Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= -\frac{1}{x} \\
\eta(x,y) &= 0 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{1}{x}} dx \end{aligned}$$

Which results in

$$S = -\frac{x^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{x}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -x \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = y \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = R$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^2}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

Which simplifies to

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x}{y}$ 	$R = y$ $S = -\frac{x^2}{2}$	$\frac{dS}{dR} = R$ 
Summary
The solution(s) found are the following

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1 \tag{1}$$

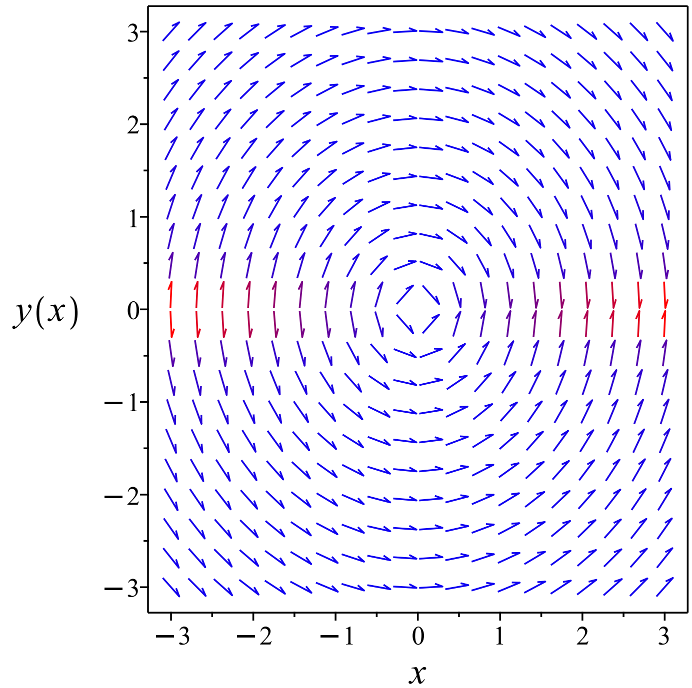

Figure 375: Slope field plot

Verification of solutions

$$-\frac{x^2}{2} = \frac{y^2}{2} + c_1$$

Verified OK.

6.13.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(-y)\,\mathrm{d}y &= (x)\,\mathrm{d}x\\ (-x)\,\mathrm{d}x + (-y)\,\mathrm{d}y &= 0 \qquad \text{(2A)}\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= -x\\ N(x, y) &= -y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-x)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(-y)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -x \, \mathrm{d}x$$
$$\phi = -\frac{x^2}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -y$. Therefore equation (4) becomes

$$-y = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (-y) \, \mathrm{d}y$$
$$f(y) = -\frac{y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{x^2}{2} - \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{x^2}{2} - \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$-\frac{x^2}{2} - \frac{y^2}{2} = c_1 \tag{1}$$

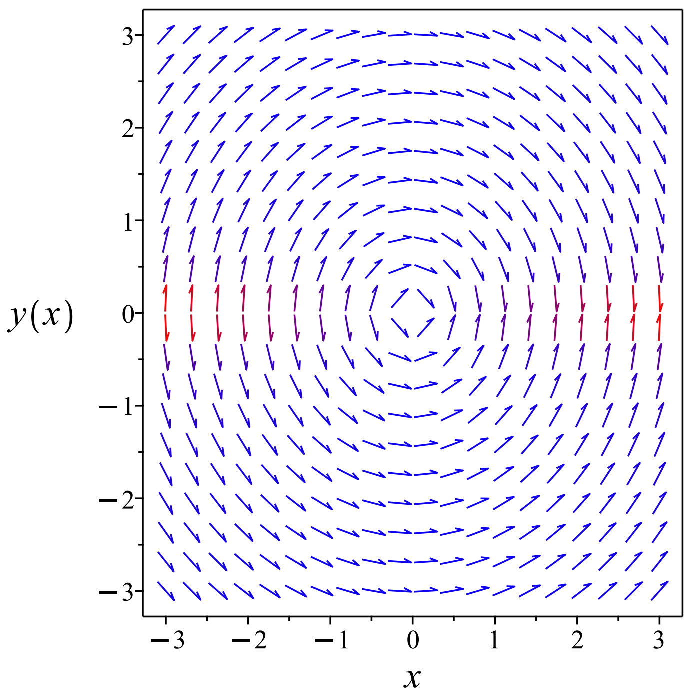

Figure 376: Slope field plot

Verification of solutions

$$-\frac{x^2}{2} - \frac{y^2}{2} = c_1$$

Verified OK.

6.13.6 Maple step by step solution

Let's solve

$\frac{x}{(x^2+y^2)^{\frac{3}{2}}}+\frac{yy'}{(x^2+y^2)^{\frac{3}{2}}}=0$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int \left(\frac{x}{(x^2+y^2)^{\frac{3}{2}}}+\frac{yy'}{(x^2+y^2)^{\frac{3}{2}}}\right)dx=\int 0dx+c_1$

- Evaluate integral

  $-\frac{1}{\sqrt{x^2+y^2}}=c_1$

- Solve for y

  $\left\{y=\frac{\sqrt{-c_1^2x^2+1}}{c_1}, y=-\frac{\sqrt{-c_1^2x^2+1}}{c_1}\right\}$

$$\boxed{e^{x}\left(x^{2}y^{2}+2xy^{2}\right)+\left(2x^{2}y\,e^{x}+2\right)y'=-6x}$$

6.14.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(2x^2y\,\mathrm{e}^x + 2\right)\mathrm{d}y &= \left(-\mathrm{e}^x\left(x^2y^2 + 2x\,y^2\right) - 6x\right)\mathrm{d}x \\
\left(\mathrm{e}^x\left(x^2y^2 + 2x\,y^2\right) + 6x\right)\mathrm{d}x + \left(2x^2y\,\mathrm{e}^x + 2\right)\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= \mathrm{e}^x\left(x^2y^2 + 2x\,y^2\right) + 6x \\
N(x,y) &= 2x^2y\,\mathrm{e}^x + 2
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\mathrm{e}^x\left(x^2y^2 + 2x\,y^2\right) + 6x\right) \\
&= 2x\,\mathrm{e}^x y(2 + x)
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(2x^2y\,\mathrm{e}^x + 2\right) \\
&= 2x\,\mathrm{e}^x y(2 + x)
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \mathrm{e}^{x}\left(x^2y^2+2x\,y^2\right)+6x\,\mathrm{d}x$$
$$\phi = x^2\left(3+y^2\mathrm{e}^{x}\right)+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2x^2y\,\mathrm{e}^{x}+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2x^2y\,\mathrm{e}^{x}+2$. Therefore equation (4) becomes

$$2x^2y\,\mathrm{e}^{x}+2 = 2x^2y\,\mathrm{e}^{x}+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (2)\,\mathrm{d}y$$
$$f(y) = 2y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x^2\left(3+y^2\mathrm{e}^{x}\right)+2y+c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x^2\left(3+y^2\mathrm{e}^{x}\right)+2y$$

Summary
The solution(s) found are the following

$$x^2(3+y^2e^x)+2y=c_1 \tag{1}$$

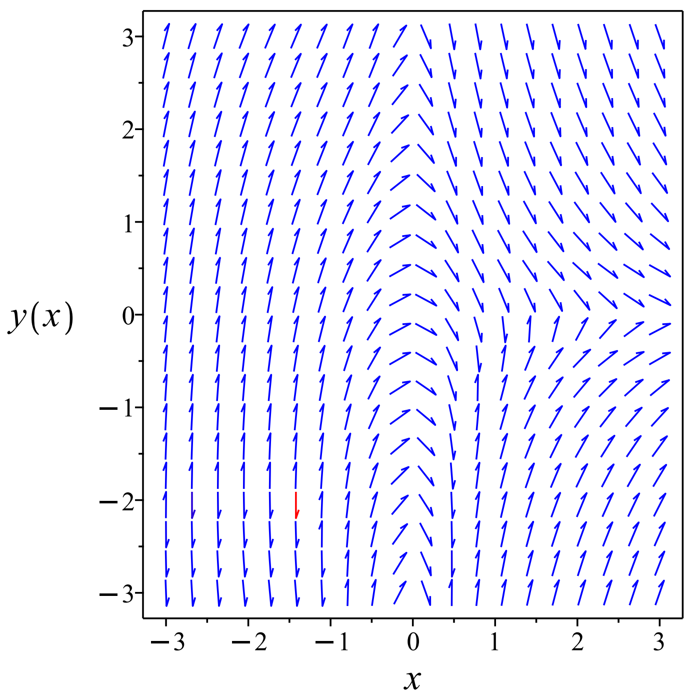

Figure 377: Slope field plot

Verification of solutions

$$x^2(3+y^2e^x)+2y=c_1$$

Verified OK.

6.14.2 Maple step by step solution

Let's solve

$e^x(x^2y^2+2xy^2)+(2x^2y\,e^x+2)\,y'=-6x$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ∘ ODE is exact if the lhs is the total derivative of a C^2 function

$F'(x, y) = 0$

- Compute derivative of lhs

  $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

- Evaluate derivatives

  $e^{x}(2y\, x^{2} + 4yx) = 4x\, e^{x} y + 2x^{2} y\, e^{x}$

- Simplify

  $2x\, e^{x} y(2 + x) = 2x\, e^{x} y(2 + x)$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int \left(e^{x}(x^{2}y^{2} + 2x\, y^{2}) + 6x\right) dx + f_1(y)$

- Evaluate integral

  $F(x, y) = y^{2}(x^{2}e^{x} - 2x\, e^{x} + 2\, e^{x}) + 2y^{2}(x\, e^{x} - e^{x}) + 3x^{2} + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

  $2x^{2}y\, e^{x} + 2 = 2y(x^{2}e^{x} - 2x\, e^{x} + 2\, e^{x}) + 4y(x\, e^{x} - e^{x}) + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 2x^{2}y\, e^{x} + 2 - 2y(x^{2}e^{x} - 2x\, e^{x} + 2\, e^{x}) - 4y(x\, e^{x} - e^{x})$

- Solve for $f_1(y)$

  $f_1(y) = 2y$

- Substitute $f_1(y)$ into equation for $F(x, y)$

  $F(x, y) = y^{2}(x^{2}e^{x} - 2x\, e^{x} + 2\, e^{x}) + 2y^{2}(x\, e^{x} - e^{x}) + 3x^{2} + 2y$

- Substitute $F(x, y)$ into the solution of the ODE

  $y^{2}(x^{2}e^{x} - 2x\, e^{x} + 2\, e^{x}) + 2y^{2}(x\, e^{x} - e^{x}) + 3x^{2} + 2y = c_1$

- Solve for y

  $\left\{y = \frac{-1+\sqrt{-3\, e^{x}x^{4} + e^{x}c_1x^{2} + 1}}{e^{x}x^{2}}, y = -\frac{1+\sqrt{-3\, e^{x}x^{4} + e^{x}c_1x^{2} + 1}}{e^{x}x^{2}}\right\}$

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

`[_exact]`

$$
\boxed{x^2 e^{x^2+y}(2x^2+3)+\left(x^3 e^{x^2+y}-12y^2\right)y'=-4x}
$$

6.15.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}
$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x,y)=0
$$

Hence

$$
\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}
$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial\phi}{\partial x}&=M\\
\frac{\partial\phi}{\partial y}&=N
\end{aligned}
$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(x^3\mathrm{e}^{x^2+y}-12y^2\right)\mathrm{d}y=\left(-x^2\mathrm{e}^{x^2+y}\left(2x^2+3\right)-4x\right)\mathrm{d}x$$
$$\left(x^2\mathrm{e}^{x^2+y}\left(2x^2+3\right)+4x\right)\mathrm{d}x+\left(x^3\mathrm{e}^{x^2+y}-12y^2\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y)=x^2\mathrm{e}^{x^2+y}\left(2x^2+3\right)+4x$$
$$N(x,y)=x^3\mathrm{e}^{x^2+y}-12y^2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(x^2\mathrm{e}^{x^2+y}\left(2x^2+3\right)+4x\right)\\&=x^2\mathrm{e}^{x^2+y}\left(2x^2+3\right)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x}&=\frac{\partial}{\partial x}\left(x^3\mathrm{e}^{x^2+y}-12y^2\right)\\&=x^2\mathrm{e}^{x^2+y}\left(2x^2+3\right)\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x}=M \tag{1}$$
$$\frac{\partial\phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int x^2 \mathrm{e}^{x^2+y} (2x^2+3) + 4x \, \mathrm{d}x$$
$$\phi = x^2 \left(\mathrm{e}^{x^2+y} x + 2 \right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = x^3 \mathrm{e}^{x^2+y} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = x^3 \mathrm{e}^{x^2+y} - 12y^2$. Therefore equation (4) becomes

$$x^3 \mathrm{e}^{x^2+y} - 12y^2 = x^3 \mathrm{e}^{x^2+y} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -12y^2$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (-12y^2) \, \mathrm{d}y$$
$$f(y) = -4y^3 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x^2 \left(\mathrm{e}^{x^2+y} x + 2 \right) - 4y^3 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x^2 \left(\mathrm{e}^{x^2+y} x + 2 \right) - 4y^3$$

Summary
The solution(s) found are the following

$$x^2\left(e^{x^2+y}x+2\right)-4y^3=c_1 \tag{1}$$

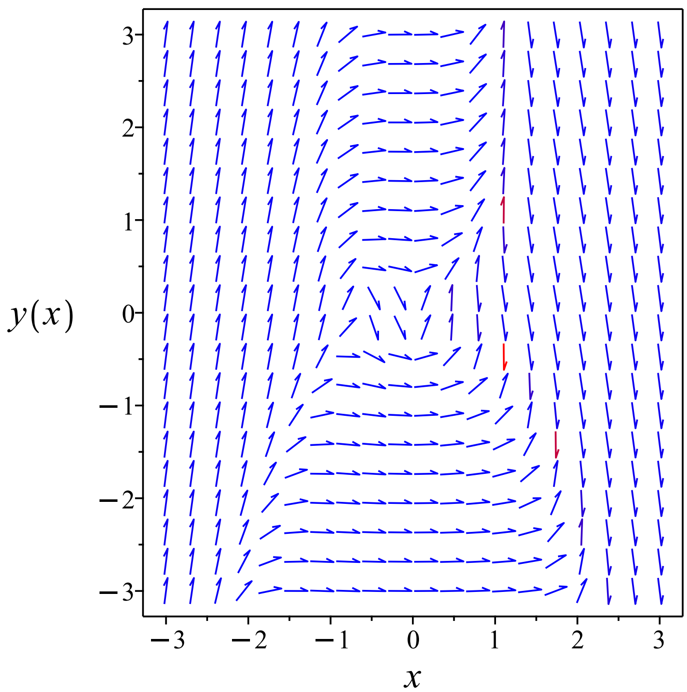

Figure 378: Slope field plot

Verification of solutions

$$x^2\left(e^{x^2+y}x+2\right)-4y^3=c_1$$

Verified OK.

6.15.2 Maple step by step solution

Let's solve

$x^2e^{x^2+y}(2x^2+3)+\left(x^3e^{x^2+y}-12y^2\right)y'=-4x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

- ODE is exact if the lhs is the total derivative of a C^2 function

  $F'(x,y) = 0$

- Compute derivative of lhs

  $F'(x,y) + \left(\frac{\partial}{\partial y} F(x,y)\right) y' = 0$

- Evaluate derivatives

  $x^2 e^{x^2+y}(2x^2+3) = 3x^2 e^{x^2+y} + 2x^4 e^{x^2+y}$

- Simplify

  $x^2 e^{x^2+y}(2x^2+3) = x^2 e^{x^2+y}(2x^2+3)$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y} F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int \left(x^2 e^{x^2+y}(2x^2+3) + 4x\right) dx + f_1(y)$

- Evaluate integral

  $F(x,y) = 3\,e^y \left(\frac{e^{x^2} x}{2} - \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{4}\right) + 2\,e^y \left(\frac{e^{x^2} x^3}{2} - \frac{3\,e^{x^2} x}{4} + \frac{3\sqrt{\pi}\,\mathrm{erfi}(x)}{8}\right) + 2x^2 + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y} F(x,y)$

- Compute derivative

  $x^3 e^{x^2+y} - 12y^2 = 3\,e^y \left(\frac{e^{x^2} x}{2} - \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{4}\right) + 2\,e^y \left(\frac{e^{x^2} x^3}{2} - \frac{3\,e^{x^2} x}{4} + \frac{3\sqrt{\pi}\,\mathrm{erfi}(x)}{8}\right) + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = x^3 e^{x^2+y} - 12y^2 - 3\,e^y \left(\frac{e^{x^2} x}{2} - \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{4}\right) - 2\,e^y \left(\frac{e^{x^2} x^3}{2} - \frac{3\,e^{x^2} x}{4} + \frac{3\sqrt{\pi}\,\mathrm{erfi}(x)}{8}\right)$

- Solve for $f_1(y)$

  $f_1(y) = -x^3 e^{x^2} e^y + x^3 e^{x^2+y} - 4y^3$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = 3\,e^y \left(\frac{e^{x^2} x}{2} - \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{4}\right) + 2\,e^y \left(\frac{e^{x^2} x^3}{2} - \frac{3\,e^{x^2} x}{4} + \frac{3\sqrt{\pi}\,\mathrm{erfi}(x)}{8}\right) + 2x^2 - x^3 e^{x^2} e^y + x^3 e^{x^2+y} - 4$

- Substitute $F(x,y)$ into the solution of the ODE

  $3\,e^y \left(\frac{e^{x^2} x}{2} - \frac{\sqrt{\pi}\,\mathrm{erfi}(x)}{4}\right) + 2\,e^y \left(\frac{e^{x^2} x^3}{2} - \frac{3\,e^{x^2} x}{4} + \frac{3\sqrt{\pi}\,\mathrm{erfi}(x)}{8}\right) + 2x^2 - x^3 e^{x^2} e^y + x^3 e^{x^2+y} - 4y^3 = c_1$

- Solve for y

  $y = RootOf\left(-x^3 e^{x^2+\_Z} + 4\_Z^3 - 2x^2 + c_1\right)$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Section 2.5 Page 79
Problem number: 16.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[_exact, [_1st_order, `_with_symmetry_[F(x),G(x)*y+H(x)]`]]
```

$$\boxed{e^{yx}\left(y x^{4}+4 x^{3}\right)+3 y+\left(x^{5} e^{yx}+3 x\right) y^{\prime}=0}$$

6.16.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y^{\prime} &= -\frac{e^{yx} x^{4} y+4\, e^{yx} x^{3}+3 y}{x\left(e^{yx} x^{4}+3\right)} \\ y^{\prime} &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_{x}+\omega\left(\eta_{y}-\xi_{x}\right)-\omega^{2} \xi_{y}-\omega_{x} \xi-\omega_{y} \eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 3 to use as anstaz gives

$$\xi=x^{3} a_{7}+y\, x^{2} a_{8}+x\, y^{2} a_{9}+y^{3} a_{10}+x^{2} a_{4}+y x a_{5}+y^{2} a_{6}+x a_{2}+y a_{3}+a_{1} \tag{1E}$$

$$\eta=x^{3} b_{7}+y\, x^{2} b_{8}+x\, y^{2} b_{9}+y^{3} b_{10}+x^{2} b_{4}+y x b_{5}+y^{2} b_{6}+x b_{2}+y b_{3}+b_{1} \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9, a_{10}, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9, b_{10}\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$3x^2b_7 + 2xyb_8 + y^2b_9 + 2xb_4 + yb_5 + b_2 \tag{5E}$$
$$- \frac{(e^{yx}x^4y + 4\,e^{yx}x^3 + 3y)\,(-3x^2a_7 + x^2b_8 - 2xya_8 + 2xyb_9 - y^2a_9 + 3y^2b_{10} - 2xa_4 + xb_5 - ya_5 + 2yb_6 -}{x\,(e^{yx}x^4 + 3)}$$
$$- \frac{(e^{yx}x^4y + 4\,e^{yx}x^3 + 3y)^2\,(x^2a_8 + 2xya_9 + 3y^2a_{10} + xa_5 + 2ya_6 + a_3)}{x^2\,(e^{yx}x^4 + 3)^2}$$
$$- \left(-\frac{e^{yx}y^2x^4 + 8\,e^{yx}x^3y + 12\,e^{yx}x^2}{x\,(e^{yx}x^4 + 3)} + \frac{e^{yx}x^4y + 4\,e^{yx}x^3 + 3y}{x^2\,(e^{yx}x^4 + 3)}\right.$$
$$\left. + \frac{(e^{yx}x^4y + 4\,e^{yx}x^3 + 3y)\,(e^{yx}x^4y + 4\,e^{yx}x^3)}{x\,(e^{yx}x^4 + 3)^2}\right)(x^3a_7 + y\,x^2a_8$$
$$+ x\,y^2a_9 + y^3a_{10} + x^2a_4 + yxa_5 + y^2a_6 + xa_2 + ya_3 + a_1)$$
$$- \left(-\frac{5\,e^{yx}x^4 + x^5e^{yx}y + 3}{x\,(e^{yx}x^4 + 3)} + \frac{(e^{yx}x^4y + 4\,e^{yx}x^3 + 3y)\,x^4e^{yx}}{(e^{yx}x^4 + 3)^2}\right)(x^3b_7$$
$$+ y\,x^2b_8 + x\,y^2b_9 + y^3b_{10} + x^2b_4 + yxb_5 + y^2b_6 + xb_2 + yb_3 + b_1) = 0$$

Putting the above in normal form gives

$$\frac{-27y^3a_6 - 12\,e^{yx}x^4y^4a_{10} - 48\,e^{yx}x^3y^3a_{10} + 18x^3yb_8 + 2\,e^{2yx}x^{10}b_2 + e^{2yx}x^9b_1 - 4\,e^{2yx}x^8a_2 - 4\,e^{2yx}x^8b_3 - 8}{}$$

$$= 0$$

Setting the numerator to zero gives

$$
\begin{aligned}
&-27y^3a_6 - 12\,\mathrm{e}^{yx}x^4y^4a_{10} - 48\,\mathrm{e}^{yx}x^3y^3a_{10} + 18x^3yb_8 \\

&- 32\,\mathrm{e}^{2yx}x^7ya_9 + 18\,\mathrm{e}^{yx}x^6ya_4 + 18\,\mathrm{e}^{yx}x^6yb_5 + 6\,\mathrm{e}^{yx}x^5y^2a_5 \\
&+ 6\,\mathrm{e}^{yx}x^5y^2b_6 - 6\,\mathrm{e}^{yx}x^4y^3a_6 + 12\,\mathrm{e}^{yx}x^4ya_5 - 24\,\mathrm{e}^{yx}x^4yb_6 \\
&- 24\,\mathrm{e}^{yx}x^3y^2a_6 + 36x^4b_7 + 18x^3ya_7 - 18x\,y^3a_9 \\
&- 18x\,y^3b_{10} + 12\,\mathrm{e}^{yx}x^5ya_2 + 12\,\mathrm{e}^{yx}x^5yb_3 + 6\,\mathrm{e}^{yx}x^4ya_1 \\
&- 2\,\mathrm{e}^{2yx}x^8y^2a_3 - \mathrm{e}^{2yx}x^8ya_1 - 16\,\mathrm{e}^{2yx}x^7ya_3 - 18y^2a_3 \\
&+ 9xb_1 - 9ya_1 + 36\,\mathrm{e}^{yx}x^8b_7 + 60\,\mathrm{e}^{yx}x^6a_7 - 12\,\mathrm{e}^{yx}x^6b_8 = 0
\end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y, \mathrm{e}^{yx}, \mathrm{e}^{2yx}\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, \mathrm{e}^{yx} = v_3, \mathrm{e}^{2yx} = v_4\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&18v_1^3v_2b_8 + 2v_4v_1^{10}b_2 + v_4v_1^9b_1 - 4v_4v_1^8a_2 - 4v_4v_1^8b_3 \\
&- 8v_4v_1^7a_1 - 16v_4v_1^6a_3 + 24v_3v_1^6b_2 + 18v_3v_1^5b_1 + 36v_3v_1^4a_2 \\
&- 12v_3v_1^4b_3 + 24v_3v_1^3a_1 + 4v_4v_1^{12}b_7 + 4v_4v_1^{10}a_7 - 4v_4v_1^{10}b_8 \\
&- 16v_4v_1^8a_8 + 9v_1^2v_2a_4 - 9v_1v_2^2a_5 - 9v_1v_2^2b_6 + 30v_3v_1^7b_4 \\
&+ 48v_3v_1^5a_4 - 12v_3v_1^5b_5 + 9v_2b_5v_1^2 + 3v_4v_1^{11}b_4 - 4v_4v_1^9b_5 \\
&- 16v_4v_1^7a_5 + 18v_1^3v_2a_7 - 18v_1v_2^3a_9 - 18v_1v_2^3b_{10} + 36v_3v_1^8b_7 \\
&+ 60v_3v_1^6a_7 - 12v_3v_1^6b_8 - 27v_2^3a_6 + 27v_1^3b_4 - 36v_2^4a_{10} \\
&+ 18b_2v_1^2 + 36v_1^4b_7 - 18v_2^2a_3 + 9v_1b_1 - 9v_2a_1 - 12v_3v_1^4v_2^4a_{10} \\
&- 48v_3v_1^3v_2^3a_{10} + 24v_3v_1^7v_2b_8 + 12v_3v_1^6v_2^2b_9 + 24v_3v_1^7v_2a_7 \\
&+ 12v_3v_1^6v_2^2a_8 + 24v_3v_1^5v_2a_8 - 24v_3v_1^5v_2b_9 - 12v_3v_1^4v_2^2a_9 \\
&- 36v_3v_1^4v_2^2b_{10} - 12v_4v_1^8v_2a_5 - 8v_4v_1^8v_2b_6 - 24v_4v_1^7v_2^2a_6 \\
&- 32v_4v_1^6v_2a_6 + v_4v_1^{10}v_2a_4 + v_4v_1^{10}v_2b_5 - v_4v_1^9v_2^2a_5 \\
&- v_4v_1^9v_2^2b_6 - 3v_4v_1^8v_2^3a_6 - 48v_4v_1^6v_2^2a_{10} + 2v_4v_1^{11}v_2b_8 \\
&+ 2v_4v_1^{11}v_2a_7 - 2v_4v_1^9v_2^3a_9 - 2v_4v_1^9v_2^3b_{10} - 8v_4v_1^9v_2a_8 \\
&- 8v_4v_1^9v_2b_9 - 20v_4v_1^8v_2^2a_9 - 12v_4v_1^8v_2^2b_{10} - 4v_4v_1^8v_2^4a_{10} \\
&- 32v_4v_1^7v_2^3a_{10} - 32v_4v_1^7v_2a_9 + 18v_3v_1^6v_2a_4 + 18v_3v_1^6v_2b_5 \\
&+ 6v_3v_1^5v_2^2a_5 + 6v_3v_1^5v_2^2b_6 - 6v_3v_1^4v_2^3a_6 + 12v_3v_1^4v_2a_5 \\
&- 24v_3v_1^4v_2b_6 - 24v_3v_1^3v_2^2a_6 + 12v_3v_1^5v_2a_2 + 12v_3v_1^5v_2b_3 \\
&+ 6v_3v_1^4v_2a_1 - 2v_4v_1^8v_2^2a_3 - v_4v_1^8v_2a_1 - 16v_4v_1^7v_2a_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(18b_8 + 18a_7)\, v_2 v_1^3 + (2b_2 + 4a_7 - 4b_8)\, v_1^{10} v_4 + (b_1 - 4b_5)\, v_1^9 v_4 \\
&+ (-4a_2 - 4b_3 - 16a_8)\, v_1^8 v_4 + (-8a_1 - 16a_5)\, v_1^7 v_4 \\

&+ (-a_5 - b_6)\, v_2^2 v_1^9 v_4 + (2b_8 + 2a_7)\, v_2 v_1^{11} v_4 + (-2a_9 - 2b_{10})\, v_2^3 v_1^9 v_4 \\
&+ (-8a_8 - 8b_9)\, v_2 v_1^9 v_4 - 12 v_3 v_1^4 v_2^4 a_{10} - 48 v_3 v_1^3 v_2^3 a_{10} \\
&- 24 v_4 v_1^7 v_2^2 a_6 - 32 v_4 v_1^6 v_2 a_6 - 3 v_4 v_1^8 v_2^3 a_6 - 48 v_4 v_1^6 v_2^2 a_{10} \\
&- 4 v_4 v_1^8 v_2^4 a_{10} - 32 v_4 v_1^7 v_2^3 a_{10} - 6 v_3 v_1^4 v_2^3 a_6 - 24 v_3 v_1^3 v_2^2 a_6 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-9a_1 &= 0\\
24a_1 &= 0\\
-18a_3 &= 0\\
-16a_3 &= 0\\
-32a_6 &= 0\\
-27a_6 &= 0\\
-24a_6 &= 0\\
-6a_6 &= 0\\
-3a_6 &= 0\\
-48a_{10} &= 0\\
-36a_{10} &= 0\\
-32a_{10} &= 0\\
-12a_{10} &= 0\\
-4a_{10} &= 0\\
9b_1 &= 0\\
18b_2 &= 0\\
3b_4 &= 0\\
27b_4 &= 0\\
30b_4 &= 0\\
4b_7 &= 0\\
36b_7 &= 0\\
-8a_1 - 16a_5 &= 0\\
36a_2 - 12b_3 &= 0\\
a_4 + b_5 &= 0\\
9a_4 + 9b_5 &= 0\\
18a_4 + 18b_5 &= 0\\
-9a_5 - 9b_6 &= 0\\
-a_5 - b_6 &= 0\\
6a_5 + 6b_6 &= 0\\
-8a_8 - 8b_9 &= 0\\
-32a_9 - 16a_3 &= 0\\
-18a_9 - 18b_{10} &= 0\\
-12a_9 - 36b_{10} &= 0\\
-2a_9 - 2b_{10} &= 0\\
b_1 - 4b_5 &= 0\\
2b_8 + 2a_7 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0\\
a_2 &= b_9\\
a_3 &= 0\\
a_4 &= 0\\
a_5 &= 0\\
a_6 &= 0\\
a_7 &= 0\\
a_8 &= -b_9\\
a_9 &= 0\\
a_{10} &= 0\\
b_1 &= 0\\
b_2 &= 0\\
b_3 &= 3b_9\\
b_4 &= 0\\
b_5 &= 0\\
b_6 &= 0\\
b_7 &= 0\\
b_8 &= 0\\
b_9 &= b_9\\
b_{10} &= 0
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -y\,x^2 + x\\
\eta &= x\,y^2 + 3y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi\\
&= x\,y^2 + 3y - \left(-\frac{\mathrm{e}^{yx}x^4y + 4\,\mathrm{e}^{yx}x^3 + 3y}{x\,(\mathrm{e}^{yx}x^4 + 3)}\right)(-y\,x^2 + x)\\
&= \frac{4\,\mathrm{e}^{yx}x^4 + 12yx}{x^5\mathrm{e}^{yx} + 3x}\\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{4\,\mathrm{e}^{yx} x^4 + 12yx}{x^5 \mathrm{e}^{yx} + 3x}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln \left(\mathrm{e}^{yx} x^4 + 3yx\right)}{4}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{\mathrm{e}^{yx} x^4 y + 4\,\mathrm{e}^{yx} x^3 + 3y}{x\left(\mathrm{e}^{yx} x^4 + 3\right)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{\mathrm{e}^{yx} x^4 y + 4\,\mathrm{e}^{yx} x^3 + 3y}{4x\left(\mathrm{e}^{yx} x^3 + 3y\right)} \\ S_y &= \frac{\mathrm{e}^{yx} x^4 + 3}{4\,\mathrm{e}^{yx} x^3 + 12y} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(x)}{4} + \frac{\ln(e^{yx}x^3 + 3y)}{4} = c_1$$

Which simplifies to

$$\frac{\ln(x)}{4} + \frac{\ln(e^{yx}x^3 + 3y)}{4} = c_1$$

Which gives

$$y = -\frac{3\,\text{LambertW}\left(\frac{x^4 e^{\frac{e^{4c_1}}{3}}}{3}\right) - e^{4c_1}}{3x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{e^{yx}x^4y+4\,e^{yx}x^3+3y}{x(e^{yx}x^4+3)}$ 	$R = x$ $S = \frac{\ln(x)}{4} + \frac{\ln(e^{yx}x^3 + 3}{4}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = -\frac{3\,\mathrm{LambertW}\left(\frac{x^4 e^{\frac{e^{4c_1}}{3}}}{3}\right) - e^{4c_1}}{3x} \tag{1}$$

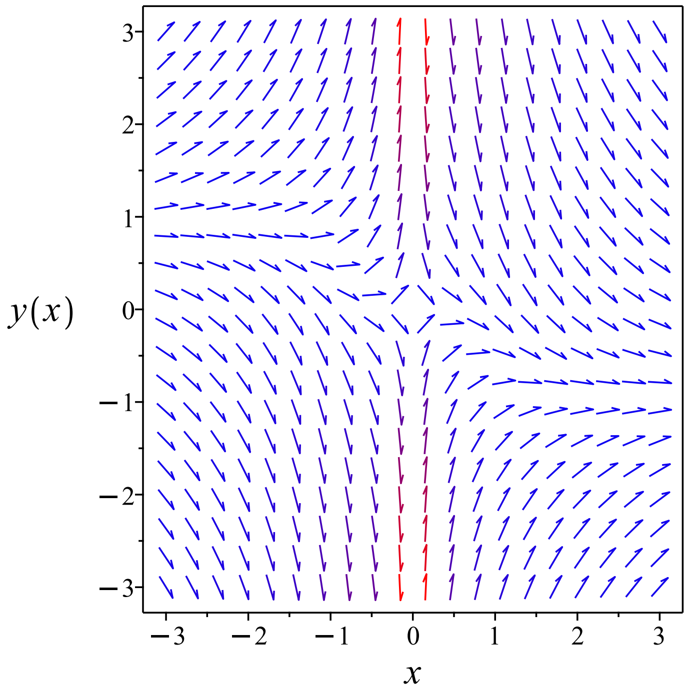

Figure 379: Slope field plot

Verification of solutions

$$y = -\frac{3\,\mathrm{LambertW}\left(\frac{x^4 \mathrm{e}^{\frac{\mathrm{e}^{4c_1}}{3}}}{3}\right) - \mathrm{e}^{4c_1}}{3x}$$

Verified OK.

6.16.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(x^5 \mathrm{e}^{yx} + 3x\right) \mathrm{d}y = \left(-\mathrm{e}^{yx}\left(x^4 y + 4x^3\right) - 3y\right) \mathrm{d}x$$
$$\left(\mathrm{e}^{yx}\left(x^4 y + 4x^3\right) + 3y\right) \mathrm{d}x + \left(x^5 \mathrm{e}^{yx} + 3x\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = \mathrm{e}^{yx}\left(x^4 y + 4x^3\right) + 3y$$
$$N(x, y) = x^5 \mathrm{e}^{yx} + 3x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\mathrm{e}^{yx}\left(x^4 y + 4x^3\right) + 3y\right) \\ &= 5 \, \mathrm{e}^{yx} x^4 + x^5 \mathrm{e}^{yx} y + 3\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x^5 \mathrm{e}^{yx} + 3x\right) \\ &= 5 \, \mathrm{e}^{yx} x^4 + x^5 \mathrm{e}^{yx} y + 3\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$
$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int \mathrm{e}^{yx}\left(x^4y+4x^3\right)+3y\,\mathrm{d}x$$
$$\phi=x\left(\mathrm{e}^{yx}x^3+3y\right)+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=x\left(\mathrm{e}^{yx}x^4+3\right)+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=x^5\mathrm{e}^{yx}+3x$. Therefore equation (4) becomes

$$x^5\mathrm{e}^{yx}+3x=x\left(\mathrm{e}^{yx}x^4+3\right)+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=0$$

Therefore

$$f(y)=c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi=x\left(\mathrm{e}^{yx}x^3+3y\right)+c_1$$

But since ϕ itself is a constant function, then let $\phi=c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1=x\left(\mathrm{e}^{yx}x^3+3y\right)$$

The solution becomes

$$y = -\frac{3\,\mathrm{LambertW}\left(\frac{x^4 e^{\frac{c_1}{3}}}{3}\right) - c_1}{3x}$$

Summary

The solution(s) found are the following

$$y = -\frac{3\,\mathrm{LambertW}\left(\frac{x^4 e^{\frac{c_1}{3}}}{3}\right) - c_1}{3x} \tag{1}$$

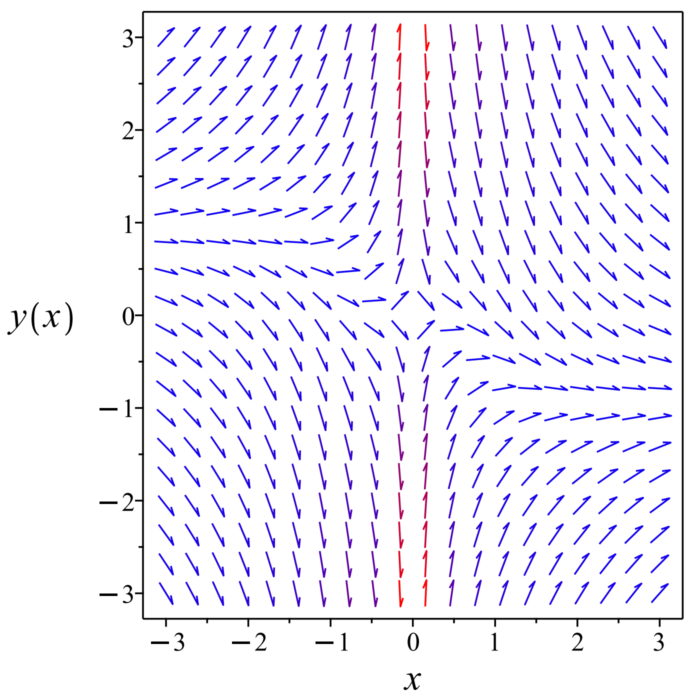

Figure 380: Slope field plot

Verification of solutions

$$y = -\frac{3\,\mathrm{LambertW}\left(\frac{x^4 e^{\frac{c_1}{3}}}{3}\right) - c_1}{3x}$$

Verified OK.

6.16.3 Maple step by step solution

Let's solve

$e^{yx}(yx^4+4x^3)+3y+(x^5e^{yx}+3x)\,y'=0$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$

  - Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

  - Evaluate derivatives

    $e^{yx}x(x^4y+4x^3)+e^{yx}x^4+3=5\,e^{yx}x^4+x^5e^{yx}y+3$

  - Simplify

    $5\,e^{yx}x^4+x^5e^{yx}y+3=5\,e^{yx}x^4+x^5e^{yx}y+3$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y)\,, N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int\left(e^{yx}(x^4y+4x^3)+3y\right)dx+f_1(y)$

- Evaluate integral

  $F(x,y)=\frac{\frac{e^{yx}y^4x^4-4y^3x^3e^{yx}+12\,e^{yx}y^2x^2-24\,e^{yx}yx+24\,e^{yx}}{y^3}+\frac{4\left(y^3x^3e^{yx}-3\,e^{yx}y^2x^2+6\,e^{yx}yx-6\,e^{yx}\right)}{y^3}}{y}+3yx+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $x^5e^{yx}+3x=-\frac{\frac{e^{yx}y^4x^4-4y^3x^3e^{yx}+12\,e^{yx}y^2x^2-24\,e^{yx}yx+24\,e^{yx}}{y^3}+\frac{4\left(y^3x^3e^{yx}-3\,e^{yx}y^2x^2+6\,e^{yx}yx-6\,e^{yx}\right)}{y^3}}{y^2}+\frac{-\frac{3\left(e^{yx}y^4x^4-4y^3x^3\right.}{}}{}$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=x^5e^{yx}+\frac{\frac{e^{yx}y^4x^4-4y^3x^3e^{yx}+12\,e^{yx}y^2x^2-24\,e^{yx}yx+24\,e^{yx}}{y^3}+\frac{4\left(y^3x^3e^{yx}-3\,e^{yx}y^2x^2+6\,e^{yx}yx-6\,e^{yx}\right)}{y^3}}{y^2}-\frac{-\frac{3\left(e^{yx}y^4x^4-4y\right.}{}}{}$

- Solve for $f_1(y)$

  $f_1(y) = 0$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $$F(x,y) = \frac{\frac{e^{yx}y^4x^4-4y^3x^3e^{yx}+12\,e^{yx}y^2x^2-24\,e^{yx}yx+24\,e^{yx}}{y^3}+\frac{4\left(y^3x^3e^{yx}-3\,e^{yx}y^2x^2+6\,e^{yx}yx-6\,e^{yx}\right)}{y^3}}{y} + 3yx$$

- Substitute $F(x,y)$ into the solution of the ODE

  $$\frac{\frac{e^{yx}y^4x^4-4y^3x^3e^{yx}+12\,e^{yx}y^2x^2-24\,e^{yx}yx+24\,e^{yx}}{y^3}+\frac{4\left(y^3x^3e^{yx}-3\,e^{yx}y^2x^2+6\,e^{yx}yx-6\,e^{yx}\right)}{y^3}}{y} + 3yx = c_1$$

- Solve for y

  $$y = -\frac{3LambertW\left(\frac{x^4e^{-\frac{c_1}{3}}}{3}\right)-c_1}{3x}$$

$$\boxed{4x^3y^2-6x^2y+\left(2yx^4-2x^3\right)y'=2x+3}$$

With initial conditions

$$[y(1)=3]$$

6.18.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= -\frac{4x^3y^2-6y\,x^2-2x-3}{2x^3\,(yx-1)} \end{aligned}$$

The x domain of $f(x,y)$ when $y=3$ is

$$\left\{-\infty\leq x<0, 0<x<\frac{1}{3}, \frac{1}{3}<x\leq\infty\right\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $f(x, y)$ when $x = 1$ is

$$\{y < 1 \lor 1 < y\}$$

And the point $y_0 = 3$ is inside this domain. Now we will look at the continuity of

$$\begin{aligned}\frac{\partial f}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{4x^3y^2 - 6y\,x^2 - 2x - 3}{2x^3\,(yx - 1)}\right) \\ &= -\frac{8y\,x^3 - 6x^2}{2x^3\,(yx - 1)} + \frac{4x^3y^2 - 6y\,x^2 - 2x - 3}{2x^2\,(yx - 1)^2}\end{aligned}$$

The x domain of $\frac{\partial f}{\partial y}$ when $y = 3$ is

$$\left\{-\infty \le x < 0, 0 < x < \frac{1}{3}, \frac{1}{3} < x \le \infty\right\}$$

And the point $x_0 = 1$ is inside this domain. The y domain of $\frac{\partial f}{\partial y}$ when $x = 1$ is

$$\{y < 1 \lor 1 < y\}$$

And the point $y_0 = 3$ is inside this domain. Therefore solution exists and is unique.

6.18.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(2x^4y - 2x^3\right)\mathrm{d}y &= \left(-4x^3y^2 + 6y\,x^2 + 2x + 3\right)\mathrm{d}x\\
\left(4x^3y^2 - 6y\,x^2 - 2x - 3\right)\mathrm{d}x + \left(2x^4y - 2x^3\right)\mathrm{d}y &= 0 \qquad \text{(2A)}
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= 4x^3y^2 - 6y\,x^2 - 2x - 3\\
N(x,y) &= 2x^4y - 2x^3
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(4x^3y^2 - 6y\,x^2 - 2x - 3\right)\\
&= 8y\,x^3 - 6x^2
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(2x^4y - 2x^3\right)\\
&= 8y\,x^3 - 6x^2
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 4x^3y^2 - 6y\,x^2 - 2x - 3 \, \mathrm{d}x$$

$$\phi = x^4y^2 - 2y\,x^3 - x^2 - 3x + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2x^4y - 2x^3 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2x^4y - 2x^3$. Therefore equation (4) becomes

$$2x^4y - 2x^3 = 2x^4y - 2x^3 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = x^4y^2 - 2y\,x^3 - x^2 - 3x + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x^4y^2 - 2y\,x^3 - x^2 - 3x$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 3$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = c_1$$

$$c_1 = -1$$

Substituting c_1 found above in the general solution gives

$$x^4y^2 - 2y\,x^3 - x^2 - 3x = -1$$

Summary
The solution(s) found are the following

$$x^4y^2 - 2yx^3 - x^2 - 3x = -1 \tag{1}$$

Verification of solutions

$$x^4y^2 - 2yx^3 - x^2 - 3x = -1$$

Verified OK.

6.18.3 Maple step by step solution

Let's solve

$[4x^3y^2 - 6x^2y + (2yx^4 - 2x^3)\,y' = 2x + 3, y(1) = 3]$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$
  - Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right)y' = 0$
  - Evaluate derivatives

    $8y\,x^3 - 6x^2 = 8y\,x^3 - 6x^2$
  - Condition met, ODE is exact
- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\,, N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$
- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (4x^3y^2 - 6y\,x^2 - 2x - 3)\,dx + f_1(y)$
- Evaluate integral

$F(x, y) = x^4 y^2 - 2y\, x^3 - x^2 - 3x + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $2x^4 y - 2x^3 = 2x^4 y - 2x^3 + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = 0$

- Solve for $f_1(y)$

  $f_1(y) = 0$

- Substitute $f_1(y)$ into equation for $F(x, y)$

  $F(x, y) = x^4 y^2 - 2y\, x^3 - x^2 - 3x$

- Substitute $F(x, y)$ into the solution of the ODE

  $x^4 y^2 - 2y\, x^3 - x^2 - 3x = c_1$

- Solve for y

  $\left\{y = \frac{x - \sqrt{2x^2 + c_1 + 3x}}{x^2}, y = \frac{x + \sqrt{2x^2 + c_1 + 3x}}{x^2}\right\}$

- Use initial condition $y(1) = 3$

  $3 = 1 - \sqrt{c_1 + 5}$

- Solution does not satisfy initial condition

- Use initial condition $y(1) = 3$

  $3 = 1 + \sqrt{c_1 + 5}$

- Solve for c_1

  $c_1 = -1$

- Substitute $c_1 = -1$ into general solution and simplify

  $y = \frac{x + \sqrt{2x^2 + 3x - 1}}{x^2}$

- Solution to the IVP

  $y = \frac{x + \sqrt{2x^2 + 3x - 1}}{x^2}$

Maple gives the following as the ode type

