- Plug in the fundamental matrix and the forcing function and compute

$$\overrightarrow{x}_p(t)=\begin{bmatrix} \frac{\left(-1450-433\sqrt{10}\right)e^{-\left(-1+\sqrt{10}\right)t}+\left(-1450+433\sqrt{10}\right)e^{\left(1+\sqrt{10}\right)t}-900t+2900}{20\left(1+\sqrt{10}\right)^2\left(-1+\sqrt{10}\right)^2} \\ \frac{\left(151\sqrt{10}-20\right)e^{-\left(-1+\sqrt{10}\right)t}}{1620}+\frac{\left(-151\sqrt{10}-20\right)e^{\left(1+\sqrt{10}\right)t}}{1620}-\frac{t}{9}+\frac{2}{81} \end{bmatrix}$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1 \vec{x}_1 + c_2 \vec{x}_2 + \left[\begin{array}{c} \frac{\left(-1450-433\sqrt{10}\right)e^{-\left(-1+\sqrt{10}\right)t}+\left(-1450+433\sqrt{10}\right)e^{\left(1+\sqrt{10}\right)t}-900t+2900}{20\left(1+\sqrt{10}\right)^2\left(-1+\sqrt{10}\right)^2} \\ \frac{\left(151\sqrt{10}-20\right)e^{-\left(-1+\sqrt{10}\right)t}}{1620} + \frac{\left(-151\sqrt{10}-20\right)e^{\left(1+\sqrt{10}\right)t}}{1620} - \frac{t}{9} + \frac{2}{81} \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} \frac{\left((-1620c_1-433)\sqrt{10}-4860c_1-1450\right)e^{-\left(-1+\sqrt{10}\right)t}}{1620} + \frac{\left((1620c_2+433)\sqrt{10}-4860c_2-1450\right)e^{\left(1+\sqrt{10}\right)t}}{1620} - \frac{5t}{9} \\ \frac{\left(1620c_1+151\sqrt{10}-20\right)e^{-\left(-1+\sqrt{10}\right)t}}{1620} + \frac{\left(1620c_2-151\sqrt{10}-20\right)e^{\left(1+\sqrt{10}\right)t}}{1620} - \frac{t}{9} + \frac{2}{81} \end{array}\right.$$

- Solution to the system of ODEs

$$\left\{x(t) = \frac{\left((-1620c_1-433)\sqrt{10}-4860c_1-1450\right)e^{-\left(-1+\sqrt{10}\right)t}}{1620} + \frac{\left((1620c_2+433)\sqrt{10}-4860c_2-1450\right)e^{\left(1+\sqrt{10}\right)t}}{1620} - \frac{5t}{9} + \frac{145}{81},\right.$$

The type(s) of ODE detected by this program : **"system of linear ODEs"**

Solve

$$
\begin{aligned}
x'(t) &= -4x(t) + y(t) - t + 3 \\
y'(t) &= -x(t) - 5y(t) + t + 1
\end{aligned}
$$

29.13.1 Solution using Matrix exponential method

In this method, we will assume we have found the matrix exponential e^{At} allready. There are different methods to determine this but will not be shown here. This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t+3 \\ t+1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation

of parameters method applied to the fundamental matrix. For the above matrix A, the matrix exponential can be found to be

$$e^{At} = \begin{bmatrix} e^{-\frac{9t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right) + \frac{\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & \frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & e^{-\frac{9t}{2}} \cos\left(\frac{\sqrt{3}\,t}{2}\right) - \frac{\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} & \frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & -\frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} \end{bmatrix}$$

Therefore the homogeneous solution is

$$\vec{x}_h(t) = e^{At}\vec{c}$$

$$= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} & \frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & -\frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} \end{bmatrix} \begin{bmatrix} c_1 \\ c_2 \end{bmatrix}$$

$$= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)c_1}{3} + \frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)c_2}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}} \sin\left(\frac{\sqrt{3}\,t}{2}\right)c_1}{3} - \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)c_2}{3} \end{bmatrix}$$

$$= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,(c_1+2c_2)\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)c_1\right)}{3} \\ -\frac{2\left(\sqrt{3}\,(c_1+\frac{c_2}{2})\sin\left(\frac{\sqrt{3}\,t}{2}\right)-\frac{3\cos\left(\frac{\sqrt{3}\,t}{2}\right)c_2}{2}\right)e^{-\frac{9t}{2}}}{3} \end{bmatrix}$$