```
[_exact, [_1st_order, `_with_symmetry_[F(x),G(x)]`], [_Abel, `2
   nd type`, `class A`]]
```

$$
\boxed{-4\cos(x)\, y + (4y - 4\sin(x))\, y' = -4\cos(x)\sin(x) - \sec(x)^2}
$$

With initial conditions

$$
\left[y\left(\frac{\pi}{4}\right) = 0\right]
$$

6.19.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}
$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x,y) = 0
$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x}=M$$
$$\frac{\partial \phi}{\partial y}=N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$(4y-4\sin(x))\,\mathrm{d}y=\left(4\cos(x)\,y-4\cos(x)\sin(x)-\sec(x)\right.$$

$$\left(\sec(x)^2-4\cos(x)\,y+4\cos(x)\sin(x)\right)\mathrm{d}x+(4y-4\sin(x))\,\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=\sec(x)^2-4\cos(x)\,y+4\cos(x)\sin(x)\\N(x,y)&=4y-4\sin(x)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(\sec(x)^2-4\cos(x)\,y+4\cos(x)\sin(x)\right)\\&=-4\cos(x)\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(4y - 4\sin(x)) \\
&= -4\cos(x)
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int \sec(x)^2 - 4\cos(x)\, y + 4\cos(x)\sin(x) \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = \tan(x) - 4\sin(x)\, y + 2\sin(x)^2 + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = -4\sin(x) + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 4y - 4\sin(x)$. Therefore equation (4) becomes

$$
4y - 4\sin(x) = -4\sin(x) + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 4y
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int (4y) \,\mathrm{d}y \\
f(y) &= 2y^2 + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \tan(x) - 4\sin(x)y + 2\sin(x)^2 + 2y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \tan(x) - 4\sin(x)y + 2\sin(x)^2 + 2y^2$$

Initial conditions are used to solve for c_1. Substituting $x = \frac{\pi}{4}$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$2 = c_1$$

$$c_1 = 2$$

Substituting c_1 found above in the general solution gives

$$\tan(x) - 4\sin(x)y + 2\sin(x)^2 + 2y^2 = 2$$

Summary

The solution(s) found are the following

$$\tan(x) - 4\sin(x)y + 2\sin(x)^2 + 2y^2 = 2 \tag{1}$$

Verification of solutions

$$\tan(x) - 4\sin(x)y + 2\sin(x)^2 + 2y^2 = 2$$

Verified OK.

6.19.2 Maple step by step solution

Let's solve

$\left[-4\cos(x)y + (4y - 4\sin(x))y' = -4\cos(x)\sin(x) - \sec(x)^2, y\left(\frac{\pi}{4}\right) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

- ODE is exact if the lhs is the total derivative of a C^2 function

  $F'(x, y) = 0$

- Compute derivative of lhs

  $F'(x, y) + \left(\frac{\partial}{\partial y} F(x, y)\right) y' = 0$

- Evaluate derivatives

  $-4\cos(x) = -4\cos(x)$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y} F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int \left(\sec(x)^2 - 4\cos(x) y + 4\cos(x)\sin(x)\right) dx + f_1(y)$

- Evaluate integral

  $F(x, y) = \tan(x) - 4\sin(x) y + 2\sin(x)^2 + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y} F(x, y)$

- Compute derivative

  $4y - 4\sin(x) = -4\sin(x) + \frac{d}{dy} f_1(y)$

- Isolate for $\frac{d}{dy} f_1(y)$

  $\frac{d}{dy} f_1(y) = 4y$

- Solve for $f_1(y)$

  $f_1(y) = 2y^2$

- Substitute $f_1(y)$ into equation for $F(x, y)$

  $F(x, y) = \tan(x) - 4\sin(x) y + 2\sin(x)^2 + 2y^2$

- Substitute $F(x, y)$ into the solution of the ODE

  $\tan(x) - 4\sin(x) y + 2\sin(x)^2 + 2y^2 = c_1$

- Solve for y

  $\left\{y = -\frac{2\sin(x)^3 - 2\sin(x) - \sqrt{4\cos(x)^2\sin(x)^4 + 4\sin(x)^6 + 2\cos(x)^4 c_1 + 4\cos(x)^4 - 2\sin(x)\cos(x)^3 - 8\sin(x)^4 - 4\cos(x)^2 + 4\sin(x)}}{2\cos(x)^2}\right.$

- Use initial condition $y\left(\frac{\pi}{4}\right) = 0$

$$0 = \frac{\sqrt{2}}{2} + \sqrt{-\frac{1}{2} + \frac{c_1}{2}}$$

- Solution does not satisfy initial condition
- Use initial condition $y\left(\frac{\pi}{4}\right) = 0$

$$0 = \frac{\sqrt{2}}{2} - \sqrt{-\frac{1}{2} + \frac{c_1}{2}}$$

- Solve for c_1

$$c_1 = 2$$

- Substitute $c_1 = 2$ into general solution and simplify

$$y = \sin(x) - \frac{\sec(x)^2 \sqrt{2}\, \sqrt{\cos(x)^3 (-\sin(x) + 2\cos(x))}}{2}$$

- Solution to the IVP

$$y = \sin(x) - \frac{\sec(x)^2 \sqrt{2}\, \sqrt{\cos(x)^3 (-\sin(x) + 2\cos(x))}}{2}$$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Section 2.5 Page 79
Problem number: 20.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "bernoulli", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(y^3-1)\,\mathrm{e}^x+3y^2(1+\mathrm{e}^x)\,y'=0}$$

With initial conditions

$$[y(0)=0]$$

6.20.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= -\frac{(y^3-1)\,\mathrm{e}^x}{3y^2\,(1+\mathrm{e}^x)} \end{aligned}$$

$f(x,y)$ is not defined at $y=0$ therefore existence and uniqueness theorem do not apply.

6.20.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{(y^3-1)\,\mathrm{e}^x}{3y^2\,(1+\mathrm{e}^x)} \end{aligned}$$

Where $f(x) = -\frac{\mathrm{e}^x}{3(1+\mathrm{e}^x)}$ and $g(y) = \frac{y^3-1}{y^2}$. Integrating both sides gives

$$\begin{aligned} \frac{1}{\frac{y^3-1}{y^2}}\,dy &= -\frac{\mathrm{e}^x}{3\,(1+\mathrm{e}^x)}\,dx \\ \int \frac{1}{\frac{y^3-1}{y^2}}\,dy &= \int -\frac{\mathrm{e}^x}{3\,(1+\mathrm{e}^x)}\,dx \\ \frac{\ln(y^3-1)}{3} &= -\frac{\ln(1+\mathrm{e}^x)}{3} + c_1 \end{aligned}$$

Raising both side to exponential gives

$$(y^3-1)^{\frac{1}{3}} = \mathrm{e}^{-\frac{\ln(1+\mathrm{e}^x)}{3}+c_1}$$

Which simplifies to

$$(y^3-1)^{\frac{1}{3}} = \frac{c_2}{(1+\mathrm{e}^x)^{\frac{1}{3}}}$$

Which can be simplified to become

$$(y^3-1)^{\frac{1}{3}} = \frac{c_2\mathrm{e}^{c_1}}{(1+\mathrm{e}^x)^{\frac{1}{3}}}$$

The solution is

$$(y^3-1)^{\frac{1}{3}} = \frac{c_2\mathrm{e}^{c_1}}{(1+\mathrm{e}^x)^{\frac{1}{3}}}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{2} + \frac{i\sqrt{3}}{2} = \frac{2^{\frac{2}{3}}c_2\mathrm{e}^{c_1}}{2}$$

$$
c_1 = \frac{\ln\left(\frac{\left(1+i\sqrt{3}\right)^3}{4c_2^3}\right)}{3}
$$

Substituting c_1 found above in the general solution gives

$$
\left(y^3-1\right)^{\frac{1}{3}} = \frac{c_2 4^{\frac{2}{3}} \left(-\frac{8}{c_2^3}\right)^{\frac{1}{3}}}{4\left(1+\mathrm{e}^x\right)^{\frac{1}{3}}}
$$

The above simplifies to

$$
-c_2 4^{\frac{2}{3}} \left(-\frac{8}{c_2^3}\right)^{\frac{1}{3}} + 4\left(y^3-1\right)^{\frac{1}{3}} \left(1+\mathrm{e}^x\right)^{\frac{1}{3}} = 0
$$

Summary

The solution(s) found are the following

$$
-4c_2 2^{\frac{1}{3}} \left(-\frac{1}{c_2^3}\right)^{\frac{1}{3}} + 4\left(y^3-1\right)^{\frac{1}{3}} \left(1+\mathrm{e}^x\right)^{\frac{1}{3}} = 0 \tag{1}
$$

Verification of solutions

$$
-4c_2 2^{\frac{1}{3}} \left(-\frac{1}{c_2^3}\right)^{\frac{1}{3}} + 4\left(y^3-1\right)^{\frac{1}{3}} \left(1+\mathrm{e}^x\right)^{\frac{1}{3}} = 0
$$

Verified OK.

6.20.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{\left(y^3-1\right)\mathrm{e}^x}{3y^2\left(1+\mathrm{e}^x\right)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 289: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$

homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x,y) = -3(1 + e^x)\, e^{-x}$$
$$\eta(x,y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-3\left(1+\mathrm{e}^{x}\right)\mathrm{e}^{-x}} dx \end{aligned}$$

Which results in

$$S = -\frac{\ln\left(1+\mathrm{e}^{x}\right)}{3}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{\left(y^3-1\right)\mathrm{e}^{x}}{3y^2\left(1+\mathrm{e}^{x}\right)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= -\frac{\mathrm{e}^{x}}{3+3\,\mathrm{e}^{x}} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{y^2}{y^3-1} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R^2}{R^3-1}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = \frac{\ln\left(\left(R-1\right)\left(R^2+R+1\right)\right)}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{\ln\left(1+\mathrm{e}^x\right)}{3} = \frac{\ln\left(\left(y-1\right)\left(y^2+y+1\right)\right)}{3} + c_1$$

Which simplifies to

$$-\frac{\ln\left(1+\mathrm{e}^x\right)}{3} = \frac{\ln\left(\left(y-1\right)\left(y^2+y+1\right)\right)}{3} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{(y^3-1)\mathrm{e}^x}{3y^2(1+\mathrm{e}^x)}$ 	$R = y$ $S = -\frac{\ln(1+\mathrm{e}^x)}{3}$	$\frac{dS}{dR} = \frac{R^2}{R^3-1}$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-\frac{\ln(2)}{3} = \frac{i\pi}{3} + c_1$$

$$
c_1 = -\frac{i\pi}{3} - \frac{\ln(2)}{3}
$$

Substituting c_1 found above in the general solution gives

$$
-\frac{\ln(1+\mathrm{e}^x)}{3} = \frac{\ln((y-1)(y^2+y+1))}{3} - \frac{i\pi}{3} - \frac{\ln(2)}{3}
$$

Summary

The solution(s) found are the following

$$
-\frac{\ln(1+\mathrm{e}^x)}{3} = \frac{\ln((y-1)(y^2+y+1))}{3} - \frac{i\pi}{3} - \frac{\ln(2)}{3} \tag{1}
$$

Verification of solutions

$$
-\frac{\ln(1+\mathrm{e}^x)}{3} = \frac{\ln((y-1)(y^2+y+1))}{3} - \frac{i\pi}{3} - \frac{\ln(2)}{3}
$$

Verified OK.

6.20.4 Solving as bernoulli ode

In canonical form, the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= -\frac{(y^3-1)\,\mathrm{e}^x}{3y^2\,(1+\mathrm{e}^x)}
\end{aligned}
$$

This is a Bernoulli ODE.

$$
y' = -\frac{\mathrm{e}^x}{3\,(1+\mathrm{e}^x)}y + \frac{\mathrm{e}^x}{3+3\,\mathrm{e}^x}\frac{1}{y^2} \tag{1}
$$

The standard Bernoulli ODE has the form

$$
y' = f_0(x)y + f_1(x)y^n \tag{2}
$$

The first step is to divide the above equation by y^n which gives

$$
\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}
$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$
\begin{aligned}
f_0(x) &= -\frac{e^x}{3\left(1+e^x\right)} \\
f_1(x) &= \frac{e^x}{3+3\,e^x} \\
n &= -2
\end{aligned}
$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y^2}$ gives

$$
y'y^2 = -\frac{e^x y^3}{3\left(1+e^x\right)} + \frac{e^x}{3+3\,e^x} \tag{4}
$$

Let

$$
\begin{aligned}
w &= y^{1-n} \\
&= y^3
\end{aligned} \tag{5}
$$

Taking derivative of equation (5) w.r.t x gives

$$
w' = 3y^2y' \tag{6}
$$

Substituting equations (5) and (6) into equation (4) gives

$$
\begin{aligned}
\frac{w'(x)}{3} &= -\frac{e^x w(x)}{3\left(1+e^x\right)} + \frac{e^x}{3+3\,e^x} \\
w' &= -\frac{e^x w}{1+e^x} + \frac{e^x}{1+e^x}
\end{aligned} \tag{7}
$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
w'(x) + p(x)w(x) = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= \frac{e^x}{1+e^x} \\
q(x) &= \frac{e^x}{1+e^x}
\end{aligned}
$$

Hence the ode is

$$
w'(x) + \frac{e^x w(x)}{1+e^x} = \frac{e^x}{1+e^x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{e^x}{1+e^x}dx} \\
&= 1 + e^x
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu w) &= (\mu)\left(\frac{e^x}{1+e^x}\right) \\
\frac{d}{dx}((1+e^x)\, w) &= (1+e^x)\left(\frac{e^x}{1+e^x}\right) \\
d((1+e^x)\, w) &= e^x\, dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
(1+e^x)\, w &= \int e^x\, dx \\
(1+e^x)\, w &= e^x + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = 1 + e^x$ results in

$$
w(x) = \frac{e^x}{1+e^x} + \frac{c_1}{1+e^x}
$$

which simplifies to

$$
w(x) = \frac{e^x + c_1}{1+e^x}
$$

Replacing w in the above by y^3 using equation (5) gives the final solution.

$$
y^3 = \frac{e^x + c_1}{1+e^x}
$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$
0 = \frac{1}{2} + \frac{c_1}{2}
$$

$$
c_1 = -1
$$

Substituting c_1 found above in the general solution gives

$$
y^3 = \frac{e^x - 1}{1+e^x}
$$

The above simplifies to

$$1+y^3\mathrm{e}^x+y^3-\mathrm{e}^x=0$$

Summary
The solution(s) found are the following

$$1+y^3\mathrm{e}^x+y^3-\mathrm{e}^x=0 \tag{1}$$

Verification of solutions

$$1+y^3\mathrm{e}^x+y^3-\mathrm{e}^x=0$$

Verified OK.

6.20.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work

and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{3y^2}{y^3-1}\right)\mathrm{d}y &= \left(\frac{\mathrm{e}^x}{1+\mathrm{e}^x}\right)\mathrm{d}x\\ \left(-\frac{\mathrm{e}^x}{1+\mathrm{e}^x}\right)\mathrm{d}x+\left(-\frac{3y^2}{y^3-1}\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\frac{\mathrm{e}^x}{1+\mathrm{e}^x}\\ N(x,y) &= -\frac{3y^2}{y^3-1}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{\mathrm{e}^x}{1+\mathrm{e}^x}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{3y^2}{y^3-1}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$

$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int -\frac{\mathrm{e}^x}{1+\mathrm{e}^x} \mathrm{d}x$$
$$\phi = -\ln(1+\mathrm{e}^x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{3y^2}{y^3-1}$. Therefore equation (4) becomes

$$-\frac{3y^2}{y^3-1} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{3y^2}{y^3-1}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(-\frac{3y^2}{y^3-1}\right) \mathrm{d}y$$
$$f(y) = -\ln\left(y^3-1\right) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(1+\mathrm{e}^x) - \ln\left(y^3-1\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(1+\mathrm{e}^x) - \ln\left(y^3-1\right)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 0$ in the above solution gives an equation to solve for the constant of integration.

$$-\ln(2) - i\pi = c_1$$

$$c_1 = -\ln(2) - i\pi$$

Substituting c_1 found above in the general solution gives

$$-\ln(1 + e^x) - \ln(y^3 - 1) = -\ln(2) - i\pi$$

Summary
The solution(s) found are the following

$$-\ln(1 + e^x) - \ln(y^3 - 1) = -\ln(2) - i\pi \tag{1}$$

Verification of solutions

$$-\ln(1 + e^x) - \ln(y^3 - 1) = -\ln(2) - i\pi$$

Verified OK.

6.20.6 Maple step by step solution

Let's solve

$\left[(y^3 - 1) e^x + 3y^2(1 + e^x) y' = 0, y(0) = 0\right]$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

  $\int ((y^3 - 1) e^x + 3y^2(1 + e^x) y') dx = \int 0 dx + c_1$

- Evaluate integral

  $y^3(1 + e^x) - e^x = c_1$

- Solve for y

  $y = \frac{\left((e^x + c_1)(1 + e^x)^2\right)^{\frac{1}{3}}}{1 + e^x}$

- Use initial condition $y(0) = 0$

  $0 = \frac{(4 + 4c_1)^{\frac{1}{3}}}{2}$

- Solve for c_1

$c_1 = -1$

- Substitute $c_1 = -1$ into general solution and simplify

$$y = \frac{\left((\mathrm{e}^x-1)(1+\mathrm{e}^x)^2\right)^{\frac{1}{3}}}{1+\mathrm{e}^x}$$

- Solution to the IVP

$$y = \frac{\left((\mathrm{e}^x-1)(1+\mathrm{e}^x)^2\right)^{\frac{1}{3}}}{1+\mathrm{e}^x}$$

The type(s) of ODE detected by this program : **"exact", "linear", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{-\sin(x)\,y + y'\cos(x) = -\sin(x) + 2\cos(x)}$$

With initial conditions

$$[y(0) = 1]$$

6.21.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\tan(x)$$
$$q(x) = -\tan(x) + 2$$

Hence the ode is

$$y' - \tan(x)\,y = -\tan(x) + 2$$

The domain of $p(x) = -\tan(x)$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z50 \lor \frac{1}{2}\pi + \pi\_Z50 < x\right\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -\tan(x) + 2$ is

$$\left\{x < \frac{1}{2}\pi + \pi\_Z50 \lor \frac{1}{2}\pi + \pi\_Z50 < x\right\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

6.21.2 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\tan(x)dx} \\ &= \cos(x)\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(-\tan(x) + 2\right) \\ \frac{d}{dx}(\cos(x)\,y) &= (\cos(x))\left(-\tan(x) + 2\right) \\ d(\cos(x)\,y) &= (-\sin(x) + 2\cos(x))\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\cos(x)\,y &= \int -\sin(x) + 2\cos(x)\,dx \\ \cos(x)\,y &= \cos(x) + 2\sin(x) + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \cos(x)$ results in

$$y = \sec(x)\left(\cos(x) + 2\sin(x)\right) + c_1\sec(x)$$

which simplifies to

$$y = 1 + 2\tan(x) + c_1\sec(x)$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 1 + c_1$$

$$c_1 = 0$$

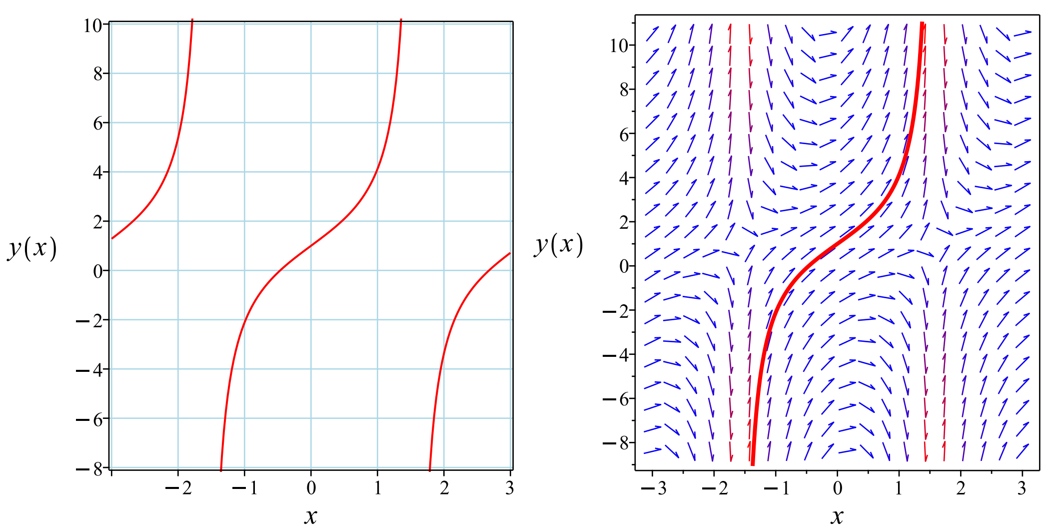
Substituting c_1 found above in the general solution gives

$$y = 1 + 2\tan(x)$$

Summary

The solution(s) found are the following

$$y = 1 + 2\tan(x) \tag{1}$$



(a) Solution plot (b) Slope field plot

Verification of solutions

$$y = 1 + 2\tan(x)$$

Verified OK.

6.21.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{-\sin(x) + \sin(x)\, y + 2\cos(x)}{\cos(x)} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 292: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \frac{1}{\cos(x)}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{1}{\cos(x)}} dy
\end{aligned}
$$

Which results in

$$
S = \cos(x)\, y
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = \frac{-\sin(x) + \sin(x)\, y + 2\cos(x)}{\cos(x)}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\sin(x)\, y \\
S_y &= \cos(x)
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\sin(x) + 2\cos(x) \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\sin(R) + 2\cos(R)
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \cos(R) + 2\sin(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\cos(x)\, y = \cos(x) + 2\sin(x) + c_1
$$

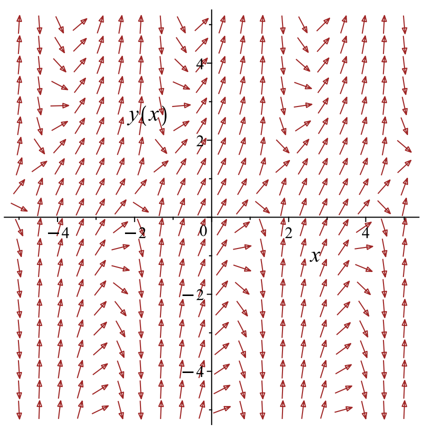
Which simplifies to

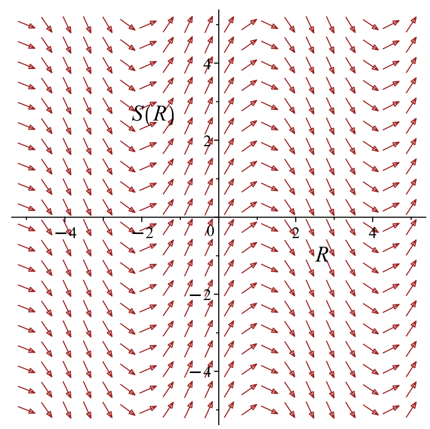
$$
\cos(x)\, y = \cos(x) + 2\sin(x) + c_1
$$

Which gives

$$
y = \frac{\cos(x) + 2\sin(x) + c_1}{\cos(x)}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = \frac{-\sin(x)+\sin(x)y+2\cos(x)}{\cos(x)}$


</td><td>$R = x$
$S = \cos(x)\, y$</td><td>$\frac{dS}{dR} = -\sin(R) + 2\cos(R)$


</td></tr>
</table>

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 1 + c_1$$

$$c_1 = 0$$

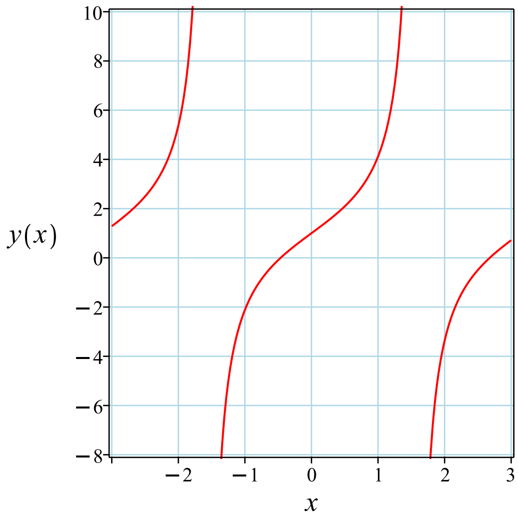
Substituting c_1 found above in the general solution gives

$$y = 1 + 2\tan(x)$$

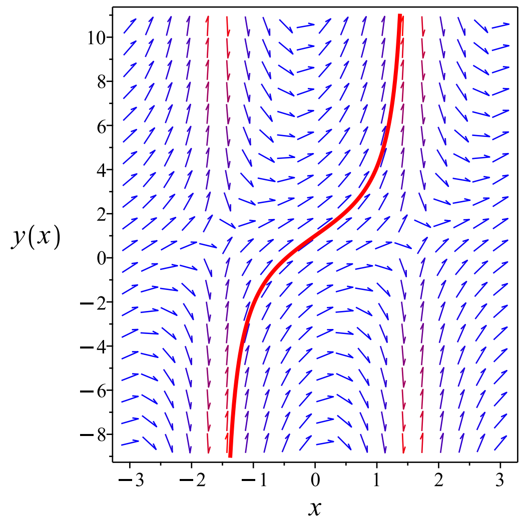
Summary

The solution(s) found are the following

$$y = 1 + 2\tan(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 1 + 2\tan(x)$$

Verified OK.

6.21.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
(\cos(x))\,\mathrm{d}y &= (-\sin(x) + \sin(x)\,y + 2\cos(x))\,\mathrm{d}x \\
(\sin(x) - \sin(x)\,y - 2\cos(x))\,\mathrm{d}x + (\cos(x))\,\mathrm{d}y &= 0 \qquad (2A)
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x, y) &= \sin(x) - \sin(x)\,y - 2\cos(x) \\
N(x, y) &= \cos(x)
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\sin(x) - \sin(x)\,y - 2\cos(x)) \\
&= -\sin(x)
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(x)) \\
&= -\sin(x)
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \sin(x) - \sin(x) \, y - 2\cos(x) \, \mathrm{d}x$$

$$\phi = \cos(x)(y-1) - 2\sin(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \cos(x) + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \cos(x)$. Therefore equation (4) becomes

$$\cos(x) = \cos(x) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \cos(x)(y-1) - 2\sin(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \cos(x)(y-1) - 2\sin(x)$$

The solution becomes

$$y = \frac{\cos(x) + 2\sin(x) + c_1}{\cos(x)}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$1 = 1 + c_1$$

$$c_1 = 0$$

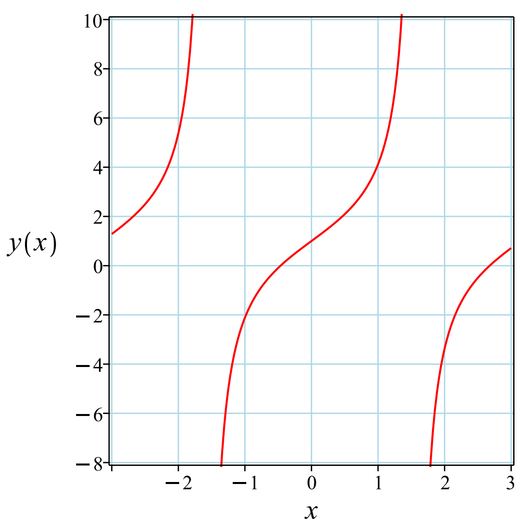
Substituting c_1 found above in the general solution gives

$$y = 1 + 2\tan(x)$$

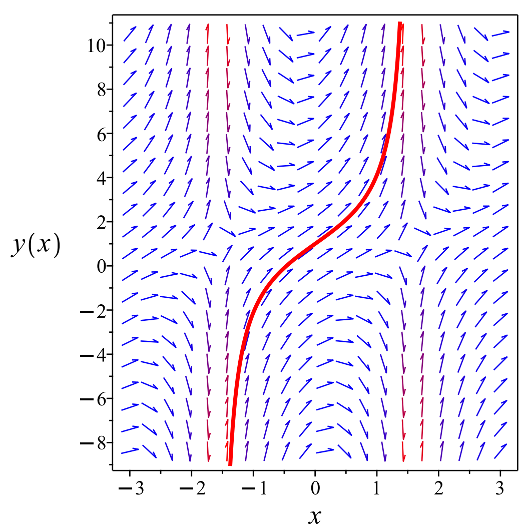
Summary

The solution(s) found are the following

$$y = 1 + 2\tan(x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = 1 + 2\tan(x)$$

Verified OK.

6.21.5 Maple step by step solution

Let's solve

$[-\sin(x)\, y + y' \cos(x) = -\sin(x) + 2\cos(x)\, , y(0) = 1]$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = \frac{\sin(x) y}{\cos(x)} + \frac{-\sin(x)+2\cos(x)}{\cos(x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' - \frac{\sin(x) y}{\cos(x)} = \frac{-\sin(x)+2\cos(x)}{\cos(x)}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' - \frac{\sin(x) y}{\cos(x)}\right) = \frac{\mu(x)(-\sin(x)+2\cos(x))}{\cos(x)}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\, y)$

  $\mu(x)\left(y' - \frac{\sin(x) y}{\cos(x)}\right) = \mu'(x)\, y + \mu(x)\, y'$

- Isolate $\mu'(x)$

  $\mu'(x) = -\frac{\mu(x)\sin(x)}{\cos(x)}$

- Solve to find the integrating factor

  $\mu(x) = \cos(x)$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\, y)\right) dx = \int \frac{\mu(x)(-\sin(x)+2\cos(x))}{\cos(x)} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\, y = \int \frac{\mu(x)(-\sin(x)+2\cos(x))}{\cos(x)} dx + c_1$

- Solve for y

  $y = \frac{\int \frac{\mu(x)(-\sin(x)+2\cos(x))}{\cos(x)} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \cos(x)$

  $y = \frac{\int (-\sin(x)+2\cos(x)) dx + c_1}{\cos(x)}$

- Evaluate the integrals on the rhs

  $y = \frac{\cos(x)+2\sin(x)+c_1}{\cos(x)}$

- Simplify

  $y = 1 + 2\tan(x) + c_1 \sec(x)$
- Use initial condition $y(0) = 1$

  $1 = 1 + c_1$
- Solve for c_1

  $c_1 = 0$
- Substitute $c_1 = 0$ into general solution and simplify

  $y = 1 + 2\tan(x)$
- Solution to the IVP

  $y = 1 + 2\tan(x)$

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "differentialType", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{(2x-1)(y-1)+(2+x)(x-3)y'=0}$$

With initial conditions

$$[y(1)=-1]$$

6.22.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1-2x}{(2+x)(x-3)} \\ q(x) &= \frac{2x-1}{(2+x)(x-3)} \end{aligned}$$

Hence the ode is

$$y' - \frac{(1-2x)\,y}{(2+x)(x-3)} = \frac{2x-1}{(2+x)(x-3)}$$

The domain of $p(x) = -\frac{1-2x}{(2+x)(x-3)}$ is

$$\{-\infty \le x < -2, -2 < x < 3, 3 < x \le \infty\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = \frac{2x-1}{(2+x)(x-3)}$ is

$$\{-\infty \le x < -2, -2 < x < 3, 3 < x \le \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

6.22.2 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{(2x-1)(-y+1)}{(2+x)(x-3)} \end{aligned}$$

Where $f(x) = \frac{2x-1}{(2+x)(x-3)}$ and $g(y) = -y+1$. Integrating both sides gives

$$\begin{aligned} \frac{1}{-y+1}\,dy &= \frac{2x-1}{(2+x)(x-3)}\,dx \\ \int \frac{1}{-y+1}\,dy &= \int \frac{2x-1}{(2+x)(x-3)}\,dx \\ -\ln(y-1) &= \ln((2+x)(x-3)) + c_1 \end{aligned}$$

Raising both side to exponential gives

$$\frac{1}{y-1} = e^{\ln((2+x)(x-3))+c_1}$$

Which simplifies to

$$\frac{1}{y-1} = c_2(2+x)(x-3)$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \frac{6\,e^{-c_1}e^{c_1}c_2 - e^{-c_1}}{6c_2}$$

$$c_1 = -\ln(12c_2)$$

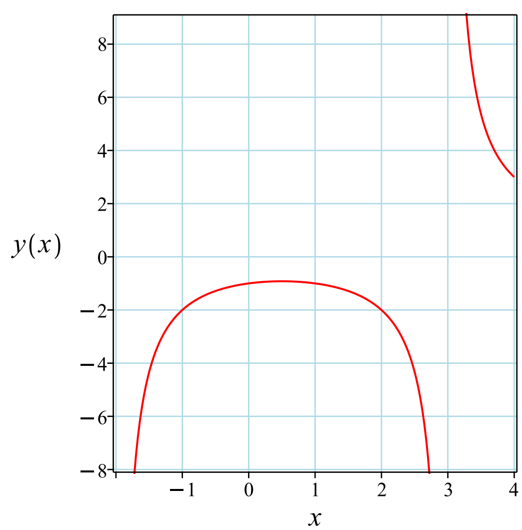
Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 - x + 6}{x^2 - x - 6}$$

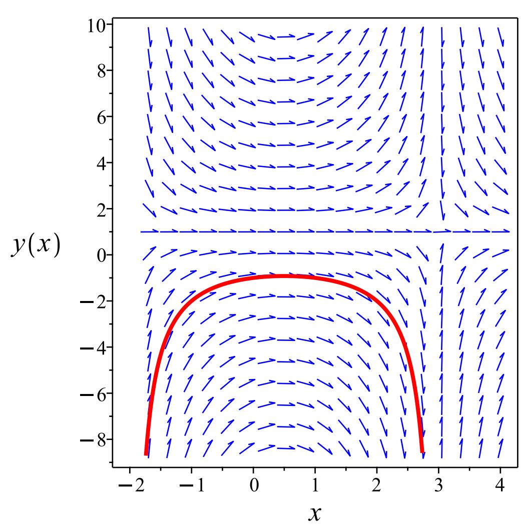
Summary

The solution(s) found are the following

$$y = \frac{x^2 - x + 6}{x^2 - x - 6} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{x^2 - x + 6}{x^2 - x - 6}$$

Verified OK.

6.22.3 Solving as linear ode

Entering Linear first order ODE solver. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{1-2x}{(2+x)(x-3)}dx} \\
&= (2+x)(x-3)
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{2x-1}{(2+x)(x-3)}\right) \\
\frac{d}{dx}((2+x)(x-3)y) &= ((2+x)(x-3))\left(\frac{2x-1}{(2+x)(x-3)}\right) \\
d((2+x)(x-3)y) &= (2x-1)\ dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
(2+x)(x-3)y &= \int 2x - 1\, dx \\
(2+x)(x-3)y &= x^2 - x + c_1
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = (2+x)(x-3)$ results in

$$y = \frac{x^2 - x}{(2+x)(x-3)} + \frac{c_1}{(2+x)(x-3)}$$

which simplifies to

$$y = \frac{x^2 + c_1 - x}{(2+x)(x-3)}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -\frac{c_1}{6}$$

$$c_1 = 6$$

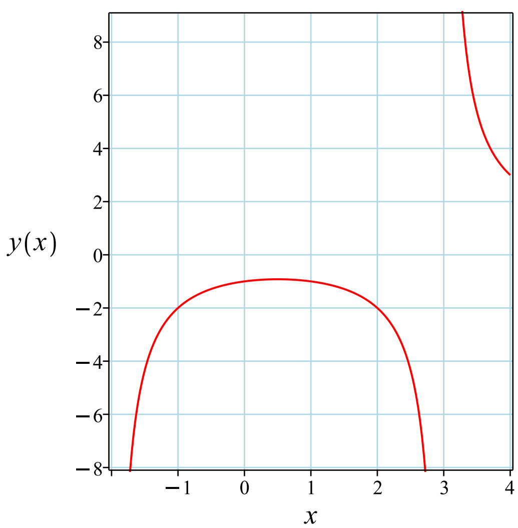
Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 - x + 6}{(2 + x)(x - 3)}$$

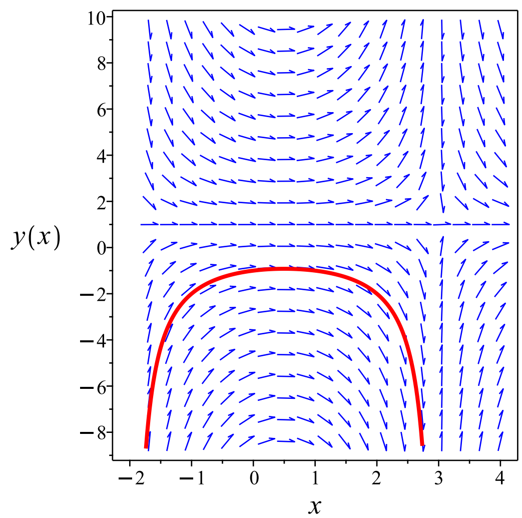
Summary

The solution(s) found are the following

$$y = \frac{x^2 - x + 6}{(2 + x)(x - 3)} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = \frac{x^2 - x + 6}{(2 + x)(x - 3)}$$

Verified OK.

6.22.4 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{(2x - 1)(y - 1)}{(2 + x)(x - 3)} \tag{1}$$

Which becomes

$$0 = (-x^2 + x + 6)\, dy + (-(y - 1)(2x - 1))\, dx \tag{2}$$

But the RHS is complete differential because

$$(-x^2 + x + 6)\, dy + (-(y-1)(2x-1))\, dx = d\big(-(y-1)(x^2 - x) + 6y\big)$$

Hence (2) becomes

$$0 = d\big(-(y-1)(x^2 - x) + 6y\big)$$

Integrating both sides gives gives these solutions

$$y = \frac{x^2 + c_1 - x}{x^2 - x - 6} + c_1$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = \frac{5c_1}{6}$$

$$c_1 = -\frac{6}{5}$$

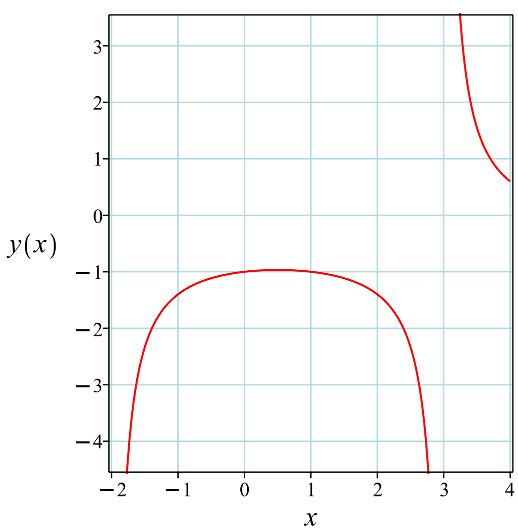
Substituting c_1 found above in the general solution gives

$$y = -\frac{x^2 - x - 30}{5(x^2 - x - 6)}$$

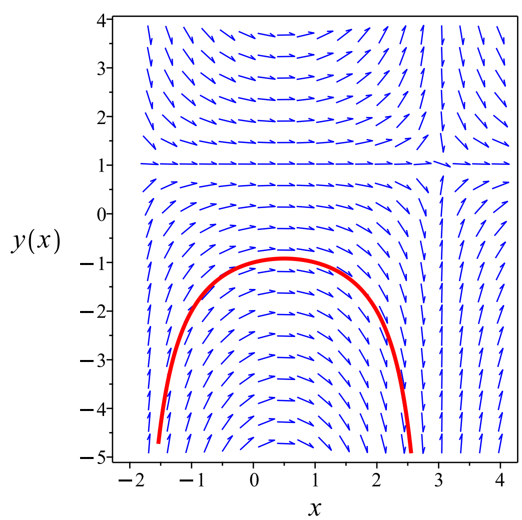
Summary

The solution(s) found are the following

$$y = -\frac{x^2 - x - 30}{5(x^2 - x - 6)} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = -\frac{x^2 - x - 30}{5 (x^2 - x - 6)}$$

Verified OK.

6.22.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{(2x - 1) (y - 1)}{(2 + x) (x - 3)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 295: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \frac{1}{(2+x)\,(x-3)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{(2+x)(x-3)}} dy \end{aligned}$$

Which results in

$$S = (2 + x)(x - 3) y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{(2x - 1)(y - 1)}{(2 + x)(x - 3)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y(2x - 1) \\ S_y &= (2 + x)(x - 3) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 2x - 1 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 2R - 1$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = R^2 - R + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$(2+x)(x-3)\,y = x^2 + c_1 - x$$

Which simplifies to

$$(2+x)(x-3)\,y = x^2 + c_1 - x$$

Which gives

$$y = \frac{x^2 + c_1 - x}{(2+x)(x-3)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{(2x-1)(y-1)}{(2+x)(x-3)}$ 	$R = x$ $S = (2+x)(x-3)\,y$	$\frac{dS}{dR} = 2R - 1$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = -\frac{c_1}{6}$$

$$c_1 = 6$$

Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 - x + 6}{(2 + x)(x - 3)}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2 - x + 6}{(2 + x)(x - 3)} \tag{1}$$

6.22.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(\frac{1}{-y+1}\right)\mathrm{d}y=\left(\frac{2x-1}{(2+x)\,(x-3)}\right)\mathrm{d}x$$
$$\left(-\frac{2x-1}{(2+x)\,(x-3)}\right)\mathrm{d}x+\left(\frac{1}{-y+1}\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned} M(x,y) &= -\frac{2x-1}{(2+x)(x-3)} \\ N(x,y) &= \frac{1}{-y+1} \end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{2x-1}{(2+x)(x-3)}\right) \\ &= 0 \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{-y+1}\right) \\ &= 0 \end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned} \int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x \\ \int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{2x-1}{(2+x)(x-3)}\, \mathrm{d}x \end{aligned}$$

$$\phi = -\ln((2+x)(x-3)) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{-y+1}$. Therefore equation (4) becomes

$$\frac{1}{-y+1} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{y-1}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{1}{y-1}\right) \mathrm{d}y$$
$$f(y) = -\ln(y-1) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln((2+x)(x-3)) - \ln(y-1) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln((2+x)(x-3)) - \ln(y-1)$$

The solution becomes

$$y = \frac{(x^2 \mathrm{e}^{c_1} - x\,\mathrm{e}^{c_1} - 6\,\mathrm{e}^{c_1} + 1)\,\mathrm{e}^{-c_1}}{x^2 - x - 6}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-1 = 1 - \frac{\mathrm{e}^{-c_1}}{6}$$

$$c_1 = -\ln(12)$$

Substituting c_1 found above in the general solution gives

$$y = \frac{x^2 - x + 6}{x^2 - x - 6}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2 - x + 6}{x^2 - x - 6} \tag{1}$$

(b) Slope field plot

Verification of solutions

$$y = \frac{x^2 - x + 6}{x^2 - x - 6}$$

Verified OK.

6.22.7 Maple step by step solution

Let's solve

$[(2x-1)(y-1)+(2+x)(x-3)y'=0, y(1)=-1]$

- Highest derivative means the order of the ODE is 1

  y'

- Integrate both sides with respect to x

$\int ((2x-1)(y-1)+(2+x)(x-3)y')\,dx = \int 0dx + c_1$

- Evaluate integral

  $(x^2-x-6)\,y - x^2 + x = c_1$

- Solve for y

  $y = \frac{x^2+c_1-x}{x^2-x-6}$

- Use initial condition $y(1) = -1$

  $-1 = -\frac{c_1}{6}$

- Solve for c_1

  $c_1 = 6$

- Substitute $c_1 = 6$ into general solution and simplify

  $y = \frac{x^2-x+6}{x^2-x-6}$

- Solution to the IVP

  $y = \frac{x^2-x+6}{x^2-x-6}$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Section 2.5 Page 79
Problem number: 23.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{4y + (4x + 3y)\, y' = -7x}$$

6.23.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$4u(x)\, x + (4x + 3u(x)\, x)\, (u'(x)\, x + u(x)) = -7x$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u^2 + 8u + 7}{x\,(3u + 4)} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = \frac{3u^2+8u+7}{3u+4}$. Integrating both sides gives

$$\frac{1}{\frac{3u^2+8u+7}{3u+4}}\,du = -\frac{1}{x}\,dx$$
$$\int \frac{1}{\frac{3u^2+8u+7}{3u+4}}\,du = \int -\frac{1}{x}\,dx$$
$$\frac{\ln\left(3u^2+8u+7\right)}{2} = -\ln(x) + c_2$$

Raising both side to exponential gives

$$\sqrt{3u^2+8u+7} = \mathrm{e}^{-\ln(x)+c_2}$$

Which simplifies to

$$\sqrt{3u^2+8u+7} = \frac{c_3}{x}$$

Which simplifies to

$$\sqrt{3u(x)^2+8u(x)+7} = \frac{c_3 \mathrm{e}^{c_2}}{x}$$

The solution is

$$\sqrt{3u(x)^2+8u(x)+7} = \frac{c_3 \mathrm{e}^{c_2}}{x}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\sqrt{\frac{3y^2}{x^2}+\frac{8y}{x}+7} = \frac{c_3 \mathrm{e}^{c_2}}{x}$$
$$\sqrt{\frac{3y^2+8yx+7x^2}{x^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x}$$

Summary

The solution(s) found are the following

$$\sqrt{\frac{3y^2+8yx+7x^2}{x^2}} = \frac{c_3 \mathrm{e}^{c_2}}{x} \tag{1}$$

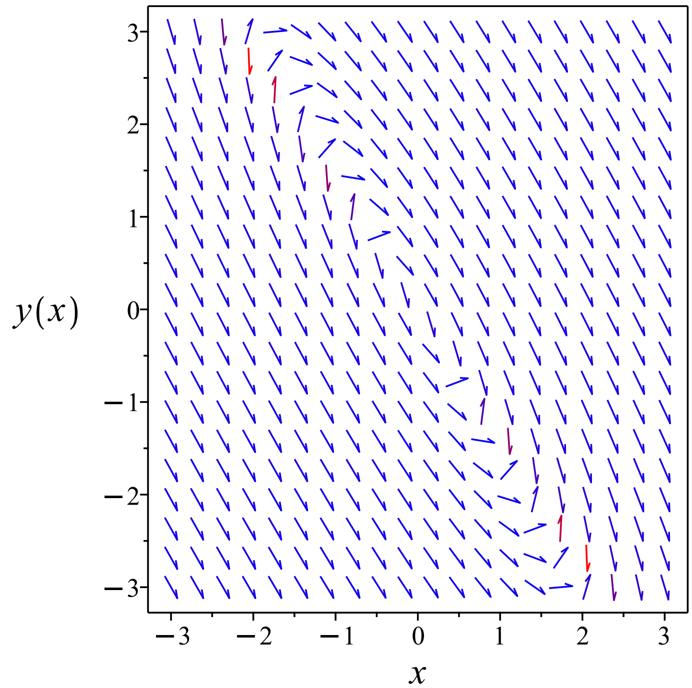

Figure 389: Slope field plot

Verification of solutions

$$\sqrt{\frac{3y^2 + 8yx + 7x^2}{x^2}} = \frac{c_3 e^{c_2}}{x}$$

Verified OK.

6.23.2 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-7x - 4y}{4x + 3y} \tag{1}$$

Which becomes

$$(3y)\, dy = (-4x)\, dy + (-7x - 4y)\, dx \tag{2}$$

But the RHS is complete differential because

$$(-4x)\, dy + (-7x - 4y)\, dx = d\left(-\frac{7}{2}x^2 - 4yx\right)$$

Hence (2) becomes

$$(3y)\, dy = d\left(-\frac{7}{2}x^2 - 4yx\right)$$

Integrating both sides gives gives these solutions

$$y = -\frac{4x}{3} + \frac{\sqrt{-5x^2 + 6c_1}}{3} + c_1$$
$$y = -\frac{4x}{3} - \frac{\sqrt{-5x^2 + 6c_1}}{3} + c_1$$

Summary
The solution(s) found are the following

$$y = -\frac{4x}{3} + \frac{\sqrt{-5x^2 + 6c_1}}{3} + c_1 \tag{1}$$
$$y = -\frac{4x}{3} - \frac{\sqrt{-5x^2 + 6c_1}}{3} + c_1 \tag{2}$$

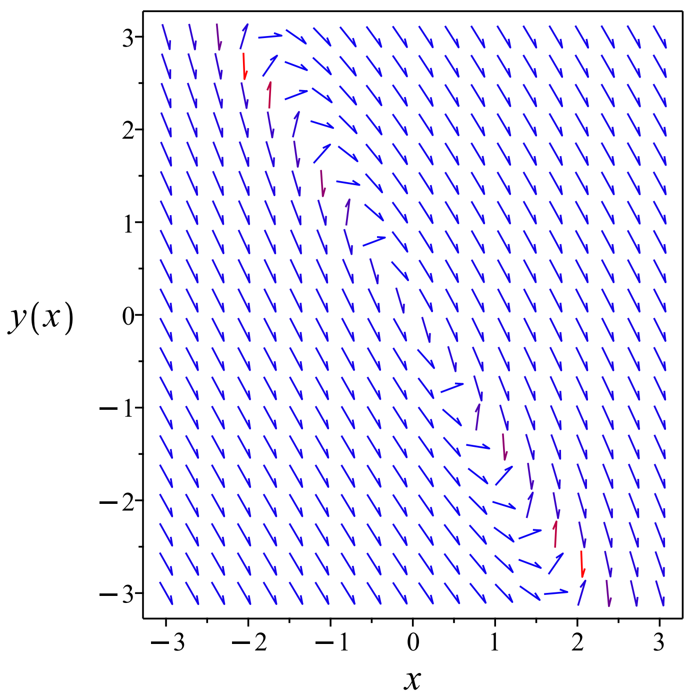

Figure 390: Slope field plot

Verification of solutions

$$y = -\frac{4x}{3} + \frac{\sqrt{-5x^2 + 6c_1}}{3} + c_1$$

Verified OK.

$$y = -\frac{4x}{3} - \frac{\sqrt{-5x^2 + 6c_1}}{3} + c_1$$

Verified OK.

6.23.3 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{7x + 4y}{4x + 3y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(7x + 4y)(b_3 - a_2)}{4x + 3y} - \frac{(7x + 4y)^2 a_3}{(4x + 3y)^2} - \left(-\frac{7}{4x + 3y} + \frac{28x + 16y}{(4x + 3y)^2}\right)(x a_2 + y a_3 + a_1) - \left(-\frac{4}{4x + 3y} + \frac{21x + 12y}{(4x + 3y)^2}\right)(x b_2 + y b_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{28x^2a_2 - 49x^2a_3 + 11x^2b_2 - 28x^2b_3 + 42xya_2 - 56xya_3 + 24xyb_2 - 42xyb_3 + 12y^2a_2 - 11y^2a_3 + 9y^2b_2 -}{(4x + 3y)^2}$$
$$= 0$$

Setting the numerator to zero gives

$$28x^2a_2 - 49x^2a_3 + 11x^2b_2 - 28x^2b_3 + 42xya_2 - 56xya_3 + 24xyb_2 - 42xyb_3 + 12y^2a_2 - 11y^2a_3 + 9y^2b_2 - 12y^2b_3 - 5xb_1 + 5ya_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$28a_2v_1^2 + 42a_2v_1v_2 + 12a_2v_2^2 - 49a_3v_1^2 - 56a_3v_1v_2 - 11a_3v_2^2 + 11b_2v_1^2 + 24b_2v_1v_2 + 9b_2v_2^2 - 28b_3v_1^2 - 42b_3v_1v_2 - 12b_3v_2^2 + 5a_1v_2 - 5b_1v_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$(28a_2 - 49a_3 + 11b_2 - 28b_3)\,v_1^2 + (42a_2 - 56a_3 + 24b_2 - 42b_3)\,v_1v_2 - 5b_1v_1 + (12a_2 - 11a_3 + 9b_2 - 12b_3)\,v_2^2 + 5a_1v_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
5a_1 &= 0\\
-5b_1 &= 0\\
12a_2 - 11a_3 + 9b_2 - 12b_3 &= 0\\
28a_2 - 49a_3 + 11b_2 - 28b_3 &= 0\\
42a_2 - 56a_3 + 24b_2 - 42b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= \frac{8a_3}{3} + b_3 \\
a_3 &= a_3 \\
b_1 &= 0 \\
b_2 &= -\frac{7a_3}{3} \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(-\frac{7x + 4y}{4x + 3y}\right)(x) \\
&= \frac{7x^2 + 8yx + 3y^2}{4x + 3y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{7x^2+8yx+3y^2}{4x+3y}} dy
\end{aligned}
$$

Which results in

$$
S = \frac{\ln(7x^2+8yx+3y^2)}{2}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{7x+4y}{4x+3y}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{7x+4y}{7x^2+8yx+3y^2} \\
S_y &= \frac{4x+3y}{7x^2+8yx+3y^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln(3y^2 + 8yx + 7x^2)}{2} = c_1$$

Which simplifies to

$$\frac{\ln(3y^2 + 8yx + 7x^2)}{2} = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{7x+4y}{4x+3y}$ 	$R = x$ $S = \frac{\ln(7x^2 + 8yx + 3y^2)}{2}$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$\frac{\ln(3y^2 + 8yx + 7x^2)}{2} = c_1 \tag{1}$$

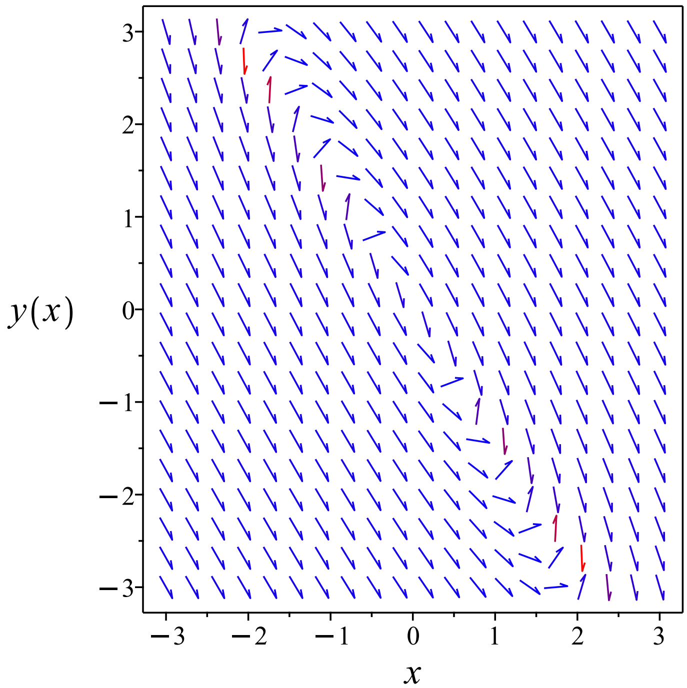

Figure 391: Slope field plot

Verification of solutions

$$\frac{\ln(3y^2 + 8yx + 7x^2)}{2} = c_1$$

Verified OK.

6.23.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(4x + 3y)\, \mathrm{d}y = (-7x - 4y)\, \mathrm{d}x$$
$$(7x + 4y)\, \mathrm{d}x + (4x + 3y)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = 7x + 4y$$
$$N(x, y) = 4x + 3y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(7x + 4y) \\ &= 4\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(4x + 3y) \\ &= 4\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int M \, dx$$
$$\int \frac{\partial \phi}{\partial x} \, dx = \int 7x + 4y \, dx$$
$$\phi = \frac{x(7x + 8y)}{2} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 4x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 4x + 3y$. Therefore equation (4) becomes

$$4x + 3y = 4x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 3y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int (3y) \, dy$$
$$f(y) = \frac{3y^2}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{x(7x + 8y)}{2} + \frac{3y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{x(7x + 8y)}{2} + \frac{3y^2}{2}$$

Summary

The solution(s) found are the following

$$\frac{x(7x + 8y)}{2} + \frac{3y^2}{2} = c_1 \tag{1}$$

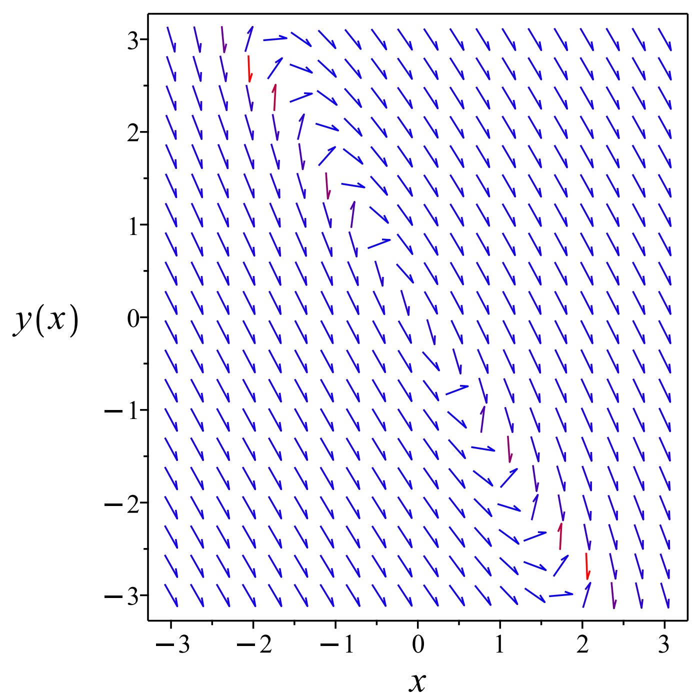

Figure 392: Slope field plot

Verification of solutions

$$\frac{x(7x + 8y)}{2} + \frac{3y^2}{2} = c_1$$

Verified OK.

6.23.5 Maple step by step solution

Let's solve

$4y + (4x + 3y)\, y' = -7x$

- Highest derivative means the order of the ODE is 1

y'

- □ Check if ODE is exact
  - ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$
  - ◦ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$
  - ◦ Evaluate derivatives

    $4 = 4$
  - ◦ Condition met, ODE is exact
- Exact ODE implies solution will be of this form

$\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

$F(x, y) = \int (7x + 4y)\, dx + f_1(y)$

- Evaluate integral

$F(x, y) = \frac{7x^2}{2} + 4yx + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

$N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

$4x + 3y = 4x + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

$\frac{d}{dy}f_1(y) = 3y$

- Solve for $f_1(y)$

$f_1(y) = \frac{3y^2}{2}$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$F(x, y) = \frac{7}{2}x^2 + 4yx + \frac{3}{2}y^2$

- Substitute $F(x, y)$ into the solution of the ODE

  $\frac{7}{2}x^2 + 4yx + \frac{3}{2}y^2 = c_1$

- Solve for y

  $\left\{y = -\frac{4x}{3} - \frac{\sqrt{-5x^2+6c_1}}{3}, y = -\frac{4x}{3} + \frac{\sqrt{-5x^2+6c_1}}{3}\right\}$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Section 2.5 Page 79
Problem number: 24.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "bernoulli", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_exact, _Bernoulli]
```

$$\boxed{e^{x}\left(x^{4}y^{2}+4x^{3}y^{2}+1\right)+\left(2x^{4}y\,e^{x}+2y\right)y'=0}$$

6.24.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y'=-\frac{e^{x}\left(x^{4}y^{2}+4x^{3}y^{2}+1\right)}{2y\left(e^{x}x^{4}+1\right)}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ,η

Table 299: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{y\,(2\,\mathrm{e}^{x} x^4 + 2)}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{y(2\,\mathrm{e}^{x} x^{4}+2)}} dy \end{aligned}$$

Which results in

$$S = \frac{y^{2}(2\,\mathrm{e}^{x} x^{4} + 2)}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{\mathrm{e}^{x}(x^{4}y^{2} + 4x^{3}y^{2} + 1)}{2y\,(\mathrm{e}^{x} x^{4} + 1)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y^{2}\mathrm{e}^{x} x^{3}(x + 4) \\ S_y &= 2y\left(\mathrm{e}^{x} x^{4} + 1\right) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\mathrm{e}^{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\mathrm{e}^{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -e^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y^2 \left(e^x x^4 + 1\right) = -e^x + c_1$$

Which simplifies to

$$y^2 \left(e^x x^4 + 1\right) = -e^x + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{e^x (x^4 y^2 + 4x^3 y^2 + 1)}{2y(e^x x^4 + 1)}$ 	$R = x$ $S = y^2 \left(e^x x^4 + 1\right)$	$\frac{dS}{dR} = -e^{R}$ 
Summary

The solution(s) found are the following

$$y^2 \left(e^x x^4 + 1\right) = -e^x + c_1 \tag{1}$$

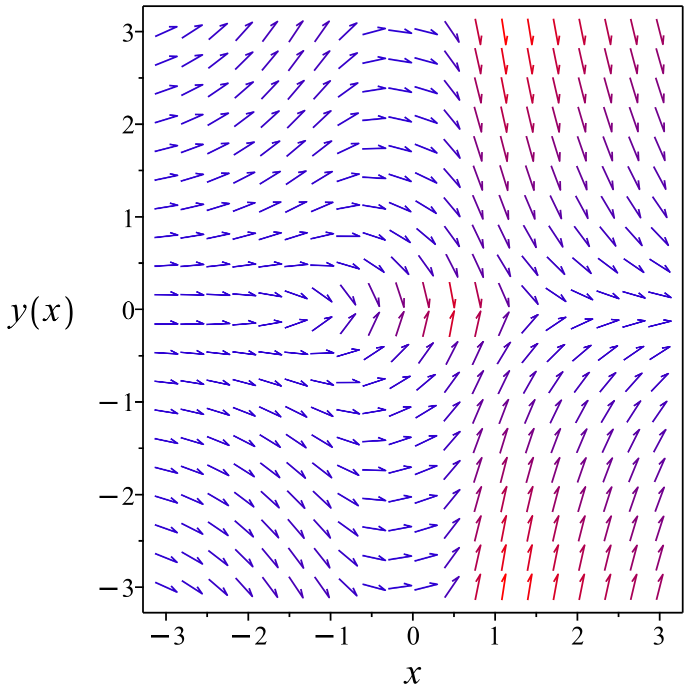

Figure 393: Slope field plot

Verification of solutions

$$y^2(e^x x^4 + 1) = -e^x + c_1$$

Verified OK.