The particular solution given by

$$\vec{x}_p(t) = e^{At} \int e^{-At}\vec{G}(t)\,dt$$

But

$$e^{-At} = (e^{At})^{-1}$$

$$= \begin{bmatrix} -\frac{\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)e^{\frac{9t}{2}}}{3} & -\frac{2\sqrt{3}\,e^{\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ \frac{2\sqrt{3}\,e^{\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & \frac{\left(\sqrt{3}\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)e^{\frac{9t}{2}}}{3} \end{bmatrix}$$

Hence

$$
\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} & \frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & -\frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} \end{bmatrix} \int \begin{bmatrix} -\frac{\left(\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)e^{\frac{9t}{2}}}{3} \\ \frac{2\sqrt{3}\,e^{\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \end{bmatrix} \\
&= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)+3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} & \frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & -\frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} \end{bmatrix} \begin{bmatrix} -\frac{2\,e^{\frac{9t}{2}}\left(\left(2t-\frac{117}{14}\right)\cos\left(\frac{\sqrt{3}\,t}{2}\right)+\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right.\right.}{21} \\ -\frac{e^{\frac{9t}{2}}\left(\left(-5t+\frac{1}{7}\right)\cos\left(\frac{\sqrt{3}\,t}{2}\right)+\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)\right.}{21} \end{bmatrix} \\
&= \begin{bmatrix} -\frac{4t}{21}+\frac{39}{49} \\ \frac{5t}{21}-\frac{1}{147} \end{bmatrix}
\end{aligned}
$$

Hence the complete solution is

$$
\begin{aligned}
\vec{x}(t) &= \vec{x}_h(t) + \vec{x}_p(t) \\
&= \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\sqrt{3}\,(c_1+2c_2)\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} + e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)c_1 - \frac{4t}{21} + \frac{39}{49} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\left(c_1+\frac{c_2}{2}\right)\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} + e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)c_2 + \frac{5t}{21} - \frac{1}{147} \end{bmatrix}
\end{aligned}
$$

29.13.2 Solution using explicit Eigenvalue and Eigenvector method

This is a system of linear ODE's given as

$$\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$$

Or

$$\begin{bmatrix} x'(t) \\ y'(t) \end{bmatrix} = \begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} \begin{bmatrix} x(t) \\ y(t) \end{bmatrix} + \begin{bmatrix} -t+3 \\ t+1 \end{bmatrix}$$

Since the system is nonhomogeneous, then the solution is given by

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

Where $\vec{x}_h(t)$ is the homogeneous solution to $\vec{x}'(t) = A\,\vec{x}(t)$ and $\vec{x}_p(t)$ is a particular solution to $\vec{x}'(t) = A\,\vec{x}(t) + \vec{G}(t)$. The particular solution will be found using variation of parameters method applied to the fundamental matrix.

The first step is find the homogeneous solution. We start by finding the eigenvalues of A. This is done by solving the following equation for the eigenvalues λ

$$\det\left(A - \lambda I\right) = 0$$

Expanding gives

$$\det\left(\begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} - \lambda \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right) = 0$$

Therefore

$$\det\left(\begin{bmatrix} -4-\lambda & 1 \\ -1 & -5-\lambda \end{bmatrix}\right) = 0$$

Which gives the characteristic equation

$$\lambda^2 + 9\lambda + 21 = 0$$

The roots of the above are the eigenvalues.

$$\lambda_1 = -\frac{9}{2} + \frac{i\sqrt{3}}{2}$$
$$\lambda_2 = -\frac{9}{2} - \frac{i\sqrt{3}}{2}$$

This table summarises the above result

eigenvalue	algebraic multiplicity	type of eigenvalue
$-\frac{9}{2} - \frac{i\sqrt{3}}{2}$	1	complex eigenvalue
$-\frac{9}{2} + \frac{i\sqrt{3}}{2}$	1	complex eigenvalue

Now the eigenvector for each eigenvalue are found.