6.24.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{e^x(x^4y^2 + 4x^3y^2 + 1)}{2y(e^x x^4 + 1)} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{e^x(x^4 + 4x^3)}{2(e^x x^4 + 1)}y - \frac{e^x}{2(e^x x^4 + 1)}\frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x) y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{e^x (x^4 + 4x^3)}{2 (e^x x^4 + 1)} \\ f_1(x) &= -\frac{e^x}{2 (e^x x^4 + 1)} \\ n &= -1 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y' y = -\frac{e^x (x^4 + 4x^3) y^2}{2 (e^x x^4 + 1)} - \frac{e^x}{2 (e^x x^4 + 1)} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= y^2 \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2 y y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} \frac{w'(x)}{2} &= -\frac{e^x (x^4 + 4x^3) w(x)}{2 (e^x x^4 + 1)} - \frac{e^x}{2 (e^x x^4 + 1)} \\ w' &= -\frac{e^x (x^4 + 4x^3) w}{e^x x^4 + 1} - \frac{e^x}{e^x x^4 + 1} \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x) w(x) = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= \frac{e^{x} x^{3} (x+4)}{e^{x} x^{4}+1} \\
q(x) &= -\frac{e^{x}}{e^{x} x^{4}+1}
\end{aligned}
$$

Hence the ode is

$$
w'(x) + \frac{e^{x} x^{3} (x+4)\, w(x)}{e^{x} x^{4}+1} = -\frac{e^{x}}{e^{x} x^{4}+1}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int \frac{e^{x} x^{3} (x+4)}{e^{x} x^{4}+1} dx} \\
&= e^{x} x^{4}+1
\end{aligned}
$$

The ode becomes

$$
\begin{aligned}
\frac{d}{dx}(\mu w) &= (\mu)\left(-\frac{e^{x}}{e^{x} x^{4}+1}\right) \\
\frac{d}{dx}\left(\left(e^{x} x^{4}+1\right) w\right) &= \left(e^{x} x^{4}+1\right)\left(-\frac{e^{x}}{e^{x} x^{4}+1}\right) \\
d\left(\left(e^{x} x^{4}+1\right) w\right) &= \left(-e^{x}\right) dx
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\left(e^{x} x^{4}+1\right) w &= \int -e^{x}\, dx \\
\left(e^{x} x^{4}+1\right) w &= -e^{x} + c_1
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = e^{x} x^{4}+1$ results in

$$
w(x) = -\frac{e^{x}}{e^{x} x^{4}+1} + \frac{c_1}{e^{x} x^{4}+1}
$$

which simplifies to

$$
w(x) = \frac{-e^{x}+c_1}{e^{x} x^{4}+1}
$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$
y^2 = \frac{-e^{x}+c_1}{e^{x} x^{4}+1}
$$

Solving for y gives

$$y(x) = \frac{\sqrt{(e^x x^4 + 1)(-e^x + c_1)}}{e^x x^4 + 1}$$
$$y(x) = -\frac{\sqrt{(e^x x^4 + 1)(-e^x + c_1)}}{e^x x^4 + 1}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{(e^x x^4 + 1)(-e^x + c_1)}}{e^x x^4 + 1} \tag{1}$$
$$y = -\frac{\sqrt{(e^x x^4 + 1)(-e^x + c_1)}}{e^x x^4 + 1} \tag{2}$$

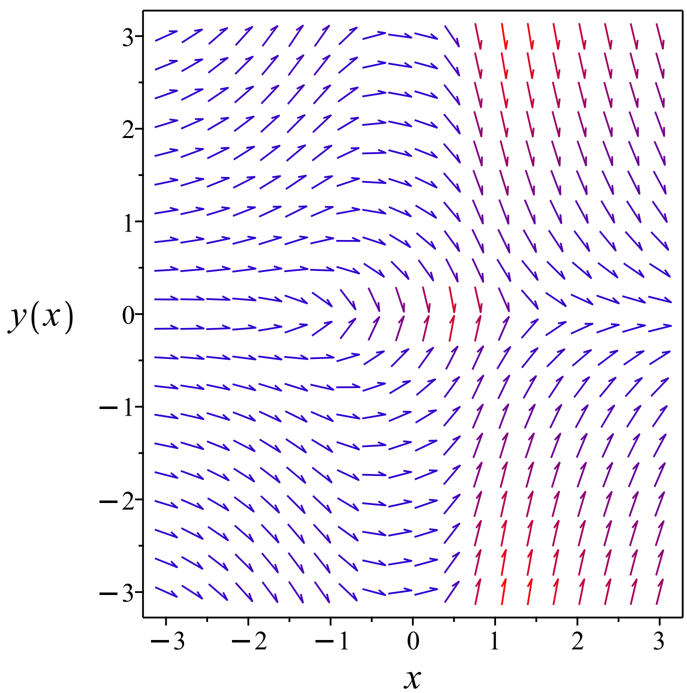

Figure 394: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{(e^x x^4 + 1)(-e^x + c_1)}}{e^x x^4 + 1}$$

Verified OK.

$$y = -\frac{\sqrt{(e^x x^4 + 1)(-e^x + c_1)}}{e^x x^4 + 1}$$

Verified OK.

6.24.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
\left(2x^4y\,\mathrm{e}^x + 2y\right)\mathrm{d}y &= \left(-\mathrm{e}^x\left(x^4y^2 + 4x^3y^2 + 1\right)\right)\mathrm{d}x\\
\left(\mathrm{e}^x\left(x^4y^2 + 4x^3y^2 + 1\right)\right)\mathrm{d}x + \left(2x^4y\,\mathrm{e}^x + 2y\right)\mathrm{d}y &= 0 \qquad (2\mathrm{A})
\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= \mathrm{e}^x\left(x^4y^2 + 4x^3y^2 + 1\right)\\
N(x,y) &= 2x^4y\,\mathrm{e}^x + 2y
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(\mathrm{e}^x\left(x^4y^2 + 4x^3y^2 + 1\right)\right)\\
&= 2\,\mathrm{e}^x y\,x^3(x+4)
\end{aligned}$$

And

$$\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(2x^4y\,\mathrm{e}^x + 2y\right)\\
&= 2\,\mathrm{e}^x y\,x^3(x+4)
\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \mathrm{e}^x\left(x^4y^2 + 4x^3y^2 + 1\right)\mathrm{d}x\\
\phi &= \left(x^4y^2 + 1\right)\mathrm{e}^x + f(y) \qquad (3)
\end{aligned}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2x^4 y\, \mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2x^4 y\, \mathrm{e}^{x} + 2y$. Therefore equation (4) becomes

$$2x^4 y\, \mathrm{e}^{x} + 2y = 2x^4 y\, \mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int (2y)\, \mathrm{d}y$$
$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \left(x^4 y^2 + 1\right) \mathrm{e}^{x} + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \left(x^4 y^2 + 1\right) \mathrm{e}^{x} + y^2$$

Summary
The solution(s) found are the following

$$\left(x^4 y^2 + 1\right) \mathrm{e}^{x} + y^2 = c_1 \tag{1}$$

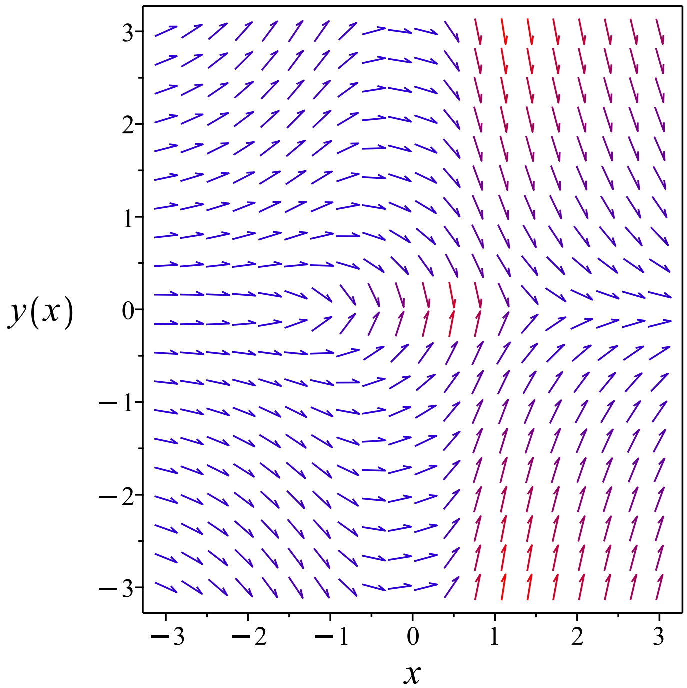

Figure 395: Slope field plot

Verification of solutions

$$\left(x^4y^2+1\right)e^x+y^2=c_1$$

Verified OK.

6.24.4 Maple step by step solution

Let's solve

$e^x(x^4y^2+4x^3y^2+1)+(2x^4y\,e^x+2y)\,y'=0$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x,y)=0$

  ◦ Compute derivative of lhs

    $F'(x,y)+\left(\frac{\partial}{\partial y}F(x,y)\right)y'=0$

- Evaluate derivatives

  $e^x (2x^4 y + 8y\,x^3) = 8\,e^x x^3 y + 2x^4 y\,e^x$

- Simplify

  $2\,e^x y\,x^3 (x+4) = 2\,e^x y\,x^3 (x+4)$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y), N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int e^x (x^4 y^2 + 4x^3 y^2 + 1)\, dx + f_1(y)$

- Evaluate integral

  $F(x,y) = (x^4 y^2 + 1)\, e^x + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $2x^4 y\, e^x + 2y = 2x^4 y\, e^x + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 2y$

- Solve for $f_1(y)$

  $f_1(y) = y^2$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = (x^4 y^2 + 1)\, e^x + y^2$

- Substitute $F(x,y)$ into the solution of the ODE

  $(x^4 y^2 + 1)\, e^x + y^2 = c_1$

- Solve for y

  $\left\{y = \frac{\sqrt{-(e^x x^4 + 1)(-c_1 + e^x)}}{e^x x^4 + 1}, y = -\frac{\sqrt{-(e^x x^4 + 1)(-c_1 + e^x)}}{e^x x^4 + 1}\right\}$

Maple gives the following as the ode type

```
[_exact, _rational]
```

$$\boxed{x^3y^4 + \left(y^3x^4 + y\right)y' = -x}$$

6.25.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(y^3x^4 + y)\,\mathrm{d}y &= (-x^3y^4 - x)\,\mathrm{d}x \\ (x^3y^4 + x)\,\mathrm{d}x + (y^3x^4 + y)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= x^3y^4 + x \\ N(x, y) &= y^3x^4 + y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^3y^4 + x) \\ &= 4y^3x^3\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y^3x^4 + y) \\ &= 4y^3x^3\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial\phi}{\partial x} = M \tag{1}$$

$$\frac{\partial\phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, dx = \int M \, dx$$
$$\int \frac{\partial \phi}{\partial x} \, dx = \int x^3 y^4 + x \, dx$$
$$\phi = \frac{(x^2 y^4 + 1)^2}{4y^4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{2(x^2 y^4 + 1)\, x^2}{y} - \frac{(x^2 y^4 + 1)^2}{y^5} + f'(y) \tag{4}$$
$$= \frac{x^4 y^8 - 1}{y^5} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^3 x^4 + y$. Therefore equation (4) becomes

$$y^3 x^4 + y = \frac{x^4 y^8 - 1}{y^5} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{y^6 + 1}{y^5}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int \left(\frac{y^6 + 1}{y^5} \right) dy$$
$$f(y) = \frac{y^2}{2} - \frac{1}{4y^4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(x^2 y^4 + 1)^2}{4y^4} + \frac{y^2}{2} - \frac{1}{4y^4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(x^2y^4+1)^2}{4y^4} + \frac{y^2}{2} - \frac{1}{4y^4}$$

Summary

The solution(s) found are the following

$$\frac{(x^2y^4+1)^2}{4y^4} + \frac{y^2}{2} - \frac{1}{4y^4} = c_1 \tag{1}$$

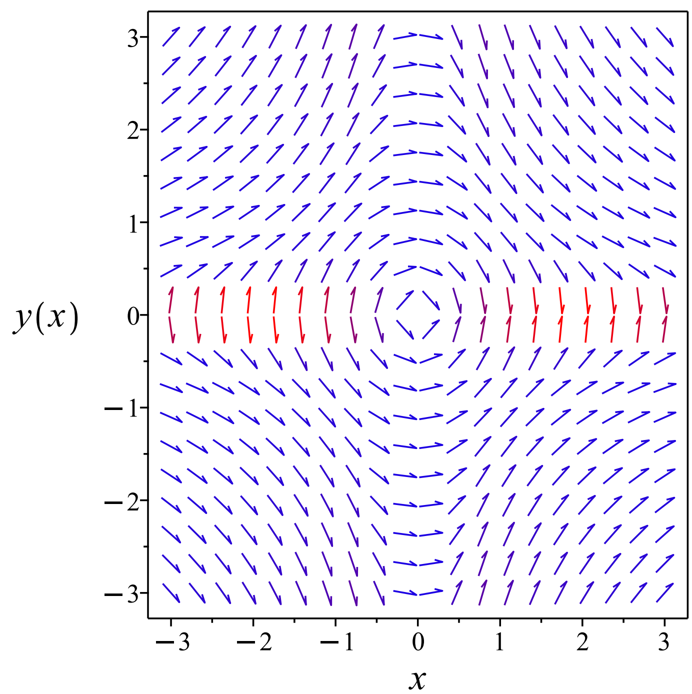

Figure 396: Slope field plot

Verification of solutions

$$\frac{(x^2y^4+1)^2}{4y^4} + \frac{y^2}{2} - \frac{1}{4y^4} = c_1$$

Verified OK.

6.25.2 Maple step by step solution

Let's solve

$x^3y^4 + (y^3x^4 + y)\, y' = -x$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  ◦ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

  ◦ Evaluate derivatives

    $4y^3x^3 = 4y^3x^3$

  ◦ Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y)\, , N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (x^3y^4 + x)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = \frac{(x^2y^4+1)^2}{4y^4} + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

  $y^3x^4 + y = \frac{2(x^2y^4+1)x^2}{y} - \frac{(x^2y^4+1)^2}{y^5} + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = y^3x^4 + y - \frac{2(x^2y^4+1)x^2}{y} + \frac{(x^2y^4+1)^2}{y^5}$

- Solve for $f_1(y)$

  $f_1(y) = \frac{y^2}{2} - \frac{1}{4y^4}$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = \frac{(x^2y^4+1)^2}{4y^4} + \frac{y^2}{2} - \frac{1}{4y^4}$
- Substitute $F(x,y)$ into the solution of the ODE

  $\frac{(x^2y^4+1)^2}{4y^4} + \frac{y^2}{2} - \frac{1}{4y^4} = c_1$
- Solve for y

  $\left\{y = \frac{\sqrt{-1-\sqrt{-2x^6+4c_1x^4+1}}}{x^2}, y = \frac{\sqrt{-1+\sqrt{-2x^6+4c_1x^4+1}}}{x^2}, y = -\frac{\sqrt{-1-\sqrt{-2x^6+4c_1x^4+1}}}{x^2}, y = -\frac{\sqrt{-1+\sqrt{-2x^6+4}}}{x^2}\right.$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Section 2.5 Page 79
Problem number: 26.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "differentialType"**

Maple gives the following as the ode type

```
[_exact, _rational, [_1st_order, `_with_symmetry_[F(x),G(x)]`],
    [_Abel, `2nd type`, `class A`]]
```

$$\boxed{2y + (2y + 2x)\, y' = -3x^2}$$

6.26.1 Solving as differentialType ode

Writing the ode as

$$y' = \frac{-3x^2 - 2y}{2y + 2x} \tag{1}$$

Which becomes

$$(2y)\, dy = (-2x)\, dy + \left(-3x^2 - 2y\right) dx \tag{2}$$

But the RHS is complete differential because

$$(-2x)\, dy + \left(-3x^2 - 2y\right) dx = d\left(-x^3 - 2yx\right)$$

Hence (2) becomes

$$(2y)\, dy = d\left(-x^3 - 2yx\right)$$

Integrating both sides gives gives these solutions

$$y = -x + \sqrt{-x^3 + x^2 + c_1} + c_1$$
$$y = -x - \sqrt{-x^3 + x^2 + c_1} + c_1$$

Summary
The solution(s) found are the following

$$y = -x + \sqrt{-x^3 + x^2 + c_1} + c_1 \tag{1}$$
$$y = -x - \sqrt{-x^3 + x^2 + c_1} + c_1 \tag{2}$$

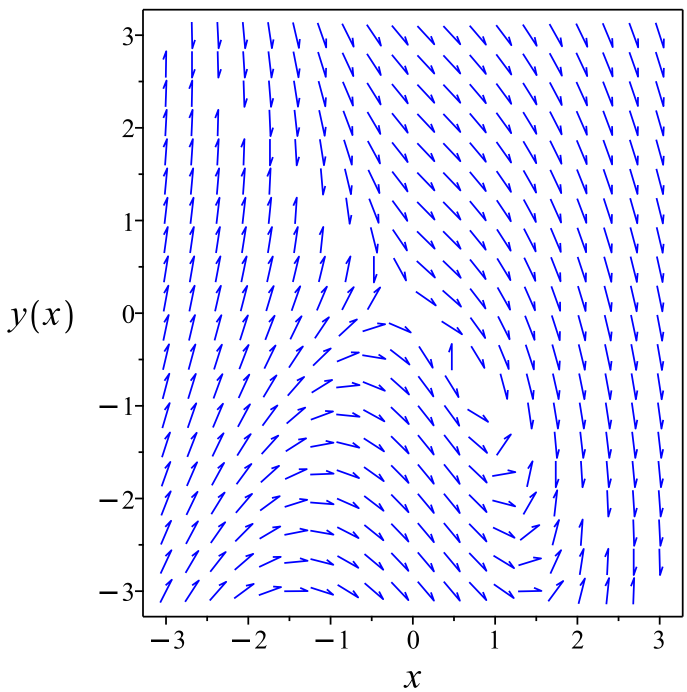

Figure 397: Slope field plot

Verification of solutions

$$y = -x + \sqrt{-x^3 + x^2 + c_1} + c_1$$

Verified OK.

$$y = -x - \sqrt{-x^3 + x^2 + c_1} + c_1$$

Verified OK.

6.26.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(2x+2y)\,\mathrm{d}y = \left(-3x^2 - 2y\right)\mathrm{d}x$$
$$\left(3x^2 + 2y\right)\mathrm{d}x + (2x+2y)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = 3x^2 + 2y$$
$$N(x,y) = 2x + 2y$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(3x^2 + 2y) \\ &= 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x + 2y) \\ &= 2\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \mathrm{d}x \\ \int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int 3x^2 + 2y \mathrm{d}x\end{aligned}$$

$$\phi = x(x^2 + 2y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2x + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2x + 2y$. Therefore equation (4) becomes

$$2x + 2y = 2x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (2y) \, \mathrm{d}y$$
$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x(x^2 + 2y) + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x(x^2 + 2y) + y^2$$

Summary

The solution(s) found are the following

$$x(x^2 + 2y) + y^2 = c_1 \tag{1}$$

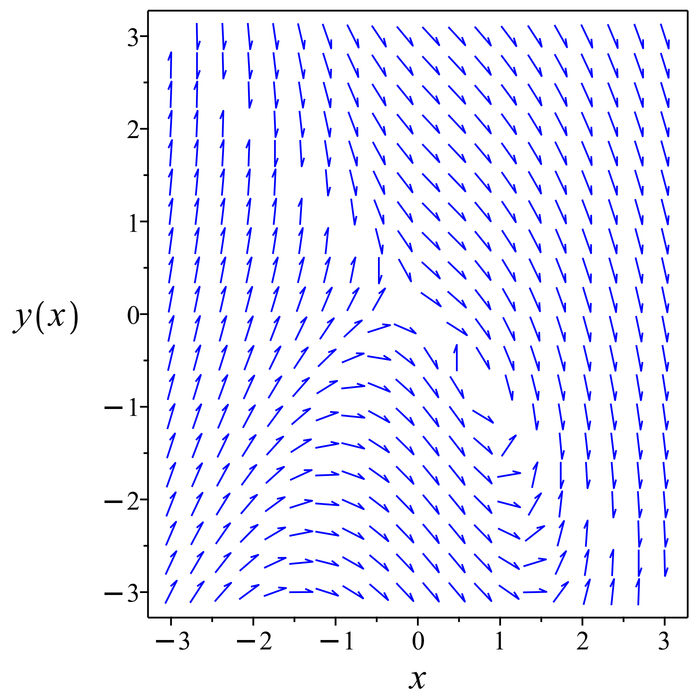

Figure 398: Slope field plot

Verification of solutions

$$x(x^2 + 2y) + y^2 = c_1$$

Verified OK.

6.26.3 Maple step by step solution

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

```
[_exact, _rational]
```

$$\boxed{x^3y^4 + \left(y^3x^4 + 3y\right) y' = -2x}$$

6.27.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(y^3x^4 + 3y)\,\mathrm{d}y &= (-x^3y^4 - 2x)\,\mathrm{d}x\\ (x^3y^4 + 2x)\,\mathrm{d}x + (y^3x^4 + 3y)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= x^3y^4 + 2x\\ N(x, y) &= y^3x^4 + 3y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^3y^4 + 2x)\\ &= 4y^3x^3\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y^3x^4 + 3y)\\ &= 4y^3x^3\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int M \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int x^3y^4 + 2x \mathrm{d}x$$
$$\phi = \frac{(x^2y^4+2)^2}{4y^4} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{2(x^2y^4+2)\,x^2}{y} - \frac{(x^2y^4+2)^2}{y^5} + f'(y) \tag{4}$$
$$= \frac{x^4y^8-4}{y^5} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y^3x^4 + 3y$. Therefore equation (4) becomes

$$y^3x^4 + 3y = \frac{x^4y^8-4}{y^5} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{3y^6+4}{y^5}$$

Integrating the above w.r.t y gives

$$\int f'(y) \mathrm{d}y = \int \left(\frac{3y^6+4}{y^5}\right) \mathrm{d}y$$
$$f(y) = \frac{3y^2}{2} - \frac{1}{y^4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(x^2y^4+2)^2}{4y^4} + \frac{3y^2}{2} - \frac{1}{y^4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(x^2y^4+2)^2}{4y^4} + \frac{3y^2}{2} - \frac{1}{y^4}$$

Summary

The solution(s) found are the following

$$\frac{(x^2y^4+2)^2}{4y^4} + \frac{3y^2}{2} - \frac{1}{y^4} = c_1 \tag{1}$$

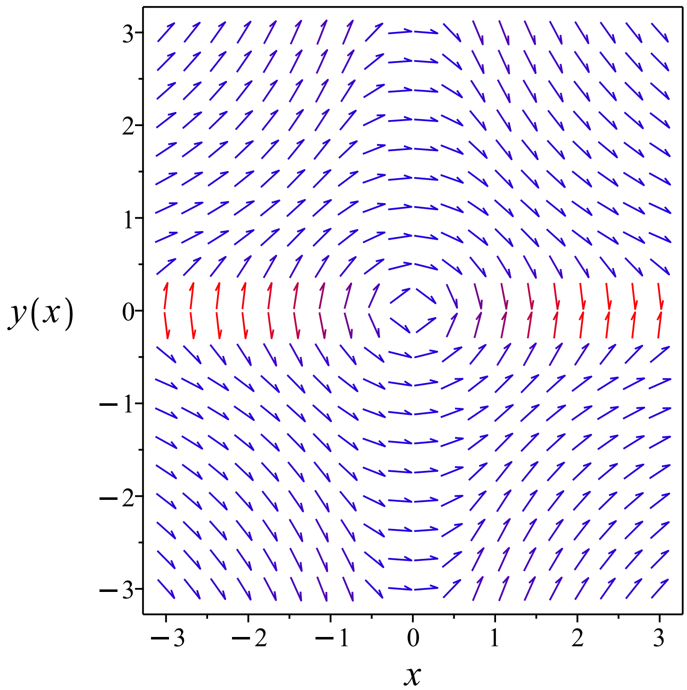

Figure 399: Slope field plot

Verification of solutions

$$\frac{(x^2y^4+2)^2}{4y^4} + \frac{3y^2}{2} - \frac{1}{y^4} = c_1$$

Verified OK.

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "bernoulli", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _exact, _rational, _Bernoulli]
```

$$\boxed{y^2 + 2y'xy = -x^2}$$

6.28.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$u(x)^2\,x^2 + 2(u'(x)\,x + u(x))\,x^2u(x) = -x^2$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u^2+1}{2ux} \end{aligned}$$

Where $f(x) = -\frac{1}{2x}$ and $g(u) = \frac{3u^2+1}{u}$. Integrating both sides gives

$$\frac{1}{\frac{3u^2+1}{u}}\,du = -\frac{1}{2x}\,dx$$

$$\int \frac{1}{\frac{3u^2+1}{u}}\,du = \int -\frac{1}{2x}\,dx$$

$$\frac{\ln(3u^2+1)}{6} = -\frac{\ln(x)}{2} + c_2$$

Raising both side to exponential gives

$$\left(3u^2+1\right)^{\frac{1}{6}} = e^{-\frac{\ln(x)}{2}+c_2}$$

Which simplifies to

$$\left(3u^2+1\right)^{\frac{1}{6}} = \frac{c_3}{\sqrt{x}}$$

Which simplifies to

$$\left(3u(x)^2+1\right)^{\frac{1}{6}} = \frac{c_3 e^{c_2}}{\sqrt{x}}$$

The solution is

$$\left(3u(x)^2+1\right)^{\frac{1}{6}} = \frac{c_3 e^{c_2}}{\sqrt{x}}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\left(\frac{3y^2}{x^2}+1\right)^{\frac{1}{6}} = \frac{c_3 e^{c_2}}{\sqrt{x}}$$

$$\left(\frac{x^2+3y^2}{x^2}\right)^{\frac{1}{6}} = \frac{c_3 e^{c_2}}{\sqrt{x}}$$

Summary

The solution(s) found are the following

$$\left(\frac{x^2+3y^2}{x^2}\right)^{\frac{1}{6}} = \frac{c_3 e^{c_2}}{\sqrt{x}} \tag{1}$$

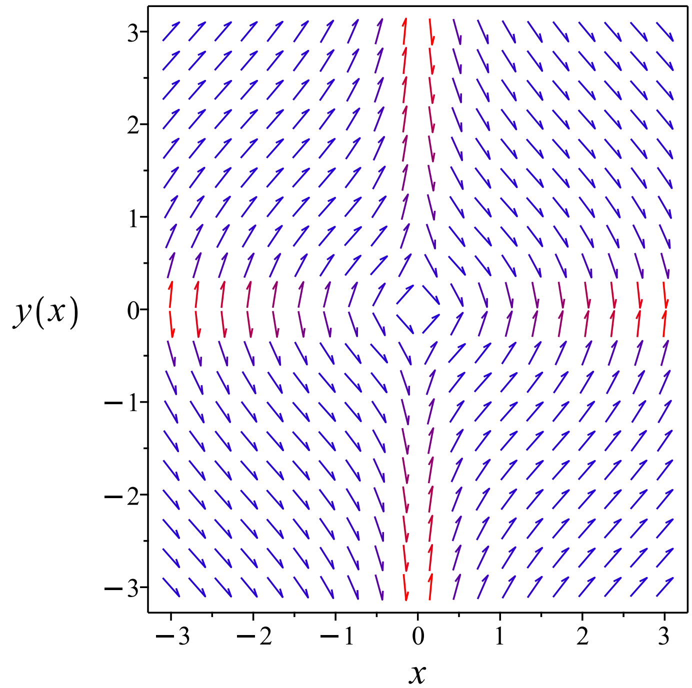

Figure 400: Slope field plot

Verification of solutions

$$\left(\frac{x^2+3y^2}{x^2}\right)^{\frac{1}{6}} = \frac{c_3 e^{c_2}}{\sqrt{x}}$$

Verified OK.

6.28.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{x^2+y^2}{2xy}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 305: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{yx}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{yx}} dy \end{aligned}$$

Which results in

$$S = \frac{x\, y^2}{2}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, y) S_y}{R_x + \omega(x, y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y) = -\frac{x^2 + y^2}{2xy}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{y^2}{2} \\ S_y &= yx \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{x^2}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{R^2}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{R^3}{6} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{xy^2}{2} = -\frac{x^3}{6} + c_1$$

Which simplifies to

$$\frac{xy^2}{2} = -\frac{x^3}{6} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x^2+y^2}{2xy}$ 	$R = x$ $S = \frac{x\,y^2}{2}$	$\frac{dS}{dR} = -\frac{R^2}{2}$ 
Summary
The solution(s) found are the following

$$\frac{xy^2}{2} = -\frac{x^3}{6} + c_1 \tag{1}$$

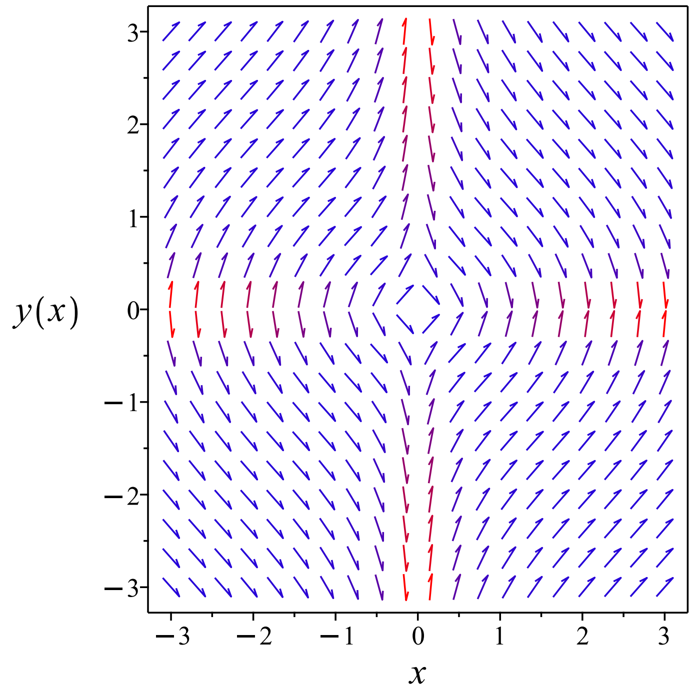

Figure 401: Slope field plot

Verification of solutions

$$\frac{x y^2}{2} = -\frac{x^3}{6} + c_1$$

Verified OK.

6.28.3 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{x^2 + y^2}{2xy} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{2x} y - \frac{x}{2} \frac{1}{y} \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x) y + f_1(x) y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x) y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned}
f_0(x) &= -\frac{1}{2x} \\
f_1(x) &= -\frac{x}{2} \\
n &= -1
\end{aligned}$$

Dividing both sides of ODE (1) by $y^n = \frac{1}{y}$ gives

$$y'y = -\frac{y^2}{2x} - \frac{x}{2} \tag{4}$$

Let

$$\begin{aligned}
w &= y^{1-n} \\
&= y^2
\end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = 2yy' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned}
\frac{w'(x)}{2} &= -\frac{w(x)}{2x} - \frac{x}{2} \\
w' &= -\frac{w}{x} - x
\end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= -x
\end{aligned}$$

Hence the ode is

$$w'(x) + \frac{w(x)}{x} = -x$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{1}{x}dx} \\ &= x\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu w) &= (\mu)(-x) \\ \frac{d}{dx}(xw) &= (x)(-x) \\ d(xw) &= (-x^2)\ dx\end{aligned}$$

Integrating gives

$$\begin{aligned}xw &= \int -x^2\,dx \\ xw &= -\frac{x^3}{3} + c_1\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$w(x) = \frac{c_1}{x} - \frac{x^2}{3}$$

Replacing w in the above by y^2 using equation (5) gives the final solution.

$$y^2 = \frac{c_1}{x} - \frac{x^2}{3}$$

Solving for y gives

$$\begin{aligned}y(x) &= \frac{\sqrt{3}\,\sqrt{-x\,(x^3 - 3c_1)}}{3x} \\ y(x) &= -\frac{\sqrt{3}\,\sqrt{-x\,(x^3 - 3c_1)}}{3x}\end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{\sqrt{3}\,\sqrt{-x\,(x^3 - 3c_1)}}{3x} \tag{1}$$

$$y = -\frac{\sqrt{3}\,\sqrt{-x\,(x^3 - 3c_1)}}{3x} \tag{2}$$

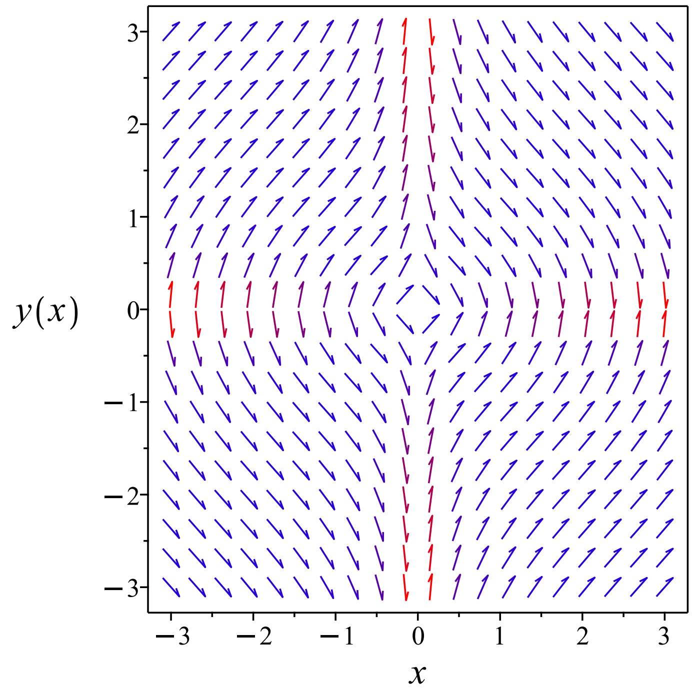

Figure 402: Slope field plot

Verification of solutions

$$y = \frac{\sqrt{3}\,\sqrt{-x\,(x^3 - 3c_1)}}{3x}$$

Verified OK.

$$y = -\frac{\sqrt{3}\,\sqrt{-x\,(x^3 - 3c_1)}}{3x}$$

Verified OK.

6.28.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y} \frac{d y}{d x}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y}=\frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}
(2yx)\,\mathrm{d}y &= \left(-x^2-y^2\right)\mathrm{d}x \\
\left(x^2+y^2\right)\mathrm{d}x + (2yx)\,\mathrm{d}y &= 0
\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}
M(x,y) &= x^2+y^2 \\
N(x,y) &= 2yx
\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(x^2+y^2\right) \\
&= 2y
\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2yx) \\
&= 2y
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int x^2 + y^2 \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{1}{3}x^3 + x\,y^2 + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 2yx + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2yx$. Therefore equation (4) becomes

$$
2yx = 2yx + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = 0
$$

Therefore

$$
f(y) = c_1
$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$
\phi = \frac{1}{3}x^3 + x\,y^2 + c_1
$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{3}x^3 + x\,y^2$$

Summary

The solution(s) found are the following

$$\frac{x^3}{3} + xy^2 = c_1 \tag{1}$$

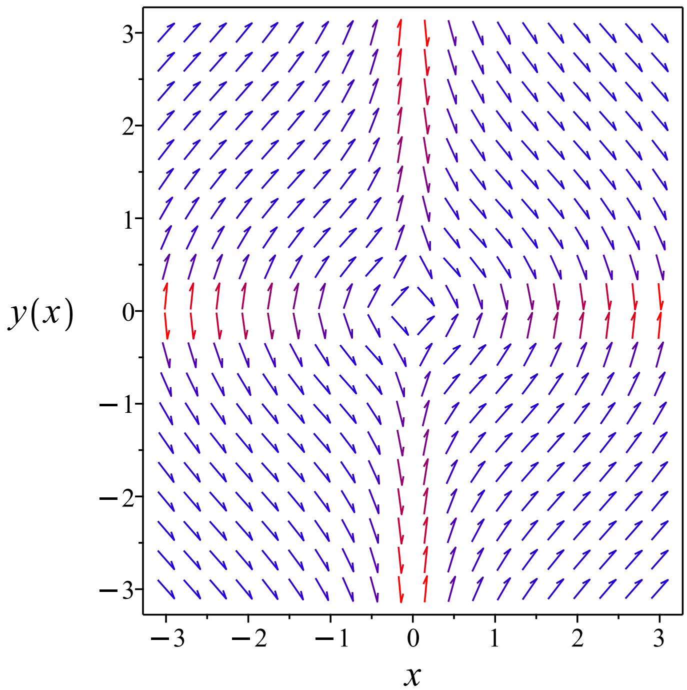

Figure 403: Slope field plot

Verification of solutions

$$\frac{x^3}{3} + xy^2 = c_1$$

Verified OK.

6.28.5 Maple step by step solution

Let's solve

$y^2 + 2y'xy = -x^2$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact
  - ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  - Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

  - Evaluate derivatives

    $2y = 2y$

  - Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x, y) = c_1, M(x, y) = F'(x, y), N(x, y) = \frac{\partial}{\partial y}F(x, y)\right]$

- Solve for $F(x, y)$ by integrating $M(x, y)$ with respect to x

  $F(x, y) = \int (x^2 + y^2)\, dx + f_1(y)$

- Evaluate integral

  $F(x, y) = \frac{x^3}{3} + x\, y^2 + f_1(y)$

- Take derivative of $F(x, y)$ with respect to y

  $N(x, y) = \frac{\partial}{\partial y}F(x, y)$

- Compute derivative

  $2yx = 2yx + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = 0$

- Solve for $f_1(y)$

  $f_1(y) = 0$

- Substitute $f_1(y)$ into equation for $F(x, y)$

$$F(x,y) = \frac{1}{3}x^3 + x\,y^2$$

- Substitute $F(x,y)$ into the solution of the ODE

$$\frac{1}{3}x^3 + x\,y^2 = c_1$$

- Solve for y

$$\left\{y = -\frac{\sqrt{3}\,\sqrt{x(-x^3+3c_1)}}{3x}, y = \frac{\sqrt{3}\,\sqrt{x(-x^3+3c_1)}}{3x}\right\}$$

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class B`]]
```

$$\boxed{y' + \frac{2y}{x} + \frac{2xy}{x^2 + 2x^2y + 1} = 0}$$

With initial conditions

$$[y(1) = -2]$$

6.29.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{2y(2y\,x^2 + 2x^2 + 1)}{x\,(2y\,x^2 + x^2 + 1)} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 2 to use as anstaz gives

$$\xi = x^2 a_4 + yx a_5 + y^2 a_6 + x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x^2 b_4 + yx b_5 + y^2 b_6 + x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, b_1, b_2, b_3, b_4, b_5, b_6\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&2x b_4 + y b_5 + b_2 \\
&- \frac{2y(2y\,x^2 + 2x^2 + 1)\left(-2x a_4 + x b_5 - y a_5 + 2y b_6 - a_2 + b_3\right)}{x\left(2y\,x^2 + x^2 + 1\right)} \\
&- \frac{4y^2(2y\,x^2 + 2x^2 + 1)^2\left(x a_5 + 2y a_6 + a_3\right)}{x^2\left(2y\,x^2 + x^2 + 1\right)^2} \\
&- \left(-\frac{2y(4yx + 4x)}{x\left(2y\,x^2 + x^2 + 1\right)} + \frac{2y(2y\,x^2 + 2x^2 + 1)}{x^2\left(2y\,x^2 + x^2 + 1\right)}\right. \\
&\left.+ \frac{2y(2y\,x^2 + 2x^2 + 1)\left(4yx + 2x\right)}{x\left(2y\,x^2 + x^2 + 1\right)^2}\right)\left(x^2 a_4 + yx a_5 + y^2 a_6 + x a_2 + y a_3 + a_1\right) \\
&- \left(-\frac{2(2y\,x^2 + 2x^2 + 1)}{x\left(2y\,x^2 + x^2 + 1\right)} - \frac{4xy}{2y\,x^2 + x^2 + 1}\right. \\
&\left.+ \frac{4y(2y\,x^2 + 2x^2 + 1)\,x}{\left(2y\,x^2 + x^2 + 1\right)^2}\right)\left(x^2 b_4 + yx b_5 + y^2 b_6 + x b_2 + y b_3 + b_1\right) = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{16x^7y^2b_4 + 8x^6y^3a_4 + 4x^6y^3b_5 - 16x^5y^4a_5 - 8x^5y^4b_6 - 40x^4y^5a_6 + 16x^7yb_4 + 12x^6y^2a_4 + 12x^6y^2b_2 - 32x}{}$$

$$= 0$$

Setting the numerator to zero gives

$$
\begin{aligned}
&16x^7y^2b_4 + 8x^6y^3a_4 + 4x^6y^3b_5 - 16x^5y^4a_5 - 8x^5y^4b_6 - 40x^4y^5a_6 \\
&+ 16x^7yb_4 + 12x^6y^2a_4 + 12x^6y^2b_2 - 32x^5y^3a_5 - 16x^5y^3b_6 \\
&- 24x^4y^4a_3 - 76x^4y^4a_6 + 6x^7b_4 + 4x^6ya_4 + 12x^6yb_2 + x^6yb_5 \\
&- 16x^5y^2a_5 + 8x^5y^2b_1 - 4x^5y^2b_3 - 4x^5y^2b_6 - 8x^4y^3a_1 - 44x^4y^3a_3 \\
&- 36x^4y^3a_6 + 5x^6b_2 + 8x^5yb_1 + 16x^5yb_4 - 12x^4y^2a_1 - 20x^4y^2a_3 \\
&+ 8x^4y^2a_4 + 4x^4y^2b_5 - 16x^3y^3a_5 - 8x^3y^3b_6 - 40x^2y^4a_6 + 4x^5b_1 \\
&+ 10x^5b_4 - 4x^4ya_1 + 10x^4ya_4 + 12x^4yb_2 + 2x^4yb_5 - 12x^3y^2a_5 \\
&- 6x^3y^2b_6 - 24x^2y^3a_3 - 34x^2y^3a_6 + 8x^4b_2 + 4x^3ya_2 + 8x^3yb_1 \\
&- 8x^2y^2a_1 - 18x^2y^2a_3 + 6x^3b_1 + 4x^3b_4 - 2x^2ya_1 + 2x^2ya_4 + yb_5x^2 \\
&- 4x\,y^2a_5 - 2x\,y^2b_6 - 10y^3a_6 + 3b_2x^2 - 6y^2a_3 + 2xb_1 - 2ya_1 = 0
\end{aligned} \tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\{x, y\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\{x = v_1, y = v_2\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&8a_4v_1^6v_2^3 - 16a_5v_1^5v_2^4 - 40a_6v_1^4v_2^5 + 16b_4v_1^7v_2^2 + 4b_5v_1^6v_2^3 - 8b_6v_1^5v_2^4 \\
&- 24a_3v_1^4v_2^4 + 12a_4v_1^6v_2^2 - 32a_5v_1^5v_2^3 - 76a_6v_1^4v_2^4 + 12b_2v_1^6v_2^2 \\
&+ 16b_4v_1^7v_2 - 16b_6v_1^5v_2^3 - 8a_1v_1^4v_2^3 - 44a_3v_1^4v_2^3 + 4a_4v_1^6v_2 - 16a_5v_1^5v_2^2 \\
&- 36a_6v_1^4v_2^3 + 8b_1v_1^5v_2^2 + 12b_2v_1^6v_2 - 4b_3v_1^5v_2^2 + 6b_4v_1^7 + b_5v_1^6v_2 \\
&- 4b_6v_1^5v_2^2 - 12a_1v_1^4v_2^2 - 20a_3v_1^4v_2^2 + 8a_4v_1^4v_2^2 - 16a_5v_1^3v_2^3 - 40a_6v_1^2v_2^4 \\
&+ 8b_1v_1^5v_2 + 5b_2v_1^6 + 16b_4v_1^5v_2 + 4b_5v_1^4v_2^2 - 8b_6v_1^3v_2^3 - 4a_1v_1^4v_2 \\
&- 24a_3v_1^2v_2^3 + 10a_4v_1^4v_2 - 12a_5v_1^3v_2^2 - 34a_6v_1^2v_2^3 + 4b_1v_1^5 + 12b_2v_1^4v_2 \\
&+ 10b_4v_1^5 + 2b_5v_1^4v_2 - 6b_6v_1^3v_2^2 - 8a_1v_1^2v_2^2 + 4a_2v_1^3v_2 - 18a_3v_1^2v_2^2 \\
&+ 8b_1v_1^3v_2 + 8b_2v_1^4 - 2a_1v_1^2v_2 + 2a_4v_1^2v_2 - 4a_5v_1v_2^2 - 10a_6v_2^3 + 6b_1v_1^3 \\
&+ 4b_4v_1^3 + b_5v_1^2v_2 - 2b_6v_1v_2^2 - 6a_3v_2^2 + 3b_2v_1^2 - 2a_1v_2 + 2b_1v_1 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&(8a_4 + 4b_5)\, v_1^6 v_2^3 + (12a_4 + 12b_2)\, v_1^6 v_2^2 + (4a_4 + 12b_2 + b_5)\, v_1^6 v_2 \\
&+ (-16a_5 - 8b_6)\, v_1^5 v_2^4 + (-32a_5 - 16b_6)\, v_1^5 v_2^3 \\
&+ (-16a_5 + 8b_1 - 4b_3 - 4b_6)\, v_1^5 v_2^2 + (8b_1 + 16b_4)\, v_1^5 v_2 \\
&+ (-24a_3 - 76a_6)\, v_1^4 v_2^4 + (-8a_1 - 44a_3 - 36a_6)\, v_1^4 v_2^3 \\
&+ (-12a_1 - 20a_3 + 8a_4 + 4b_5)\, v_1^4 v_2^2 + (-4a_1 + 10a_4 + 12b_2 + 2b_5)\, v_1^4 v_2 \\
&+ (-16a_5 - 8b_6)\, v_1^3 v_2^3 + (-12a_5 - 6b_6)\, v_1^3 v_2^2 + (4a_2 + 8b_1)\, v_1^3 v_2 \\
&+ (-24a_3 - 34a_6)\, v_1^2 v_2^3 + (-8a_1 - 18a_3)\, v_1^2 v_2^2 + (-2a_1 + 2a_4 + b_5)\, v_1^2 v_2 \\
&+ (-4a_5 - 2b_6)\, v_1 v_2^2 + (4b_1 + 10b_4)\, v_1^5 + 6b_4 v_1^7 + 5b_2 v_1^6 + 8b_2 v_1^4 \\
&- 10a_6 v_2^3 - 6a_3 v_2^2 + 3b_2 v_1^2 - 2a_1 v_2 + 2b_1 v_1 - 40a_6 v_1^4 v_2^5 \\
&+ 16b_4 v_1^7 v_2^2 + 16b_4 v_1^7 v_2 - 40a_6 v_1^2 v_2^4 + (6b_1 + 4b_4)\, v_1^3 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-2a_1 &= 0 \\
-6a_3 &= 0 \\
-40a_6 &= 0 \\
-10a_6 &= 0 \\
2b_1 &= 0 \\
3b_2 &= 0 \\
5b_2 &= 0 \\
8b_2 &= 0 \\
6b_4 &= 0 \\
16b_4 &= 0 \\
-8a_1 - 18a_3 &= 0 \\
4a_2 + 8b_1 &= 0 \\
-24a_3 - 76a_6 &= 0 \\
-24a_3 - 34a_6 &= 0 \\
8a_4 + 4b_5 &= 0 \\
12a_4 + 12b_2 &= 0 \\
-32a_5 - 16b_6 &= 0 \\
-16a_5 - 8b_6 &= 0 \\
-12a_5 - 6b_6 &= 0 \\
-4a_5 - 2b_6 &= 0 \\
4b_1 + 10b_4 &= 0 \\
6b_1 + 4b_4 &= 0 \\
8b_1 + 16b_4 &= 0 \\
-8a_1 - 44a_3 - 36a_6 &= 0 \\
-2a_1 + 2a_4 + b_5 &= 0 \\
4a_4 + 12b_2 + b_5 &= 0 \\
-12a_1 - 20a_3 + 8a_4 + 4b_5 &= 0 \\
-4a_1 + 10a_4 + 12b_2 + 2b_5 &= 0 \\
-16a_5 + 8b_1 - 4b_3 - 4b_6 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= 0 \\
a_3 &= 0 \\
a_4 &= 0 \\
a_5 &= -\frac{b_6}{2} \\
a_6 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_6 \\
b_4 &= 0 \\
b_5 &= 0 \\
b_6 &= b_6
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -\frac{yx}{2} \\
\eta &= y^2 + y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y^2 + y - \left(-\frac{2y(2y\,x^2 + 2x^2 + 1)}{x\,(2y\,x^2 + x^2 + 1)}\right)\left(-\frac{yx}{2}\right) \\
&= \frac{x^2y^2 + y\,x^2 + y}{2y\,x^2 + x^2 + 1} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{x^2 y^2 + y\,x^2 + y}{2y\,x^2 + x^2 + 1}} dy \end{aligned}$$

Which results in

$$S = \ln\left(y\left(y\,x^2 + x^2 + 1\right)\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{2y(2y\,x^2 + 2x^2 + 1)}{x\,(2y\,x^2 + x^2 + 1)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{2x(y+1)}{1 + (y+1)\,x^2} \\ S_y &= \frac{1}{y} + \frac{x^2}{1 + (y+1)\,x^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{2}{x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{2}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -2\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(y) + \ln\left(1 + (1 + y)\, x^2\right) = -2\ln(x) + c_1$$

Which simplifies to

$$\ln(y) + \ln\left(1 + (1 + y)\, x^2\right) = -2\ln(x) + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2y(2y\,x^2+2x^2+1)}{x(2y\,x^2+x^2+1)}$ 	$R = x$ $S = \ln(y) + \ln(1 + (y +$	$\frac{dS}{dR} = -\frac{2}{R}$ 
Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$-\infty = c_1$$

Unable to solve for constant of integration. Warning: Unable to solve for constant of integration.

<u>Verification of solutions</u> N/A

6.29.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x\left(2y\,x^2+x^2+1\right)\right)\mathrm{d}y&=\left(-2y\left(2y\,x^2+2x^2+1\right)\right)\mathrm{d}x\\ \left(2y\left(2y\,x^2+2x^2+1\right)\right)\mathrm{d}x+\left(x\left(2y\,x^2+x^2+1\right)\right)\mathrm{d}y&=0\end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=2y\left(2y\,x^2+2x^2+1\right)\\ N(x,y)&=x\left(2y\,x^2+x^2+1\right)\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(2y\left(2y\,x^{2}+2x^{2}+1\right)\right)\\ &= 2+\left(8y+4\right)x^{2}\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x\left(2y\,x^{2}+x^{2}+1\right)\right)\\ &= 1+\left(6y+3\right)x^{2}\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\ &= \frac{1}{\left(1+2y\right)x^{3}+x}\left(\left(8y\,x^{2}+4x^{2}+2\right)-\left(2y\,x^{2}+x^{2}+1+x(4yx+2x)\right)\right)\\ &= \frac{1}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int \frac{1}{x}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\ln(x)}\\ &= x\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= x\left(2y\left(2y\,x^{2}+2x^{2}+1\right)\right)\\ &= 4\left(\frac{1}{2}+\left(y+1\right)x^{2}\right)xy\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= x\left(x\left(2y\,x^2+x^2+1\right)\right) \\
&= (1+2y)\,x^4+x^2
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(4\left(\frac{1}{2}+(y+1)\,x^2\right)xy\right)+\left((1+2y)\,x^4+x^2\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial\phi}{\partial x}=\overline{M} \tag{1}
$$

$$
\frac{\partial\phi}{\partial y}=\overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int\overline{M}\,\mathrm{d}x \\
\int\frac{\partial\phi}{\partial x}\,\mathrm{d}x &= \int 4\left(\frac{1}{2}+(y+1)\,x^2\right)xy\,\mathrm{d}x
\end{aligned}
$$

$$
\phi=\frac{\left(2y\,x^2+2x^2+1\right)^2 y}{4y+4}+f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\begin{aligned}
\frac{\partial\phi}{\partial y} &= \frac{4(2y\,x^2+2x^2+1)\,y\,x^2}{4y+4}+\frac{\left(2y\,x^2+2x^2+1\right)^2}{4y+4}-\frac{4\left(2y\,x^2+2x^2+1\right)^2 y}{(4y+4)^2}+f'(y) \qquad (4) \\
&= \frac{1+8\left(\frac{1}{2}+y\right)(y+1)^2\,x^4+4(y+1)^2\,x^2}{4\,(y+1)^2}+f'(y)
\end{aligned}
$$

But equation (2) says that $\frac{\partial\phi}{\partial y}=(1+2y)\,x^4+x^2$. Therefore equation (4) becomes

$$
(1+2y)\,x^4+x^2=\frac{1+8\left(\frac{1}{2}+y\right)(y+1)^2\,x^4+4(y+1)^2\,x^2}{4\,(y+1)^2}+f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{1}{4\left(y+1\right)^{2}}$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(-\frac{1}{4\left(y+1\right)^{2}}\right) \mathrm{d}y$$

$$f(y) = \frac{1}{4y+4} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{\left(2y\,x^{2}+2x^{2}+1\right)^{2} y}{4y+4} + \frac{1}{4y+4} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{\left(2y\,x^{2}+2x^{2}+1\right)^{2} y}{4y+4} + \frac{1}{4y+4}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = -2$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{1}{4} = c_1$$

$$c_1 = \frac{1}{4}$$

Substituting c_1 found above in the general solution gives

$$\frac{\left(2y\,x^{2}+2x^{2}+1\right)^{2} y}{4y+4} + \frac{1}{4y+4} = \frac{1}{4}$$

Summary

The solution(s) found are the following

$$\frac{1}{4} + \left(y^{2}+y\right)x^{4} + x^{2}y = \frac{1}{4} \tag{1}$$

Verification of solutions

$$\frac{1}{4}+\left(y^2+y\right)x^4+x^2y=\frac{1}{4}$$

Verified OK.

6.30.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(x\left(3x^5 + 3x^3 + 2y\right)\right)\mathrm{d}y = \left(8x^8 + 3y\,x^5 + 9y\,x^3 + 6y^2\right)\mathrm{d}x$$
$$\left(-8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2\right)\mathrm{d}x + \left(x\left(3x^5 + 3x^3 + 2y\right)\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2$$
$$N(x, y) = x\left(3x^5 + 3x^3 + 2y\right)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2\right)\\ &= -3x^5 - 9x^3 - 12y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x\left(3x^5 + 3x^3 + 2y\right)\right)\\ &= 18x^5 + 12x^3 + 2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{3x^6 + 3x^4 + 2yx}\left(\left(-3x^5 - 9x^3 - 12y\right) - \left(3x^5 + 3x^3 + 2y + x\left(15x^4 + 9x^2\right)\right)\right) \\
&= -\frac{7}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \,\mathrm{d}x} \\
&= e^{\int -\frac{7}{x} \,\mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-7\ln(x)} \\
&= \frac{1}{x^7}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^7}\left(-8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2\right) \\
&= \frac{-8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2}{x^7}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^7}\left(x\left(3x^5 + 3x^3 + 2y\right)\right) \\
&= \frac{3x^5 + 3x^3 + 2y}{x^6}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{-8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2}{x^7}\right) + \left(\frac{3x^5 + 3x^3 + 2y}{x^6}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{-8x^8 - 3y\,x^5 - 9y\,x^3 - 6y^2}{x^7} \mathrm{d}x$$
$$\phi = -4x^2 + \frac{3y}{x} + \frac{y^2}{x^6} + \frac{3y}{x^3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{3}{x} + \frac{2y}{x^6} + \frac{3}{x^3} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{3x^5+3x^3+2y}{x^6}$. Therefore equation (4) becomes

$$\frac{3x^5 + 3x^3 + 2y}{x^6} = \frac{3x^5 + 3x^3 + 2y}{x^6} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = -4x^2 + \frac{3y}{x} + \frac{y^2}{x^6} + \frac{3y}{x^3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -4x^2 + \frac{3y}{x} + \frac{y^2}{x^6} + \frac{3y}{x^3}$$

Initial conditions are used to solve for c_1. Substituting $x = 1$ and $y = 1$ in the above solution gives an equation to solve for the constant of integration.

$$3 = c_1$$

$$c_1 = 3$$

Substituting c_1 found above in the general solution gives

$$-4x^2 + \frac{3y}{x} + \frac{y^2}{x^6} + \frac{3y}{x^3} = 3$$

The above simplifies to

$$-4x^8 - 3x^6 + 3y\,x^5 + 3y\,x^3 + y^2 = 0$$

Summary
The solution(s) found are the following

$$-4x^8 - 3x^6 + 3yx^5 + 3yx^3 + y^2 = 0 \tag{1}$$

Verification of solutions

$$-4x^8 - 3x^6 + 3yx^5 + 3yx^3 + y^2 = 0$$

Verified OK.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_Abel, `2nd type`, `class B`]]
```

$$\boxed{2yx + y' + \frac{e^{-x^2}\left(3x + 2\,e^{x^2} y\right)}{2x + 3\,e^{x^2} y} = 0}$$

With initial conditions

$$[y(0) = -1]$$

6.31.1 Existence and uniqueness analysis

This is non linear first order ODE. In canonical form it is written as

$$\begin{aligned} y' &= f(x,y) \\ &= -\frac{6\,e^{x^2} x\,y^2 + 2y\,e^{-x^2} e^{x^2} + 4y\,x^2 + 3x\,e^{-x^2}}{2x + 3\,e^{x^2} y} \end{aligned}$$

The x domain of $f(x,y)$ when $y = -1$ is

$$\left\{x < \frac{\sqrt{2}}{2\sqrt{-\frac{1}{\mathrm{LambertW}\left(\_Z66, -\frac{9}{2}\right)}}} \vee \frac{\sqrt{2}}{2\sqrt{-\frac{1}{\mathrm{LambertW}\left(\_Z66, -\frac{9}{2}\right)}}} < x\right\}$$

But the point $x_0 = 0$ is not inside this domain. Hence existence and uniqueness theorem does not apply. There could be infinite number of solutions, or one solution or no solution at all.

6.31.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{6\,\mathrm{e}^{x^2} x\, y^2 + 2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2} + 4y\, x^2 + 3x\,\mathrm{e}^{-x^2}}{2x + 3\,\mathrm{e}^{x^2} y} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 3 to use as anstaz gives

$$
\xi = x^3 a_7 + y\, x^2 a_8 + x\, y^2 a_9 + y^3 a_{10} + x^2 a_4 + y x a_5 + y^2 a_6 + x a_2 + y a_3 + a_1 \tag{1E}
$$

$$
\eta = x^3 b_7 + y\, x^2 b_8 + x\, y^2 b_9 + y^3 b_{10} + x^2 b_4 + y x b_5 + y^2 b_6 + x b_2 + y b_3 + b_1 \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9, a_{10}, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9, b_{10}\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&3x^2b_7+2xyb_8+y^2b_9+2xb_4+yb_5+b_2 \qquad (5E)\\
&-\frac{\left(6\,e^{x^2}x\,y^2+2y\,e^{-x^2}e^{x^2}+4y\,x^2+3x\,e^{-x^2}\right)\left(-3x^2a_7+x^2b_8-2xya_8+2xyb_9-y^2a_9+3y^2b_{10}-2xa_4+x\right.}{2x+3\,e^{x^2}y}\\
&-\frac{\left(6\,e^{x^2}x\,y^2+2y\,e^{-x^2}e^{x^2}+4y\,x^2+3x\,e^{-x^2}\right)^2\left(x^2a_8+2xya_9+3y^2a_{10}+xa_5+2ya_6+a_3\right)}{\left(2x+3\,e^{x^2}y\right)^2}\\
&-\left(-\frac{12\,e^{x^2}x^2y^2+6\,e^{x^2}y^2+8yx+3\,e^{-x^2}-6x^2e^{-x^2}}{2x+3\,e^{x^2}y}\right.\\
&\left.+\frac{\left(6\,e^{x^2}x\,y^2+2y\,e^{-x^2}e^{x^2}+4y\,x^2+3x\,e^{-x^2}\right)\left(2+6x\,e^{x^2}y\right)}{\left(2x+3\,e^{x^2}y\right)^2}\right)\left(x^3a_7\right.\\
&\left.+y\,x^2a_8+x\,y^2a_9+y^3a_{10}+x^2a_4+yxa_5+y^2a_6+xa_2+ya_3+a_1\right)\\
&-\left(-\frac{12x\,e^{x^2}y+2\,e^{x^2}e^{-x^2}+4x^2}{2x+3\,e^{x^2}y}\right.\\
&\left.+\frac{3\left(6\,e^{x^2}x\,y^2+2y\,e^{-x^2}e^{x^2}+4y\,x^2+3x\,e^{-x^2}\right)e^{x^2}}{\left(2x+3\,e^{x^2}y\right)^2}\right)\left(x^3b_7+y\,x^2b_8\right.\\
&\left.+x\,y^2b_9+y^3b_{10}+x^2b_4+yxb_5+y^2b_6+xb_2+yb_3+b_1\right)=0
\end{aligned}
$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

Expression too large to display (6E)

Simplifying the above gives

Expression too large to display (6E)

Looking at the above PDE shows the following are all the terms with $\{x,y\}$ in them.

$$\left\{x,y,e^{x^2},e^{-2x^2},e^{-x^2},e^{2x^2}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2, e^{x^2} = v_3, e^{-2x^2} = v_4, e^{-x^2} = v_5, e^{2x^2} = v_6\}$$

The above PDE (6E) now becomes

$$\text{Expression too large to display} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5, v_6\}$$

Equation (7E) now becomes

$$\text{Expression too large to display} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
a_3 &= 0\\
5a_1 &= 0\\
-12a_3 &= 0\\
-9a_3 &= 0\\
-12a_4 &= 0\\
54a_4 &= 0\\
60a_4 &= 0\\
-48a_5 &= 0\\
-36a_5 &= 0\\
-16a_5 &= 0\\
-9a_5 &= 0\\
-132a_6 &= 0\\
-96a_6 &= 0\\
-72a_6 &= 0\\
-60a_6 &= 0\\
-36a_6 &= 0\\
-32a_6 &= 0\\
-24a_6 &= 0\\
-18a_6 &= 0\\
-3a_6 &= 0\\
18a_6 &= 0\\
-12a_7 &= 0\\
-4a_7 &= 0\\
72a_7 &= 0\\
84a_7 &= 0\\
-48a_8 &= 0\\
-36a_8 &= 0\\
-16a_8 &= 0\\
-9a_8 &= 0\\
-96a_9 &= 0\\
-72a_9 &= 0\\
-60a_9 &= 0\\
-32a_9 &= 0\\
-18a_9 &= 0\\
-184a_{10} &= 0\\
-144a_{10} &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= 0 \\
a_2 &= -\frac{b_8}{2} \\
a_3 &= 0 \\
a_4 &= 0 \\
a_5 &= 0 \\
a_6 &= 0 \\
a_7 &= 0 \\
a_8 &= 0 \\
a_9 &= 0 \\
a_{10} &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= -\frac{b_8}{2} \\
b_4 &= 0 \\
b_5 &= 0 \\
b_6 &= 0 \\
b_7 &= 0 \\
b_8 &= b_8 \\
b_9 &= 0 \\
b_{10} &= 0
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= -\frac{x}{2} \\
\eta &= y\,x^2 - \frac{1}{2}y
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y\,x^2 - \frac{1}{2}y - \left(-\frac{6\,\mathrm{e}^{x^2} x\,y^2 + 2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2} + 4y\,x^2 + 3x\,\mathrm{e}^{-x^2}}{2x + 3\,\mathrm{e}^{x^2} y}\right)\left(-\frac{x}{2}\right) \\
&= \frac{-3\,\mathrm{e}^{x^2} y^2 - 3x^2\mathrm{e}^{-x^2} - 4yx}{6\,\mathrm{e}^{x^2} y + 4x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-3\,\mathrm{e}^{x^2} y^2 - 3x^2\mathrm{e}^{-x^2} - 4yx}{6\,\mathrm{e}^{x^2} y + 4x}} dy
\end{aligned}
$$

Which results in

$$
S = -\ln\left(3\,\mathrm{e}^{2x^2} y^2 + 4x\,\mathrm{e}^{x^2} y + 3x^2\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{6\,\mathrm{e}^{x^2} x\,y^2 + 2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2} + 4y\,x^2 + 3x\,\mathrm{e}^{-x^2}}{2x + 3\,\mathrm{e}^{x^2} y}
$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{-12\,\mathrm{e}^{2x^2} x\, y^2 + (-8y\, x^2 - 4y)\,\mathrm{e}^{x^2} - 6x}{3\,\mathrm{e}^{2x^2} y^2 + 4x\,\mathrm{e}^{x^2} y + 3x^2} \\
S_y &= \frac{-6\,\mathrm{e}^{2x^2} y - 4\,\mathrm{e}^{x^2} x}{3\,\mathrm{e}^{2x^2} y^2 + 4x\,\mathrm{e}^{x^2} y + 3x^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\ln\left(3\,\mathrm{e}^{2x^2} y^2 + 4yx\,\mathrm{e}^{x^2} + 3x^2\right) = c_1$$

Which simplifies to

$$-\ln\left(3\,\mathrm{e}^{2x^2} y^2 + 4yx\,\mathrm{e}^{x^2} + 3x^2\right) = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{6\,e^{x^2} x\,y^2+2y\,e^{-x^2} e^{x^2}+4y\,x^2+3x\,e^{-x^2}}{2x+3\,e^{x^2} y}$ 	$R = x$ $S = -\ln\left(3\,e^{2x^2} y^2 + 4x\,e^{x}\right.$	$\frac{dS}{dR} = 0$ 
Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$-\ln(3) = c_1$$

$$c_1 = -\ln(3)$$

Substituting c_1 found above in the general solution gives

$$-\ln\left(3\,e^{2x^2} y^2 + 4x\,e^{x^2} y + 3x^2\right) = -\ln(3)$$

Summary

The solution(s) found are the following

$$-\ln\left(3\,e^{2x^2} y^2 + 4yx\,e^{x^2} + 3x^2\right) = -\ln(3) \tag{1}$$

Verification of solutions

$$-\ln\left(3\,e^{2x^2} y^2 + 4yx\,e^{x^2} + 3x^2\right) = -\ln(3)$$

Verified OK.

6.31.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\left(2x+3\,\mathrm{e}^{x^2}y\right)\mathrm{d}y=\left(-6\,\mathrm{e}^{x^2}x\,y^2-2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2}-4y\,x^2-3x$$

$$\left(6\,\mathrm{e}^{x^2}x\,y^2+2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2}+4y\,x^2+3x\,\mathrm{e}^{-x^2}\right)\mathrm{d}x+\left(2x+3\,\mathrm{e}^{x^2}y\right)\mathrm{d}y=0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=6\,\mathrm{e}^{x^2}x\,y^2+2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2}+4y\,x^2+3x\,\mathrm{e}^{-x^2}\\ N(x,y)&=2x+3\,\mathrm{e}^{x^2}y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(6\,\mathrm{e}^{x^2} x\,y^2 + 2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2} + 4y\,x^2 + 3x\,\mathrm{e}^{-x^2}\right)\\ &= 12x\,\mathrm{e}^{x^2} y + 2 + 4x^2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(2x + 3\,\mathrm{e}^{x^2} y\right)\\ &= 2 + 6x\,\mathrm{e}^{x^2} y\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x + 3\,\mathrm{e}^{x^2} y}\left(\left(12x\,\mathrm{e}^{x^2} y + 2\,\mathrm{e}^{x^2}\mathrm{e}^{-x^2} + 4x^2\right) - \left(2 + 6x\,\mathrm{e}^{x^2} y\right)\right)\\ &= 2x\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int 2x\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{x^2}\\ &= \mathrm{e}^{x^2}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{x^2}\left(6\,\mathrm{e}^{x^2} x\,y^2 + 2y\,\mathrm{e}^{-x^2}\mathrm{e}^{x^2} + 4y\,x^2 + 3x\,\mathrm{e}^{-x^2}\right)\\ &= 6\,\mathrm{e}^{2x^2} x\,y^2 + 2\,\mathrm{e}^{x^2} y\left(2x^2 + 1\right) + 3x\end{aligned}$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{x^2}\left(2x + 3\,\mathrm{e}^{x^2} y\right) \\
&= 3\,\mathrm{e}^{2x^2} y + 2\,\mathrm{e}^{x^2} x
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(6\,\mathrm{e}^{2x^2} x\,y^2 + 2\,\mathrm{e}^{x^2} y\left(2x^2+1\right) + 3x\right) + \left(3\,\mathrm{e}^{2x^2} y + 2\,\mathrm{e}^{x^2} x\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int \overline{M}\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int 6\,\mathrm{e}^{2x^2} x\,y^2 + 2\,\mathrm{e}^{x^2} y\left(2x^2+1\right) + 3x\,\mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{3x^2}{2} + 2x\,\mathrm{e}^{x^2} y + \frac{3\,\mathrm{e}^{2x^2} y^2}{2} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 3\,\mathrm{e}^{2x^2} y + 2\,\mathrm{e}^{x^2} x + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 3\,\mathrm{e}^{2x^2} y + 2\,\mathrm{e}^{x^2} x$. Therefore equation (4) becomes

$$
3\,\mathrm{e}^{2x^2} y + 2\,\mathrm{e}^{x^2} x = 3\,\mathrm{e}^{2x^2} y + 2\,\mathrm{e}^{x^2} x + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{3x^2}{2} + 2x\,e^{x^2} y + \frac{3\,e^{2x^2} y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{3x^2}{2} + 2x\,e^{x^2} y + \frac{3\,e^{2x^2} y^2}{2}$$

Initial conditions are used to solve for c_1. Substituting $x = 0$ and $y = -1$ in the above solution gives an equation to solve for the constant of integration.

$$\frac{3}{2} = c_1$$

$$c_1 = \frac{3}{2}$$

Substituting c_1 found above in the general solution gives

$$\frac{3x^2}{2} + 2x\,e^{x^2} y + \frac{3\,e^{2x^2} y^2}{2} = \frac{3}{2}$$

Summary

The solution(s) found are the following

$$\frac{3x^2}{2} + 2yx\,e^{x^2} + \frac{3\,e^{2x^2} y^2}{2} = \frac{3}{2} \tag{1}$$

Verification of solutions

$$\frac{3x^2}{2} + 2yx\,e^{x^2} + \frac{3\,e^{2x^2} y^2}{2} = \frac{3}{2}$$

Verified OK.

The solution

$$-\ln\left(3\,e^{2x^2} y^2 + 4yx\,e^{x^2} + 3x^2\right) = -\ln(3)$$

can be simplified to

$$\ln \left(3\, \mathrm{e}^{2x^2} y^2 + 4yx\, \mathrm{e}^{x^2} + 3x^2\right) = \ln (3)$$

The type(s) of ODE detected by this program : **"exact", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{y + \left(2x + \frac{1}{y}\right) y' = 0}$$

7.1.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{y^2}{2yx + 1}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$
$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{y^2(b_3 - a_2)}{2yx+1} - \frac{y^4 a_3}{(2yx+1)^2} - \frac{2y^3(xa_2 + ya_3 + a_1)}{(2yx+1)^2} - \left(-\frac{2y}{2yx+1} + \frac{2y^2 x}{(2yx+1)^2}\right)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{6x^2y^2b_2 - 3y^4a_3 + 2x\,y^2b_1 - 2y^3a_1 + 6xyb_2 + y^2a_2 + y^2b_3 + 2yb_1 + b_2}{(2yx+1)^2} = 0$$

Setting the numerator to zero gives

$$6x^2y^2b_2 - 3y^4a_3 + 2x\,y^2b_1 - 2y^3a_1 + 6xyb_2 + y^2a_2 + y^2b_3 + 2yb_1 + b_2 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-3a_3v_2^4 + 6b_2v_1^2v_2^2 - 2a_1v_2^3 + 2b_1v_1v_2^2 + a_2v_2^2 + 6b_2v_1v_2 + b_3v_2^2 + 2b_1v_2 + b_2 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$6b_2v_1^2v_2^2 + 2b_1v_1v_2^2 + 6b_2v_1v_2 - 3a_3v_2^4 - 2a_1v_2^3 + (a_2 + b_3)\,v_2^2 + 2b_1v_2 + b_2 = 0 \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
b_2 &= 0 \\
-2a_1 &= 0 \\
-3a_3 &= 0 \\
2b_1 &= 0 \\
6b_2 &= 0 \\
a_2 + b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= -b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -x \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(-\frac{y^2}{2yx + 1}\right)(-x) \\
&= \frac{x\,y^2 + y}{2yx + 1} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x}+\eta \frac{\partial}{\partial y}\right) S(x, y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$R=x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} d y \\ &= \int \frac{1}{\frac{x y^{2}+y}{2 y x+1}} d y \end{aligned}$$

Which results in

$$S=\ln (y(y x+1))$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{d S}{d R}=\frac{S_{x}+\omega(x, y) S_{y}}{R_{x}+\omega(x, y) R_{y}} \tag{2}$$

Where in the above $R_{x}, R_{y}, S_{x}, S_{y}$ are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x, y)=-\frac{y^{2}}{2 y x+1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_{x} &= 1 \\ R_{y} &= 0 \\ S_{x} &= \frac{y}{y x+1} \\ S_{y} &= \frac{1}{y}+\frac{x}{y x+1} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{d S}{d R}=0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{d S}{d R}=0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(y) + \ln(yx + 1) = c_1$$

Which simplifies to

$$\ln(y) + \ln(yx + 1) = c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y^2}{2yx+1}$ 	$R = x$ $S = \ln(y) + \ln(yx + 1)$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$\ln(y) + \ln(yx + 1) = c_1 \tag{1}$$

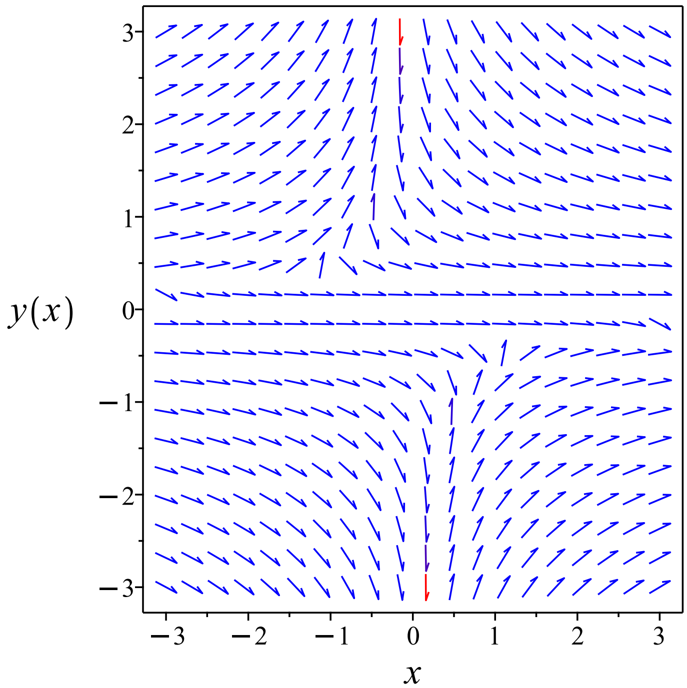

Figure 404: Slope field plot

Verification of solutions

$$\ln(y) + \ln(yx + 1) = c_1$$

Verified OK.

7.1.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2yx + 1)\,\mathrm{d}y &= \left(-y^2\right)\mathrm{d}x\\ \left(y^2\right)\mathrm{d}x + (2yx + 1)\,\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= y^2\\ N(x, y) &= 2yx + 1\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y^2\right)\\ &= 2y\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2yx + 1)\\ &= 2y\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int M \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int y^2 \,\mathrm{d}x$$
$$\phi = x\,y^2 + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2yx + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2yx + 1$. Therefore equation (4) becomes

$$2yx + 1 = 2yx + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 1$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (1) \,\mathrm{d}y$$
$$f(y) = y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = x\,y^2 + y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = x\,y^2 + y$$

Summary

The solution(s) found are the following

$$y + xy^2 = c_1 \tag{1}$$

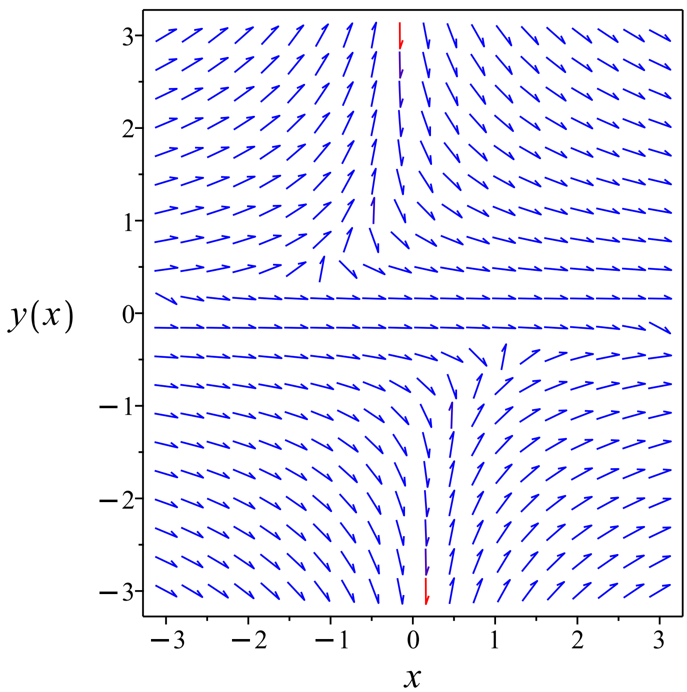

Figure 405: Slope field plot

Verification of solutions

$$y + xy^2 = c_1$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 2(a).
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "riccati", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{-y^2 + y'x^2 = 0}$$

7.2.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y^2}{x^2} \end{aligned}$$

Where $f(x) = \frac{1}{x^2}$ and $g(y) = y^2$. Integrating both sides gives

$$\frac{1}{y^2}\,dy = \frac{1}{x^2}\,dx$$
$$\int \frac{1}{y^2}\,dy = \int \frac{1}{x^2}\,dx$$
$$-\frac{1}{y} = -\frac{1}{x} + c_1$$

Which results in

$$y = -\frac{x}{c_1 x - 1}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{c_1 x - 1} \tag{1}$$

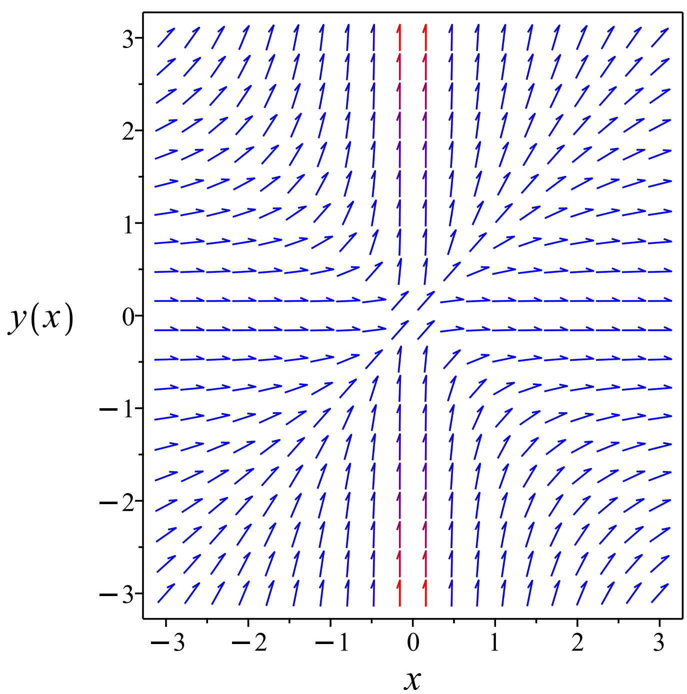

Figure 406: Slope field plot

Verification of solutions

$$y = -\frac{x}{c_1 x - 1}$$

Verified OK.

7.2.2 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$-u(x)^2\,x^2 + (u'(x)\,x + u(x))\,x^2 = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u(u-1)}{x}
\end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u(u-1)$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u\,(u-1)}\,du &= \frac{1}{x}\,dx \\
\int \frac{1}{u\,(u-1)}\,du &= \int \frac{1}{x}\,dx \\
-\ln\left(u\right) + \ln\left(u-1\right) &= \ln\left(x\right) + c_2
\end{aligned}$$

Raising both side to exponential gives

$$\mathrm{e}^{-\ln(u)+\ln(u-1)} = \mathrm{e}^{\ln(x)+c_2}$$

Which simplifies to

$$\frac{u-1}{u} = c_3 x$$

Therefore the solution y is

$$\begin{aligned}
y &= xu \\
&= -\frac{x}{c_3 x - 1}
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = -\frac{x}{c_3 x - 1} \tag{1}$$

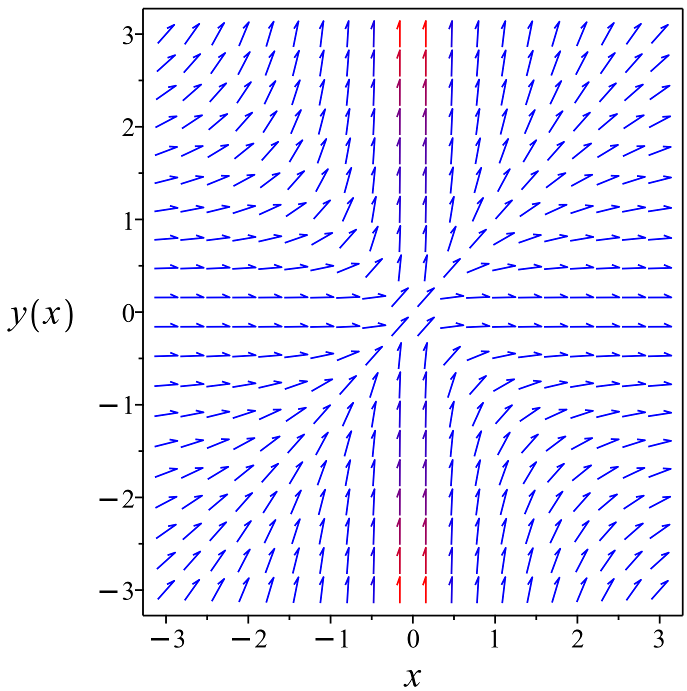

Figure 407: Slope field plot

Verification of solutions

$$y = -\frac{x}{c_3 x - 1}$$

Verified OK.

7.2.3 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y^2}{x^2}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 308: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x, y) = x^2$$
$$\eta(x, y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{x^2} dx \end{aligned}$$

Which results in

$$S = -\frac{1}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y^2}{x^2}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{1}{x^2} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{1}{y^2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{1}{R^2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{1}{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{x} = -\frac{1}{y} + c_1$$

Which simplifies to

$$-\frac{1}{x} = -\frac{1}{y} + c_1$$

Which gives

$$y = \frac{x}{c_1 x + 1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

$$y = \frac{x}{c_1 x + 1}$$

Verified OK.

7.2.4 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx} \phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{y^2}\right)\mathrm{d}y&=\left(\frac{1}{x^2}\right)\mathrm{d}x\\ \left(-\frac{1}{x^2}\right)\mathrm{d}x+\left(\frac{1}{y^2}\right)\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-\frac{1}{x^2}\\ N(x,y)&=\frac{1}{y^2}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-\frac{1}{x^2}\right)\\ &=0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y^2}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \qquad (1)\\
\frac{\partial \phi}{\partial y} &= N \qquad (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \mathrm{d}x\\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -\frac{1}{x^2} \mathrm{d}x\\
\phi &= \frac{1}{x} + f(y) \qquad (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \qquad (4)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y^2}$. Therefore equation (4) becomes

$$
\frac{1}{y^2} = 0 + f'(y) \qquad (5)
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = \frac{1}{y^2}
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{1}{y^2}\right)\mathrm{d}y$$
$$f(y) = -\frac{1}{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{x} - \frac{1}{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{x} - \frac{1}{y}$$

The solution becomes

$$y = -\frac{x}{c_1 x - 1}$$

Summary

The solution(s) found are the following

$$y = -\frac{x}{c_1 x - 1} \tag{1}$$

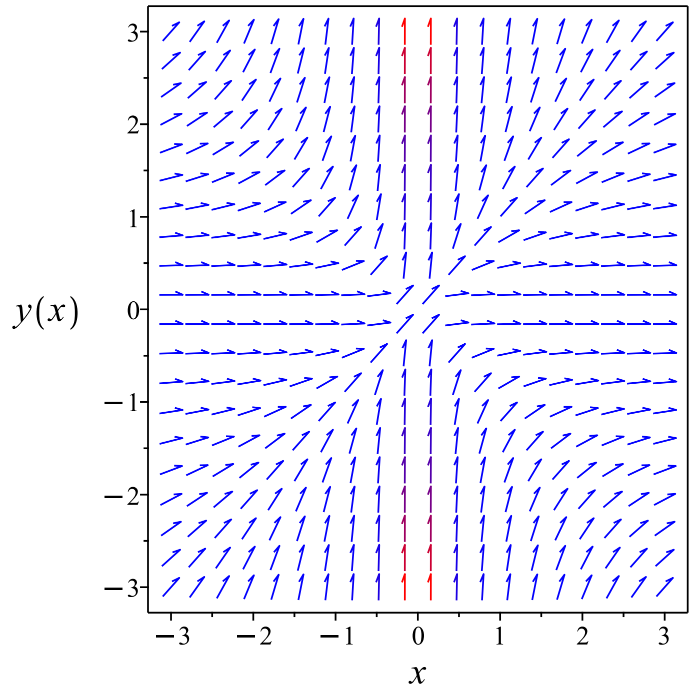

Figure 409: Slope field plot

Verification of solutions

$$y = -\frac{x}{c_1 x - 1}$$

Verified OK.

7.2.5 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{y^2}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{y^2}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = 0$ and $f_2(x) = \frac{1}{x^2}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\frac{u}{x^2}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{2}{x^3} \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\frac{u''(x)}{x^2} + \frac{2u'(x)}{x^3} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 + \frac{c_2}{x}$$

The above shows that

$$u'(x) = -\frac{c_2}{x^2}$$

Using the above in (1) gives the solution

$$y = \frac{c_2}{c_1 + \frac{c_2}{x}}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{1}{c_3 + \frac{1}{x}}$$

Summary

The solution(s) found are the following

$$y = \frac{1}{c_3 + \frac{1}{x}} \tag{1}$$

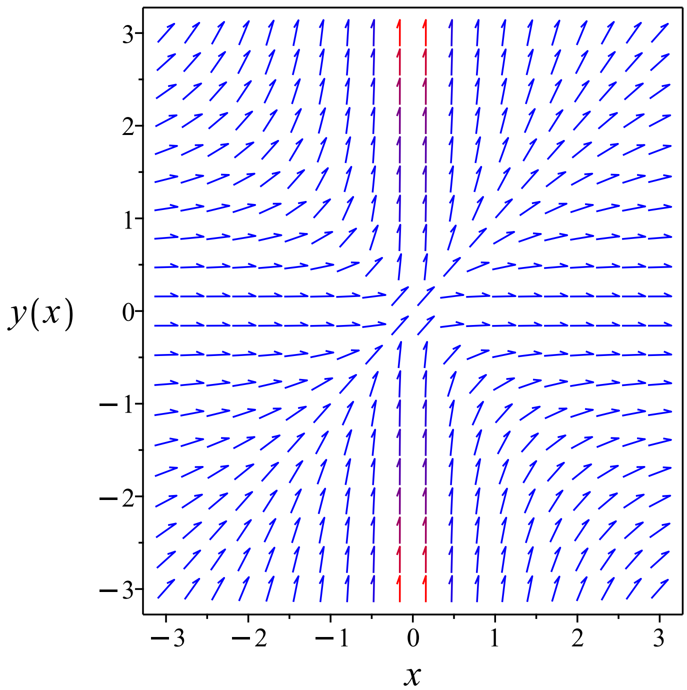

Figure 410: Slope field plot

Verification of solutions

$$y = \frac{1}{c_3 + \frac{1}{x}}$$

Verified OK.

7.2.6 Maple step by step solution

Let's solve

$-y^2 + y' x^2 = 0$

- Highest derivative means the order of the ODE is 1

y'

- Separate variables

$\frac{y'}{y^2} = \frac{1}{x^2}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y^2} dx = \int \frac{1}{x^2} dx + c_1$

- Evaluate integral

  $-\frac{1}{y} = -\frac{1}{x} + c_1$

- Solve for y

  $y = -\frac{x}{c_1 x - 1}$

ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{-y'x + y = 0}$$

7.3.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y}{x} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y}\,dy &= \frac{1}{x}\,dx \\
\int \frac{1}{y}\,dy &= \int \frac{1}{x}\,dx \\
\ln(y) &= \ln(x) + c_1 \\
y &= \mathrm{e}^{\ln(x)+c_1} \\
&= c_1 x
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 x \tag{1}$$

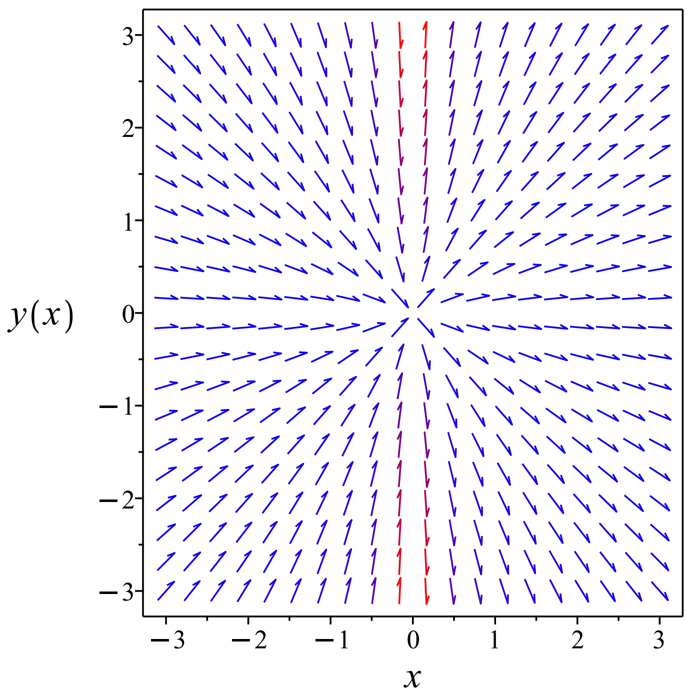

Figure 411: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 x$$

Verified OK.

7.3.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}\mu y &= 0 \\ \frac{d}{dx}\left(\frac{y}{x}\right) &= 0 \end{aligned}$$

Integrating gives

$$\frac{y}{x} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = c_1 x$$

Summary
The solution(s) found are the following

$$y = c_1 x \tag{1}$$

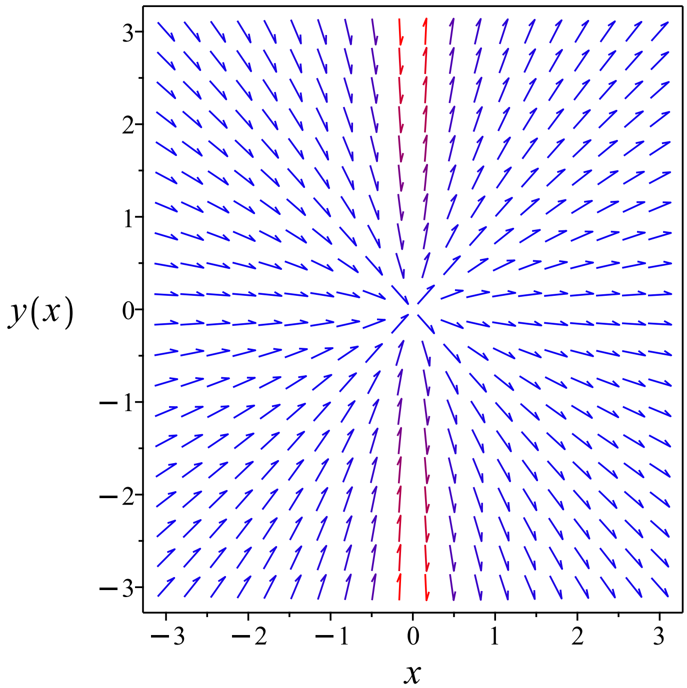

Figure 412: Slope field plot

Verification of solutions

$$y = c_1 x$$

Verified OK.

7.3.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$-(u'(x)\, x + u(x))\, x + u(x)\, x = 0$$

Integrating both sides gives

$$\begin{aligned} u(x) &= \int 0 \, \mathrm{d}x \\ &= c_2 \end{aligned}$$

Therefore the solution y is

$$\begin{aligned} y &= ux \\ &= c_2 x \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 x \tag{1}$$

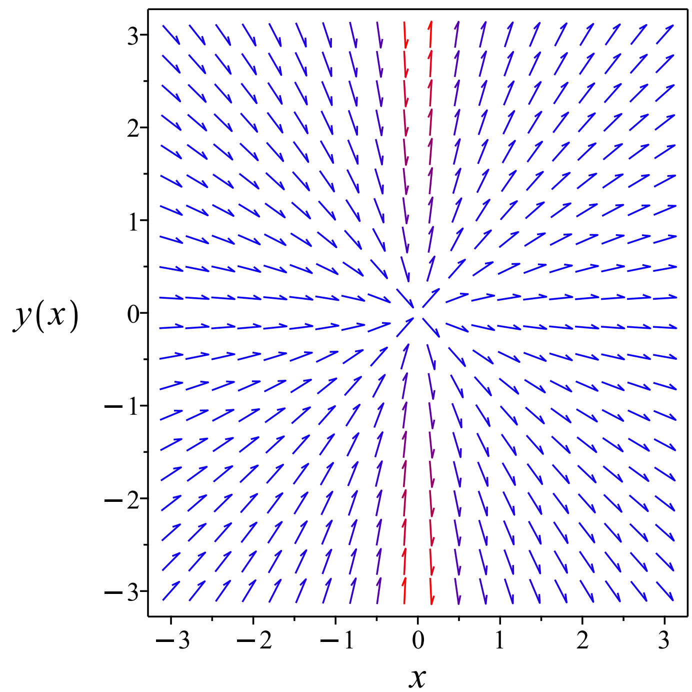

Figure 413: Slope field plot

Verification of solutions

$$y = c_2 x$$

Verified OK.

7.3.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 311: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= 0 \\ \eta(x, y) &= x \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x} dy \end{aligned}$$

Which results in

$$S = \frac{y}{x}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{x^2} \\ S_y &= \frac{1}{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{y}{x} = c_1$$

Which simplifies to

$$\frac{y}{x} = c_1$$

Which gives

$$y = c_1 x$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = \frac{y}{x}$
</td><td>$R = x$
$S = \frac{y}{x}$</td><td>$\frac{dS}{dR} = 0$
</td></tr>
</table>

Summary
The solution(s) found are the following

$$y = c_1 x \tag{1}$$

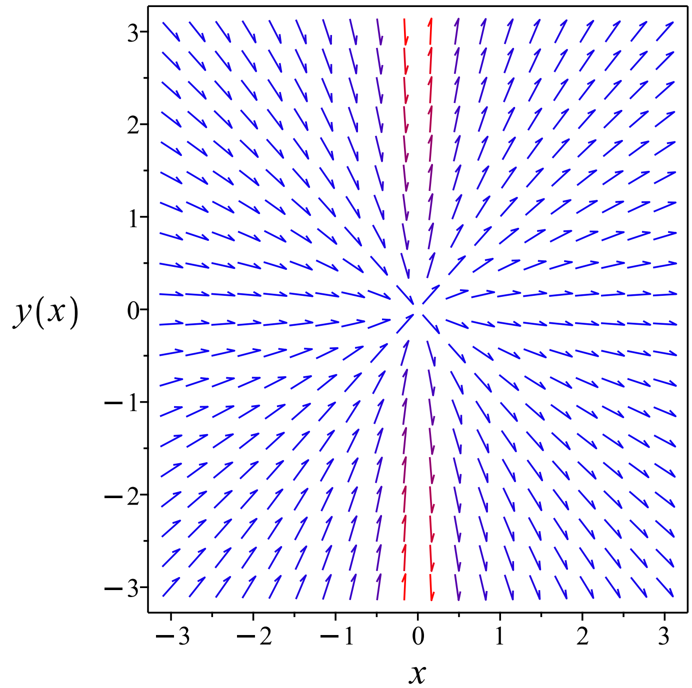

Figure 414: Slope field plot

<u>Verification of solutions</u>

$$y = c_1 x$$

Verified OK.

7.3.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{1}{y}\right) \mathrm{d}y = \left(\frac{1}{x}\right) \mathrm{d}x$$
$$\left(-\frac{1}{x}\right) \mathrm{d}x + \left(\frac{1}{y}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{1}{x}$$
$$N(x, y) = \frac{1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right) \\ &= 0\end{aligned}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(\frac{1}{y}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\frac{1}{x} \, \mathrm{d}x$$
$$\phi = -\ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(\frac{1}{y}\right) \mathrm{d}y$$
$$f(y) = \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \ln(y) - \ln(x) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \ln(y) - \ln(x)$$

The solution becomes

$$y = x\,e^{c_1}$$

Summary

The solution(s) found are the following

$$y = x\,e^{c_1} \tag{1}$$

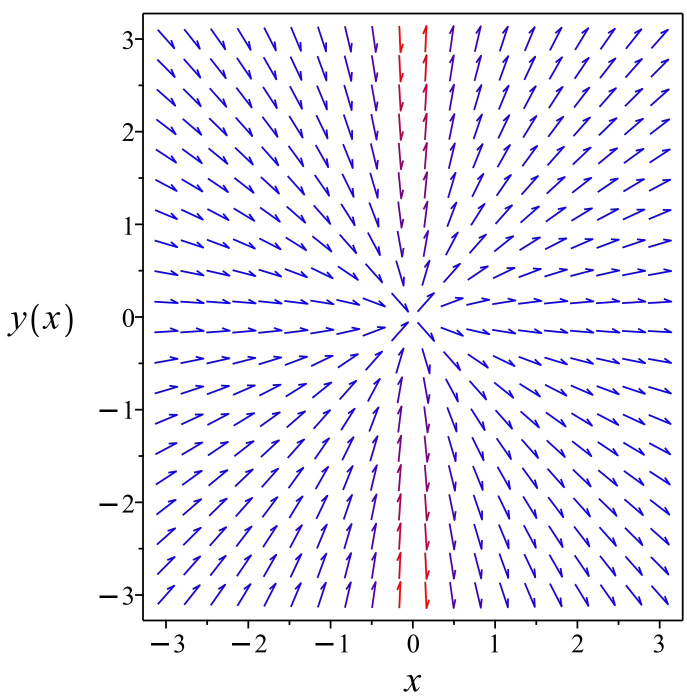

Figure 415: Slope field plot

Verification of solutions

$$y = x\,e^{c_1}$$

Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{3x^2y + 2x^3y' = 0}$$

7.4.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{3y}{2x} \end{aligned}$$

Where $f(x) = -\frac{3}{2x}$ and $g(y) = y$. Integrating both sides gives

$$\frac{1}{y}\,dy = -\frac{3}{2x}\,dx$$
$$\int \frac{1}{y}\,dy = \int -\frac{3}{2x}\,dx$$
$$\ln(y) = -\frac{3\ln(x)}{2} + c_1$$
$$y = e^{-\frac{3\ln(x)}{2}+c_1}$$
$$= \frac{c_1}{x^{\frac{3}{2}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x^{\frac{3}{2}}} \tag{1}$$

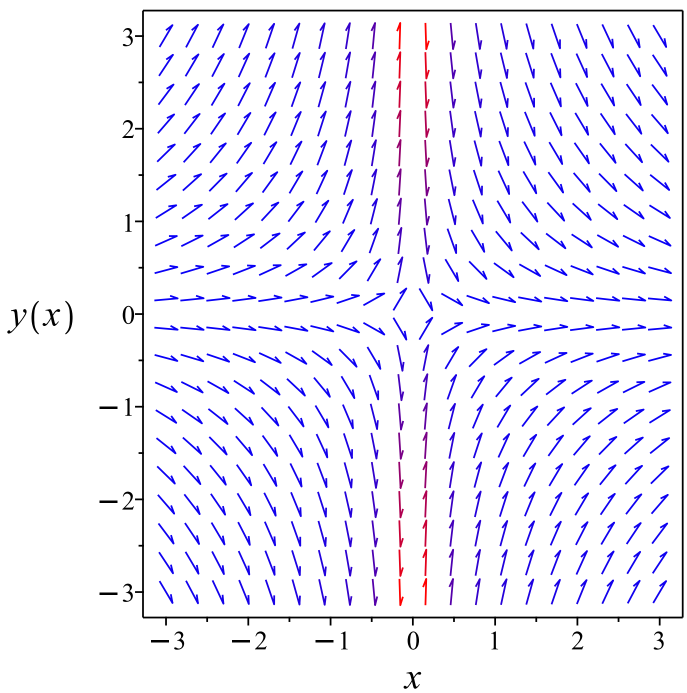

Figure 416: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x^{\frac{3}{2}}}$$

Verified OK.

7.4.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{3}{2x} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' + \frac{3y}{2x} = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int \frac{3}{2x}dx} \\ &= x^{\frac{3}{2}} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}\mu y &= 0 \\ \frac{d}{dx}\left(x^{\frac{3}{2}}y\right) &= 0 \end{aligned}$$

Integrating gives

$$x^{\frac{3}{2}}y = c_1$$

Dividing both sides by the integrating factor $\mu = x^{\frac{3}{2}}$ results in

$$y = \frac{c_1}{x^{\frac{3}{2}}}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x^{\frac{3}{2}}} \tag{1}$$

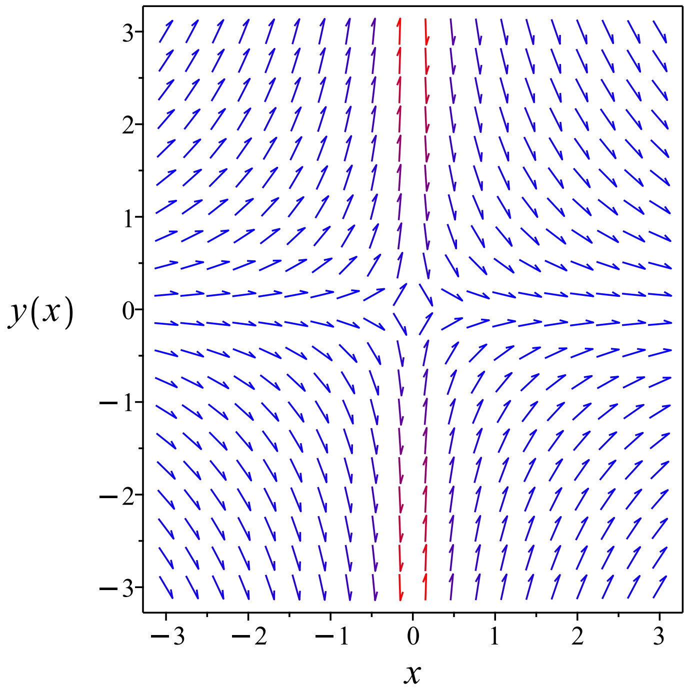

Figure 417: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x^{\frac{3}{2}}}$$

Verified OK.

7.4.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$3x^3 u(x) + 2x^3 (u'(x)\, x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x) g(u) \\ &= -\frac{5u}{2x} \end{aligned}$$

Where $f(x) = -\frac{5}{2x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{5}{2x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{5}{2x}\,dx \\
\ln(u) &= -\frac{5\ln(x)}{2} + c_2 \\
u &= e^{-\frac{5\ln(x)}{2}+c_2} \\
&= \frac{c_2}{x^{\frac{5}{2}}}
\end{aligned}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= xu \\
&= \frac{c_2}{x^{\frac{3}{2}}}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_2}{x^{\frac{3}{2}}} \tag{1}
$$

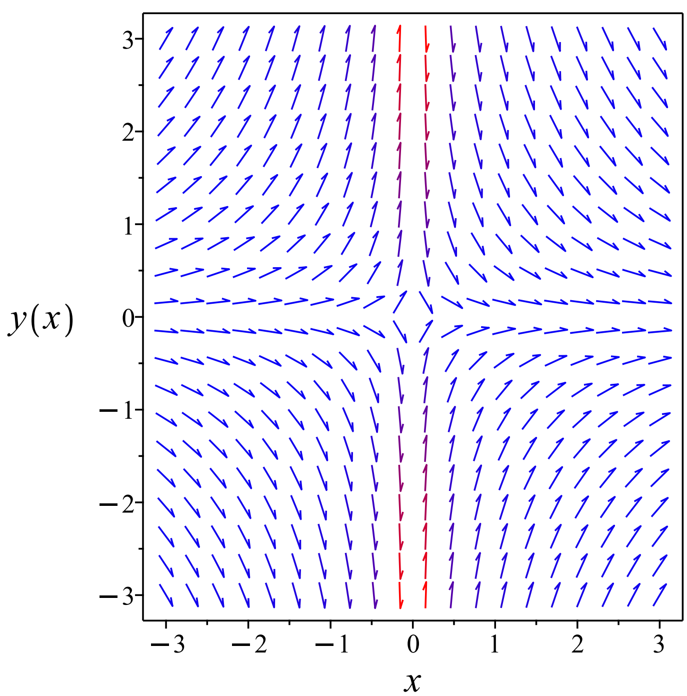

Figure 418: Slope field plot

Verification of solutions

$$y = \frac{c_2}{x^{\frac{3}{2}}}$$

Verified OK.

7.4.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{3y}{2x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 314: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x^{\frac{3}{2}}}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x^{\frac{3}{2}}}} dy\end{aligned}$$

Which results in

$$S = x^{\frac{3}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{3y}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{3y\sqrt{x}}{2} \\ S_y &= x^{\frac{3}{2}}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$y x^{\frac{3}{2}} = c_1$$

Which simplifies to

$$y x^{\frac{3}{2}} = c_1$$

Which gives

$$y = \frac{c_1}{x^{\frac{3}{2}}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = -\frac{3y}{2x}$
</td><td>$R = x$
$S = x^{\frac{3}{2}} y$</td><td>$\frac{dS}{dR} = 0$
</td></tr>
</table>

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x^{\frac{3}{2}}} \tag{1}$$

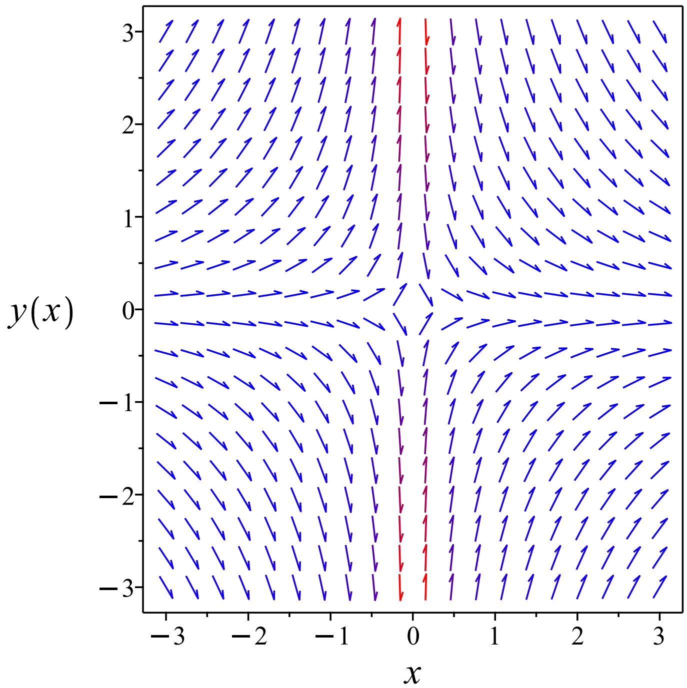

Figure 419: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x^{\frac{3}{2}}}$$

Verified OK.

7.4.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x} &= M\\ \frac{\partial\phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{2}{3y}\right)\mathrm{d}y &= \left(\frac{1}{x}\right)\mathrm{d}x\\ \left(-\frac{1}{x}\right)\mathrm{d}x + \left(-\frac{2}{3y}\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= -\frac{1}{x}\\ N(x,y) &= -\frac{2}{3y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x}\right)\\ &= 0\end{aligned}$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(-\frac{2}{3y}\right)$$
$$= 0$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int -\frac{1}{x} \, \mathrm{d}x$$
$$\phi = -\ln(x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{2}{3y}$. Therefore equation (4) becomes

$$-\frac{2}{3y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = -\frac{2}{3y}$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int \left(-\frac{2}{3y}\right) \mathrm{d}y$$
$$f(y) = -\frac{2\ln(y)}{3} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \frac{2\ln(y)}{3} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \frac{2\ln(y)}{3}$$

The solution becomes

$$y = e^{-\frac{3\ln(x)}{2} - \frac{3c_1}{2}}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{3\ln(x)}{2} - \frac{3c_1}{2}} \tag{1}$$

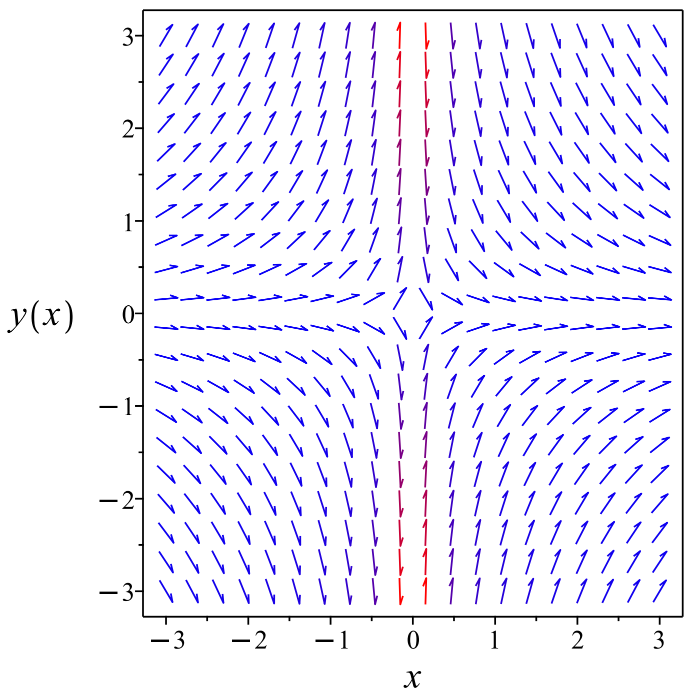

Figure 420: Slope field plot

Verification of solutions

$$y = e^{-\frac{3\ln(x)}{2}-\frac{3c_1}{2}}$$

Verified OK.

7.4.6 Maple step by step solution

Let's solve

$3x^2y + 2x^3y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = -\frac{3}{2x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int -\frac{3}{2x}dx + c_1$

- Evaluate integral

  $\ln(y) = -\frac{3\ln(x)}{2} + c_1$

- Solve for y

  $y = e^{-\frac{3\ln(x)}{2}+c_1}$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{5yx + 2y + 2y'x = -5}$$

7.6.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-5x - 2}{2x}$$
$$q(x) = -\frac{5}{2x}$$

Hence the ode is

$$y' - \frac{(-5x - 2)\,y}{2x} = -\frac{5}{2x}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-5x-2}{2x}dx}$$
$$= e^{\frac{5x}{2}+\ln(x)}$$

Which simplifies to

$$\mu = x\,e^{\frac{5x}{2}}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(-\frac{5}{2x}\right)$$
$$\frac{d}{dx}\left(x\,e^{\frac{5x}{2}}y\right) = \left(x\,e^{\frac{5x}{2}}\right)\left(-\frac{5}{2x}\right)$$
$$d\left(x\,e^{\frac{5x}{2}}y\right) = \left(-\frac{5\,e^{\frac{5x}{2}}}{2}\right)dx$$

Integrating gives

$$x\,e^{\frac{5x}{2}}y = \int -\frac{5\,e^{\frac{5x}{2}}}{2}\,dx$$
$$x\,e^{\frac{5x}{2}}y = -e^{\frac{5x}{2}} + c_1$$

Dividing both sides by the integrating factor $\mu = x\,e^{\frac{5x}{2}}$ results in

$$y = -\frac{e^{-\frac{5x}{2}}e^{\frac{5x}{2}}}{x} + \frac{c_1 e^{-\frac{5x}{2}}}{x}$$

which simplifies to

$$y = \frac{c_1 e^{-\frac{5x}{2}} - 1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 e^{-\frac{5x}{2}} - 1}{x} \tag{1}$$

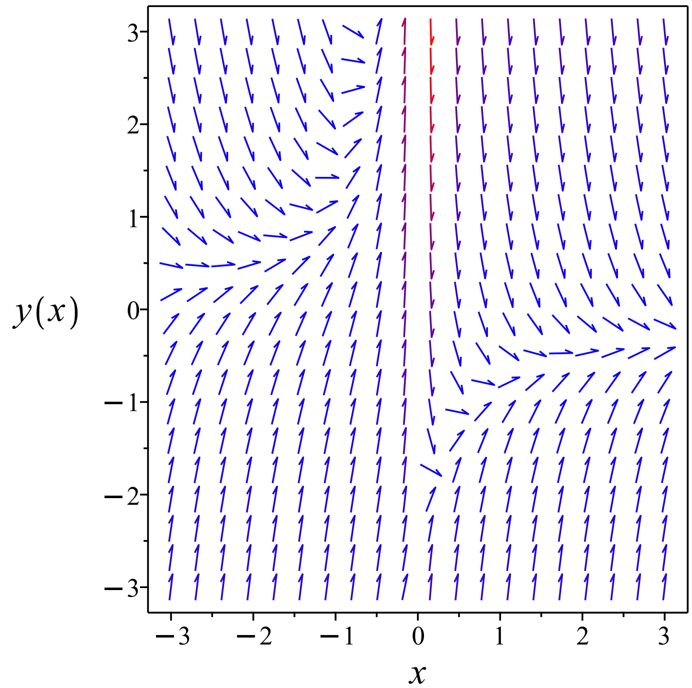

Figure 422: Slope field plot

Verification of solutions

$$y = \frac{c_1 \mathrm{e}^{-\frac{5x}{2}} - 1}{x}$$

Verified OK.

7.6.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{5yx + 2y + 5}{2x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 318: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x,y) &= 0 \\ \eta(x,y) &= \mathrm{e}^{-\frac{5x}{2}-\ln(x)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\mathrm{e}^{-\frac{5x}{2}-\ln(x)}} dy
\end{aligned}$$

Which results in

$$S = x\,\mathrm{e}^{\frac{5x}{2}} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{5yx + 2y + 5}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \mathrm{e}^{\frac{5x}{2}} y \left(\frac{5x}{2} + 1\right) \\
S_y &= x\,\mathrm{e}^{\frac{5x}{2}}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{5\,\mathrm{e}^{\frac{5x}{2}}}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{5\,\mathrm{e}^{\frac{5R}{2}}}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\mathrm{e}^{\frac{5R}{2}} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$x\,\mathrm{e}^{\frac{5x}{2}} y = -\mathrm{e}^{\frac{5x}{2}} + c_1$$

Which simplifies to

$$x\,\mathrm{e}^{\frac{5x}{2}} y = -\mathrm{e}^{\frac{5x}{2}} + c_1$$

Which gives

$$y = -\frac{\left(\mathrm{e}^{\frac{5x}{2}} - c_1\right)\mathrm{e}^{-\frac{5x}{2}}}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{5yx+2y+5}{2x}$ 	$R = x$ $S = x\,\mathrm{e}^{\frac{5x}{2}} y$	$\frac{dS}{dR} = -\frac{5\,\mathrm{e}^{\frac{5R}{2}}}{2}$ 
Summary
The solution(s) found are the following

$$y = -\frac{\left(e^{\frac{5x}{2}} - c_1\right) e^{-\frac{5x}{2}}}{x} \tag{1}$$

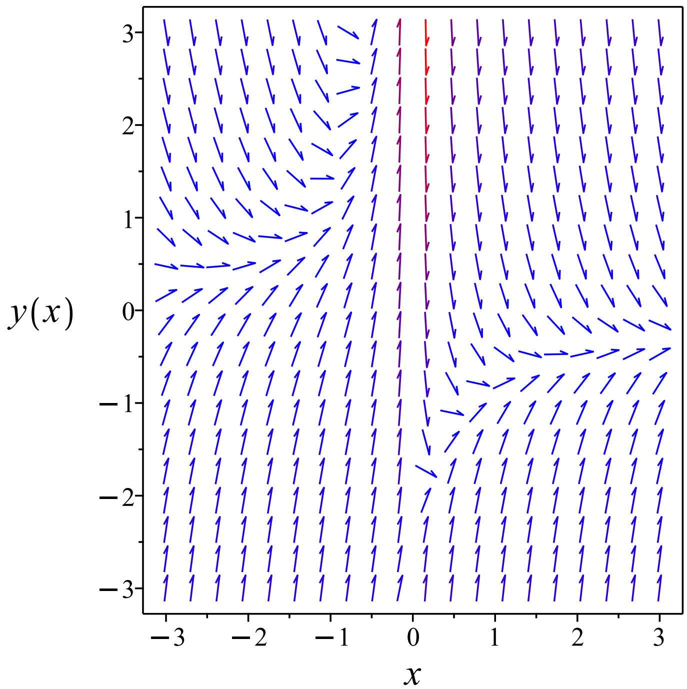

Figure 423: Slope field plot

Verification of solutions

$$y = -\frac{\left(e^{\frac{5x}{2}} - c_1\right) e^{-\frac{5x}{2}}}{x}$$

Verified OK.

7.6.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M \\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(2x)\,\mathrm{d}y &= (-5yx - 2y - 5)\,\mathrm{d}x \\ (5yx + 2y + 5)\,\mathrm{d}x + (2x)\,\mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 5yx + 2y + 5 \\ N(x,y) &= 2x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(5yx+2y+5)\\ &= 5x+2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x)\\ &= 2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x}((5x+2)-(2))\\ &= \frac{5}{2}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int \frac{5}{2}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\frac{5x}{2}}\\ &= \mathrm{e}^{\frac{5x}{2}}\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= \mathrm{e}^{\frac{5x}{2}}(5yx+2y+5)\\ &= (5+(5x+2)\,y)\,\mathrm{e}^{\frac{5x}{2}}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \mathrm{e}^{\frac{5x}{2}}(2x)\\ &= 2x\,\mathrm{e}^{\frac{5x}{2}}\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$
$$\left(\left(5+\left(5x+2\right)y\right)\mathrm{e}^{\frac{5x}{2}}\right) + \left(2x\,\mathrm{e}^{\frac{5x}{2}}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \left(5+\left(5x+2\right)y\right)\mathrm{e}^{\frac{5x}{2}}\,\mathrm{d}x$$
$$\phi = 2\,\mathrm{e}^{\frac{5x}{2}}\left(yx+1\right) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2x\,\mathrm{e}^{\frac{5x}{2}} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 2x\,\mathrm{e}^{\frac{5x}{2}}$. Therefore equation (4) becomes

$$2x\,\mathrm{e}^{\frac{5x}{2}} = 2x\,\mathrm{e}^{\frac{5x}{2}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = 2\,\mathrm{e}^{\frac{5x}{2}}\left(yx+1\right) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = 2\,\mathrm{e}^{\frac{5x}{2}}(yx+1)$$

The solution becomes

$$y = -\frac{\left(2\,\mathrm{e}^{\frac{5x}{2}} - c_1\right)\mathrm{e}^{-\frac{5x}{2}}}{2x}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(2\,\mathrm{e}^{\frac{5x}{2}} - c_1\right)\mathrm{e}^{-\frac{5x}{2}}}{2x} \tag{1}$$

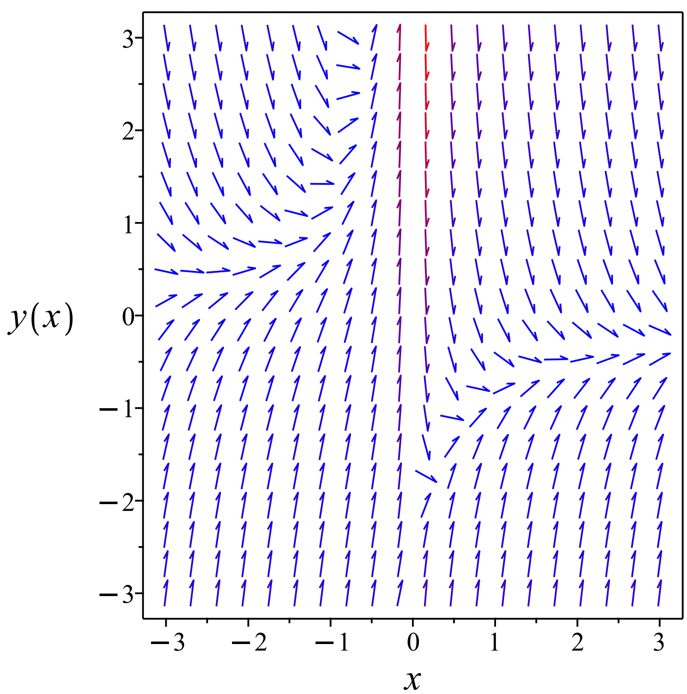

Figure 424: Slope field plot

Verification of solutions

$$y = -\frac{\left(2\,\mathrm{e}^{\frac{5x}{2}} - c_1\right)\mathrm{e}^{-\frac{5x}{2}}}{2x}$$

Verified OK.

7.6.4 Maple step by step solution

Let's solve

$5yx + 2y + 2y'x = -5$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -\frac{(5x+2)y}{2x} - \frac{5}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{(5x+2)y}{2x} = -\frac{5}{2x}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{(5x+2)y}{2x}\right) = -\frac{5\mu(x)}{2x}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' + \frac{(5x+2)y}{2x}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)(5x+2)}{2x}$

- Solve to find the integrating factor

  $\mu(x) = x\,\mathrm{e}^{\frac{5x}{2}}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int -\frac{5\mu(x)}{2x} dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int -\frac{5\mu(x)}{2x} dx + c_1$

- Solve for y

  $y = \frac{\int -\frac{5\mu(x)}{2x} dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = x\mathrm{e}^{\frac{5x}{2}}$

  $y = \frac{\int -\frac{5\,\mathrm{e}^{\frac{5x}{2}}}{2} dx + c_1}{x\,\mathrm{e}^{\frac{5x}{2}}}$

- Evaluate the integrals on the rhs

  $y = \frac{-\mathrm{e}^{\frac{5x}{2}} + c_1}{x\,\mathrm{e}^{\frac{5x}{2}}}$

- Simplify

  $$y = \frac{c_1 e^{-\frac{5x}{2}} - 1}{x}$$

7.7 problem 7

Internal problem ID [1067]
Internal file name [`OUTPUT/1068_Sunday_June_05_2022_02_01_49_AM_77231025/index.tex`]

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 7.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{yx + 2y + (x + 1)\, y' = -x - 1}$$

7.7.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-x - 2}{x + 1}$$
$$q(x) = -1$$

Hence the ode is

$$y' - \frac{(-x - 2)\, y}{x + 1} = -1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-x-2}{x+1}dx}$$
$$= \mathrm{e}^{x+\ln(x+1)}$$

Which simplifies to

$$\mu = (x+1)\,\mathrm{e}^{x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\,(-1)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}(\mathrm{e}^{x} y(x+1)) = ((x+1)\,\mathrm{e}^{x})\,(-1)$$
$$\mathrm{d}(\mathrm{e}^{x} y(x+1)) = (-(x+1)\,\mathrm{e}^{x})\;\mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{x} y(x+1) = \int -(x+1)\,\mathrm{e}^{x}\,\mathrm{d}x$$
$$\mathrm{e}^{x} y(x+1) = -x\,\mathrm{e}^{x} + c_1$$

Dividing both sides by the integrating factor $\mu = (x+1)\,\mathrm{e}^{x}$ results in

$$y = -\frac{\mathrm{e}^{-x} x\,\mathrm{e}^{x}}{x+1} + \frac{c_1 \mathrm{e}^{-x}}{x+1}$$

which simplifies to

$$y = \frac{c_1 \mathrm{e}^{-x} - x}{x+1}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \mathrm{e}^{-x} - x}{x+1} \tag{1}$$

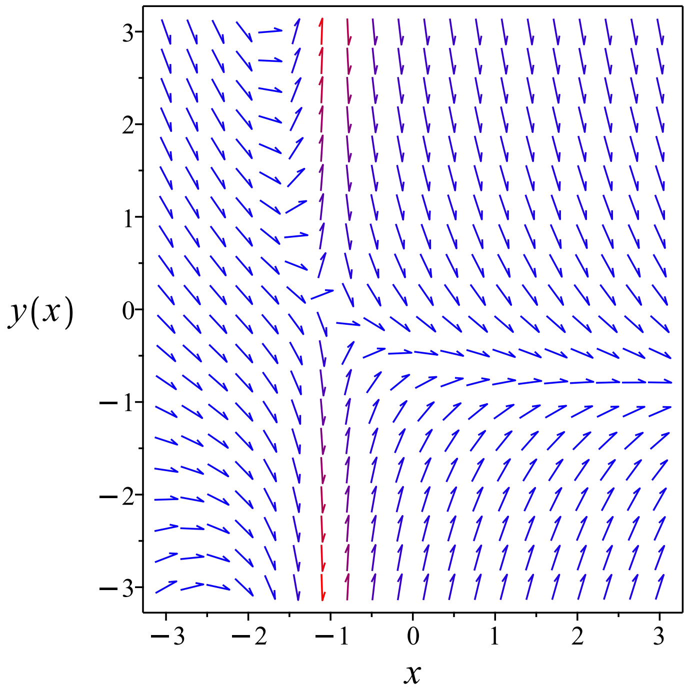

Figure 425: Slope field plot

Verification of solutions

$$y = \frac{c_1 e^{-x} - x}{x + 1}$$

Verified OK.

7.7.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{yx + x + 2y + 1}{x + 1}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 321: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned} \xi(x, y) &= 0 \\ \eta(x, y) &= \mathrm{e}^{-x-\ln(x+1)} \end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-x-\ln(x+1)}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{x} y(x+1)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{yx + x + 2y + 1}{x+1}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \mathrm{e}^{x} y(2+x) \\ S_y &= (x+1)\,\mathrm{e}^{x} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \mathrm{e}^{x}(-x-1) \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \mathrm{e}^{R}(-R-1)$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -R\,\mathrm{e}^{R} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\mathrm{e}^{x} y(x+1) = -x\,\mathrm{e}^{x} + c_1$$

Which simplifies to

$$\mathrm{e}^{x} y(x+1) = -x\,\mathrm{e}^{x} + c_1$$

Which gives

$$y = -\frac{(x\,\mathrm{e}^{x} - c_1)\,\mathrm{e}^{-x}}{x+1}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{yx+x+2y+1}{x+1}$ 	$R = x$ $S = \mathrm{e}^{x} y(x+1)$	$\frac{dS}{dR} = \mathrm{e}^{R}(-R-1)$ 
Summary

The solution(s) found are the following

$$y = -\frac{(x\,\mathrm{e}^{x} - c_1)\,\mathrm{e}^{-x}}{x+1} \tag{1}$$

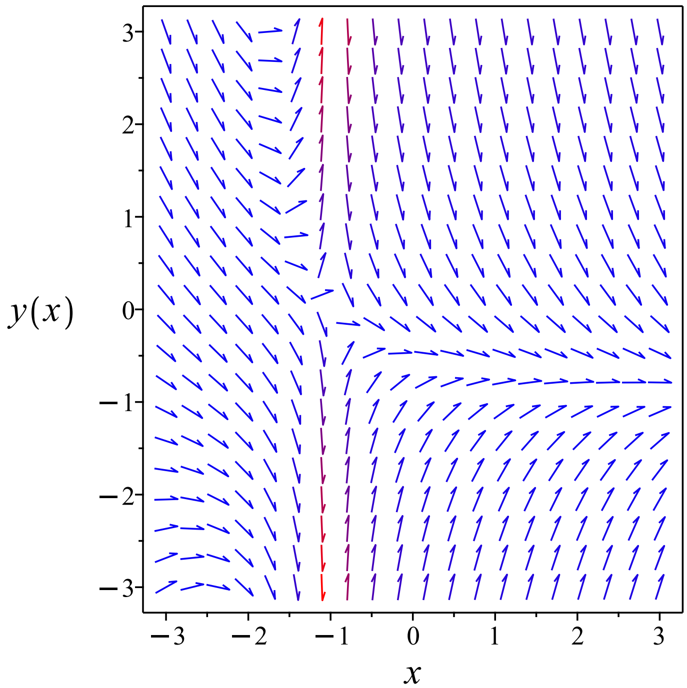

Figure 426: Slope field plot

Verification of solutions

$$y = -\frac{(x\,e^{x} - c_1)\,e^{-x}}{x+1}$$

Verified OK.

7.7.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(x + 1)\, \mathrm{d}y = (-yx - x - 2y - 1)\, \mathrm{d}x$$
$$(yx + x + 2y + 1)\, \mathrm{d}x + (x + 1)\, \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = yx + x + 2y + 1$$
$$N(x, y) = x + 1$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}(yx + x + 2y + 1)$$
$$= 2 + x$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}(x + 1)$$
$$= 1$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x+1}((2+x) - (1)) \\
&= 1
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int 1 \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{x} \\
&= \mathrm{e}^{x}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{x}(yx + x + 2y + 1) \\
&= \mathrm{e}^{x}(yx + x + 2y + 1)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{x}(x+1) \\
&= (x+1)\,\mathrm{e}^{x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
(\mathrm{e}^{x}(yx + x + 2y + 1)) + ((x+1)\,\mathrm{e}^{x})\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \mathrm{e}^{x}(yx + x + 2y + 1) \, \mathrm{d}x$$
$$\phi = (yx + x + y) \, \mathrm{e}^{x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = (x+1) \, \mathrm{e}^{x} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (x+1) \, \mathrm{e}^{x}$. Therefore equation (4) becomes

$$(x+1) \, \mathrm{e}^{x} = (x+1) \, \mathrm{e}^{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = (yx + x + y) \, \mathrm{e}^{x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = (yx + x + y) \, \mathrm{e}^{x}$$

The solution becomes

$$y = -\frac{(x\,e^{x} - c_1)\,e^{-x}}{x+1}$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{(x\,e^{x} - c_1)\,e^{-x}}{x+1} \tag{1}$$

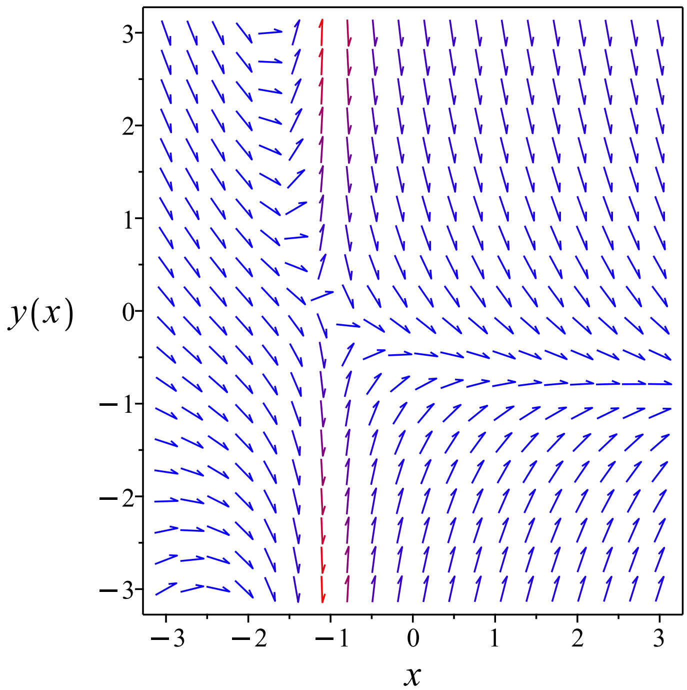

Figure 427: Slope field plot

<u>Verification of solutions</u>

$$y = -\frac{(x\,e^{x} - c_1)\,e^{-x}}{x+1}$$

Verified OK.

7.7.4 Maple step by step solution

Let's solve

$yx + 2y + (x+1)\,y' = -x - 1$

- Highest derivative means the order of the ODE is 1

  y'

- Isolate the derivative

  $y' = -1 - \frac{(2+x)y}{x+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y' + \frac{(2+x)y}{x+1} = -1$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x)\left(y' + \frac{(2+x)y}{x+1}\right) = -\mu(x)$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,y)$

  $\mu(x)\left(y' + \frac{(2+x)y}{x+1}\right) = \mu'(x)\,y + \mu(x)\,y'$

- Isolate $\mu'(x)$

  $\mu'(x) = \frac{\mu(x)(2+x)}{x+1}$

- Solve to find the integrating factor

  $\mu(x) = \mathrm{e}^{x+\ln(x+1)}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{dx}(\mu(x)\,y)\right) dx = \int -\mu(x)\,dx + c_1$

- Evaluate the integral on the lhs

  $\mu(x)\,y = \int -\mu(x)\,dx + c_1$

- Solve for y

  $y = \frac{\int -\mu(x)dx + c_1}{\mu(x)}$

- Substitute $\mu(x) = \mathrm{e}^{x+\ln(x+1)}$

  $y = \frac{\int -\mathrm{e}^{x+\ln(x+1)}dx + c_1}{\mathrm{e}^{x+\ln(x+1)}}$

- Evaluate the integrals on the rhs

  $y = \frac{-\frac{x\,\mathrm{e}^{x+\ln(x+1)}}{x+1} + c_1}{\mathrm{e}^{x+\ln(x+1)}}$

- Simplify

$y = \frac{c_1 e^{-x} - x}{x+1}$

7.8 problem 8

Internal problem ID [1068]
Internal file name [`OUTPUT/1069_Sunday_June_05_2022_02_01_50_AM_54127861/index.tex`]

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 8.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class A`], _rational, [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{27xy^2 + 8y^3 + \left(18x^2y + 12xy^2\right) y' = 0}$$

7.8.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$27x^3u(x)^2 + 8u(x)^3\, x^3 + \left(18x^3u(x) + 12x^3u(x)^2\right)\left(u'(x)\, x + u(x)\right) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{5u(4u+9)}{6x\,(2u+3)} \end{aligned}$$

Where $f(x) = -\frac{5}{6x}$ and $g(u) = \frac{u(4u+9)}{2u+3}$. Integrating both sides gives

$$\frac{1}{\frac{u(4u+9)}{2u+3}} du = -\frac{5}{6x} dx$$

$$\int \frac{1}{\frac{u(4u+9)}{2u+3}} du = \int -\frac{5}{6x} dx$$

$$\frac{\ln (4u+9)}{6} + \frac{\ln (u)}{3} = -\frac{5 \ln (x)}{6} + c_2$$

Raising both side to exponential gives

$$e^{\frac{\ln(4u+9)}{6} + \frac{\ln(u)}{3}} = e^{-\frac{5\ln(x)}{6} + c_2}$$

Which simplifies to

$$(4u+9)^{\frac{1}{6}} u^{\frac{1}{3}} = \frac{c_3}{x^{\frac{5}{6}}}$$

The solution is

$$(4u(x)+9)^{\frac{1}{6}} u(x)^{\frac{1}{3}} = \frac{c_3}{x^{\frac{5}{6}}}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\left(\frac{4y}{x} + 9\right)^{\frac{1}{6}} \left(\frac{y}{x}\right)^{\frac{1}{3}} = \frac{c_3}{x^{\frac{5}{6}}}$$

$$\left(\frac{4y+9x}{x}\right)^{\frac{1}{6}} \left(\frac{y}{x}\right)^{\frac{1}{3}} = \frac{c_3}{x^{\frac{5}{6}}}$$

Summary

The solution(s) found are the following

$$\left(\frac{4y+9x}{x}\right)^{\frac{1}{6}} \left(\frac{y}{x}\right)^{\frac{1}{3}} = \frac{c_3}{x^{\frac{5}{6}}} \tag{1}$$

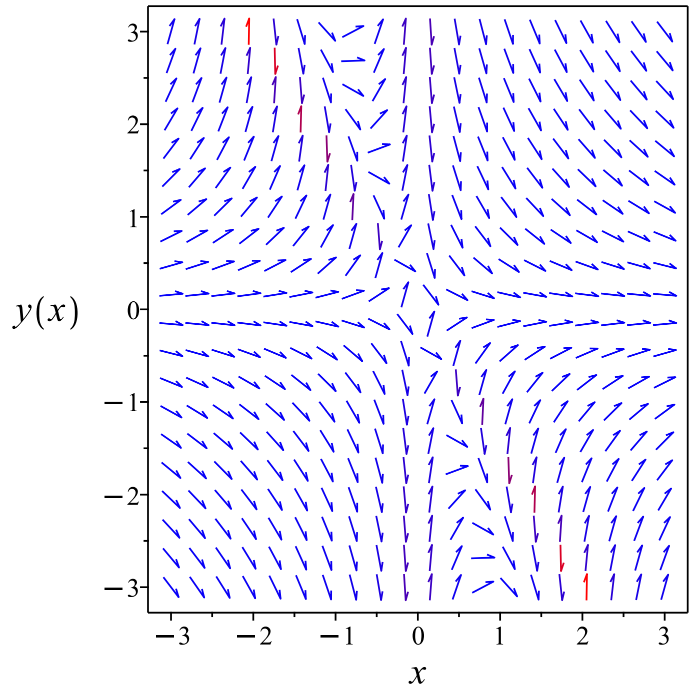

Figure 428: Slope field plot

Verification of solutions

$$\left(\frac{4y+9x}{x}\right)^{\frac{1}{6}}\left(\frac{y}{x}\right)^{\frac{1}{3}}=\frac{c_3}{x^{\frac{5}{6}}}$$

Verified OK.

7.8.2 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y'=-\frac{y(27x+8y)}{6x\,(3x+2y)}$$
$$y'=\omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi=xa_2+ya_3+a_1 \tag{1E}$$
$$\eta=xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} & b_2 - \frac{y(27x+8y)\,(b_3-a_2)}{6x\,(3x+2y)} - \frac{y^2(27x+8y)^2\,a_3}{36x^2\,(3x+2y)^2} \\ & - \left(-\frac{9y}{2x\,(3x+2y)} + \frac{y(27x+8y)}{6x^2\,(3x+2y)} + \frac{y(27x+8y)}{2x\,(3x+2y)^2}\right)(xa_2+ya_3+a_1) \\ & - \left(-\frac{27x+8y}{6\,(3x+2y)\,x} - \frac{4y}{3x\,(3x+2y)} + \frac{y(27x+8y)}{3x\,(3x+2y)^2}\right)(xb_2+yb_3+b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{810x^4b_2 + 720x^3yb_2 + 180x^2y^2a_2 - 1215x^2y^2a_3 + 240x^2y^2b_2 - 180x^2y^2b_3 - 720x\,y^3a_3 - 160y^4a_3 + 486x^3}{36x^2\,(3x+2y)^2}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} & 810x^4b_2 + 720x^3yb_2 + 180x^2y^2a_2 - 1215x^2y^2a_3 + 240x^2y^2b_2 \\ & - 180x^2y^2b_3 - 720x\,y^3a_3 - 160y^4a_3 + 486x^3b_1 - 486x^2ya_1 \\ & + 288x^2yb_1 - 288x\,y^2a_1 + 96x\,y^2b_1 - 96y^3a_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\begin{aligned} & 180a_2v_1^2v_2^2 - 1215a_3v_1^2v_2^2 - 720a_3v_1v_2^3 - 160a_3v_2^4 + 810b_2v_1^4 \\ & + 720b_2v_1^3v_2 + 240b_2v_1^2v_2^2 - 180b_3v_1^2v_2^2 - 486a_1v_1^2v_2 \\ & - 288a_1v_1v_2^2 - 96a_1v_2^3 + 486b_1v_1^3 + 288b_1v_1^2v_2 + 96b_1v_1v_2^2 = 0 \end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}&810b_2v_1^4 + 720b_2v_1^3v_2 + 486b_1v_1^3 + (180a_2 - 1215a_3 + 240b_2 - 180b_3)\, v_1^2v_2^2 \\ &+ (-486a_1 + 288b_1)\, v_1^2v_2 - 720a_3v_1v_2^3 \\ &+ (-288a_1 + 96b_1)\, v_1v_2^2 - 160a_3v_2^4 - 96a_1v_2^3 = 0\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}-96a_1 &= 0\\ -720a_3 &= 0\\ -160a_3 &= 0\\ 486b_1 &= 0\\ 720b_2 &= 0\\ 810b_2 &= 0\\ -486a_1 + 288b_1 &= 0\\ -288a_1 + 96b_1 &= 0\\ 180a_2 - 1215a_3 + 240b_2 - 180b_3 &= 0\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}a_1 &= 0\\ a_2 &= b_3\\ a_3 &= 0\\ b_1 &= 0\\ b_2 &= 0\\ b_3 &= b_3\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}\xi &= x\\ \eta &= y\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{y(27x+8y)}{6x\,(3x+2y)}\right)(x) \\
&= \frac{45yx+20y^2}{18x+12y} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta}dy \\
&= \int \frac{1}{\frac{45yx+20y^2}{18x+12y}}dy
\end{aligned}
$$

Which results in

$$
S = \frac{2\ln(y)}{5} + \frac{\ln(9x+4y)}{5}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{y(27x+8y)}{6x\,(3x+2y)}
$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{9}{45x + 20y} \\
S_y &= \frac{18x + 12y}{45yx + 20y^2}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{2}{5x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{2}{5R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{2\ln(R)}{5} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{2\ln(y)}{5} + \frac{\ln(4y + 9x)}{5} = -\frac{2\ln(x)}{5} + c_1$$

Which simplifies to

$$\frac{2\ln(y)}{5} + \frac{\ln(4y + 9x)}{5} = -\frac{2\ln(x)}{5} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(27x+8y)}{6x(3x+2y)}$ 	$R = x$ $S = \frac{2\ln(y)}{5} + \frac{\ln(9x+4y)}{5}$	$\frac{dS}{dR} = -\frac{2}{5R}$ 
Summary

The solution(s) found are the following

$$\frac{2\ln(y)}{5} + \frac{\ln(4y+9x)}{5} = -\frac{2\ln(x)}{5} + c_1 \tag{1}$$

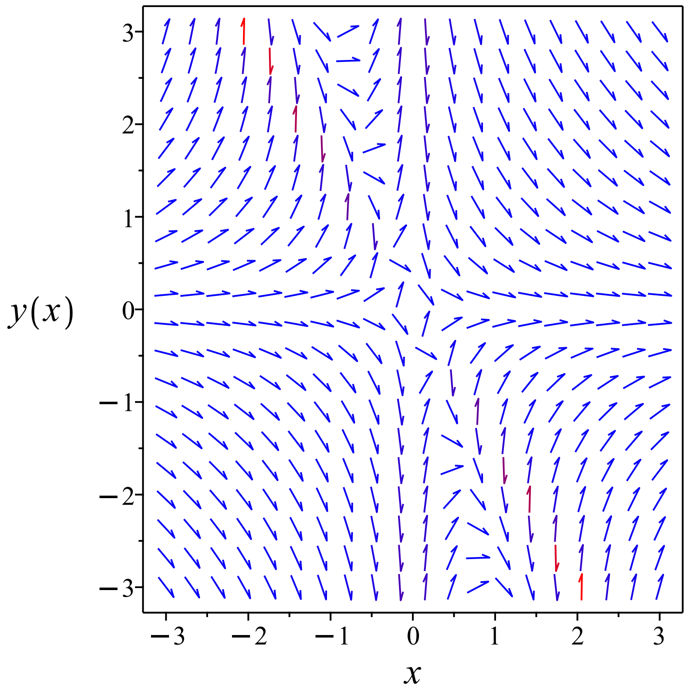

Figure 429: Slope field plot

Verification of solutions

$$\frac{2\ln(y)}{5}+\frac{\ln(4y+9x)}{5}=-\frac{2\ln(x)}{5}+c_1$$

Verified OK.

7.8.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(18y\,x^2 + 12x\,y^2\right)\mathrm{d}y = \left(-27x\,y^2 - 8y^3\right)\mathrm{d}x$$
$$\left(27x\,y^2 + 8y^3\right)\mathrm{d}x + \left(18y\,x^2 + 12x\,y^2\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = 27x\,y^2 + 8y^3$$
$$N(x,y) = 18y\,x^2 + 12x\,y^2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(27x\,y^2 + 8y^3\right)$$
$$= 54yx + 24y^2$$

And

$$\frac{\partial N}{\partial x} = \frac{\partial}{\partial x}\left(18y\,x^2 + 12x\,y^2\right)$$
$$= 36yx + 12y^2$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{18y\,x^2 + 12x\,y^2}\left(\left(54yx + 24y^2\right) - \left(36yx + 12y^2\right)\right)\\ &= \frac{1}{x}\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int A\,\mathrm{d}x}\\ &= e^{\int \frac{1}{x}\,\mathrm{d}x}\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{\ln(x)}\\ &= x\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}\overline{M} &= \mu M\\ &= x\left(27x\,y^2 + 8y^3\right)\\ &= y^2(27x + 8y)\,x\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= x\left(18y\,x^2 + 12x\,y^2\right)\\ &= 6y\,x^2(3x + 2y)\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned}\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(y^2(27x + 8y)\,x\right) + \left(6y\,x^2(3x + 2y)\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int y^2(27x+8y)\, x \, \mathrm{d}x$$

$$\phi = y^2x^2(9x+4y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 2y\, x^2(9x+4y) + 4x^2y^2 + f'(y) \tag{4}$$

$$= 6y\, x^2(3x+2y) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = 6y\, x^2(3x+2y)$. Therefore equation (4) becomes

$$6y\, x^2(3x+2y) = 6y\, x^2(3x+2y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = y^2x^2(9x+4y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y^2x^2(9x+4y)$$

Summary

The solution(s) found are the following

$$y^2x^2(4y + 9x) = c_1 \tag{1}$$

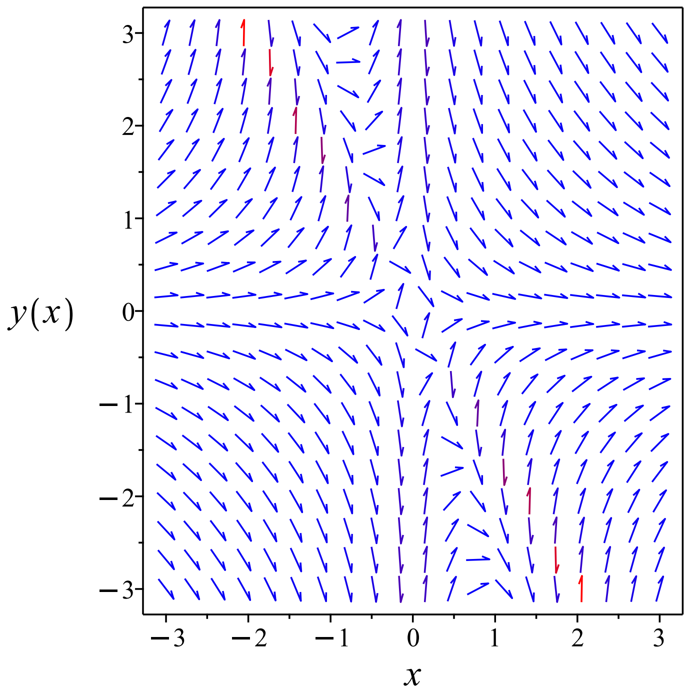

Figure 430: Slope field plot

Verification of solutions

$$y^2x^2(4y + 9x) = c_1$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 10.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor"**

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x)*G(y),0]`]]
```