Considering the eigenvalue $\lambda_1 = -\frac{9}{2} - \frac{i\sqrt{3}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} - \left(-\frac{9}{2} - \frac{i\sqrt{3}}{2}\right)\begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}\right)\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$
$$\begin{bmatrix} \frac{1}{2} + \frac{i\sqrt{3}}{2} & 1 \\ -1 & -\frac{1}{2} + \frac{i\sqrt{3}}{2} \end{bmatrix}\begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{1}{2} + \frac{i\sqrt{3}}{2} & 1 & 0 \\ -1 & -\frac{1}{2} + \frac{i\sqrt{3}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{\frac{1}{2} + \frac{i\sqrt{3}}{2}} \implies \left[\begin{array}{cc|c} \frac{1}{2} + \frac{i\sqrt{3}}{2} & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{1}{2} + \frac{i\sqrt{3}}{2} & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = -\frac{2t}{1+i\sqrt{3}}\right\}$

Hence the solution is

$$\begin{bmatrix} -\frac{2t}{1+\mathrm{I}\sqrt{3}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2t}{1+i\sqrt{3}} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} -\frac{2t}{1+\mathrm{I}\sqrt{3}} \\ t \end{bmatrix} = t \begin{bmatrix} -\frac{2}{1+i\sqrt{3}} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} -\frac{2t}{1+\mathrm{I}\sqrt{3}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2}{1+i\sqrt{3}} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} -\frac{2t}{1+\mathrm{I}\sqrt{3}} \\ t \end{bmatrix} = \begin{bmatrix} -\frac{2}{1+i\sqrt{3}} \\ 1 \end{bmatrix}$$

Considering the eigenvalue $\lambda_2 = -\frac{9}{2} + \frac{i\sqrt{3}}{2}$

We need to solve $A\vec{v} = \lambda\vec{v}$ or $(A - \lambda I)\vec{v} = \vec{0}$ which becomes

$$\left(\begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} - \left(-\frac{9}{2} + \frac{i\sqrt{3}}{2} \right) \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \right) \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

$$\begin{bmatrix} \frac{1}{2} - \frac{i\sqrt{3}}{2} & 1 \\ -1 & -\frac{1}{2} - \frac{i\sqrt{3}}{2} \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

Now forward elimination is applied to solve for the eigenvector $\vec{v}$. The augmented matrix is

$$\left[\begin{array}{cc|c} \frac{1}{2}-\frac{i\sqrt{3}}{2} & 1 & 0 \\ -1 & -\frac{1}{2}-\frac{i\sqrt{3}}{2} & 0 \end{array}\right]$$

$$R_2 = R_2 + \frac{R_1}{\frac{1}{2}-\frac{i\sqrt{3}}{2}} \Longrightarrow \left[\begin{array}{cc|c} \frac{1}{2}-\frac{i\sqrt{3}}{2} & 1 & 0 \\ 0 & 0 & 0 \end{array}\right]$$

Therefore the system in Echelon form is

$$\begin{bmatrix} \frac{1}{2}-\frac{i\sqrt{3}}{2} & 1 \\ 0 & 0 \end{bmatrix} \begin{bmatrix} v_1 \\ v_2 \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \end{bmatrix}$$

The free variables are $\{v_2\}$ and the leading variables are $\{v_1\}$. Let $v_2 = t$. Now we start back substitution. Solving the above equation for the leading variables in terms of free variables gives equation $\left\{v_1 = \frac{2t}{i\sqrt{3}-1}\right\}$

Hence the solution is

$$\begin{bmatrix} \frac{2t}{\mathrm{I}\sqrt{3}-1} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2t}{i\sqrt{3}-1} \\ t \end{bmatrix}$$

Since there is one free Variable, we have found one eigenvector associated with this eigenvalue. The above can be written as

$$\begin{bmatrix} \frac{2t}{\mathrm{I}\sqrt{3}-1} \\ t \end{bmatrix} = t \begin{bmatrix} \frac{2}{i\sqrt{3}-1} \\ 1 \end{bmatrix}$$