$$\boxed{y^2 + \left(x y^2 + 6 y x + \frac{1}{y}\right) y' = 0}$$

7.10.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(x\,y^2 + 6yx + \frac{1}{y}\right)\mathrm{d}y = \left(-y^2\right)\mathrm{d}x$$
$$\left(y^2\right)\mathrm{d}x + \left(x\,y^2 + 6yx + \frac{1}{y}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = y^2$$
$$N(x,y) = x\,y^2 + 6yx + \frac{1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y^2\right)\\ &= 2y\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x\,y^2+6yx+\frac{1}{y}\right)\\
&= y^2+6y
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y}-\frac{\partial N}{\partial x}\right)\\
&= \frac{y}{1+y^2\,(y+6)\,x}\left((2y)-\left(y^2+6y\right)\right)\\
&= -\frac{y^2(y+4)}{1+y^2\,(y+6)\,x}
\end{aligned}
$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$
\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x}-\frac{\partial M}{\partial y}\right)\\
&= \frac{1}{y^2}\left(\left(y^2+6y\right)-(2y)\right)\\
&= \frac{y+4}{y}
\end{aligned}
$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$
\begin{aligned}
\mu &= e^{\int B\,\mathrm{d}y}\\
&= e^{\int \frac{y+4}{y}\,\mathrm{d}y}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{y+4\ln(y)}\\
&= y^4\mathrm{e}^y
\end{aligned}
$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M\\
&= y^4\mathrm{e}^y\left(y^2\right)\\
&= y^6\mathrm{e}^y
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= y^4 \mathrm{e}^y \left(x\,y^2 + 6yx + \frac{1}{y} \right) \\
&= \left(x\,y^3 + 6x\,y^2 + 1 \right) y^3 \mathrm{e}^y
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N} \frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(y^6 \mathrm{e}^y \right) + \left(\left(x\,y^3 + 6x\,y^2 + 1 \right) y^3 \mathrm{e}^y \right) \frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int \overline{M} \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int y^6 \mathrm{e}^y \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = y^6 \mathrm{e}^y x + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 6y^5 \mathrm{e}^y x + y^6 \mathrm{e}^y x + f'(y) \tag{4}
$$

$$
= \mathrm{e}^y x\,y^5 (y + 6) + f'(y)
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \left(x\,y^3 + 6x\,y^2 + 1 \right) y^3 \mathrm{e}^y$. Therefore equation (4) becomes

$$
\left(x\,y^3 + 6x\,y^2 + 1 \right) y^3 \mathrm{e}^y = \mathrm{e}^y x\,y^5 (y + 6) + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = y^3 e^y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, dy = \int (y^3 e^y) \, dy$$
$$f(y) = (y^3 - 3y^2 + 6y - 6) e^y + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = y^6 e^y x + (y^3 - 3y^2 + 6y - 6) e^y + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y^6 e^y x + (y^3 - 3y^2 + 6y - 6) e^y$$

Summary

The solution(s) found are the following

$$y^6 e^y x + (y^3 - 3y^2 + 6y - 6) e^y = c_1 \tag{1}$$

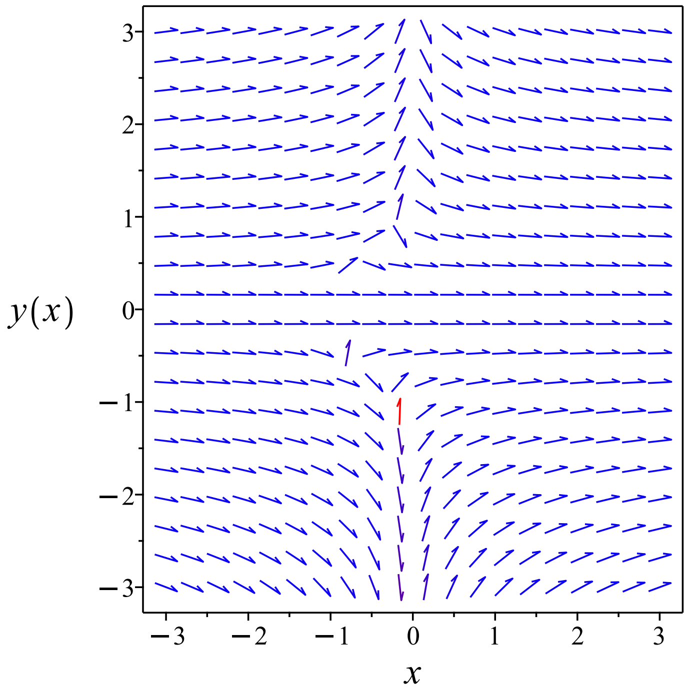

Figure 431: Slope field plot

Verification of solutions

$$y^6 e^y x + (y^3 - 3y^2 + 6y - 6) e^y = c_1$$

Verified OK.

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class B`]]
```

$$\boxed{12yx^3+24x^2y^2+\left(9x^4+32yx^3+4y\right)y'=0}$$

7.11.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x}=M$$
$$\frac{\partial\phi}{\partial y}=N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(9x^4+32y\,x^3+4y\right)\mathrm{d}y &= \left(-12y\,x^3-24x^2y^2\right)\mathrm{d}x\\ \left(12y\,x^3+24x^2y^2\right)\mathrm{d}x + \left(9x^4+32y\,x^3+4y\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= 12y\,x^3+24x^2y^2\\ N(x,y) &= 9x^4+32y\,x^3+4y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(12y\,x^3+24x^2y^2\right)\\ &= 12x^2(x+4y)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(9x^4+32y\,x^3+4y\right)\\ &= 36x^3+96y\,x^2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{9x^4+32y\,x^3+4y}\left(\left(12x^3+48y\,x^2\right)-\left(36x^3+96y\,x^2\right)\right)\\ &= -\frac{24x^2(x+2y)}{9x^4+32y\,x^3+4y}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$
\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= \frac{1}{12y\,x^2\,(x+2y)}\left(\left(36x^3+96y\,x^2\right)-\left(12x^3+48y\,x^2\right)\right) \\
&= \frac{2}{y}
\end{aligned}
$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$
\begin{aligned}
\mu &= e^{\int B\,\mathrm{d}y} \\
&= e^{\int \frac{2}{y}\,\mathrm{d}y}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{2\ln(y)} \\
&= y^2
\end{aligned}
$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= y^2\left(12y\,x^3+24x^2y^2\right) \\
&= 12y^3x^2(x+2y)
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= y^2\left(9x^4+32y\,x^3+4y\right) \\
&= \left(32x^3+4\right)y^3+9x^4y^2
\end{aligned}
$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$
\begin{aligned}
\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(12y^3x^2(x+2y)\right)+\left(\left(32x^3+4\right)y^3+9x^4y^2\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int 12y^3x^2(x+2y) \, \mathrm{d}x$$

$$\phi = y^3x^3(3x+8y) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 3y^2x^3(3x+8y) + 8y^3x^3 + f'(y) \tag{4}$$

$$= x^3y^2(9x+32y) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (32x^3+4)\,y^3 + 9x^4y^2$. Therefore equation (4) becomes

$$(32x^3+4)\,y^3 + 9x^4y^2 = x^3y^2(9x+32y) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 4y^3$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (4y^3) \, \mathrm{d}y$$

$$f(y) = y^4 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = y^3x^3(3x+8y) + y^4 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = y^3 x^3 (3x + 8y) + y^4$$

Summary
The solution(s) found are the following

$$y^3 x^3 (3x + 8y) + y^4 = c_1 \tag{1}$$

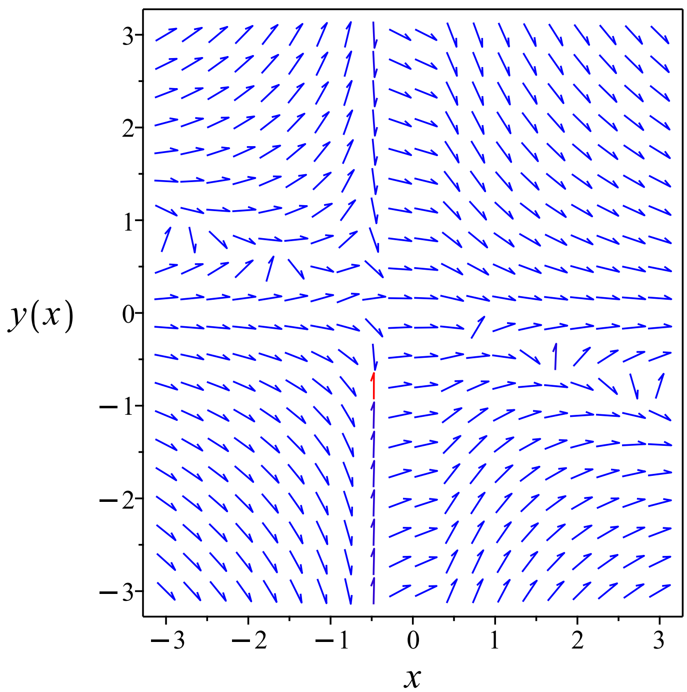

Figure 432: Slope field plot

Verification of solutions

$$y^3 x^3 (3x + 8y) + y^4 = c_1$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 12.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{x^2y + 4yx + 2y + (x^2 + x)\, y' = 0}$$

7.12.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y(x^2 + 4x + 2)}{x\,(x+1)} \end{aligned}$$

Where $f(x) = -\frac{x^2+4x+2}{x(x+1)}$ and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y}\,dy &= -\frac{x^2+4x+2}{x\,(x+1)}\,dx\\
\int \frac{1}{y}\,dy &= \int -\frac{x^2+4x+2}{x\,(x+1)}\,dx\\
\ln(y) &= -x - 2\ln(x) - \ln(x+1) + c_1\\
y &= \mathrm{e}^{-x-2\ln(x)-\ln(x+1)+c_1}\\
&= c_1\mathrm{e}^{-x-2\ln(x)-\ln(x+1)}
\end{aligned}
$$

Which simplifies to

$$
y = \frac{c_1\mathrm{e}^{-x}}{x^2\,(x+1)}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1\mathrm{e}^{-x}}{x^2\,(x+1)} \tag{1}
$$

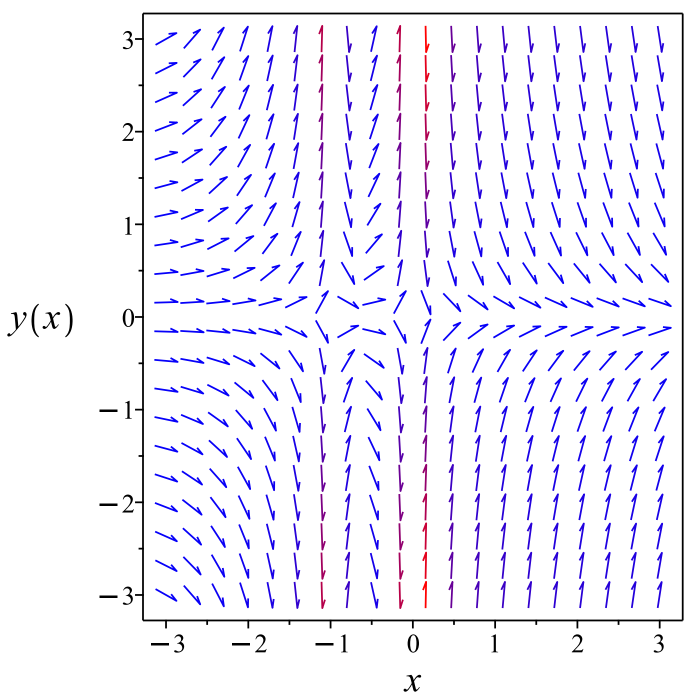

Figure 433: Slope field plot

Verification of solutions

$$y = \frac{c_1 e^{-x}}{x^2 (x+1)}$$

Verified OK.

7.12.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-x^2 - 4x - 2}{x (x+1)}$$
$$q(x) = 0$$

Hence the ode is

$$y' - \frac{(-x^2 - 4x - 2)\, y}{x (x+1)} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-x^2-4x-2}{x(x+1)} dx}$$
$$= e^{x+2\ln(x)+\ln(x+1)}$$

Which simplifies to

$$\mu = e^x x^2 (x+1)$$

The ode becomes

$$\frac{d}{dx} \mu y = 0$$
$$\frac{d}{dx} \left(e^x x^2 (x+1)\, y\right) = 0$$

Integrating gives

$$e^x x^2 (x+1)\, y = c_1$$

Dividing both sides by the integrating factor $\mu = e^x x^2 (x+1)$ results in

$$y = \frac{c_1 e^{-x}}{x^2 (x+1)}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 e^{-x}}{x^2 (x+1)} \tag{1}$$

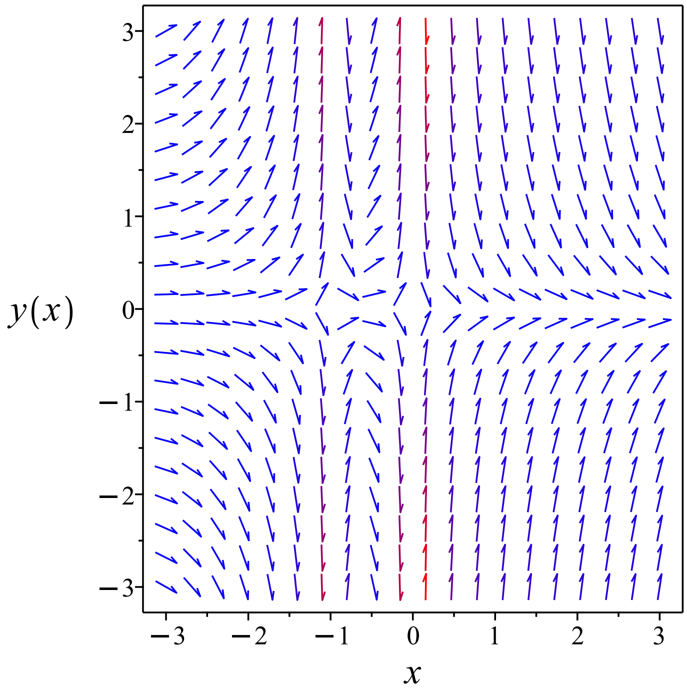

Figure 434: Slope field plot

Verification of solutions

$$y = \frac{c_1 e^{-x}}{x^2 (x+1)}$$

Verified OK.

7.12.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$x^3 u(x) + 4u(x)\,x^2 + 2u(x)\,x + (x^2 + x)\,(u'(x)\,x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u(x^2+5x+3)}{x\left(x+1\right)}
\end{aligned}$$

Where $f(x) = -\frac{x^2+5x+3}{x(x+1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{x^2+5x+3}{x\left(x+1\right)}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{x^2+5x+3}{x\left(x+1\right)}\,dx \\
\ln\left(u\right) &= -x-3\ln\left(x\right)-\ln\left(x+1\right)+c_2 \\
u &= \mathrm{e}^{-x-3\ln(x)-\ln(x+1)+c_2} \\
&= c_2\mathrm{e}^{-x-3\ln(x)-\ln(x+1)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_2\mathrm{e}^{-x}}{x^3\left(x+1\right)}$$

Therefore the solution y is

$$\begin{aligned}
y &= ux \\
&= \frac{c_2\mathrm{e}^{-x}}{x^2\left(x+1\right)}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2\mathrm{e}^{-x}}{x^2\left(x+1\right)} \tag{1}$$

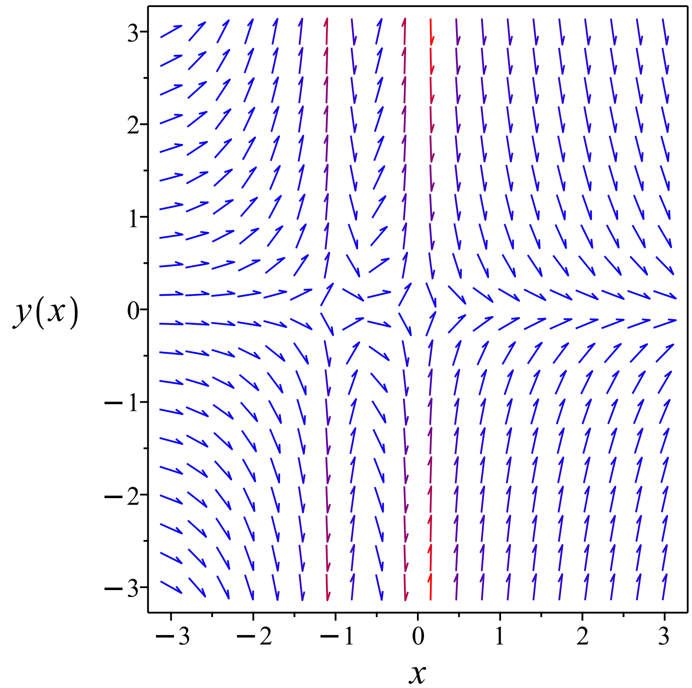

Figure 435: Slope field plot

Verification of solutions

$$y = \frac{c_2 \mathrm{e}^{-x}}{x^2 (x+1)}$$

Verified OK.

7.12.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y(x^2+4x+2)}{x(x+1)}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 324: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= e^{-x-2\ln(x)-\ln(x+1)}
\end{aligned}
\tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{-x-2\ln(x)-\ln(x+1)}} dy \end{aligned}$$

Which results in

$$S = \mathrm{e}^{x} x^{2}(x+1)\, y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(x^2+4x+2)}{x\,(x+1)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \mathrm{e}^{x} y x\,(x^2+4x+2) \\ S_y &= \mathrm{e}^{x} x^{2}(x+1) \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$e^x x^2 (x+1)\, y = c_1$$

Which simplifies to

$$e^x x^2 (x+1)\, y = c_1$$

Which gives

$$y = \frac{c_1 e^{-x}}{x^2 (x+1)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(x^2+4x+2)}{x(x+1)}$ 	$R = x$ $S = e^x x^2 (x+1)\, y$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \frac{c_1 e^{-x}}{x^2 (x+1)} \tag{1}$$

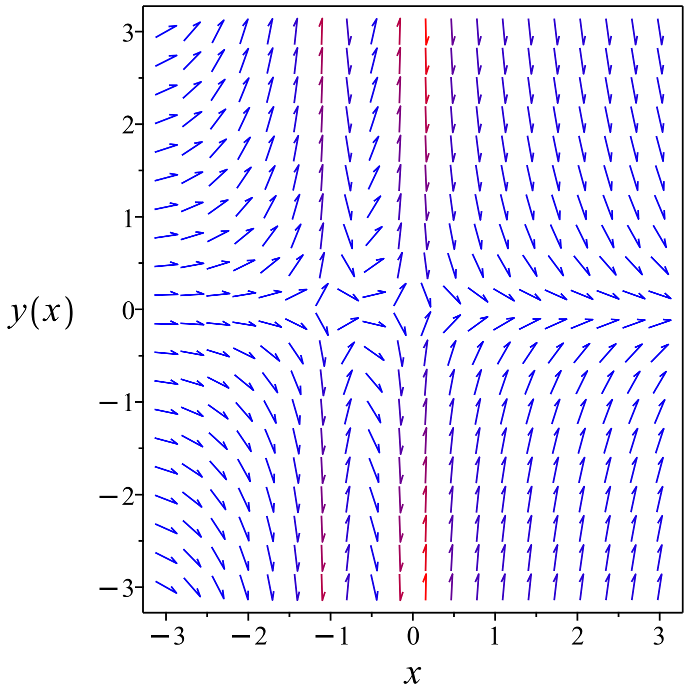

Figure 436: Slope field plot

Verification of solutions

$$y = \frac{c_1 \mathrm{e}^{-x}}{x^2 (x+1)}$$

Verified OK.

7.12.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
\left(-\frac{1}{y}\right) \mathrm{d}y &= \left(\frac{x^2 + 4x + 2}{x (x + 1)}\right) \mathrm{d}x \\
\left(-\frac{x^2 + 4x + 2}{x (x + 1)}\right) \mathrm{d}x + \left(-\frac{1}{y}\right) \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= -\frac{x^2 + 4x + 2}{x (x + 1)} \\
N(x, y) &= -\frac{1}{y}
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x^2 + 4x + 2}{x (x + 1)}\right) \\
&= 0
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int M \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int -\frac{x^2 + 4x + 2}{x(x+1)} \mathrm{d}x
\end{aligned}
$$

$$
\phi = -x - 2\ln(x) - \ln(x+1) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y}$. Therefore equation (4) becomes

$$
-\frac{1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \mathrm{d}y &= \int \left(-\frac{1}{y}\right) \mathrm{d}y \\
f(y) &= -\ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -x - 2\ln(x) - \ln(x+1) - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -x - 2\ln(x) - \ln(x+1) - \ln(y)$$

The solution becomes

$$y = \frac{e^{-x-c_1}}{(x+1)\,x^2}$$

Summary

The solution(s) found are the following

$$y = \frac{e^{-x-c_1}}{(x+1)\,x^2} \tag{1}$$

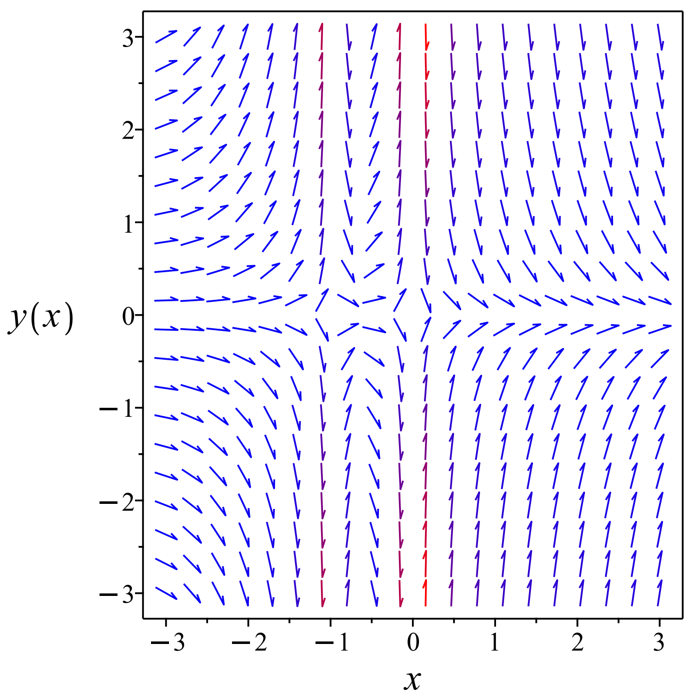

Figure 437: Slope field plot

Verification of solutions

$$y = \frac{e^{-x-c_1}}{(x+1)\,x^2}$$

Verified OK.

7.12.6 Maple step by step solution

Let's solve

$x^2y + 4yx + 2y + (x^2 + x)\,y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = -\frac{x^2+4x+2}{x(x+1)}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int -\frac{x^2+4x+2}{x(x+1)}dx + c_1$

- Evaluate integral

  $\ln(y) = -x - 2\ln(x) - \ln(x+1) + c_1$

- Solve for y

  $y = \frac{e^{-x+c_1}}{(x+1)x^2}$

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{-y + (x^4 - x)\, y' = 0}$$

7.13.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y}{x\,(x^3-1)} \end{aligned}$$

Where $f(x) = \frac{1}{x(x^3-1)}$ and $g(y) = y$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{y}\, dy &= \frac{1}{x\,(x^3-1)}\, dx \\
\int \frac{1}{y}\, dy &= \int \frac{1}{x\,(x^3-1)}\, dx \\
\ln (y) &= \frac{\ln (x^2+x+1)}{3} - \ln (x) + \frac{\ln (x-1)}{3} + c_1 \\
y &= \mathrm{e}^{\frac{\ln\left(x^2+x+1\right)}{3} - \ln(x) + \frac{\ln(x-1)}{3} + c_1} \\
&= c_1 \mathrm{e}^{\frac{\ln\left(x^2+x+1\right)}{3} - \ln(x) + \frac{\ln(x-1)}{3}}
\end{aligned}$$

Which simplifies to

$$y = \frac{c_1 (x^2+x+1)^{\frac{1}{3}} (x-1)^{\frac{1}{3}}}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 (x^2+x+1)^{\frac{1}{3}} (x-1)^{\frac{1}{3}}}{x} \tag{1}$$

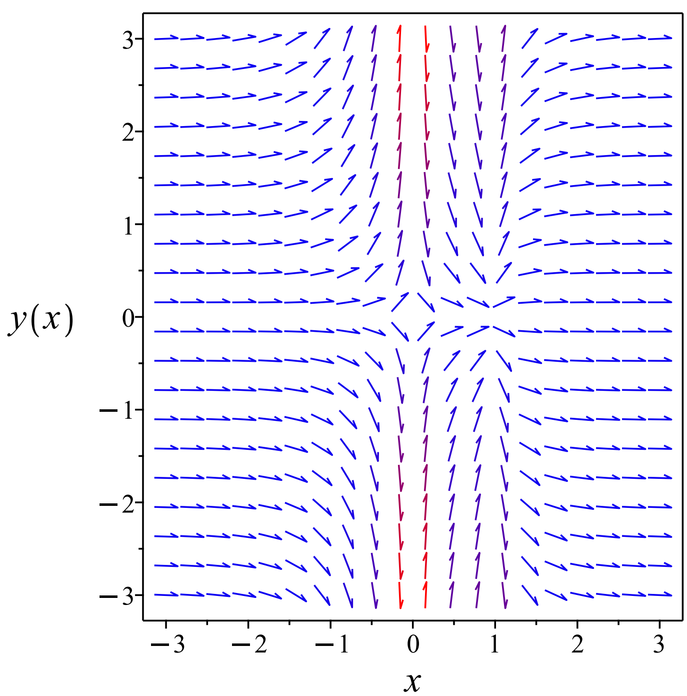

Figure 438: Slope field plot

Verification of solutions

$$y = \frac{c_1(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x}$$

Verified OK.

7.13.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x^4-x}$$
$$q(x) = 0$$

Hence the ode is

$$y' - \frac{y}{x^4-x} = 0$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x^4-x}dx}$$
$$= e^{-\frac{\ln(x^2+x+1)}{3}+\ln(x)-\frac{\ln(x-1)}{3}}$$

Which simplifies to

$$\mu = \frac{x}{(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}$$

The ode becomes

$$\frac{d}{dx}\mu y = 0$$
$$\frac{d}{dx}\left(\frac{xy}{(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}\right) = 0$$

Integrating gives

$$\frac{xy}{(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}} = c_1$$

Dividing both sides by the integrating factor $\mu = \frac{x}{(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}$ results in

$$y = \frac{c_1(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x} \tag{1}$$

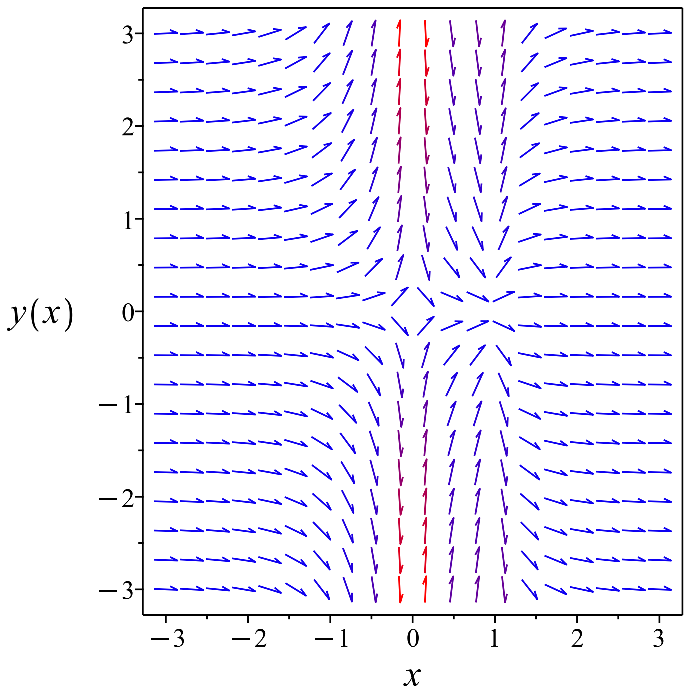

Figure 439: Slope field plot

Verification of solutions

$$y = \frac{c_1(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x}$$

Verified OK.

7.13.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$-u(x)\,x + (x^4 - x)\,(u'(x)\,x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{u(x^3-2)}{x\,(x^3-1)}
\end{aligned}$$

Where $f(x) = -\frac{x^3-2}{x(x^3-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{x^3-2}{x\,(x^3-1)}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{x^3-2}{x\,(x^3-1)}\,dx \\
\ln(u) &= \frac{\ln(x^2+x+1)}{3} - 2\ln(x) + \frac{\ln(x-1)}{3} + c_2 \\
u &= \mathrm{e}^{\frac{\ln(x^2+x+1)}{3} - 2\ln(x) + \frac{\ln(x-1)}{3} + c_2} \\
&= c_2 \mathrm{e}^{\frac{\ln(x^2+x+1)}{3} - 2\ln(x) + \frac{\ln(x-1)}{3}}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_2(x^2+x+1)^{\frac{1}{3}}\,(x-1)^{\frac{1}{3}}}{x^2}$$

Therefore the solution y is

$$\begin{aligned}
y &= ux \\
&= \frac{c_2(x^2+x+1)^{\frac{1}{3}}\,(x-1)^{\frac{1}{3}}}{x}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_2(x^2+x+1)^{\frac{1}{3}}\,(x-1)^{\frac{1}{3}}}{x} \tag{1}$$

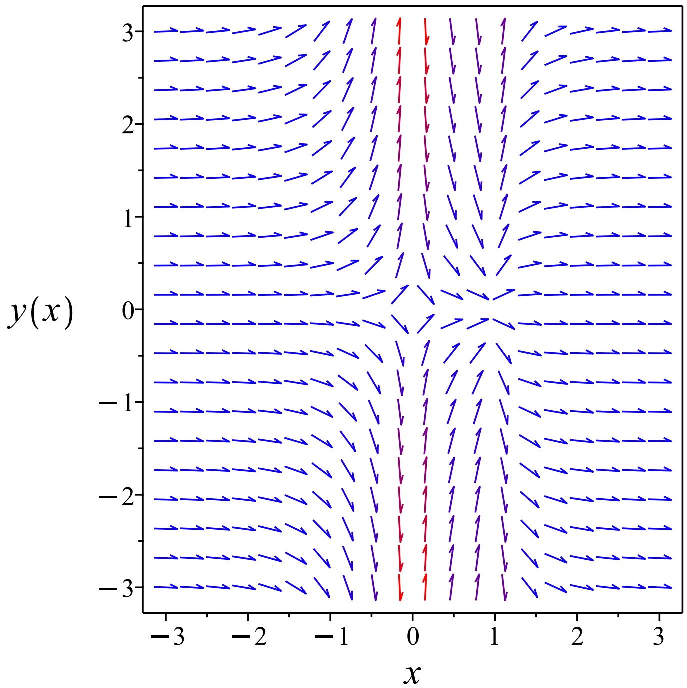

Figure 440: Slope field plot

Verification of solutions

$$y = \frac{c_2(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x}$$

Verified OK.

7.13.4 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = \frac{y}{x(x^3-1)}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 327: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \mathrm{e}^{\frac{\ln\left(x^2+x+1\right)}{3} - \ln(x) + \frac{\ln(x-1)}{3}}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\mathrm{e}^{\frac{\ln\left(x^2+x+1\right)}{3} - \ln(x) + \frac{\ln(x-1)}{3}}} dy \end{aligned}$$

Which results in

$$S = x\,\mathrm{e}^{\ln\left(\frac{1}{\left(x^2+x+1\right)^{\frac{1}{3}}}\right) + \ln\left(\frac{1}{(x-1)^{\frac{1}{3}}}\right)} y$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y}{x\left(x^3 - 1\right)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{y}{\left(x^2+x+1\right)^{\frac{4}{3}} (x-1)^{\frac{4}{3}}} \\ S_y &= \frac{x}{\left(x^2+x+1\right)^{\frac{1}{3}} (x-1)^{\frac{1}{3}}} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{xy}{(x^2+x+1)^{\frac{1}{3}} (x-1)^{\frac{1}{3}}} = c_1$$

Which simplifies to

$$\frac{xy}{(x^2+x+1)^{\frac{1}{3}} (x-1)^{\frac{1}{3}}} = c_1$$

Which gives

$$y = \frac{c_1 (x^2+x+1)^{\frac{1}{3}} (x-1)^{\frac{1}{3}}}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = \frac{y}{x(x^3-1)}$ 	$R = x$ $S = \frac{xy}{(x^2+x+1)^{\frac{1}{3}} (x-1}$	$\frac{dS}{dR} = 0$ 
Summary

The solution(s) found are the following

$$y = \frac{c_1(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x} \tag{1}$$

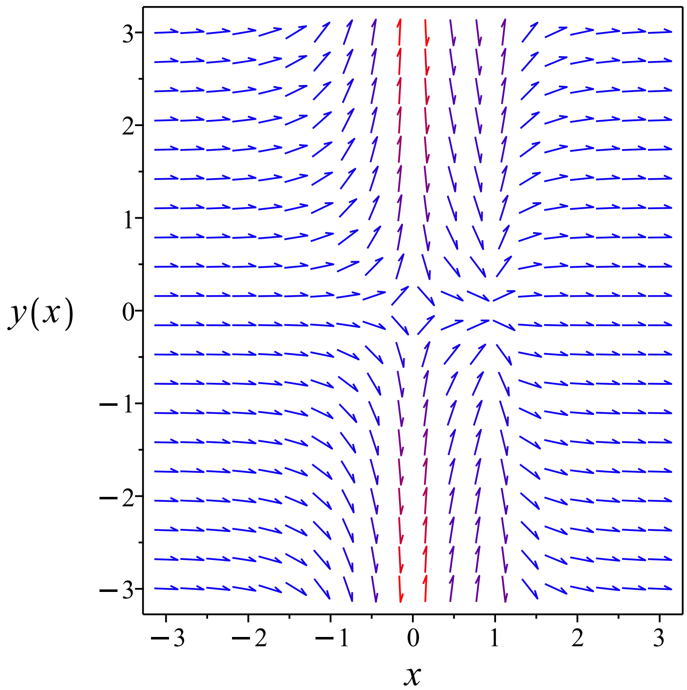

Figure 441: Slope field plot

Verification of solutions

$$y = \frac{c_1(x^2+x+1)^{\frac{1}{3}}(x-1)^{\frac{1}{3}}}{x}$$

Verified OK.

7.13.5 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the

ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x}&=M\\ \frac{\partial \phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(\frac{1}{y}\right)\mathrm{d}y&=\left(\frac{1}{x\,(x^3-1)}\right)\mathrm{d}x\\ \left(-\frac{1}{x\,(x^3-1)}\right)\mathrm{d}x+\left(\frac{1}{y}\right)\mathrm{d}y&=0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-\frac{1}{x\,(x^3-1)}\\ N(x,y)&=\frac{1}{y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x\,(x^3-1)}\right)\\ &= 0\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{1}{y}\right)\\ &= 0\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$

$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned}\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x\\ \int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{1}{x\,(x^3-1)}\,\mathrm{d}x\end{aligned}$$

$$\phi = -\frac{\ln(x^2+x+1)}{3} + \ln(x) - \frac{\ln(x-1)}{3} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{1}{y}$. Therefore equation (4) becomes

$$\frac{1}{y} = 0 + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \frac{1}{y}$$

Integrating the above w.r.t y gives

$$\int f'(y)\, \mathrm{d}y = \int \left(\frac{1}{y}\right) \mathrm{d}y$$
$$f(y) = \ln(y) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\frac{\ln(x^2+x+1)}{3} + \ln(x) - \frac{\ln(x-1)}{3} + \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\frac{\ln(x^2+x+1)}{3} + \ln(x) - \frac{\ln(x-1)}{3} + \ln(y)$$

The solution becomes

$$y = \frac{\mathrm{e}^{\frac{\ln(x^2+x+1)}{3} + \frac{\ln(x-1)}{3} + c_1}}{x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \frac{\mathrm{e}^{\frac{\ln(x^2+x+1)}{3} + \frac{\ln(x-1)}{3} + c_1}}{x} \tag{1}$$

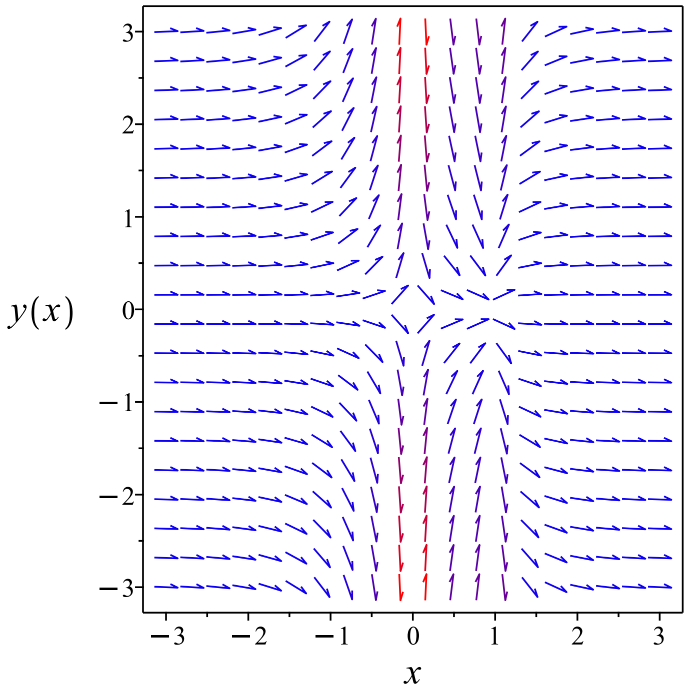

Figure 442: Slope field plot

<u>Verification of solutions</u>

$$y = \frac{e^{\frac{\ln(x^2+x+1)}{3}+\frac{\ln(x-1)}{3}+c_1}}{x}$$

Verified OK.

7.13.6 Maple step by step solution

Let's solve

$-y + (x^4 - x)\, y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = \frac{1}{x^4-x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int \frac{1}{x^4-x}dx + c_1$

- Evaluate integral

  $\ln(y) = \frac{\ln(x^2+x+1)}{3} - \ln(x) + \frac{\ln(x-1)}{3} + c_1$

- Solve for y

  $y = \frac{e^{\frac{\ln\left(x^2+x+1\right)}{3}+\frac{\ln(x-1)}{3}+c_1}}{x}$

7.14.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}(\cos(y)\sin(x) - \sin(y)\sin(x) + y)\,\mathrm{d}y &= (-\cos(x)\cos(y))\,\mathrm{d}x\\ (\cos(x)\cos(y))\,\mathrm{d}x + (\cos(y)\sin(x) - \sin(y)\sin(x) + y)\,\mathrm{d}y &= 0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y) &= \cos(x)\cos(y)\\ N(x,y) &= \cos(y)\sin(x) - \sin(y)\sin(x) + y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(\cos(x)\cos(y))\\ &= -\sin(y)\cos(x)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\cos(y)\sin(x) - \sin(y)\sin(x) + y)\\ &= \cos(x)(-\sin(y) + \cos(y))\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is <u>not exact</u>. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{\sin(x)(-\sin(y) + \cos(y)) + y}((-\sin(y)\cos(x)) - (\cos(x)\cos(y) - \sin(y)\cos(x)))\\ &= -\frac{\cos(x)\cos(y)}{\sin(x)(-\sin(y) + \cos(y)) + y}\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= \sec(y)\sec(x)\left((\cos(x)\cos(y) - \sin(y)\cos(x)) - (-\sin(y)\cos(x))\right) \\
&= 1
\end{aligned}$$

Since B does not depend on x, it can be used to obtain an integrating factor. Let the integrating factor be μ. Then

$$\begin{aligned}
\mu &= e^{\int B\,\mathrm{d}y} \\
&= e^{\int 1\,\mathrm{d}y}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{y} \\
&= \mathrm{e}^{y}
\end{aligned}$$

M and N are now multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{y}(\cos(x)\cos(y)) \\
&= \cos(x)\cos(y)\,\mathrm{e}^{y}
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{y}(\cos(y)\sin(x) - \sin(y)\sin(x) + y) \\
&= (\sin(x)(-\sin(y) + \cos(y)) + y)\,\mathrm{e}^{y}
\end{aligned}$$

So now a modified ODE is obtained from the original ODE which will be exact and can be solved using the standard method. The modified ODE is

$$\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
(\cos(x)\cos(y)\,\mathrm{e}^{y}) + ((\sin(x)(-\sin(y) + \cos(y)) + y)\,\mathrm{e}^{y})\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \cos(x)\cos(y)\,\mathrm{e}^{y} \mathrm{d}x$$
$$\phi = \sin(x)\cos(y)\,\mathrm{e}^{y} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\sin(x)\sin(y)\,\mathrm{e}^{y} + \sin(x)\cos(y)\,\mathrm{e}^{y} + f'(y) \tag{4}$$
$$= \mathrm{e}^{y}\sin(x)\left(-\sin(y) + \cos(y)\right) + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (\sin(x)(-\sin(y) + \cos(y)) + y)\,\mathrm{e}^{y}$. Therefore equation (4) becomes

$$(\sin(x)(-\sin(y) + \cos(y)) + y)\,\mathrm{e}^{y} = \mathrm{e}^{y}\sin(x)(-\sin(y) + \cos(y)) + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \mathrm{e}^{y} y$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int (\mathrm{e}^{y} y)\,\mathrm{d}y$$
$$f(y) = (y-1)\,\mathrm{e}^{y} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \sin(x)\cos(y)\,\mathrm{e}^{y} + (y-1)\,\mathrm{e}^{y} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \sin(x)\cos(y)\,\mathrm{e}^{y} + (y-1)\,\mathrm{e}^{y}$$

Summary
The solution(s) found are the following

$$\sin(x)\cos(y)\,e^{y} + (y-1)\,e^{y} = c_1 \tag{1}$$

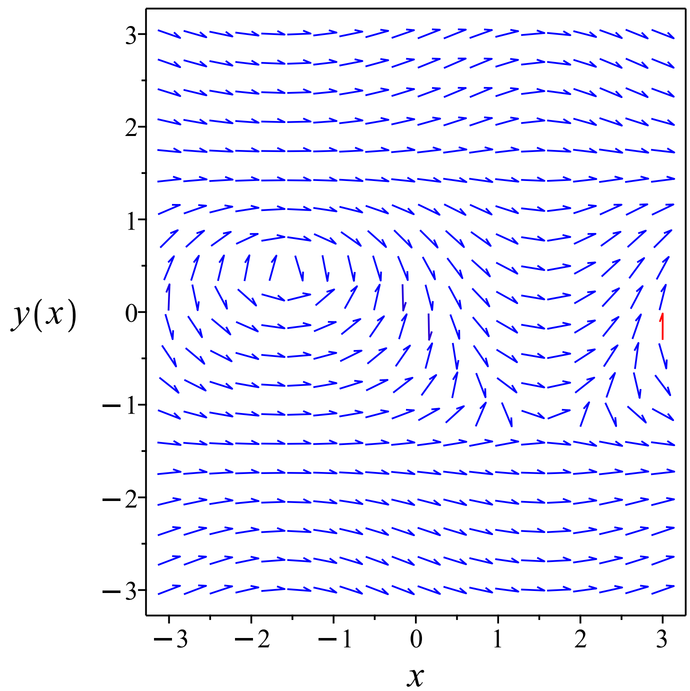

Figure 443: Slope field plot

Verification of solutions

$$\sin(x)\cos(y)\,e^{y} + (y-1)\,e^{y} = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{y \sin(y) + x(\sin(y) - y\cos(y))\, y' = 0}$$

7.16.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= \frac{y\sin(y)}{x(-\sin(y) + y\cos(y))} \end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(y) = \frac{y\sin(y)}{-\sin(y)+y\cos(y)}$. Integrating both sides gives

$$\frac{1}{\frac{y\sin(y)}{-\sin(y)+y\cos(y)}}\, dy = \frac{1}{x}\, dx$$

$$\int \frac{1}{\frac{y\sin(y)}{-\sin(y)+y\cos(y)}}dy = \int \frac{1}{x}\,dx$$

$$-\ln(y)+\ln(\sin(y)) = \ln(x)+c_1$$

Raising both side to exponential gives

$$\mathrm{e}^{-\ln(y)+\ln(\sin(y))} = \mathrm{e}^{\ln(x)+c_1}$$

Which simplifies to

$$\frac{\sin(y)}{y} = c_2 x$$

Summary
The solution(s) found are the following

$$y = \mathrm{RootOf}\left(\_Zc_2x-\sin(\_Z)\right) \tag{1}$$

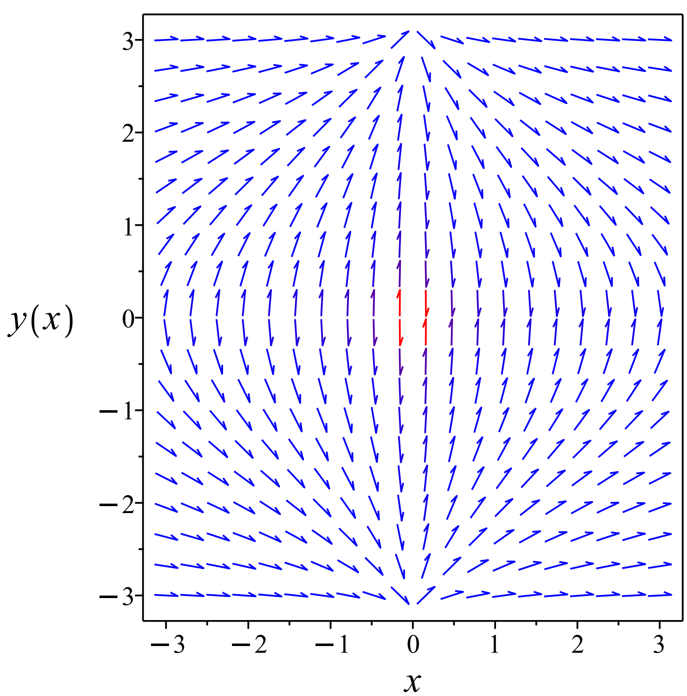

Figure 444: Slope field plot

Verification of solutions

$$y = \mathrm{RootOf}\left(\_Zc_2x-\sin(\_Z)\right)$$

Verified OK.

7.16.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= \frac{y \sin(y)}{x(-\sin(y) + y\cos(y))} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 330: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= x\\ \eta(x,y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi} dx\\ &= \int \frac{1}{x} dx\end{aligned}$$

Which results in

$$S = \ln(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y\sin(y)}{x(-\sin(y) + y\cos(y))}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= \frac{1}{x} \\
S_y &= 0
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{-1 + \cot(y)\, y}{y} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{-1 + \cot(R)\, R}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\ln(R) + \ln(\sin(R)) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\ln(x) = -\ln(y) + \ln(\sin(y)) + c_1$$

Which simplifies to

$$\ln(x) = -\ln(y) + \ln(\sin(y)) + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

<table>
<tr><th>Original ode in x, y coordinates</th><th>Canonical coordinates transformation</th><th>ODE in canonical coordinates (R, S)</th></tr>
<tr><td>$\frac{dy}{dx} = \frac{y\sin(y)}{x(-\sin(y)+y\cos(y))}$
</td><td>$R = y$

</td></tr>
</table>

Summary

The solution(s) found are the following

$$\ln(x) = -\ln(y) + \ln(\sin(y)) + c_1 \tag{1}$$

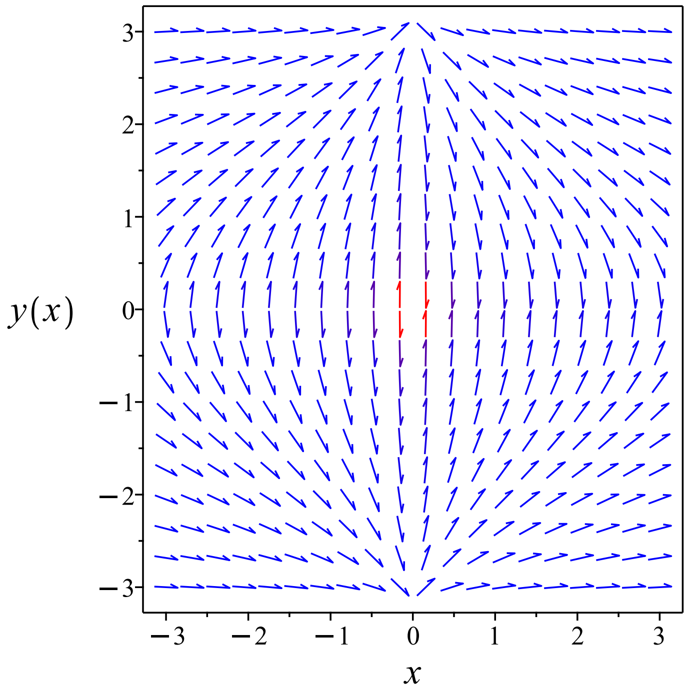

Figure 445: Slope field plot

Verification of solutions

$$\ln(x) = -\ln(y) + \ln(\sin(y)) + c_1$$

Verified OK.

7.16.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(\frac{-\sin(y) + y\cos(y)}{y\sin(y)}\right)\mathrm{d}y = \left(\frac{1}{x}\right)\mathrm{d}x$$
$$\left(-\frac{1}{x}\right)\mathrm{d}x + \left(\frac{-\sin(y) + y\cos(y)}{y\sin(y)}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{1}{x}$$
$$N(x, y) = \frac{-\sin(y) + y\cos(y)}{y\sin(y)}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{1}{x}\right)$$
$$= 0$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(\frac{-\sin(y) + y\cos(y)}{y\sin(y)}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is <u>exact</u> The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int M\, \mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\, \mathrm{d}x &= \int -\frac{1}{x}\, \mathrm{d}x \\
\phi &= -\ln(x) + f(y)
\end{aligned} \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{-\sin(y) + y\cos(y)}{y\sin(y)}$. Therefore equation (4) becomes

$$
\frac{-\sin(y) + y\cos(y)}{y\sin(y)} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
\begin{aligned}
f'(y) &= -\frac{\sin(y) - y\cos(y)}{y\sin(y)} \\
&= \frac{-1 + \cot(y)\, y}{y}
\end{aligned}
$$

Integrating the above w.r.t y results in

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{-1+\cot(y)\,y}{y}\right)\mathrm{d}y$$
$$f(y) = -\ln(y) + \ln(\sin(y)) + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \ln(y) + \ln(\sin(y)) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \ln(y) + \ln(\sin(y))$$

Summary
The solution(s) found are the following

$$-\ln(x) - \ln(y) + \ln(\sin(y)) = c_1 \tag{1}$$

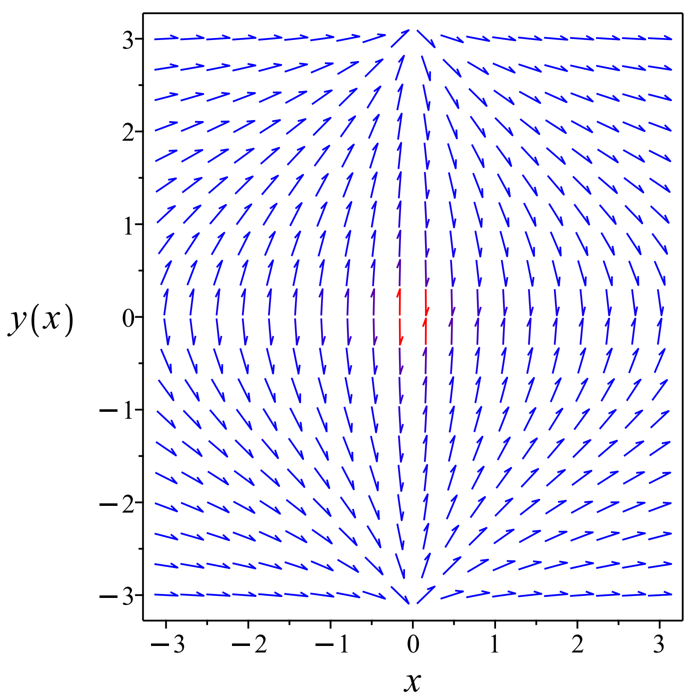

Figure 446: Slope field plot

Verification of solutions

$$-\ln(x)-\ln(y)+\ln(\sin(y))=c_1$$

Verified OK.

7.16.4 Maple step by step solution

Let's solve

$y\sin(y)+x(\sin(y)-y\cos(y))\,y'=0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(\sin(y)-y\cos(y))}{y\sin(y)}=-\frac{1}{x}$

- Integrate both sides with respect to x

  $\int\frac{y'(\sin(y)-y\cos(y))}{y\sin(y)}dx=\int-\frac{1}{x}dx+c_1$

- Evaluate integral

  $\ln(y)-\ln(\sin(y))=-\ln(x)+c_1$

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{ay + bxy + (cx + dxy)\, y' = 0}$$

7.17.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y(bx+a)}{x\,(dy+c)} \end{aligned}$$

Where $f(x) = -\frac{bx+a}{x}$ and $g(y) = \frac{y}{dy+c}$. Integrating both sides gives

$$\frac{1}{\frac{y}{dy+c}}\, dy = -\frac{bx+a}{x}\, dx$$

$$\int \frac{1}{\frac{y}{dy+c}}\, dy = \int -\frac{bx+a}{x}\, dx$$
$$dy + c\ln(y) = -bx - a\ln(x) + c_1$$

Which results in

$$y = e^{-\frac{c\,\mathrm{LambertW}\left(\frac{d\,e^{-\frac{bx+a\ln(x)-c_1}{c}}}{c}\right)+a\ln(x)+bx-c_1}{c}}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{c\,\mathrm{LambertW}\left(\frac{d\,e^{-\frac{bx+a\ln(x)-c_1}{c}}}{c}\right)+a\ln(x)+bx-c_1}{c}} \tag{1}$$

Verification of solutions

$$y = e^{-\frac{c\,\mathrm{LambertW}\left(\frac{d\,e^{-\frac{bx+a\ln(x)-c_1}{c}}}{c}\right)+a\ln(x)+bx-c_1}{c}}$$

Verified OK.

7.17.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y(bx+a)}{x(dy+c)}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 333: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= -\frac{x}{bx + a} \\
\eta(x, y) &= 0
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{x}{bx+a}} dx \end{aligned}$$

Which results in

$$S = -bx - a \ln(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(bx+a)}{x(dy+c)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 0 \\ R_y &= 1 \\ S_x &= \frac{-bx-a}{x} \\ S_y &= 0 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{dy+c}{y} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{Rd+c}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = Rd + c\ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-bx - a\ln(x) = dy + c\ln(y) + c_1$$

Which simplifies to

$$-bx - a\ln(x) = dy + c\ln(y) + c_1$$

Which gives

$$y = e^{-\frac{a\ln(x)+bx+c\,\mathrm{LambertW}\left(\frac{d\,e^{-\frac{a\ln(x)+bx+c_1}{c}}}{c}\right)+c_1}{c}}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{a\ln(x)+bx+c\,\mathrm{LambertW}\left(\frac{d\,e^{-\frac{a\ln(x)+bx+c_1}{c}}}{c}\right)+c_1}{c}} \tag{1}$$

Verification of solutions

$$y = e^{-\frac{a\ln(x)+bx+c\,\mathrm{LambertW}\left(\frac{d\,e^{-\frac{a\ln(x)+bx+c_1}{c}}}{c}\right)+c_1}{c}}$$

Verified OK.

7.17.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(-\frac{dy+c}{y}\right)\mathrm{d}y&=\left(\frac{bx+a}{x}\right)\mathrm{d}x\\ \left(-\frac{bx+a}{x}\right)\mathrm{d}x+\left(-\frac{dy+c}{y}\right)\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=-\frac{bx+a}{x}\\ N(x,y)&=-\frac{dy+c}{y}\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y}&=\frac{\partial}{\partial y}\left(-\frac{bx+a}{x}\right)\\ &=0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{dy+c}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -\frac{bx+a}{x} \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -bx - a\ln(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{dy+c}{y}$. Therefore equation (4) becomes

$$
-\frac{dy+c}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{dy+c}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(\frac{-dy-c}{y}\right) \mathrm{d}y \\
f(y) &= -dy - c\ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -bx - a\ln(x) - dy - c\ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -bx - a\ln(x) - dy - c\ln(y)$$

The solution becomes

$$y = \mathrm{e}^{-\frac{a\ln(x)+bx+c\,\mathrm{LambertW}\left(\frac{d\,\mathrm{e}^{-\frac{a\ln(x)+bx+c_1}{c}}}{c}\right)+c_1}{c}}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{a\ln(x)+bx+c\,\mathrm{LambertW}\left(\frac{d\,\mathrm{e}^{-\frac{a\ln(x)+bx+c_1}{c}}}{c}\right)+c_1}{c}} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-\frac{a\ln(x)+bx+c\,\mathrm{LambertW}\left(\frac{d\,\mathrm{e}^{-\frac{a\ln(x)+bx+c_1}{c}}}{c}\right)+c_1}{c}}$$

Verified OK.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{2y + 3(x^2 + y^3x^2)\, y' = 0}$$

7.19.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{2y}{3x^2\,(y^3+1)} \end{aligned}$$

Where $f(x) = -\frac{2}{3x^2}$ and $g(y) = \frac{y}{y^3+1}$. Integrating both sides gives

$$\frac{1}{\frac{y}{y^3+1}}\, dy = -\frac{2}{3x^2}\, dx$$

$$\int \frac{1}{\frac{y}{y^3+1}}\, dy = \int -\frac{2}{3x^2}\, dx$$
$$\frac{y^3}{3} + \ln(y) = \frac{2}{3x} + c_1$$

Which results in

$$y = e^{-\frac{x\,\mathrm{LambertW}\left(e^{\frac{3c_1x+2}{x}}\right)-3c_1x-2}{3x}}$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{x\,\mathrm{LambertW}\left(e^{\frac{3c_1x+2}{x}}\right)-3c_1x-2}{3x}} \tag{1}$$

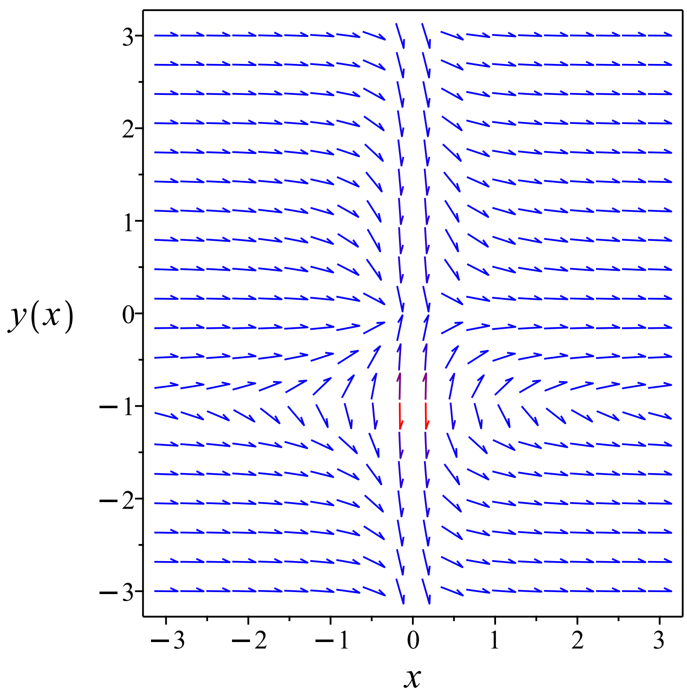

Figure 447: Slope field plot

Verification of solutions

$$y = e^{-\frac{x\,\mathrm{LambertW}\left(e^{\frac{3c_1x+2}{x}}\right)-3c_1x-2}{3x}}$$

Verified OK.

7.19.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{2y}{3x^2(y^3+1)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 336: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int b f(x) dx - h(x)}}{g(x)}$	$\frac{f(x) e^{-\int b f(x) dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1 x + b_1 y + c_1}{a_2 x + b_2 y + c_2}$	$\frac{a_1 b_2 x - a_2 b_1 x - b_1 c_2 + b_2 c_1}{a_1 b_2 - a_2 b_1}$	$\frac{a_1 b_2 y - a_2 b_1 y - a_1 c_2 - a_2 c_1}{a_1 b_2 - a_2 b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1) f(x) dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\begin{aligned}\xi(x,y) &= -\frac{3x^2}{2} \\ \eta(x,y) &= 0\end{aligned} \tag{A1}$$

The next step is to determine the canonical coordinates R,S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\xi}dx \\ &= \int \frac{1}{-\frac{3x^2}{2}}dx\end{aligned}$$

Which results in

$$S = \frac{2}{3x}$$

Now that R,S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{2y}{3x^2(y^3+1)}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\frac{2}{3x^2} \\
S_y &= 0
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = \frac{y^3+1}{y} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = \frac{R^3+1}{R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \frac{R^3}{3} + \ln(R) + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{2}{3x} = \frac{y^3}{3} + \ln(y) + c_1$$

Which simplifies to

$$\frac{2}{3x} = \frac{y^3}{3} + \ln(y) + c_1$$

Which gives

$$y = e^{-\frac{x \operatorname{LambertW}\left(e^{-\frac{3c_1x-2}{x}}\right)+3c_1x-2}{3x}}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2y}{3x^2(y^3+1)}$ 	$R = y$ $S = \frac{2}{3x}$	$\frac{dS}{dR} = \frac{R^3+1}{R}$ 
Summary

The solution(s) found are the following

$$y = e^{-\frac{x \operatorname{LambertW}\left(e^{-\frac{3c_1 x - 2}{x}}\right) + 3c_1 x - 2}{3x}} \tag{1}$$

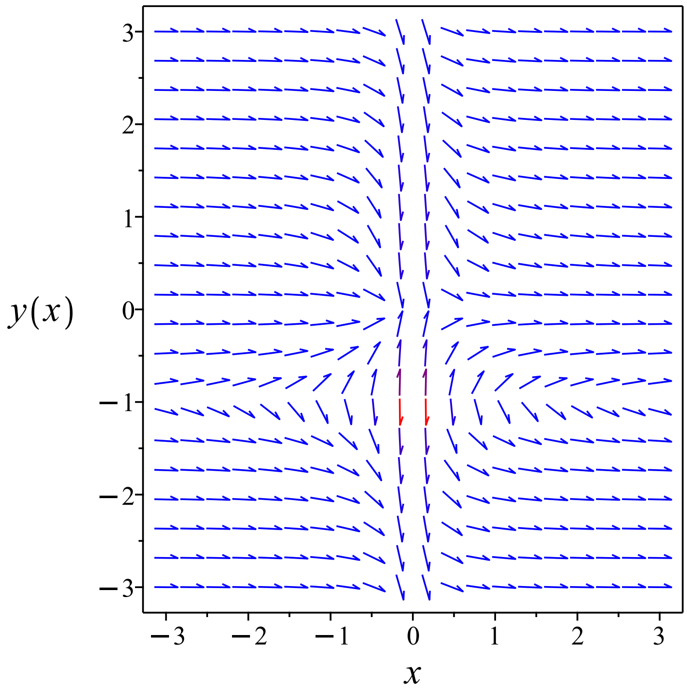

Figure 448: Slope field plot

Verification of solutions

$$y = e^{-\frac{x \operatorname{LambertW}\left(e^{-\frac{3c_1x-2}{x}}\right)+3c_1x-2}{3x}}$$

Verified OK.

7.19.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, dx + N(x, y) \, dy = 0 \tag{1A}$$

Therefore

$$\left(-\frac{3(y^3 + 1)}{2y}\right) dy = \left(\frac{1}{x^2}\right) dx$$
$$\left(-\frac{1}{x^2}\right) dx + \left(-\frac{3(y^3 + 1)}{2y}\right) dy = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{1}{x^2}$$
$$N(x, y) = -\frac{3(y^3 + 1)}{2y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{1}{x^2}\right) \\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{3(y^3+1)}{2y}\right)\\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int M \, \mathrm{d}x\\
\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x &= \int -\frac{1}{x^2} \, \mathrm{d}x
\end{aligned}
$$

$$
\phi = \frac{1}{x} + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{3(y^3+1)}{2y}$. Therefore equation (4) becomes

$$
-\frac{3(y^3+1)}{2y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{3(y^3+1)}{2y}
$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\frac{-3y^3-3}{2y}\right)\mathrm{d}y$$

$$f(y) = -\frac{y^3}{2} - \frac{3\ln(y)}{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{1}{x} - \frac{y^3}{2} - \frac{3\ln(y)}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{1}{x} - \frac{y^3}{2} - \frac{3\ln(y)}{2}$$

The solution becomes

$$y = \mathrm{e}^{-\frac{x\,\mathrm{LambertW}\left(\mathrm{e}^{-\frac{2(c_1x-1)}{x}}\right)+2c_1x-2}{3x}}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{x\,\mathrm{LambertW}\left(\mathrm{e}^{-\frac{2(c_1x-1)}{x}}\right)+2c_1x-2}{3x}} \tag{1}$$

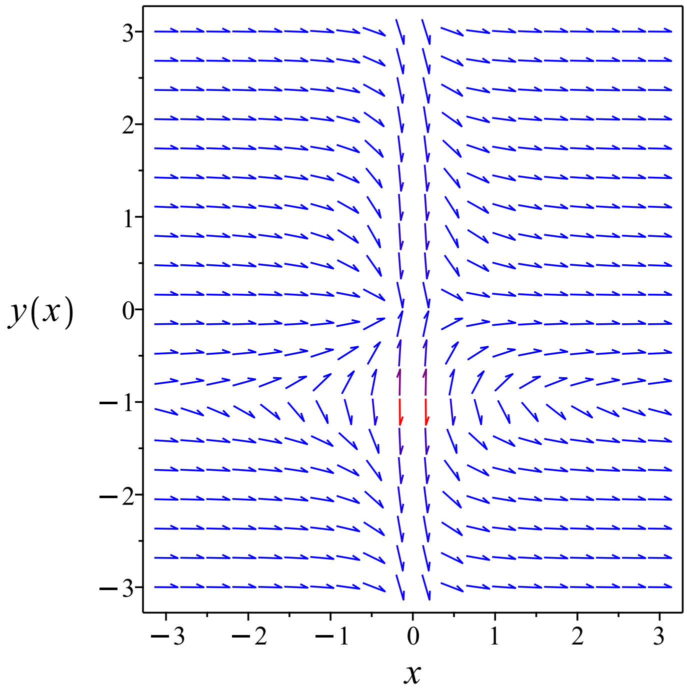

Figure 449: Slope field plot

Verification of solutions

$$y = e^{-\frac{x\,\mathrm{LambertW}\left(e^{-\frac{2(c_1 x-1)}{x}}\right)+2c_1 x-2}{3x}}$$

Verified OK.

7.19.4 Maple step by step solution

Let's solve

$2y + 3(x^2 + y^3x^2)\, y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(1+y)(y^2-y+1)}{y} = -\frac{2}{3x^2}$

- Integrate both sides with respect to x

  $\int \frac{y'(1+y)(y^2-y+1)}{y}dx = \int -\frac{2}{3x^2}dx + c_1$

- Evaluate integral

  $\frac{y^3}{3} + \ln(y) = \frac{2}{3x} + c_1$

- Solve for y

  $y = e^{-\frac{x \mathit{LambertW}\left(e^{\frac{3c_1x+2}{x}}\right) - 3c_1x - 2}{3x}}$

Problem number: 21.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"linear", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_linear]`

$$\boxed{a\cos(x)\,y-\sin(x)\,y^2+(b\cos(x)\,y-\sin(x)\,xy)\,y'=0}$$

7.20.1 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$p(x)=-\frac{\sin(x)}{b\cos(x)-\sin(x)\,x}$$
$$q(x)=\frac{\cos(x)\,a}{\sin(x)\,x-b\cos(x)}$$

Hence the ode is

$$y'-\frac{\sin(x)\,y}{b\cos(x)-\sin(x)\,x}=\frac{\cos(x)\,a}{\sin(x)\,x-b\cos(x)}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{\cos(x)a}{\sin(x)x-b\cos(x)}\right)$$

$$\frac{d}{dx}\left(e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx} y\right) = \left(e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx}\right)\left(\frac{\cos(x)a}{\sin(x)x-b\cos(x)}\right)$$

$$d\left(e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx} y\right) = \left(\frac{\cos(x)a\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)}\right) dx$$

Integrating gives

$$e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx} y = \int \frac{\cos(x)a\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)}\, dx$$

$$e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx} y = \int \frac{\cos(x)a\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)} dx + c_1$$

Dividing both sides by the integrating factor $\mu = e^{\int -\frac{\sin(x)}{b\cos(x)-\sin(x)x}dx}$ results in

$$y = e^{-\left(\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx\right)}\left(\int \frac{\cos(x)a\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)} dx\right) + c_1 e^{-\left(\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx\right)}$$

which simplifies to

$$y = e^{-\left(\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx\right)}\left(a\left(\int \frac{\cos(x)\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)} dx\right) + c_1\right)$$

Summary

The solution(s) found are the following

$$y = e^{-\left(\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx\right)}\left(a\left(\int \frac{\cos(x)\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)} dx\right) + c_1\right) \quad (1)$$

Verification of solutions

$$y = e^{-\left(\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx\right)}\left(a\left(\int \frac{\cos(x)\,e^{\int \frac{\sin(x)}{\sin(x)x-b\cos(x)}dx}}{\sin(x)x-b\cos(x)} dx\right) + c_1\right)$$

Verified OK.

7.20.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{-\cos(x)\, a + \sin(x)\, y}{\sin(x)\, x - b\cos(x)} \\
y' &= \omega(x, y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 339: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x,y) &= 0 \\
\eta(x,y) &= \mathrm{e}^{-\ln(-ib+x)-\frac{i\left(\int -\frac{4b}{(ix+b)\left(ix\,\mathrm{e}^{2ix}+b\,\mathrm{e}^{2ix}-ix+b\right)}dx\right)}{2}} \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R,S. The canonical coordinates map $(x,y)\to(R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x}+\eta\frac{\partial}{\partial y}\right)S(x,y)=1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi=0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta}dy \\
&= \int \frac{1}{\mathrm{e}^{-\ln(-ib+x)-\frac{i\left(\int -\frac{4b}{(ix+b)\left(ix\,\mathrm{e}^{2ix}+b\,\mathrm{e}^{2ix}-ix+b\right)}dx\right)}{2}}}dy
\end{aligned}
$$

7.20.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$
M(x,y)+N(x,y)\frac{dy}{dx} = 0 \qquad \text{(A)}
$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$
\frac{d}{dx}\phi(x,y) = 0
$$

Hence

$$
\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \qquad \text{(B)}
$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(\sin(x)\,x - b\cos(x))\,\mathrm{d}y = (-\sin(x)\,y + \cos(x)\,a)\,\mathrm{d}x$$
$$(-\cos(x)\,a + \sin(x)\,y)\,\mathrm{d}x + (\sin(x)\,x - b\cos(x))\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\cos(x)\,a + \sin(x)\,y$$
$$N(x, y) = \sin(x)\,x - b\cos(x)$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(-\cos(x)\,a + \sin(x)\,y)\\ &= \sin(x)\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(\sin(x)\,x - b\cos(x))\\ &= x\cos(x) + \sin(x) + b\sin(x)\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{\sin(x)\,x - b\cos(x)}\left((\sin(x)) - (x\cos(x) + \sin(x) + b\sin(x))\right) \\
&= \frac{x\cos(x) + b\sin(x)}{b\cos(x) - \sin(x)\,x}
\end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int A\,\mathrm{d}x} \\
&= e^{\int \frac{x\cos(x)+b\sin(x)}{b\cos(x)-\sin(x)x}\,\mathrm{d}x}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}
\mu &= e^{-ix+\int -\frac{2i(ib+x)}{-ib\,\mathrm{e}^{2ix}+x\,\mathrm{e}^{2ix}-ib-x}dx} \\
&= \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}
\end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned}
\overline{M} &= \mu M \\
&= \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}(-\cos(x)\,a + \sin(x)\,y) \\
&= (-\cos(x)\,a + \sin(x)\,y)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}
\end{aligned}$$

And

$$\begin{aligned}
\overline{N} &= \mu N \\
&= \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}(\sin(x)\,x - b\cos(x)) \\
&= (\sin(x)\,x - b\cos(x))\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}
\end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x}$$

$$\left((-\cos(x)\,a + \sin(x)\,y)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}\right) + \left((\sin(x)\,x - b\cos(x))\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}\right)\frac{\mathrm{d}y}{\mathrm{d}x}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int \overline{M} \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int (-\cos(x)\, a + \sin(x)\, y)\, \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x} dx\right)} \, \mathrm{d}x$$
$$\phi = \int^{x} (-\cos(\_a)\, a + \sin(\_a)\, y)\, \mathrm{e}^{-i\_a+2\left(\int \frac{i\_a-b}{(ib-\_a)\mathrm{e}^{2i\_a}+ib+\_a} d\_a\right)} d\_a + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \int^{x} \sin(\_a)\, \mathrm{e}^{-i\_a+2\left(\int \frac{i\_a-b}{(ib-\_a)\mathrm{e}^{2i\_a}+ib+\_a} d\_a\right)} d\_a + f'(y) \tag{4}$$
$$= \int^{x} \sin(\_a)\, \mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a} d\_a\right)} d\_a + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (\sin(x)\, x - b\cos(x))\, \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x} dx\right)}$. Therefore equation (4) becomes

$$(\sin(x)\, x - b\cos(x))\, \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x} dx\right)} = \int^{x} \sin(\_a)\, \mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a} d\_a\right)} d\_a + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = \sin(x)\, \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x} dx\right)} x - \cos(x)\, \mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x} dx\right)} b - \left(\int^{x} \sin(\_a)\, \mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a} d\_a\right)} d\_a\right)$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y = \int \left(\sin(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}x - \cos(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}b - \left(\int^{x} \sin(\_a)\,\mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a}d\_a\right)}d\_a\right)\right)\mathrm{d}y$$

$$f(y) = \int_{0}^{y} \left(\sin(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}x - \cos(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}b - \left(\int^{x} \sin(\_a)\,\mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a}d\_a\right)}d\_a\right)\right)d\_a + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \int^{x} (-\cos(\_a)\,a + \sin(\_a)\,y)\,\mathrm{e}^{-i\_a+2\left(\int \frac{i\_a-b}{(ib-\_a)\mathrm{e}^{2i\_a}+ib+\_a}d\_a\right)}d\_a + \int_{0}^{y} \left(\sin(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}x - \cos(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}b - \left(\int^{x} \sin(\_a)\,\mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a}d\_a\right)}d\_a\right)\right)d\_a + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \int^{x} (-\cos(\_a)\,a + \sin(\_a)\,y)\,\mathrm{e}^{-i\_a+2\left(\int \frac{i\_a-b}{(ib-\_a)\mathrm{e}^{2i\_a}+ib+\_a}d\_a\right)}d\_a + \int_{0}^{y} \left(\sin(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}x - \cos(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}b - \left(\int^{x} \sin(\_a)\,\mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a}d\_a\right)}d\_a\right)\right)d\_a$$

Summary

The solution(s) found are the following

$$\int^{x} (-\cos(\_a)\,a + \sin(\_a)\,y)\,\mathrm{e}^{-i\_a+2\left(\int \frac{i\_a-b}{(ib-\_a)\mathrm{e}^{2i\_a}+ib+\_a}d\_a\right)}d\_a + \int_{0}^{y} \left(\sin(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}x - \cos(x)\,\mathrm{e}^{-ix+2\left(\int \frac{ix-b}{(ib-x)\mathrm{e}^{2ix}+ib+x}dx\right)}b - \left(\int^{x} \sin(\_a)\,\mathrm{e}^{-i\_a+2\left(\int \frac{ib+\_a}{\mathrm{e}^{2i\_a}(i\_a+b)+b-i\_a}d\_a\right)}d\_a\right)\right)d\_a = c_1 \tag{1}$$

Verification of solutions

$$\int^{x} \left(-\cos\left(\_a\right) a+\sin\left(\_a\right) y\right) \mathrm{e}^{-i\_a+2\left(\int \frac{i\_a-b}{\left(i b-\_a\right) \mathrm{e}^{2 i\_a}+i b+\_a}d\_a\right)}d\_a \\ +\int_{0}^{y} \left(\sin\left(x\right) \mathrm{e}^{-i x+2\left(\int \frac{i x-b}{\left(i b-x\right) \mathrm{e}^{2 i x}+i b+x}d x\right)} x-\cos\left(x\right) \mathrm{e}^{-i x+2\left(\int \frac{i x-b}{\left(i b-x\right) \mathrm{e}^{2 i x}+i b+x}d x\right)} b \\ -\left(\int^{x} \sin\left(\_a\right) \mathrm{e}^{-i\_a+2\left(\int \frac{i b+\_a}{\mathrm{e}^{2 i\_a} \left(i\_a+b\right)+b-i\_a}d\_a\right)}d\_a\right)\right) d\_a = c_{1}$$

Warning, solution could not be verified

7.20.4 Maple step by step solution

Let's solve

$a \cos\left(x\right) y-\sin\left(x\right) y^{2}+\left(b \cos\left(x\right) y-\sin\left(x\right) x y\right) y^{\prime}=0$

- Highest derivative means the order of the ODE is 1

  $y^{\prime}$

- Isolate the derivative

  $y^{\prime}=-\frac{\sin\left(x\right) y}{\sin\left(x\right) x-b \cos\left(x\right)}+\frac{\cos\left(x\right) a}{\sin\left(x\right) x-b \cos\left(x\right)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE

  $y^{\prime}+\frac{\sin\left(x\right) y}{\sin\left(x\right) x-b \cos\left(x\right)}=\frac{\cos\left(x\right) a}{\sin\left(x\right) x-b \cos\left(x\right)}$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

  $\mu(x) \left(y^{\prime}+\frac{\sin\left(x\right) y}{\sin\left(x\right) x-b \cos\left(x\right)}\right)=\frac{\mu(x) \cos\left(x\right) a}{\sin\left(x\right) x-b \cos\left(x\right)}$

- Assume the lhs of the ODE is the total derivative $\frac{d}{d x}\left(\mu(x) y\right)$

  $\mu(x) \left(y^{\prime}+\frac{\sin\left(x\right) y}{\sin\left(x\right) x-b \cos\left(x\right)}\right)=\mu^{\prime}(x) y+\mu(x) y^{\prime}$

- Isolate $\mu^{\prime}(x)$

  $\mu^{\prime}(x)=\frac{\mu(x) \sin\left(x\right)}{\sin\left(x\right) x-b \cos\left(x\right)}$

- Solve to find the integrating factor

  $\mu(x)=\mathrm{e}^{\int \frac{\sin\left(x\right)}{\sin\left(x\right) x-b \cos\left(x\right)}d x}$

- Integrate both sides with respect to x

  $\int \left(\frac{d}{d x}\left(\mu(x) y\right)\right)d x=\int \frac{\mu(x) \cos\left(x\right) a}{\sin\left(x\right) x-b \cos\left(x\right)}d x+c_{1}$

- Evaluate the integral on the lhs

$$\mu(x)\, y = \int \frac{\mu(x)\cos(x) a}{\sin(x) x - b\cos(x)} dx + c_1$$

- Solve for y

$$y = \frac{\int \frac{\mu(x)\cos(x) a}{\sin(x) x - b\cos(x)} dx + c_1}{\mu(x)}$$

- Substitute $\mu(x) = e^{\int \frac{\sin(x)}{\sin(x) x - b\cos(x)} dx}$

$$y = \frac{\int \frac{\cos(x) a\, e^{\int \frac{\sin(x)}{\sin(x) x - b\cos(x)} dx}}{\sin(x) x - b\cos(x)} dx + c_1}{e^{\int \frac{\sin(x)}{\sin(x) x - b\cos(x)} dx}}$$

- Evaluate the integrals on the rhs

$$y = \frac{\int \frac{\cos(x) a\, e^{\ln(-\mathrm{I}b + x) - \frac{\mathrm{I}\left(\int \frac{4b}{(\mathrm{I}x + b)\left(\mathrm{I}x\left(e^{\mathrm{I}x}\right)^2 + b\left(e^{\mathrm{I}x}\right)^2 - \mathrm{I}x + b\right)} dx\right)}{2}}}{\sin(x) x - b\cos(x)} dx + c_1}{e^{\ln(-\mathrm{I}b + x) - \frac{\mathrm{I}\left(\int \frac{4b}{(\mathrm{I}x + b)\left(\mathrm{I}x\left(e^{\mathrm{I}x}\right)^2 + b\left(e^{\mathrm{I}x}\right)^2 - \mathrm{I}x + b\right)} dx\right)}{2}}}$$

- Simplify

$$y = \frac{\left(a\left(\int \frac{(-\mathrm{I}b + x)\cos(x) e^{2\,\mathrm{I}b\left(\int \frac{1}{(\mathrm{I}b - x)\left((\mathrm{I}b - x)e^{2\,\mathrm{I}x} + \mathrm{I}b + x\right)} dx\right)}}{b\cos(x) - \sin(x) x} dx\right) - c_1\right) e^{-2\,\mathrm{I}b\left(\int \frac{1}{(\mathrm{I}b - x)\left((\mathrm{I}b - x)e^{2\,\mathrm{I}x} + \mathrm{I}b + x\right)} dx\right)}}{\mathrm{I}b - x}$$

The type(s) of ODE detected by this program : **"exact", "linear", "separable", "differentialType", "homogeneousTypeD2", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[_separable]
```