Let $t = 1$ the eigenvector becomes

$$\begin{bmatrix} \frac{2t}{\mathrm{I}\sqrt{3}-1} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2}{i\sqrt{3}-1} \\ 1 \end{bmatrix}$$

Which is normalized to

$$\begin{bmatrix} \frac{2t}{\mathrm{I}\sqrt{3}-1} \\ t \end{bmatrix} = \begin{bmatrix} \frac{2}{i\sqrt{3}-1} \\ 1 \end{bmatrix}$$

The following table gives a summary of this result. It shows for each eigenvalue the algebraic multiplicity m, and its geometric multiplicity k and the eigenvectors associated with the eigenvalue. If $m > k$ then the eigenvalue is defective which means the number of normal linearly independent eigenvectors associated with this eigenvalue (called the geometric multiplicity k) does not equal the algebraic multiplicity m, and we need to determine an additional $m-k$ generalized eigenvectors for this eigenvalue.

	multiplicity			
eigenvalue	algebraic m	geometric k	defective?	eigenvectors
$-\frac{9}{2}+\frac{i\sqrt{3}}{2}$	1	1	No	$\left[\begin{array}{c}\frac{1}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} \\ 1\end{array}\right]$
$-\frac{9}{2}-\frac{i\sqrt{3}}{2}$	1	1	No	$\left[\begin{array}{c}\frac{1}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ 1\end{array}\right]$

Now that we found the eigenvalues and associated eigenvectors, we will go over each eigenvalue and generate the solution basis. The only problem we need to take care of is if the eigenvalue is defective. Therefore the homogeneous solution is

$$
\vec{x}_h(t) = c_1 \vec{x}_1(t) + c_2 \vec{x}_2(t)
$$

Which is written as

$$
\left[\begin{array}{c}x(t) \\ y(t)\end{array}\right] = c_1 \left[\begin{array}{c}\frac{\mathrm{e}^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} \\ \mathrm{e}^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}\end{array}\right] + c_2 \left[\begin{array}{c}\frac{\mathrm{e}^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ \mathrm{e}^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}\end{array}\right]
$$

Now that we found homogeneous solution above, we need to find a particular solution $\vec{x}_p(t)$. We will use Variation of parameters. The fundamental matrix is

$$
\Phi = \left[\vec{x}_1 \quad \vec{x}_2 \quad \cdots\right]
$$

Where $\vec{x}_i$ are the solution basis found above. Therefore the fundamental matrix is

$$
\Phi(t) = \left[\begin{array}{cc}\frac{\mathrm{e}^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} & \frac{\mathrm{e}^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ \mathrm{e}^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t} & \mathrm{e}^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}\end{array}\right]
$$

The particular solution is then given by

$$
\vec{x}_p(t) = \Phi \int \Phi^{-1} \vec{G}(t)\, dt
$$

But

$$\Phi^{-1} = \begin{bmatrix} \frac{i\sqrt{3}\,e^{-\frac{(-9+i\sqrt{3})t}{2}}}{3} & \frac{\sqrt{3}\,e^{-\frac{(-9+i\sqrt{3})t}{2}}(\sqrt{3}+i)}{6} \\ -\frac{i\sqrt{3}\,e^{\frac{(i\sqrt{3}+9)t}{2}}}{3} & -\frac{\sqrt{3}\,e^{\frac{(i\sqrt{3}+9)t}{2}}(i-\sqrt{3})}{6} \end{bmatrix}$$