$$\boxed{x^4y^4 + x^5y^3y' = 0}$$

7.21.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)g(y) \\ &= -\frac{y}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(y) = y$. Integrating both sides gives

$$\frac{1}{y}\,dy = -\frac{1}{x}\,dx$$
$$\int \frac{1}{y}\,dy = \int -\frac{1}{x}\,dx$$
$$\ln(y) = -\ln(x) + c_1$$
$$y = e^{-\ln(x)+c_1}$$
$$= \frac{c_1}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

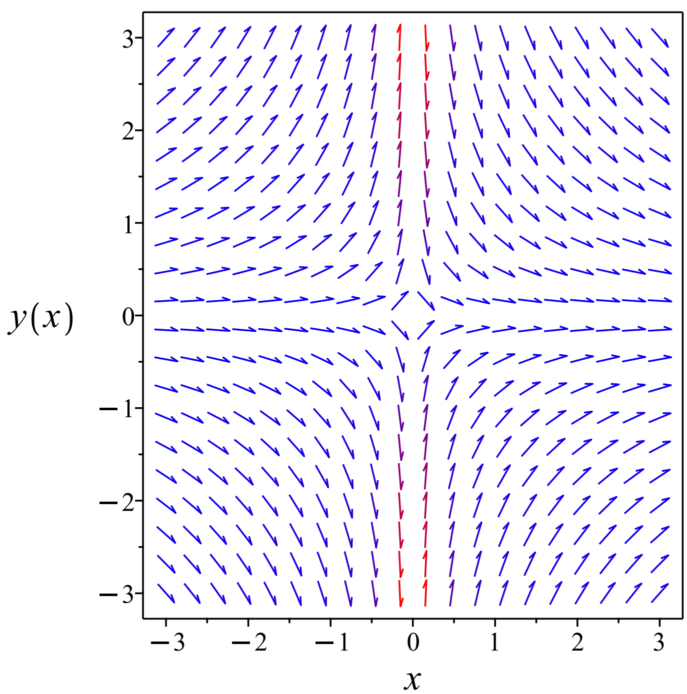

Figure 450: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

7.21.2 Solving as linear ode

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= 0 \end{aligned}$$

Hence the ode is

$$y' + \frac{y}{x} = 0$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int \frac{1}{x}dx} \\ &= x \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}\mu y &= 0 \\ \frac{\mathrm{d}}{\mathrm{d}x}(yx) &= 0 \end{aligned}$$

Integrating gives

$$yx = c_1$$

Dividing both sides by the integrating factor $\mu = x$ results in

$$y = \frac{c_1}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

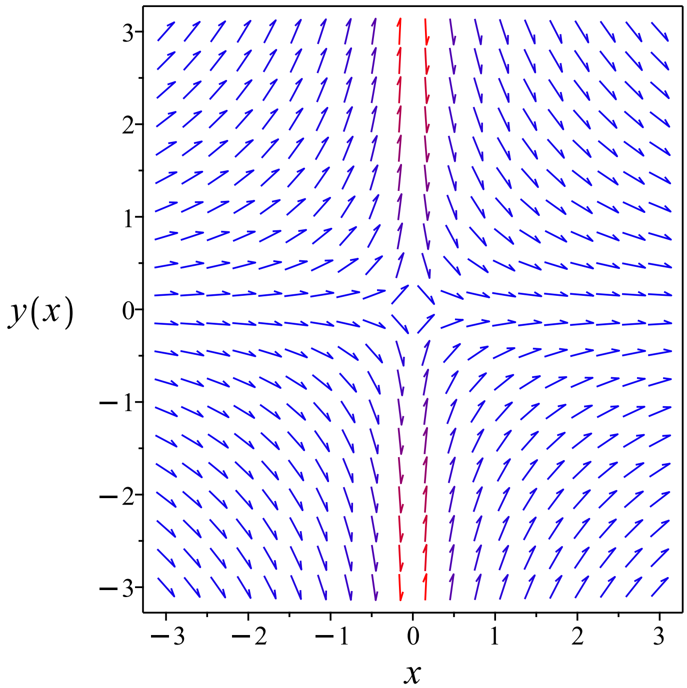

Figure 451: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

7.21.3 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\,x$ on the above ode results in new ode in $u(x)$

$$x^8 u(x)^4 + x^8 u(x)^3 \left(u'(x)\,x + u(x)\right) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{2}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{2}{x}\,dx \\
\ln(u) &= -2\ln(x) + c_2 \\
u &= e^{-2\ln(x)+c_2} \\
&= \frac{c_2}{x^2}
\end{aligned}
$$

Therefore the solution y is

$$
\begin{aligned}
y &= xu \\
&= \frac{c_2}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_2}{x} \tag{1}
$$

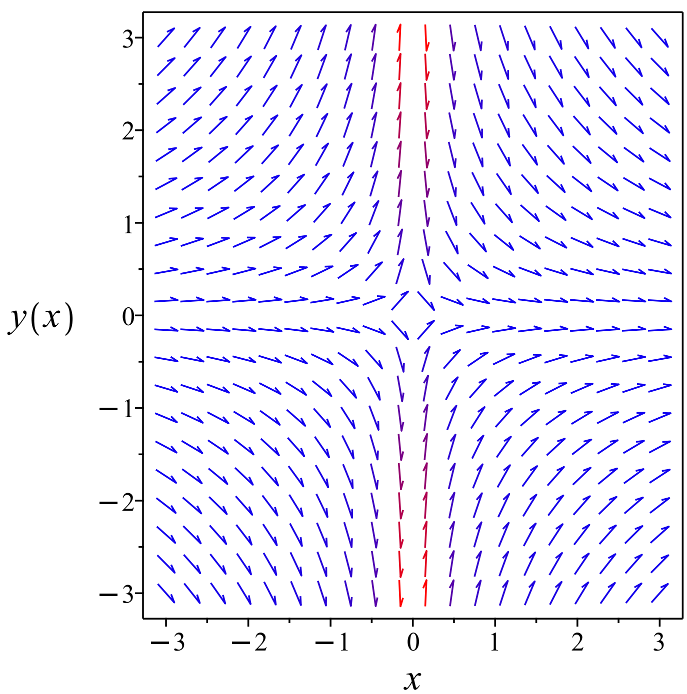

Figure 452: Slope field plot

Verification of solutions

$$y = \frac{c_2}{x}$$

Verified OK.

7.21.4 Solving as differentialType ode

Writing the ode as

$$y' = -\frac{y}{x} \tag{1}$$

Which becomes

$$0 = (-x)\,dy + (-y)\,dx \tag{2}$$

But the RHS is complete differential because

$$(-x)\,dy + (-y)\,dx = d(-yx)$$

Hence (2) becomes

$$0 = d(-yx)$$

Integrating both sides gives gives these solutions

$$y = \frac{c_1}{x} + c_1$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + c_1 \tag{1}$$

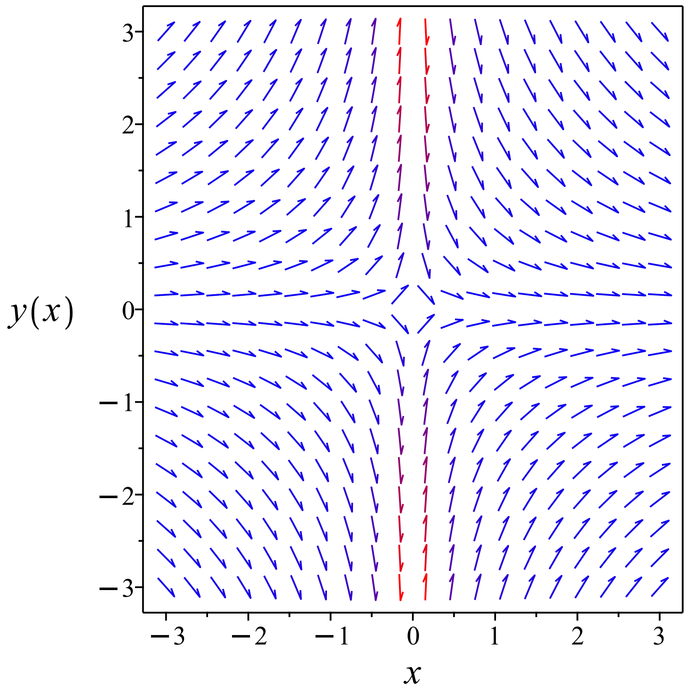

Figure 453: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x} + c_1$$

Verified OK.

7.21.5 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$y' = -\frac{y}{x}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is known. It is of type `linear`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 342: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= \frac{1}{x}
\end{aligned} \tag{A1}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{1}{x}} dy \end{aligned}$$

Which results in

$$S = yx$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y}{x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= y \\ S_y &= x \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$yx = c_1$$

Which simplifies to

$$yx = c_1$$

Which gives

$$y = \frac{c_1}{x}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y}{x}$ 	$R = x$ $S = yx$	$\frac{dS}{dR} = 0$ 
Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} \tag{1}$$

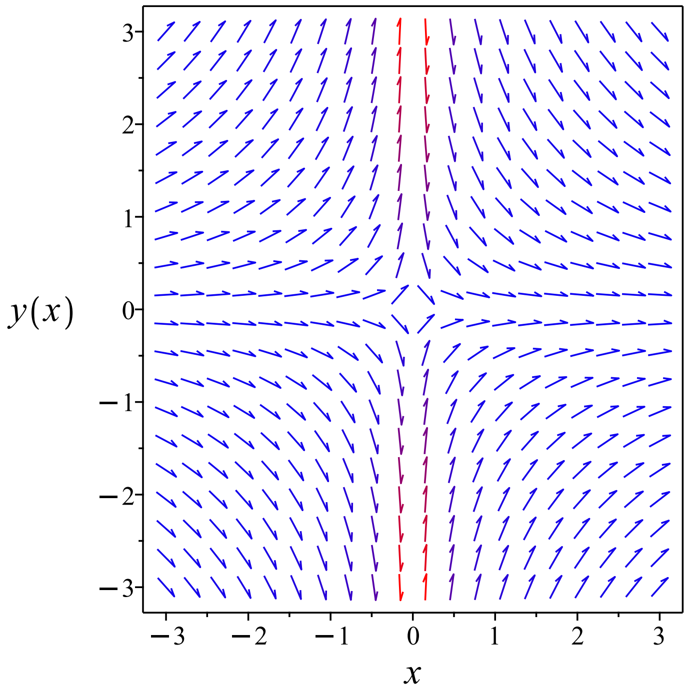

Figure 454: Slope field plot

Verification of solutions

$$y = \frac{c_1}{x}$$

Verified OK.

7.21.6 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x, y) + N(x, y) \frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x, y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x, y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\, \mathrm{d}x + N(x, y)\, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{1}{y}\right) \mathrm{d}y = \left(\frac{1}{x}\right) \mathrm{d}x$$
$$\left(-\frac{1}{x}\right) \mathrm{d}x + \left(-\frac{1}{y}\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{1}{x}$$
$$N(x, y) = -\frac{1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\frac{\partial M}{\partial y} = \frac{\partial}{\partial y}\left(-\frac{1}{x}\right)$$
$$= 0$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\frac{\partial \phi}{\partial x} = M \tag{1}
$$

$$
\frac{\partial \phi}{\partial y} = N \tag{2}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int M \,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x &= \int -\frac{1}{x} \,\mathrm{d}x
\end{aligned}
$$

$$
\phi = -\ln(x) + f(y) \tag{3}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{1}{y}$. Therefore equation (4) becomes

$$
-\frac{1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y) \,\mathrm{d}y &= \int \left(-\frac{1}{y}\right) \mathrm{d}y \\
f(y) &= -\ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\ln(x) - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\ln(x) - \ln(y)$$

The solution becomes

$$y = \frac{e^{-c_1}}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{e^{-c_1}}{x} \tag{1}$$

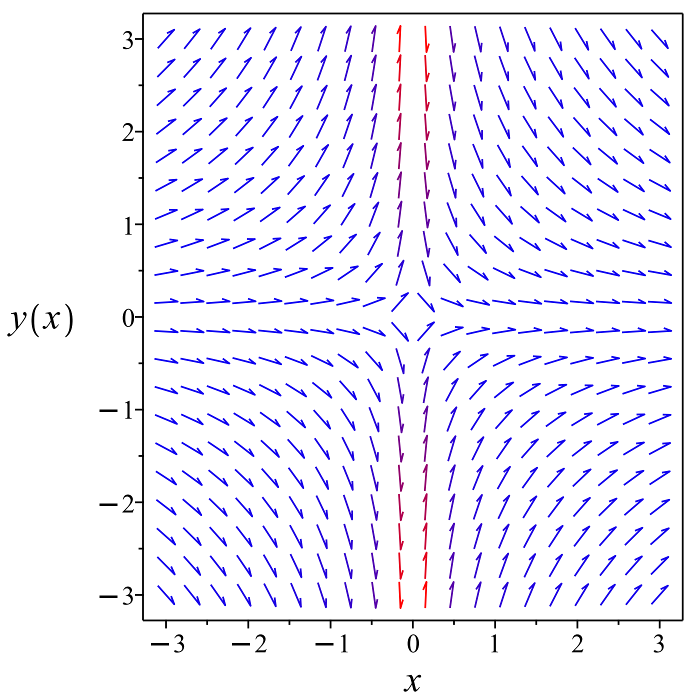

Figure 455: Slope field plot

Verification of solutions

$$y = \frac{e^{-c_1}}{x}$$

Verified OK.

7.21.7 Maple step by step solution

Let's solve

$x^4y^4 + x^5y^3y' = 0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'}{y} = -\frac{1}{x}$

- Integrate both sides with respect to x

  $\int \frac{y'}{y}dx = \int -\frac{1}{x}dx + c_1$

- Evaluate integral

  $\ln(y) = -\ln(x) + c_1$

- Solve for y

  $y = \frac{e^{c_1}}{x}$

ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "separable", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

`[_separable]`

$$\boxed{y(x\cos(x)+2\sin(x))+x(1+y)\,y'=0}$$

7.22.1 Solving as separable ode

In canonical form the ODE is

$$\begin{aligned}
y' &= F(x,y)\\
&= f(x)g(y)\\
&= -\frac{y(x\cos(x)+2\sin(x))}{x\,(y+1)}
\end{aligned}$$

Where $f(x)=-\frac{x\cos(x)+2\sin(x)}{x}$ and $g(y)=\frac{y}{y+1}$. Integrating both sides gives

$$\frac{1}{\frac{y}{y+1}}\,dy=-\frac{x\cos(x)+2\sin(x)}{x}\,dx$$

$$\int \frac{1}{\frac{y}{y+1}} dy = \int -\frac{x\cos(x) + 2\sin(x)}{x} dx$$

$$y + \ln(y) = -\sin(x) - 2\,\mathrm{Si}(x) + c_1$$

Which results in

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)+c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)+c_1}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)+c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)+c_1} \tag{1}$$

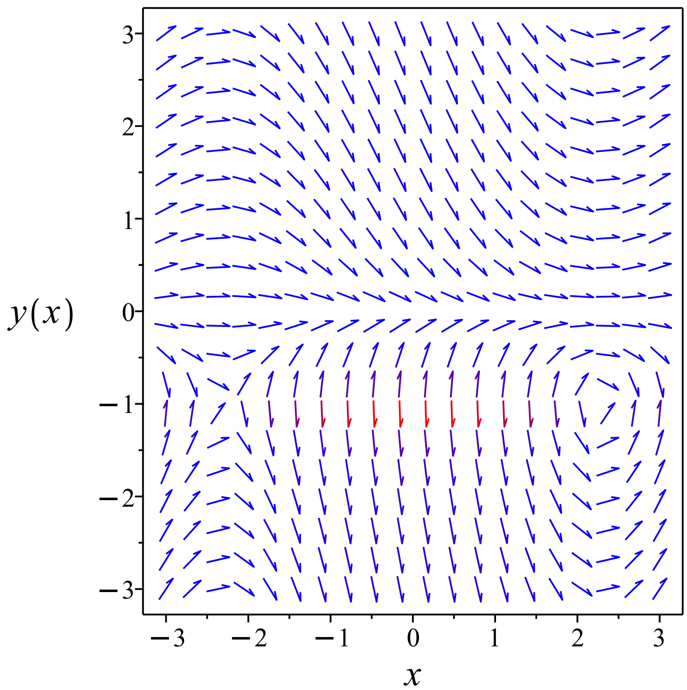

Figure 456: Slope field plot

Verification of solutions

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)+c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)+c_1}$$

Verified OK.

7.22.2 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$
\begin{aligned}
y' &= -\frac{y(x\cos(x) + 2\sin(x))}{x(y+1)} \\
y' &= \omega(x,y)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}
$$

The type of this ode is known. It is of type `separable`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 345: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f(\frac{y}{x})$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F(\frac{y}{x})$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx - h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx - h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x - a_2b_1x - b_1c_2 + b_2c_1}{a_1b_2 - a_2b_1}$	$\frac{a_1b_2y - a_2b_1y - a_1c_2 - a_2c_1}{a_1b_2 - a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int (n-1)f(x)dx} y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$\xi(x,y) = -\frac{x}{x\cos(x) + 2\sin(x)}$$
$$\eta(x,y) = 0 \tag{A1}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\eta = 0$ then in this special case

$$R = y$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\xi} dx \\ &= \int \frac{1}{-\frac{x}{x\cos(x)+2\sin(x)}} dx \end{aligned}$$

Which results in

$$S = -\sin(x) - 2\,\mathrm{Si}(x)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(x\cos(x) + 2\sin(x))}{x(y+1)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 0 \\
R_y &= 1 \\
S_x &= -\cos(x) - \frac{2\sin(x)}{x} \\
S_y &= 0
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{y+1}{y} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{R+1}{R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = R + \ln(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\sin(x) - 2\ \mathrm{Si}(x) = y + \ln(y) + c_1
$$

Which simplifies to

$$
-\sin(x) - 2\ \mathrm{Si}(x) = y + \ln(y) + c_1
$$

Which gives

$$
y = \mathrm{e}^{-\operatorname{LambertW}\left(\mathrm{e}^{-\sin(x)-2\ \mathrm{Si}(x)-c_1}\right)-\sin(x)-2\ \mathrm{Si}(x)-c_1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(x\cos(x)+2\sin(x))}{x(y+1)}$ 	$R = y$ $S = -\sin(x) - 2\,\mathrm{Si}(x)$	$\frac{dS}{dR} = \frac{R+1}{R}$ 
Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)-c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)-c_1} \tag{1}$$

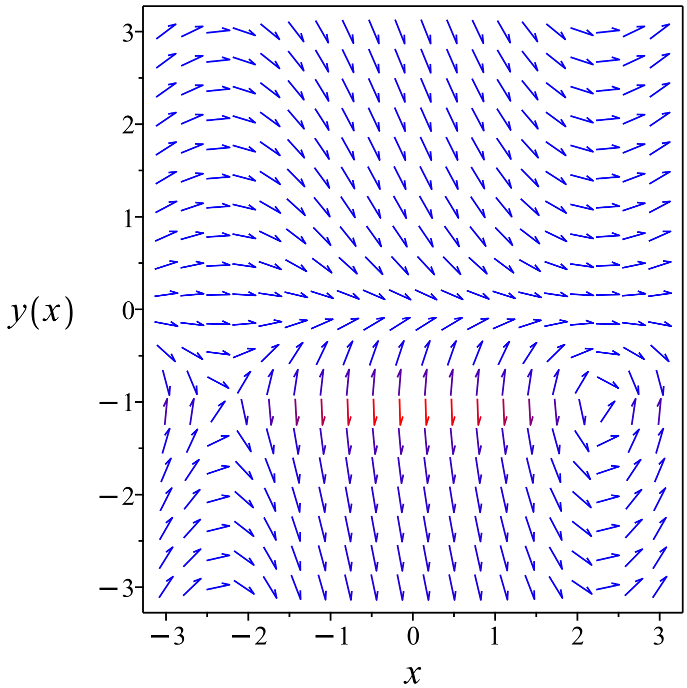

Figure 457: Slope field plot

Verification of solutions

$$y = e^{-\operatorname{LambertW}\left(e^{-\sin(x)-2\operatorname{Si}(x)-c_1}\right)-\sin(x)-2\operatorname{Si}(x)-c_1}$$

Verified OK.

7.22.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(-\frac{y+1}{y}\right)\mathrm{d}y = \left(\frac{x\cos(x) + 2\sin(x)}{x}\right)\mathrm{d}x$$
$$\left(-\frac{x\cos(x) + 2\sin(x)}{x}\right)\mathrm{d}x + \left(-\frac{y+1}{y}\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = -\frac{x\cos(x) + 2\sin(x)}{x}$$
$$N(x, y) = -\frac{y+1}{y}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(-\frac{x\cos(x) + 2\sin(x)}{x}\right) \\ &= 0\end{aligned}$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(-\frac{y+1}{y}\right) \\
&= 0
\end{aligned}
$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M && (1) \\
\frac{\partial \phi}{\partial y} &= N && (2)
\end{aligned}
$$

Integrating (1) w.r.t. x gives

$$
\begin{aligned}
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int M\,\mathrm{d}x \\
\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x &= \int -\frac{x\cos(x)+2\sin(x)}{x}\,\mathrm{d}x \\
\phi &= -\sin(x) - 2\ \mathrm{Si}(x) + f(y) && (3)
\end{aligned}
$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$
\frac{\partial \phi}{\partial y} = 0 + f'(y) \tag{4}
$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = -\frac{y+1}{y}$. Therefore equation (4) becomes

$$
-\frac{y+1}{y} = 0 + f'(y) \tag{5}
$$

Solving equation (5) for $f'(y)$ gives

$$
f'(y) = -\frac{y+1}{y}
$$

Integrating the above w.r.t y gives

$$
\begin{aligned}
\int f'(y)\,\mathrm{d}y &= \int \left(\frac{-y-1}{y}\right)\mathrm{d}y \\
f(y) &= -y - \ln(y) + c_1
\end{aligned}
$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = -\sin(x) - 2\,\mathrm{Si}(x) - y - \ln(y) + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = -\sin(x) - 2\,\mathrm{Si}(x) - y - \ln(y)$$

The solution becomes

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)-c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)-c_1}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)-c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)-c_1} \tag{1}$$

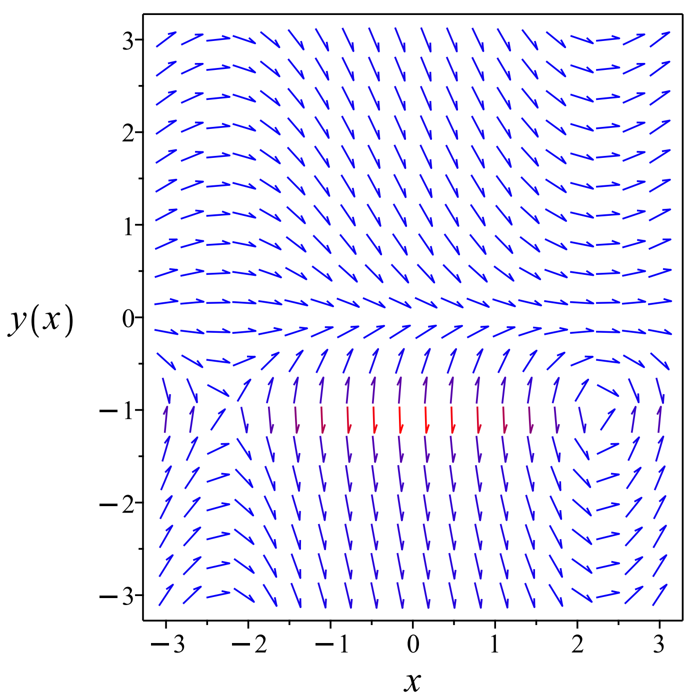

Figure 458: Slope field plot

<u>Verification of solutions</u>

$$y = \mathrm{e}^{-\mathrm{LambertW}\left(\mathrm{e}^{-\sin(x)-2\,\mathrm{Si}(x)-c_1}\right)-\sin(x)-2\,\mathrm{Si}(x)-c_1}$$

Verified OK.

7.22.4 Maple step by step solution

Let's solve

$y(x\cos(x)+2\sin(x))+x(1+y)\,y'=0$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'(1+y)}{y}=-\frac{x\cos(x)+2\sin(x)}{x}$

- Integrate both sides with respect to x

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{y^3x^4 + y + (y^2x^5 - x)\, y' = 0}$$

7.23.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{y(x^4y^2 + 1)}{x\,(x^4y^2 - 1)}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
& b_2 - \frac{y(x^4y^2+1)(b_3-a_2)}{x(x^4y^2-1)} - \frac{y^2(x^4y^2+1)^2 a_3}{x^2(x^4y^2-1)^2} \\
& - \left(-\frac{4y^3x^2}{x^4y^2-1} + \frac{y(x^4y^2+1)}{x^2(x^4y^2-1)} + \frac{4y^3(x^4y^2+1)x^2}{(x^4y^2-1)^2}\right)(xa_2+ya_3+a_1) \\
& - \left(-\frac{x^4y^2+1}{x(x^4y^2-1)} - \frac{2y^2x^3}{x^4y^2-1} + \frac{2y^2(x^4y^2+1)x^3}{(x^4y^2-1)^2}\right)(xb_2+yb_3+b_1) = 0
\end{aligned}
\tag{5E}
$$

Putting the above in normal form gives

$$\frac{2x^{10}y^4b_2 - 2x^8y^6a_3 + x^9y^4b_1 - x^8y^5a_1 - 6x^6y^2b_2 - 8x^5y^3a_2 - 4x^5y^3b_3 - 10x^4y^4a_3 - 4x^5y^2b_1 - 8x^4y^3a_1 -}{(x^4y^2-1)^2 x^2}$$
$$= 0$$

Setting the numerator to zero gives

$$
\begin{aligned}
& 2x^{10}y^4b_2 - 2x^8y^6a_3 + x^9y^4b_1 - x^8y^5a_1 - 6x^6y^2b_2 - 8x^5y^3a_2 \\
& - 4x^5y^3b_3 - 10x^4y^4a_3 - 4x^5y^2b_1 - 8x^4y^3a_1 - xb_1 + ya_1 = 0
\end{aligned}
\tag{6E}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
& -2a_3v_1^8v_2^6 + 2b_2v_1^{10}v_2^4 - a_1v_1^8v_2^5 + b_1v_1^9v_2^4 - 8a_2v_1^5v_2^3 - 10a_3v_1^4v_2^4 \\
& - 6b_2v_1^6v_2^2 - 4b_3v_1^5v_2^3 - 8a_1v_1^4v_2^3 - 4b_1v_1^5v_2^2 + a_1v_2 - b_1v_1 = 0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} 2b_2v_1^{10}v_2^4 + b_1v_1^9v_2^4 - 2a_3v_1^8v_2^6 - a_1v_1^8v_2^5 - 6b_2v_1^6v_2^2 + (-8a_2 - 4b_3)\,v_1^5v_2^3 \\ - 4b_1v_1^5v_2^2 - 10a_3v_1^4v_2^4 - 8a_1v_1^4v_2^3 - b_1v_1 + a_1v_2 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a_1 &= 0 \\ b_1 &= 0 \\ -8a_1 &= 0 \\ -a_1 &= 0 \\ -10a_3 &= 0 \\ -2a_3 &= 0 \\ -4b_1 &= 0 \\ -b_1 &= 0 \\ -6b_2 &= 0 \\ 2b_2 &= 0 \\ -8a_2 - 4b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= a_2 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= -2a_2 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= x \\ \eta &= -2y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= -2y - \left(-\frac{y(x^4y^2+1)}{x\,(x^4y^2-1)}\right)(x) \\
&= \frac{-y^3x^4+3y}{x^4y^2-1} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-y^3x^4+3y}{x^4y^2-1}} dy
\end{aligned}
$$

Which results in

$$
S = -\frac{\ln\left(y(x^4y^2-3)\right)}{3}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{y(x^4y^2+1)}{x\,(x^4y^2-1)}
$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{4x^3y^2}{3x^4y^2 - 9} \\
S_y &= \frac{-x^4y^2 + 1}{y\left(x^4y^2 - 3\right)}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{1}{3x} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{1}{3R}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = -\frac{\ln\left(R\right)}{3} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{\ln\left(y\right)}{3} - \frac{\ln\left(x^4y^2 - 3\right)}{3} = -\frac{\ln\left(x\right)}{3} + c_1$$

Which simplifies to

$$-\frac{\ln\left(y\right)}{3} - \frac{\ln\left(x^4y^2 - 3\right)}{3} = -\frac{\ln\left(x\right)}{3} + c_1$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(x^4y^2+1)}{x(x^4y^2-1)}$ 	$R = x$ $S = -\frac{\ln (y)}{3} - \frac{\ln (x^4 y^2 -}{3}$	$\frac{dS}{dR} = -\frac{1}{3R}$ 
Summary

The solution(s) found are the following

$$-\frac{\ln (y)}{3} - \frac{\ln (x^4 y^2 - 3)}{3} = -\frac{\ln (x)}{3} + c_1 \tag{1}$$

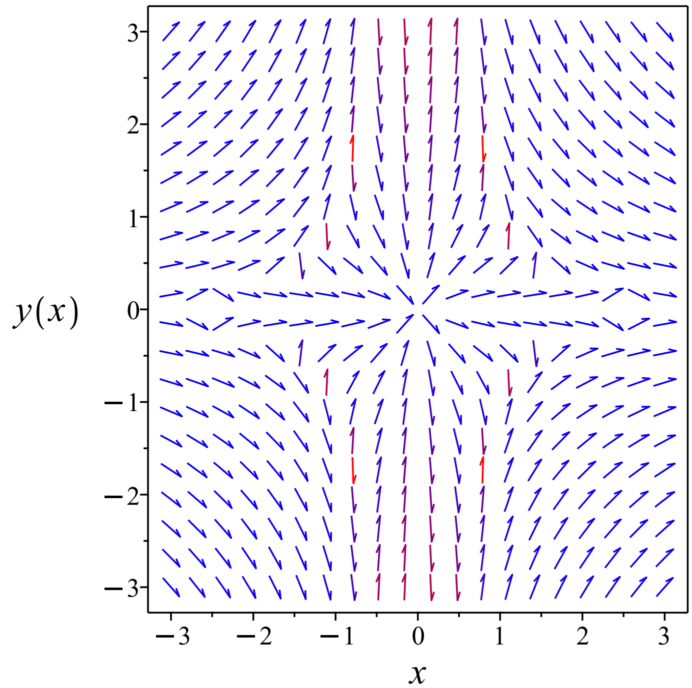

Figure 459: Slope field plot

Verification of solutions

$$-\frac{\ln(y)}{3} - \frac{\ln(x^4y^2-3)}{3} = -\frac{\ln(x)}{3} + c_1$$

Verified OK.

7.23.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \,\mathrm{d}x + N(x, y) \,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(y^2 x^5 - x\right) \mathrm{d}y = \left(-y^3 x^4 - y\right) \mathrm{d}x$$
$$\left(y^3 x^4 + y\right) \mathrm{d}x + \left(y^2 x^5 - x\right) \mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = y^3 x^4 + y$$
$$N(x, y) = y^2 x^5 - x$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(y^3 x^4 + y\right) \\ &= 3x^4 y^2 + 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(y^2 x^5 - x\right) \\ &= 5x^4 y^2 - 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{y^2x^5 - x}\left(\left(3x^4y^2 + 1\right) - \left(5x^4y^2 - 1\right)\right) \\
&= -\frac{2}{x}
\end{aligned}
$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int A \, \mathrm{d}x} \\
&= e^{\int -\frac{2}{x} \, \mathrm{d}x}
\end{aligned}
$$

The result of integrating gives

$$
\begin{aligned}
\mu &= e^{-2\ln(x)} \\
&= \frac{1}{x^2}
\end{aligned}
$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$
\begin{aligned}
\overline{M} &= \mu M \\
&= \frac{1}{x^2}\left(y^3x^4 + y\right) \\
&= \frac{y^3x^4 + y}{x^2}
\end{aligned}
$$

And

$$
\begin{aligned}
\overline{N} &= \mu N \\
&= \frac{1}{x^2}\left(y^2x^5 - x\right) \\
&= \frac{x^4y^2 - 1}{x}
\end{aligned}
$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$
\begin{aligned}
\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\
\left(\frac{y^3x^4 + y}{x^2}\right) + \left(\frac{x^4y^2 - 1}{x}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0
\end{aligned}
$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$
$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \overline{M} \,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \frac{y^3x^4 + y}{x^2} \,\mathrm{d}x$$
$$\phi = \frac{y(x^4y^2 - 3)}{3x} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{x^4y^2 - 3}{3x} + \frac{2x^3y^2}{3} + f'(y) \tag{4}$$
$$= \frac{x^4y^2 - 1}{x} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{x^4y^2-1}{x}$. Therefore equation (4) becomes

$$\frac{x^4y^2 - 1}{x} = \frac{x^4y^2 - 1}{x} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{y(x^4y^2 - 3)}{3x} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{y(x^4y^2 - 3)}{3x}$$

Summary

The solution(s) found are the following

$$\frac{y(x^4y^2 - 3)}{3x} = c_1 \tag{1}$$

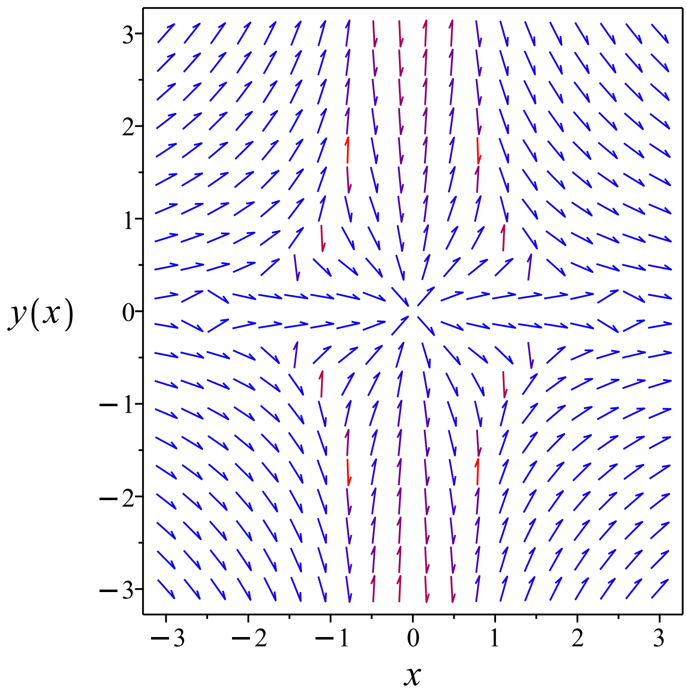

Figure 460: Slope field plot

Verification of solutions

$$\frac{y(x^4y^2 - 3)}{3x} = c_1$$

Verified OK.