Hence

$$\begin{aligned}
\vec{x}_p(t) &= \begin{bmatrix} \frac{e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} & \frac{e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t} & e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t} \end{bmatrix} \int \begin{bmatrix} \frac{i\sqrt{3}\,e^{-\frac{(-9+i\sqrt{3})t}{2}}}{3} & \frac{\sqrt{3}\,e^{-\frac{(-9+i\sqrt{3})t}{2}}(\sqrt{3}+i)}{6} \\ -\frac{i\sqrt{3}\,e^{\frac{(i\sqrt{3}+9)t}{2}}}{3} & -\frac{\sqrt{3}\,e^{\frac{(i\sqrt{3}+9)t}{2}}(i-\sqrt{3})}{6} \end{bmatrix} \begin{bmatrix} -t+3 \\ t+1 \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} & \frac{e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t} & e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t} \end{bmatrix} \int \begin{bmatrix} \frac{e^{-\frac{(-9+i\sqrt{3})t}{2}}\left(3-i(t-7)\sqrt{3}+3t\right)}{6} \\ \frac{e^{\frac{(i\sqrt{3}+9)t}{2}}\left(3+i(t-7)\sqrt{3}+3t\right)}{6} \end{bmatrix} dt \\
&= \begin{bmatrix} \frac{e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} & \frac{e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t} & e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t} \end{bmatrix} \begin{bmatrix} -\frac{\sqrt{3}\,e^{-\frac{(-9+i\sqrt{3})t}{2}}\left(-7\sqrt{3}\,t-116\sqrt{3}+63it-118i\right)\left(t+i\sqrt{3}\,t-7+i\sqrt{3}\right)}{1764\left(2i\sqrt{3}+t-1\right)} \\ \frac{\sqrt{3}\,e^{\frac{(i\sqrt{3}+9)t}{2}}\left(7\sqrt{3}\,t+116\sqrt{3}+63it-118i\right)\left(-t+i\sqrt{3}\,t+7+i\sqrt{3}\right)}{3528i\sqrt{3}-1764t+1764} \end{bmatrix} \\
&= \begin{bmatrix} \frac{28t^3-173t^2+598t-1521}{-1764-147(t-1)^2} \\ \frac{-35t^3+71t^2-457t+13}{-1764-147(t-1)^2} \end{bmatrix}
\end{aligned}$$

Now that we found particular solution, the final solution is

$$\vec{x}(t) = \vec{x}_h(t) + \vec{x}_p(t)$$

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{c_1 e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}+\frac{i\sqrt{3}}{2}} \\ c_1 e^{\left(-\frac{9}{2}+\frac{i\sqrt{3}}{2}\right)t} \end{bmatrix} + \begin{bmatrix} \frac{c_2 e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t}}{-\frac{1}{2}-\frac{i\sqrt{3}}{2}} \\ c_2 e^{\left(-\frac{9}{2}-\frac{i\sqrt{3}}{2}\right)t} \end{bmatrix} + \begin{bmatrix} \frac{28t^3-173t^2+598t-1521}{-1764-147(t-1)^2} \\ \frac{-35t^3+71t^2-457t+13}{-1764-147(t-1)^2} \end{bmatrix}$$

Which becomes

$$\begin{bmatrix} x(t) \\ y(t) \end{bmatrix} = \begin{bmatrix} \frac{39}{49} + \frac{c_1\left(-i\sqrt{3}-1\right)e^{\frac{(-9+i\sqrt{3})t}{2}}}{2} + \frac{c_2\left(i\sqrt{3}-1\right)e^{-\frac{(i\sqrt{3}+9)t}{2}}}{2} - \frac{4t}{21} \\ c_1 e^{\frac{(-9+i\sqrt{3})t}{2}} + c_2 e^{-\frac{(i\sqrt{3}+9)t}{2}} + \frac{5t}{21} - \frac{1}{147} \end{bmatrix}$$

29.13.3 Maple step by step solution

Let's solve

$[x'(t) = -4x(t) + y(t) - t + 3, y'(t) = -x(t) - 5y(t) + t + 1]$

- Define vector

$$\vec{x}(t) = \begin{bmatrix} x(t) \\ y(t) \end{bmatrix}$$

- Convert system into a vector equation

$$\vec{x}'(t) = \begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t+3 \\ t+1 \end{bmatrix}$$

- System to solve

$$\vec{x}'(t) = \begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix} \cdot \vec{x}(t) + \begin{bmatrix} -t+3 \\ t+1 \end{bmatrix}$$

- Define the forcing function

$$\vec{f}(t) = \begin{bmatrix} -t+3 \\ t+1 \end{bmatrix}$$

- Define the coefficient matrix

$$A = \begin{bmatrix} -4 & 1 \\ -1 & -5 \end{bmatrix}$$

- Rewrite the system as

$$\vec{x}'(t) = A \cdot \vec{x}(t) + \vec{f}$$

- To solve the system, find the eigenvalues and eigenvectors of A
- Eigenpairs of A

$$\left[\left[-\frac{9}{2} - \frac{\mathrm{I}\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{-\frac{1}{2}-\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right], \left[-\frac{9}{2} + \frac{\mathrm{I}\sqrt{3}}{2}, \begin{bmatrix} \frac{1}{-\frac{1}{2}+\frac{\mathrm{I}\sqrt{3}}{2}} \\ 1 \end{bmatrix}\right]\right]$$

- Consider complex eigenpair, complex conjugate eigenvalue can be ignored

$$\left[-\frac{9}{2}-\frac{I\sqrt{3}}{2}, \left[\begin{array}{c}\frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1\end{array}\right]\right]$$

- Solution from eigenpair

$$e^{\left(-\frac{9}{2}-\frac{I\sqrt{3}}{2}\right)t} \cdot \left[\begin{array}{c}\frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1\end{array}\right]$$

- Use Euler identity to write solution in terms of $\sin$ and $\cos$

$$e^{-\frac{9t}{2}} \cdot \left(\cos\left(\frac{\sqrt{3}\,t}{2}\right) - I\sin\left(\frac{\sqrt{3}\,t}{2}\right)\right) \cdot \left[\begin{array}{c}\frac{1}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ 1\end{array}\right]$$

- Simplify expression

$$e^{-\frac{9t}{2}} \cdot \left[\begin{array}{c}\frac{\cos\left(\frac{\sqrt{3}\,t}{2}\right)-I\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{-\frac{1}{2}-\frac{I\sqrt{3}}{2}} \\ \cos\left(\frac{\sqrt{3}\,t}{2}\right) - I\sin\left(\frac{\sqrt{3}\,t}{2}\right)\end{array}\right]$$

- Both real and imaginary parts are solutions to the homogeneous system

$$\left[\vec{x}_1(t) = e^{-\frac{9t}{2}} \cdot \left[\begin{array}{c}-\frac{\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2}+\frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} \\ \cos\left(\frac{\sqrt{3}\,t}{2}\right)\end{array}\right], \vec{x}_2(t) = e^{-\frac{9t}{2}} \cdot \left[\begin{array}{c}\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} \\ -\sin\left(\frac{\sqrt{3}\,t}{2}\right)\end{array}\right]\right]$$

- General solution of the system of ODEs can be written in terms of the particular solution $\vec{x}_p($

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \vec{x}_p(t)$$

☐ Fundamental matrix

- ○ Let $\phi(t)$ be the matrix whose columns are the independent solutions of the homogeneous syst

$$\phi(t) = \left[\begin{array}{cc}e^{-\frac{9t}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2}+\frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2}\right) & e^{-\frac{9t}{2}}\left(\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2}+\frac{\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2}\right) \\ e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right) & -e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)\end{array}\right]$$

- ○ The fundamental matrix, $\Phi(t)$ is a normalized version of $\phi(t)$ satisfying $\Phi(0) = I$ where I is th

$$\Phi(t) = \phi(t) \cdot \frac{1}{\phi(0)}$$

- ○ Substitute the value of $\phi(t)$ and $\phi(0)$

$$\Phi(t) = \begin{bmatrix} e^{-\frac{9t}{2}}\left(-\frac{\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} + \frac{\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2}\right) & e^{-\frac{9t}{2}}\left(\frac{\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} + \frac{\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2}\right) \\ e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right) & -e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right) \end{bmatrix} \cdot \frac{1}{\begin{bmatrix} -\frac{1}{2} & \frac{\sqrt{3}}{2} \\ 1 & 0 \end{bmatrix}}$$

- Evaluate and simplify to get the fundamental matrix

$$\Phi(t) = \begin{bmatrix} \frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,\cos\left(\frac{\sqrt{3}\,t}{2}\right)+\sin\left(\frac{\sqrt{3}\,t}{2}\right)\right)\sqrt{3}}{3} & \frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} \\ -\frac{2\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{3} & -\frac{e^{-\frac{9t}{2}}\left(\sqrt{3}\,\sin\left(\frac{\sqrt{3}\,t}{2}\right)-3\cos\left(\frac{\sqrt{3}\,t}{2}\right)\right)}{3} \end{bmatrix}$$

☐ Find a particular solution of the system of ODEs using variation of parameters

- Let the particular solution be the fundamental matrix multiplied by $\vec{v}(t)$ and solve for $\vec{v}(t)$

  $\vec{x}_p(t) = \Phi(t) \cdot \vec{v}(t)$
- Take the derivative of the particular solution

  $\vec{x}'_p(t) = \Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t)$
- Substitute particular solution and its derivative into the system of ODEs

  $\Phi'(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- The fundamental matrix has columns that are solutions to the homogeneous system so its der

  $A \cdot \Phi(t) \cdot \vec{v}(t) + \Phi(t) \cdot \vec{v}'(t) = A \cdot \Phi(t) \cdot \vec{v}(t) + \vec{f}(t)$
- Cancel like terms

  $\Phi(t) \cdot \vec{v}'(t) = \vec{f}(t)$
- Multiply by the inverse of the fundamental matrix

  $\vec{v}'(t) = \frac{1}{\Phi(t)} \cdot \vec{f}(t)$
- Integrate to solve for $\vec{v}(t)$

  $\vec{v}(t) = \int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds$
- Plug $\vec{v}(t)$ into the equation for the particular solution

  $\vec{x}_p(t) = \Phi(t) \cdot \left(\int_0^t \frac{1}{\Phi(s)} \cdot \vec{f}(s)\,ds\right)$
- Plug in the fundamental matrix and the forcing function and compute

$$\vec{x}_p(t) = \left[\begin{array}{c} -\frac{115\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{441} - \frac{4t}{21} + \frac{39}{49} - \frac{39\,e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{49} \\ \frac{233\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{441} + \frac{5t}{21} + \frac{e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{147} - \frac{1}{147} \end{array}\right]$$

- Plug particular solution back into general solution

$$\vec{x}(t) = c_1\vec{x}_1(t) + c_2\vec{x}_2(t) + \left[\begin{array}{c} -\frac{115\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{441} - \frac{4t}{21} + \frac{39}{49} - \frac{39\,e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{49} \\ \frac{233\sqrt{3}\,e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{441} + \frac{5t}{21} + \frac{e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{147} - \frac{1}{147} \end{array}\right]$$

- Substitute in vector of dependent variables

$$\left[\begin{array}{c} x(t) \\ y(t) \end{array}\right] = \left[\begin{array}{c} -\frac{e^{-\frac{9t}{2}}\left(-c_2\sqrt{3}+c_1+\frac{78}{49}\right)\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} + \frac{\left(\left(c_1-\frac{230}{441}\right)\sqrt{3}+c_2\right)e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} - \frac{4t}{21} + \frac{39}{49} \\ \frac{(441c_1+3)e^{-\frac{9t}{2}}\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{441} - \left(c_2 - \frac{233\sqrt{3}}{441}\right)e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right) + \frac{5t}{21} - \frac{1}{147} \end{array}\right]$$

- Solution to the system of ODEs

$$\left\{x(t) = -\frac{e^{-\frac{9t}{2}}\left(-c_2\sqrt{3}+c_1+\frac{78}{49}\right)\cos\left(\frac{\sqrt{3}\,t}{2}\right)}{2} + \frac{\left(\left(c_1-\frac{230}{441}\right)\sqrt{3}+c_2\right)e^{-\frac{9t}{2}}\sin\left(\frac{\sqrt{3}\,t}{2}\right)}{2} - \frac{4t}{21} + \frac{39}{49}, y(t) = \frac{(441c_1+3)e^{-\frac{9t}{2}}c}{441}\right.$$