Section: Chapter 2, First order equations. Exact equations. Integrating factors. Section 2.6 Page 91
Problem number: 25.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"homogeneousTypeD2", "exactWithIntegrationFactor"**

Maple gives the following as the ode type

```
[[_homogeneous, `class D`], _rational, [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{3yx + 2y^2 + y + (x^2 + 2yx + x + 2y)\, y' = 0}$$

7.24.1 Solving as homogeneousTypeD2 ode

Using the change of variables $y = u(x)\, x$ on the above ode results in new ode in $u(x)$

$$3u(x)\, x^2 + 2u(x)^2\, x^2 + u(x)\, x + (x^2 + 2u(x)\, x^2 + x + 2u(x)\, x)\, (u'(x)\, x + u(x)) = 0$$

In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2u(1+2x)\,(u+1)}{x\,(x+1)\,(2u+1)} \end{aligned}$$

Where $f(x) = -\frac{2(1+2x)}{x(x+1)}$ and $g(u) = \frac{u(u+1)}{2u+1}$. Integrating both sides gives

$$\frac{1}{\frac{u(u+1)}{2u+1}}\, du = -\frac{2(1+2x)}{x\,(x+1)}\, dx$$

$$\int \frac{1}{\frac{u(u+1)}{2u+1}}\, du = \int -\frac{2(1+2x)}{x\,(x+1)}\, dx$$

$$\ln\left(u(u+1)\right) = -2\ln\left(x(x+1)\right) + c_2$$

Raising both side to exponential gives

$$u(u+1) = \mathrm{e}^{-2\ln(x(x+1))+c_2}$$

Which simplifies to

$$u(u+1) = \frac{c_3}{x^2\,(x+1)^2}$$

Which simplifies to

$$u(x)\,(u(x)+1) = \frac{c_3 \mathrm{e}^{c_2}}{x^2\,(x+1)^2}$$

The solution is

$$u(x)\,(u(x)+1) = \frac{c_3 \mathrm{e}^{c_2}}{x^2\,(x+1)^2}$$

Replacing $u(x)$ in the above solution by $\frac{y}{x}$ results in the solution for y in implicit form

$$\frac{y\left(1+\frac{y}{x}\right)}{x} = \frac{c_3 \mathrm{e}^{c_2}}{x^2\,(x+1)^2}$$

$$\frac{y(x+y)}{x^2} = \frac{c_3 \mathrm{e}^{c_2}}{x^2\,(x+1)^2}$$

Which simplifies to

$$y(x+y) = \frac{c_3 \mathrm{e}^{c_2}}{(x+1)^2}$$

Summary

The solution(s) found are the following

$$y(x+y) = \frac{c_3 \mathrm{e}^{c_2}}{(x+1)^2} \tag{1}$$

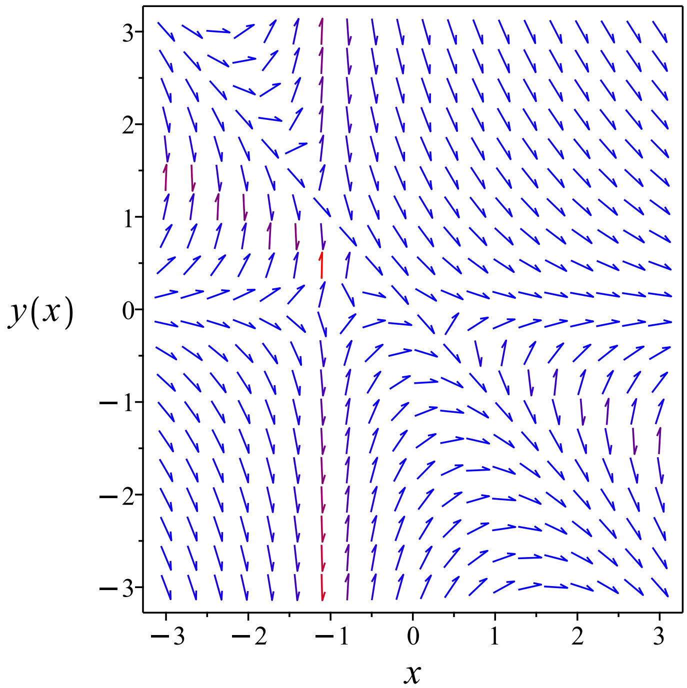

Figure 461: Slope field plot

Verification of solutions

$$y(x+y) = \frac{c_3 e^{c_2}}{(x+1)^2}$$

Verified OK.

7.24.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x} + \frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial \phi}{\partial x} &= M\\ \frac{\partial \phi}{\partial y} &= N\end{aligned}$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned}\left(x^2 + 2yx + x + 2y\right)\mathrm{d}y &= \left(-3yx - 2y^2 - y\right)\mathrm{d}x\\ \left(3yx + 2y^2 + y\right)\mathrm{d}x + \left(x^2 + 2yx + x + 2y\right)\mathrm{d}y &= 0 \qquad (2A)\end{aligned}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x, y) &= 3yx + 2y^2 + y\\ N(x, y) &= x^2 + 2yx + x + 2y\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(3yx + 2y^2 + y\right)\\ &= 3x + 4y + 1\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(x^2 + 2yx + x + 2y\right)\\ &= 2x + 2y + 1\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned} A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\ &= \frac{1}{(x+1)(x+2y)}((3x+4y+1) - (2x+2y+1)) \\ &= \frac{1}{x+1} \end{aligned}$$

Since A does not depend on y, then it can be used to find an integrating factor. The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int A \, \mathrm{d}x} \\ &= e^{\int \frac{1}{x+1} \, \mathrm{d}x} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{\ln(x+1)} \\ &= x+1 \end{aligned}$$

M and N are multiplied by this integrating factor, giving new M and new N which are called $\overline{M}$ and $\overline{N}$ for now so not to confuse them with the original M and N.

$$\begin{aligned} \overline{M} &= \mu M \\ &= x+1\left(3yx + 2y^2 + y\right) \\ &= y(3x+2y+1)(x+1) \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= x+1\left(x^2 + 2yx + x + 2y\right) \\ &= (x+1)^2 (x+2y) \end{aligned}$$

Now a modified ODE is ontained from the original ODE, which is exact and can be solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ (y(3x+2y+1)(x+1)) + \left((x+1)^2 (x+2y)\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int \overline{M} \,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \,\mathrm{d}x = \int y(3x + 2y + 1)\,(x + 1)\,\mathrm{d}x$$

$$\phi = \left(x^2 + (2 + y)\,x + 2y + 1\right) xy + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = (2 + x)\,xy + \left(x^2 + (2 + y)\,x + 2y + 1\right) x + f'(y) \tag{4}$$

$$= \left(x^2 + (2y + 2)\,x + 4y + 1\right) x + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = (x + 1)^2\,(x + 2y)$. Therefore equation (4) becomes

$$(x + 1)^2\,(x + 2y) = \left(x^2 + (2y + 2)\,x + 4y + 1\right) x + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 2y$$

Integrating the above w.r.t y gives

$$\int f'(y) \,\mathrm{d}y = \int (2y) \,\mathrm{d}y$$

$$f(y) = y^2 + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \left(x^2 + (2 + y)\,x + 2y + 1\right) xy + y^2 + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \left(x^2 + (2+y)\,x + 2y + 1\right) xy + y^2$$

<u>Summary</u>
The solution(s) found are the following

$$\left(x^2 + (2+y)\,x + 2y + 1\right) xy + y^2 = c_1 \tag{1}$$

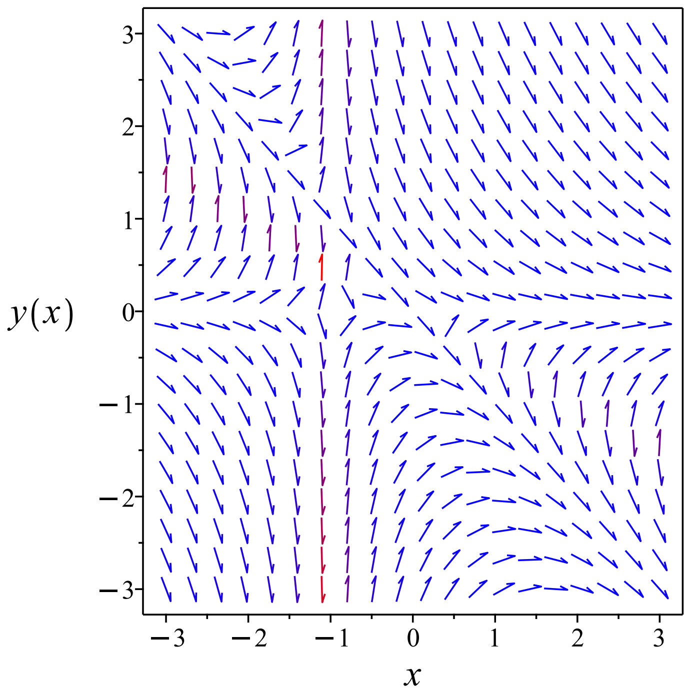

Figure 462: Slope field plot

<u>Verification of solutions</u>

$$\left(x^2 + (2+y)\,x + 2y + 1\right) xy + y^2 = c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational]
```

$$\boxed{12yx + 6y^3 + (9x^2 + 10xy^2)\, y' = 0}$$

7.25.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{6y(y^2 + 2x)}{x\,(10y^2 + 9x)} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$

$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{6y(y^2+2x)(b_3-a_2)}{x(10y^2+9x)} - \frac{36y^2(y^2+2x)^2 a_3}{x^2(10y^2+9x)^2} - \left(-\frac{12y}{(10y^2+9x)x} + \frac{6y(y^2+2x)}{x^2(10y^2+9x)} + \frac{54y(y^2+2x)}{x(10y^2+9x)^2}\right)(xa_2+ya_3+a_1) - \left(-\frac{6(y^2+2x)}{x(10y^2+9x)} - \frac{12y^2}{x(10y^2+9x)} + \frac{120y^2(y^2+2x)}{x(10y^2+9x)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{160x^2y^4b_2 - 96y^6a_3 + 222x^3y^2b_2 + 66x^2y^3a_2 - 132x^2y^3b_3 - 252x\,y^4a_3 + 60x\,y^4b_1 - 60y^5a_1 + 189x^4b_2 - 2}{x^2(10y^2+9x)^2} = 0$$

Setting the numerator to zero gives

$$160x^2y^4b_2 - 96y^6a_3 + 222x^3y^2b_2 + 66x^2y^3a_2 - 132x^2y^3b_3 - 252x\,y^4a_3 + 60x\,y^4b_1 - 60y^5a_1 + 189x^4b_2 - 252x^2y^2a_3 + 42x^2y^2b_1 - 108x\,y^3a_1 + 108x^3b_1 - 108x^2ya_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-96a_3v_2^6 + 160b_2v_1^2v_2^4 - 60a_1v_2^5 + 66a_2v_1^2v_2^3 - 252a_3v_1v_2^4 + 60b_1v_1v_2^4 + 222b_2v_1^3v_2^2 - 132b_3v_1^2v_2^3 - 108a_1v_1v_2^3 - 252a_3v_1^2v_2^2 + 42b_1v_1^2v_2^2 + 189b_2v_1^4 - 108a_1v_1^2v_2 + 108b_1v_1^3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} &189b_2v_1^4 + 222b_2v_1^3v_2^2 + 108b_1v_1^3 + 160b_2v_1^2v_2^4 \\ &+ (66a_2 - 132b_3)\, v_1^2v_2^3 + (-252a_3 + 42b_1)\, v_1^2v_2^2 - 108a_1v_1^2v_2 \\ &+ (-252a_3 + 60b_1)\, v_1v_2^4 - 108a_1v_1v_2^3 - 96a_3v_2^6 - 60a_1v_2^5 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -108a_1 &= 0 \\ -60a_1 &= 0 \\ -96a_3 &= 0 \\ 108b_1 &= 0 \\ 160b_2 &= 0 \\ 189b_2 &= 0 \\ 222b_2 &= 0 \\ 66a_2 - 132b_3 &= 0 \\ -252a_3 + 42b_1 &= 0 \\ -252a_3 + 60b_1 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 2b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 2x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{6y(y^2+2x)}{x\,(10y^2+9x)}\right)(2x) \\
&= \frac{22y^3+33yx}{10y^2+9x} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{22y^3+33yx}{10y^2+9x}} dy
\end{aligned}$$

Which results in

$$S = \frac{3\ln(y)}{11} + \frac{\ln(2y^2+3x)}{11}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{6y(y^2+2x)}{x\,(10y^2+9x)}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{3}{22y^2 + 33x} \\
S_y &= \frac{10y^2 + 9x}{22y^3 + 33yx}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{3}{11x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{3}{11R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\frac{3\ln(R)}{11} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{3\ln(y)}{11} + \frac{\ln(2y^2 + 3x)}{11} = -\frac{3\ln(x)}{11} + c_1
$$

Which simplifies to

$$
\frac{3\ln(y)}{11} + \frac{\ln(2y^2 + 3x)}{11} = -\frac{3\ln(x)}{11} + c_1
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{6y(y^2+2x)}{x(10y^2+9x)}$  	$R = x$ $S = \frac{3\ln(y)}{11} + \frac{\ln(2y^2 + 3}{11}$	$\frac{dS}{dR} = -\frac{3}{11R}$ 
Summary

The solution(s) found are the following

$$\frac{3\ln(y)}{11} + \frac{\ln(2y^2 + 3x)}{11} = -\frac{3\ln(x)}{11} + c_1 \tag{1}$$

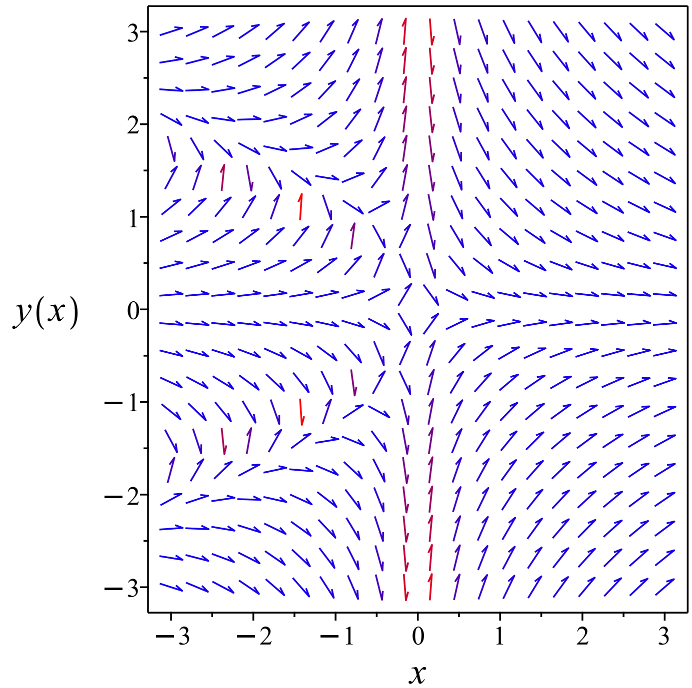

Figure 463: Slope field plot

<u>Verification of solutions</u>

$$\frac{3\ln(y)}{11} + \frac{\ln(2y^2+3x)}{11} = -\frac{3\ln(x)}{11} + c_1$$

Verified OK.

7.25.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial\phi}{\partial x} = M$$
$$\frac{\partial\phi}{\partial y} = N$$

But since $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y} = \frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x + N(x,y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\left(10x\,y^2 + 9x^2\right)\mathrm{d}y = \left(-6y^3 - 12yx\right)\mathrm{d}x$$
$$\left(6y^3 + 12yx\right)\mathrm{d}x + \left(10x\,y^2 + 9x^2\right)\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x,y) = 6y^3 + 12yx$$
$$N(x,y) = 10x\,y^2 + 9x^2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(6y^3 + 12yx\right)\\ &= 18y^2 + 12x\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}\left(10x\,y^2 + 9x^2\right)\\ &= 10y^2 + 18x\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$
\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{10x\,y^2 + 9x^2}\left(\left(18y^2 + 12x\right) - \left(10y^2 + 18x\right)\right) \\
&= \frac{8y^2 - 6x}{10x\,y^2 + 9x^2}
\end{aligned}
$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$
\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= \frac{1}{6y^3 + 12yx}\left(\left(10y^2 + 18x\right) - \left(18y^2 + 12x\right)\right) \\
&= \frac{-4y^2 + 3x}{3y^3 + 6yx}
\end{aligned}
$$

Since B depends on x, it can not be used to obtain an integrating factor.We will now try a third method to find an integrating factor. Let

$$
R = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN}
$$

R is now checked to see if it is a function of only $t = xy$. Therefore

$$
\begin{aligned}
R &= \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN} \\
&= \frac{(10y^2 + 18x) - (18y^2 + 12x)}{x\,(6y^3 + 12yx) - y\,(10x\,y^2 + 9x^2)} \\
&= \frac{2}{yx}
\end{aligned}
$$

Replacing all powers of terms xy by t gives

$$
R = \frac{2}{t}
$$

Since R depends on t only, then it can be used to find an integrating factor. Let the integrating factor be μ then

$$
\begin{aligned}
\mu &= e^{\int R \,\mathrm{d}t} \\
&= e^{\int \left(\frac{2}{t}\right) \mathrm{d}t}
\end{aligned}
$$

The result of integrating gives

$$\mu = e^{2\ln(t)} \\ = t^2$$

Now t is replaced back with xy giving

$$\mu = x^2 y^2$$

Multiplying M and N by this integrating factor gives new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N

$$\begin{aligned} \overline{M} &= \mu M \\ &= x^2 y^2 (6y^3 + 12yx) \\ &= 6x^2 y^5 + 12y^3 x^3 \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= x^2 y^2 (10x\, y^2 + 9x^2) \\ &= x^3 (10y^2 + 9x)\, y^2 \end{aligned}$$

A modified ODE is now obtained from the original ODE, which is exact and can solved. The modified ODE is

$$\begin{aligned} \overline{M} + \overline{N} \frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \\ (6x^2 y^5 + 12y^3 x^3) + (x^3 (10y^2 + 9x)\, y^2) \frac{\mathrm{d}y}{\mathrm{d}x} &= 0 \end{aligned}$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\begin{aligned} \int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int \overline{M} \,\mathrm{d}x \\ \int \frac{\partial \phi}{\partial x} \mathrm{d}x &= \int 6x^2 y^5 + 12y^3 x^3 \,\mathrm{d}x \end{aligned}$$

$$\phi = y^3 x^3 (2y^2 + 3x) + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\begin{aligned}\frac{\partial \phi}{\partial y} &= 3y^2x^3\left(2y^2+3x\right)+4y^4x^3+f'(y) \\ &= x^3\left(10y^2+9x\right)y^2+f'(y)\end{aligned} \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=x^3(10y^2+9x)\,y^2$. Therefore equation (4) becomes

$$x^3\left(10y^2+9x\right)y^2=x^3\left(10y^2+9x\right)y^2+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=0$$

Therefore

$$f(y)=c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi=y^3x^3\left(2y^2+3x\right)+c_1$$

But since ϕ itself is a constant function, then let $\phi=c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1=y^3x^3\left(2y^2+3x\right)$$

Summary

The solution(s) found are the following

$$y^3x^3\left(2y^2+3x\right)=c_1 \tag{1}$$

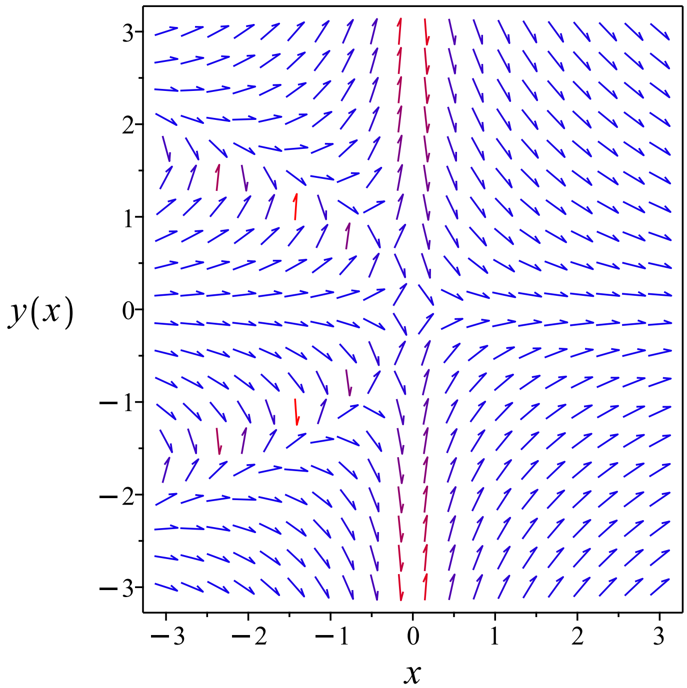

Figure 464: Slope field plot

Verification of solutions

$$y^3x^3(2y^2+3x)=c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati", "bernoulli", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_lookup"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Bernoulli]
```

$$\boxed{3x^2y^2 + 2y + 2y'x = 0}$$

7.26.1 Solving as first order ode lie symmetry lookup ode

Writing the ode as

$$\begin{aligned} y' &= -\frac{y(3y\,x^2 + 2)}{2x} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is known. It is of type `Bernoulli`. Therefore we do not need to solve the PDE (A), and can just use the lookup table shown below to find ξ, η

Table 348: Lie symmetry infinitesimal lookup table for known first order ODE's

ODE class	Form	ξ	η
linear ode	$y' = f(x)y(x) + g(x)$	0	$e^{\int f dx}$
separable ode	$y' = f(x)\, g(y)$	$\frac{1}{f}$	0
quadrature ode	$y' = f(x)$	0	1
quadrature ode	$y' = g(y)$	1	0
homogeneous ODEs of Class A	$y' = f\left(\frac{y}{x}\right)$	x	y
homogeneous ODEs of Class C	$y' = (a + bx + cy)^{\frac{n}{m}}$	1	$-\frac{b}{c}$
homogeneous class D	$y' = \frac{y}{x} + g(x)\, F\left(\frac{y}{x}\right)$	x^2	xy
First order special form ID 1	$y' = g(x)\, e^{h(x)+by} + f(x)$	$\frac{e^{-\int bf(x)dx-h(x)}}{g(x)}$	$\frac{f(x)e^{-\int bf(x)dx-h(x)}}{g(x)}$
polynomial type ode	$y' = \frac{a_1x+b_1y+c_1}{a_2x+b_2y+c_2}$	$\frac{a_1b_2x-a_2b_1x-b_1c_2+b_2c_1}{a_1b_2-a_2b_1}$	$\frac{a_1b_2y-a_2b_1y-a_1c_2-a_2c_1}{a_1b_2-a_2b_1}$
Bernoulli ode	$y' = f(x)\, y + g(x)\, y^n$	0	$e^{-\int(n-1)f(x)dx}y^n$
Reduced Riccati	$y' = f_1(x)\, y + f_2(x)\, y^2$	0	$e^{-\int f_1 dx}$

The above table shows that

$$
\begin{aligned}
\xi(x, y) &= 0 \\
\eta(x, y) &= x\, y^2 \qquad \text{(A1)}
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \qquad (1)
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the

canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{x\, y^2} dy \end{aligned}$$

Which results in

$$S = -\frac{1}{yx}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{y(3y\, x^2 + 2)}{2x}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{1}{x^2 y} \\ S_y &= \frac{1}{x\, y^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = -\frac{3}{2} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = -\frac{3}{2}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = -\frac{3R}{2} + c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$-\frac{1}{yx} = -\frac{3x}{2} + c_1$$

Which simplifies to

$$-\frac{1}{yx} = -\frac{3x}{2} + c_1$$

Which gives

$$y = -\frac{2}{x\left(-3x + 2c_1\right)}$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{y(3y\,x^2+2)}{2x}$ 	$R = x$ $S = -\frac{1}{yx}$	$\frac{dS}{dR} = -\frac{3}{2}$ 
Summary

The solution(s) found are the following

$$y = -\frac{2}{x(-3x + 2c_1)} \tag{1}$$

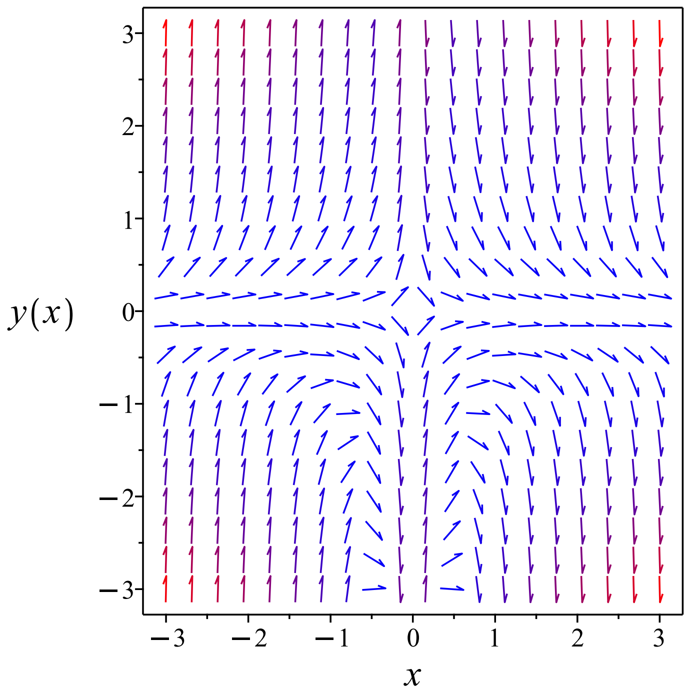

Figure 465: Slope field plot

Verification of solutions

$$y = -\frac{2}{x(-3x + 2c_1)}$$

Verified OK.

7.26.2 Solving as bernoulli ode

In canonical form, the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{y(3y\,x^2 + 2)}{2x} \end{aligned}$$

This is a Bernoulli ODE.

$$y' = -\frac{1}{x}y - \frac{3x}{2}y^2 \tag{1}$$

The standard Bernoulli ODE has the form

$$y' = f_0(x)y + f_1(x)y^n \tag{2}$$

The first step is to divide the above equation by y^n which gives

$$\frac{y'}{y^n} = f_0(x)y^{1-n} + f_1(x) \tag{3}$$

The next step is use the substitution $w = y^{1-n}$ in equation (3) which generates a new ODE in $w(x)$ which will be linear and can be easily solved using an integrating factor. Backsubstitution then gives the solution $y(x)$ which is what we want.

This method is now applied to the ODE at hand. Comparing the ODE (1) With (2) Shows that

$$\begin{aligned} f_0(x) &= -\frac{1}{x} \\ f_1(x) &= -\frac{3x}{2} \\ n &= 2 \end{aligned}$$

Dividing both sides of ODE (1) by $y^n = y^2$ gives

$$y'\frac{1}{y^2} = -\frac{1}{yx} - \frac{3x}{2} \tag{4}$$

Let

$$\begin{aligned} w &= y^{1-n} \\ &= \frac{1}{y} \end{aligned} \tag{5}$$

Taking derivative of equation (5) w.r.t x gives

$$w' = -\frac{1}{y^2}y' \tag{6}$$

Substituting equations (5) and (6) into equation (4) gives

$$\begin{aligned} -w'(x) &= -\frac{w(x)}{x} - \frac{3x}{2} \\ w' &= \frac{w}{x} + \frac{3x}{2} \end{aligned} \tag{7}$$

The above now is a linear ODE in $w(x)$ which is now solved.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$w'(x) + p(x)w(x) = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{3x}{2} \end{aligned}$$

Hence the ode is

$$w'(x) - \frac{w(x)}{x} = \frac{3x}{2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu w) &= (\mu)\left(\frac{3x}{2}\right) \\ \frac{d}{dx}\left(\frac{w}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{3x}{2}\right) \\ d\left(\frac{w}{x}\right) &= \frac{3}{2}\,dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{w}{x} &= \int \frac{3}{2}\,dx \\ \frac{w}{x} &= \frac{3x}{2} + c_1 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$w(x) = \frac{3}{2}x^2 + c_1 x$$

Replacing w in the above by $\frac{1}{y}$ using equation (5) gives the final solution.

$$\frac{1}{y} = \frac{3}{2}x^2 + c_1 x$$

Or

$$y = \frac{1}{\frac{3}{2}x^2 + c_1 x}$$

Which is simplified to

$$y = \frac{2}{x(3x + 2c_1)}$$

Summary

The solution(s) found are the following

$$y = \frac{2}{x(3x + 2c_1)} \tag{1}$$

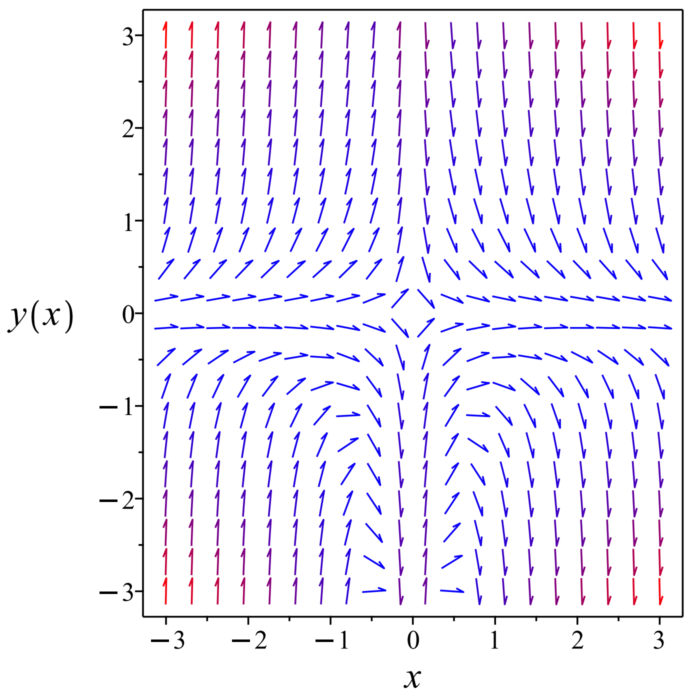

Figure 466: Slope field plot

Verification of solutions

$$y = \frac{2}{x(3x + 2c_1)}$$

Verified OK.

7.26.3 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx}=0 \tag{A}$$

We assume there exists a function $\phi(x,y)=c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y)=0$$

Hence

$$\frac{\partial\phi}{\partial x}+\frac{\partial\phi}{\partial y}\frac{dy}{dx}=0 \tag{B}$$

Comparing (A,B) shows that

$$\begin{aligned}\frac{\partial\phi}{\partial x}&=M\\ \frac{\partial\phi}{\partial y}&=N\end{aligned}$$

But since $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x,y)$ but at least we know now that we can do that since the condition $\frac{\partial^2\phi}{\partial x\partial y}=\frac{\partial^2\phi}{\partial y\partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x,y)\,\mathrm{d}x+N(x,y)\,\mathrm{d}y=0 \tag{1A}$$

Therefore

$$\begin{aligned}(2x)\,\mathrm{d}y&=\left(-3x^2y^2-2y\right)\mathrm{d}x\\ \left(3x^2y^2+2y\right)\mathrm{d}x+(2x)\,\mathrm{d}y&=0 \end{aligned}\tag{2A}$$

Comparing (1A) and (2A) shows that

$$\begin{aligned}M(x,y)&=3x^2y^2+2y\\ N(x,y)&=2x\end{aligned}$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(3x^2y^2 + 2y\right)\\ &= 6y\,x^2 + 2\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(2x)\\ &= 2\end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right)\\ &= \frac{1}{2x}\left(\left(6y\,x^2 + 2\right) - (2)\right)\\ &= 3yx\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right)\\ &= \frac{1}{3x^2y^2 + 2y}\left((2) - \left(6y\,x^2 + 2\right)\right)\\ &= -\frac{6x^2}{3y\,x^2 + 2}\end{aligned}$$

Since B depends on x, it can not be used to obtain an integrating factor.We will now try a third method to find an integrating factor. Let

$$R = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN}$$

R is now checked to see if it is a function of only $t = xy$. Therefore

$$\begin{aligned} R &= \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN} \\ &= \frac{(2) - (6y\,x^2 + 2)}{x\,(3x^2y^2 + 2y) - y\,(2x)} \\ &= -\frac{2}{yx} \end{aligned}$$

Replacing all powers of terms xy by t gives

$$R = -\frac{2}{t}$$

Since R depends on t only, then it can be used to find an integrating factor. Let the integrating factor be μ then

$$\begin{aligned} \mu &= e^{\int R \, \mathrm{d}t} \\ &= e^{\int \left(-\frac{2}{t}\right) \mathrm{d}t} \end{aligned}$$

The result of integrating gives

$$\begin{aligned} \mu &= e^{-2\ln(t)} \\ &= \frac{1}{t^2} \end{aligned}$$

Now t is replaced back with xy giving

$$\mu = \frac{1}{x^2y^2}$$

Multiplying M and N by this integrating factor gives new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N

$$\begin{aligned} \overline{M} &= \mu M \\ &= \frac{1}{x^2y^2}\left(3x^2y^2 + 2y\right) \\ &= \frac{3y\,x^2 + 2}{x^2y} \end{aligned}$$

And

$$\begin{aligned} \overline{N} &= \mu N \\ &= \frac{1}{x^2y^2}(2x) \\ &= \frac{2}{x\,y^2} \end{aligned}$$

A modified ODE is now obtained from the original ODE, which is exact and can solved. The modified ODE is

$$\overline{M} + \overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

$$\left(\frac{3y\,x^2+2}{x^2y}\right) + \left(\frac{2}{x\,y^2}\right)\frac{\mathrm{d}y}{\mathrm{d}x} = 0$$

The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial \phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \overline{M}\,\mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x = \int \frac{3y\,x^2+2}{x^2y}\,\mathrm{d}x$$

$$\phi = \frac{3y\,x^2-2}{yx} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = \frac{3x}{y} - \frac{3y\,x^2-2}{y^2x} + f'(y) \tag{4}$$

$$= \frac{2}{x\,y^2} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{2}{x\,y^2}$. Therefore equation (4) becomes

$$\frac{2}{x\,y^2} = \frac{2}{x\,y^2} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{3y\,x^2 - 2}{yx} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{3y\,x^2 - 2}{yx}$$

The solution becomes

$$y = -\frac{2}{(-3x + c_1)\,x}$$

Summary
The solution(s) found are the following

$$y = -\frac{2}{(-3x + c_1)\,x} \tag{1}$$

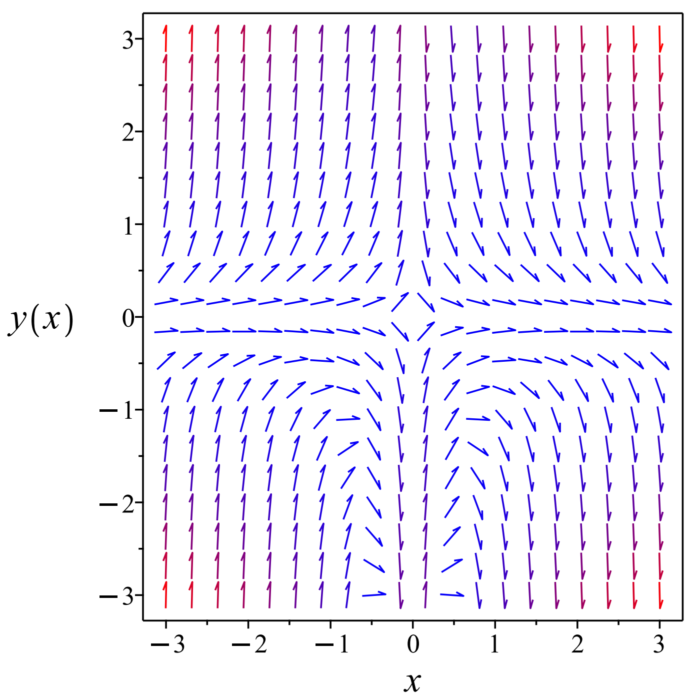

Figure 467: Slope field plot

Verification of solutions

$$y = -\frac{2}{(-3x + c_1)\, x}$$

Verified OK.

7.26.4 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -\frac{y(3y\, x^2 + 2)}{2x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{3x\, y^2}{2} - \frac{y}{x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = 0$, $f_1(x) = -\frac{1}{x}$ and $f_2(x) = -\frac{3x}{2}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-\frac{3xu}{2}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{3}{2} \\ f_1 f_2 &= \frac{3}{2} \\ f_2^2 f_0 &= 0 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-\frac{3xu''(x)}{2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1x + c_2$$

The above shows that

$$u'(x) = c_1$$

Using the above in (1) gives the solution

$$y = \frac{2c_1}{3x\,(c_1x + c_2)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{2c_3}{3x\,(c_3x + 1)}$$

Summary

The solution(s) found are the following

$$y = \frac{2c_3}{3x\,(c_3x + 1)} \tag{1}$$

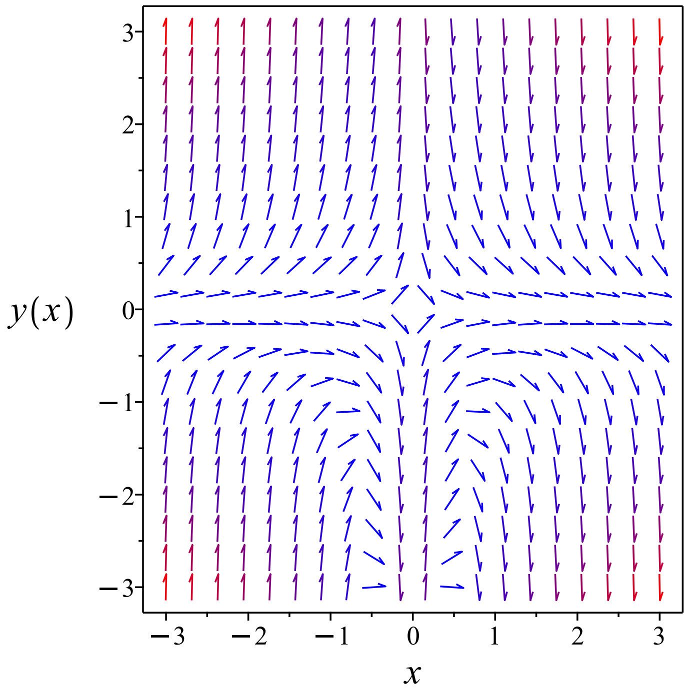

Figure 468: Slope field plot

Verification of solutions

$$y = \frac{2c_3}{3x(c_3x + 1)}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 7y' + 10y = 0}$$

With initial conditions

$$[y(0) = -1, y'(0) = 1]$$

8.1.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -7 \\ q(x) &= 10 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 7y' + 10y = 0$$

The domain of $p(x) = -7$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 10$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

8.1.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -7, C = 10$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 7\lambda\, \mathrm{e}^{\lambda x} + 10\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 7\lambda + 10 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -7, C = 10$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{7}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-7^2 - (4)\,(1)\,(10)}\\ &= \frac{7}{2} \pm \frac{3}{2}\end{aligned}$$

Hence

$$\lambda_1 = \frac{7}{2} + \frac{3}{2}$$

$$\lambda_2 = \frac{7}{2} - \frac{3}{2}$$

Which simplifies to

$$\lambda_1 = 5$$
$$\lambda_2 = 2$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(5)x} + c_2 e^{(2)x}$$

Or

$$y = c_1 \mathrm{e}^{5x} + c_2 \mathrm{e}^{2x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{5x} + c_2 \mathrm{e}^{2x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$-1 = c_1 + c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 5c_1 \mathrm{e}^{5x} + 2c_2 \mathrm{e}^{2x}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = 5c_1 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 1$$
$$c_2 = -2$$

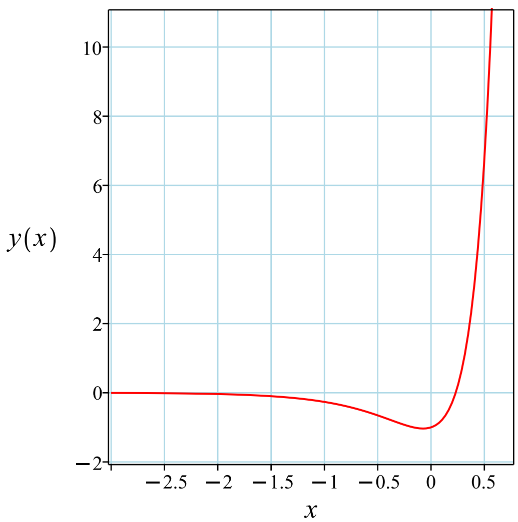
Substituting these values back in above solution results in

$$y = \mathrm{e}^{5x} - 2\,\mathrm{e}^{2x}$$

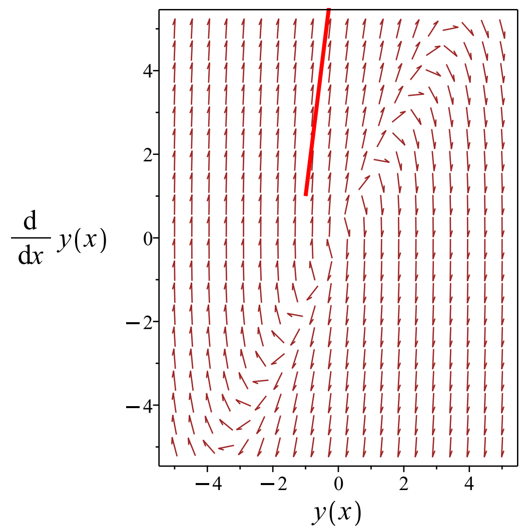
Summary

The solution(s) found are the following

$$y = e^{5x} - 2\,e^{2x} \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{5x} - 2\,e^{2x}$$

Verified OK.

8.1.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 7y' + 10y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -7 \\ C &= 10 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{9}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 9$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{9z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 350: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{9}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{3x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-7}{1}\,dx}\\ &= z_1 e^{\frac{7x}{2}}\\ &= z_1\left(\mathrm{e}^{\frac{7x}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-7}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{7x}}{(y_1)^2}\,dx\\ &= y_1\left(\frac{\mathrm{e}^{3x}}{3}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2x}\right) + c_2 \left(\mathrm{e}^{2x} \left(\frac{\mathrm{e}^{3x}}{3}\right)\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{2x} + \frac{c_2 \mathrm{e}^{5x}}{3} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -1$ and $x = 0$ in the above gives

$$
-1 = c_1 + \frac{c_2}{3} \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2c_1 \mathrm{e}^{2x} + \frac{5c_2 \mathrm{e}^{5x}}{3}
$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$
1 = 2c_1 + \frac{5c_2}{3} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -2 \\
c_2 &= 3
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \mathrm{e}^{5x} - 2\,\mathrm{e}^{2x}
$$

Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{5x} - 2\,\mathrm{e}^{2x} \tag{1}
$$

8.1.4 Maple step by step solution

Let's solve

$\left[y'' - 7y' + 10y = 0, y(0) = -1, y'\Big|_{\{x=0\}} = 1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 7r + 10 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-5) = 0$

- Roots of the characteristic polynomial

  $r = (2, 5)$

- 1st solution of the ODE

$y_1(x) = e^{2x}$

- 2nd solution of the ODE

  $y_2(x) = e^{5x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{2x} + c_2 e^{5x}$

- □ Check validity of solution $y = c_1 e^{2x} + c_2 e^{5x}$
  - Use initial condition $y(0) = -1$

    $-1 = c_1 + c_2$

  - Compute derivative of the solution

    $y' = 2c_1 e^{2x} + 5c_2 e^{5x}$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 1$

    $1 = 2c_1 + 5c_2$

  - Solve for c_1 and c_2

    $\{c_1 = -2, c_2 = 1\}$

  - Substitute constant values into general solution and simplify

    $y = e^{5x} - 2e^{2x}$

- Solution to the IVP

  $y = e^{5x} - 2e^{2x}$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.1 Homogeneous linear equations. Page 203
Problem number: 2c.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_x]]`

$$\boxed{y'' - 2y' + 2y = 0}$$

With initial conditions

$$[y(0) = 3, y'(0) = -2]$$

8.2.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 2y' + 2y = 0$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

8.2.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(2)}\\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i\\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\lambda_1 = 1 + i$$
$$\lambda_2 = 1 - i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x}(-\sin(x) c_1 + c_2 \cos(x))$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 3$$
$$c_2 = -5$$

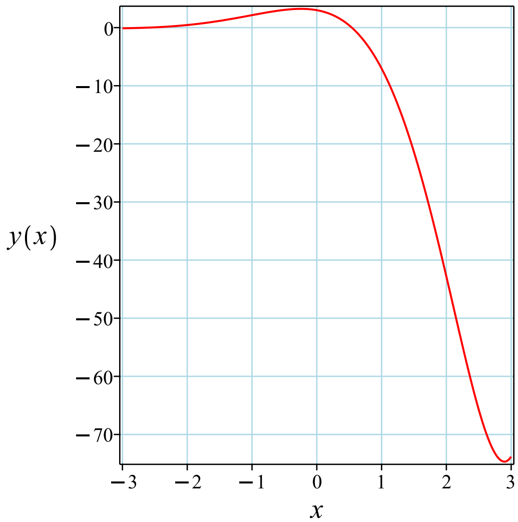
Substituting these values back in above solution results in

$$y = e^{x}(3 \cos(x) - 5 \sin(x))$$

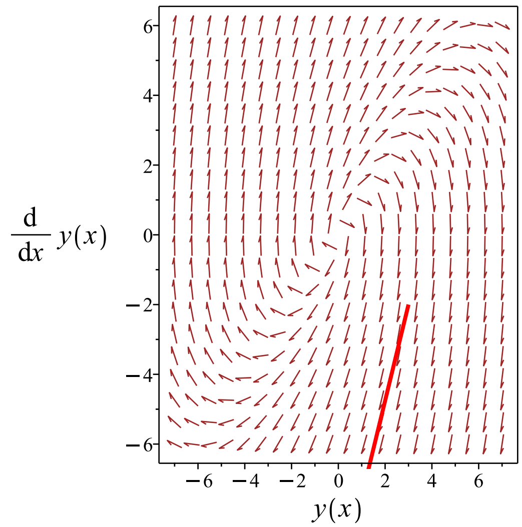
Summary

The solution(s) found are the following

$$y = e^{x}(3\cos(x) - 5\sin(x)) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{x}(3\cos(x) - 5\sin(x))$$

Verified OK.

8.2.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 352: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x})\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)\,\mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx \\ &= y_1(\tan(x))\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos (x) \mathrm{e}^x) + c_2(\cos (x) \mathrm{e}^x (\tan (x)))
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \cos (x) \mathrm{e}^x + c_2 \sin (x) \mathrm{e}^x \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$
3 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = -c_1 \sin (x) \mathrm{e}^x + c_1 \cos (x) \mathrm{e}^x + c_2 \cos (x) \mathrm{e}^x + c_2 \sin (x) \mathrm{e}^x
$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$
-2 = c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 3 \\
c_2 &= -5
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = 3 \cos (x) \mathrm{e}^x - 5 \sin (x) \mathrm{e}^x
$$

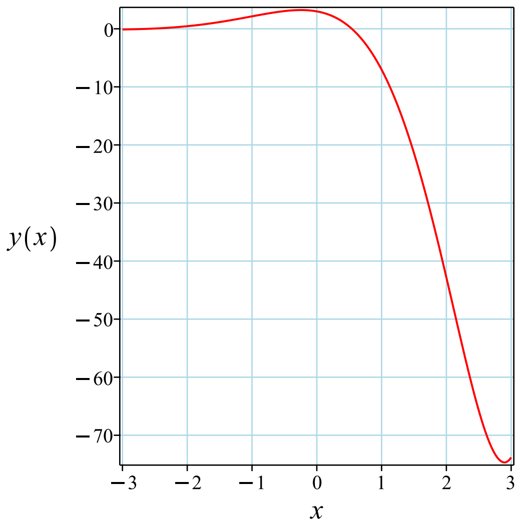
Which simplifies to

$$
y = \mathrm{e}^x (3 \cos (x) - 5 \sin (x))
$$

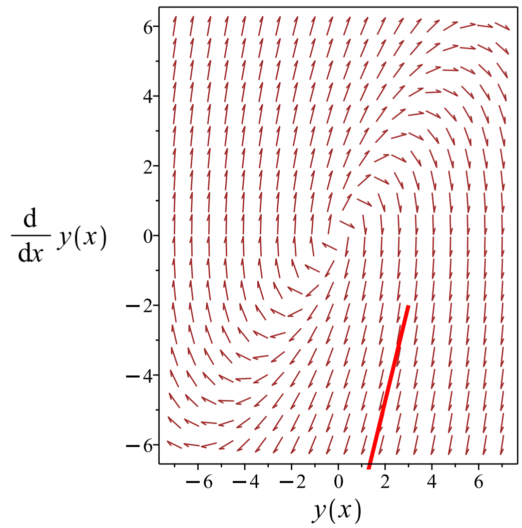
Summary

The solution(s) found are the following

$$
y = \mathrm{e}^x (3 \cos (x) - 5 \sin (x)) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

<u>Verification of solutions</u>

$$y = e^x(3\cos(x) - 5\sin(x))$$

Verified OK.

8.2.4 Maple step by step solution

Let's solve

$$\left[y'' - 2y' + 2y = 0, y(0) = 3, y'\Big|_{\{x=0\}} = -2\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (1 - I, 1 + I)$

- 1st solution of the ODE

$y_1(x) = \cos(x)\, e^x$

- 2nd solution of the ODE

  $y_2(x) = \sin(x)\, e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \cos(x)\, e^x + c_2 \sin(x)\, e^x$

□ Check validity of solution $y = c_1 \cos(x)\, e^x + c_2 \sin(x)\, e^x$

  - Use initial condition $y(0) = 3$

    $3 = c_1$

  - Compute derivative of the solution

    $y' = -c_1 \sin(x)\, e^x + c_1 \cos(x)\, e^x + c_2 \cos(x)\, e^x + c_2 \sin(x)\, e^x$

  - Use the initial condition $y'\Big|_{\{x=0\}} = -2$

    $-2 = c_1 + c_2$

  - Solve for c_1 and c_2

    $\{c_1 = 3, c_2 = -5\}$

  - Substitute constant values into general solution and simplify

    $y = e^x(3\cos(x) - 5\sin(x))$

- Solution to the IVP

  $y = e^x(3\cos(x) - 5\sin(x))$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2y' + 2y = 0}$$

With initial conditions

$$[y(0) = k_0, y'(0) = k_1]$$

8.3.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 2 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 2y' + 2y = 0$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

8.3.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(2)} \\ &= 1 \pm i\end{aligned}$$

Hence

$$\lambda_1 = 1 + i$$
$$\lambda_2 = 1 - i$$

Which simplifies to

$$\lambda_1 = 1 + i$$
$$\lambda_2 = 1 - i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x))$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = k_0$ and $x = 0$ in the above gives

$$k_0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x}(-\sin(x) c_1 + c_2 \cos(x))$$

substituting $y' = k_1$ and $x = 0$ in the above gives

$$k_1 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = k_0$$
$$c_2 = k_1 - k_0$$

Substituting these values back in above solution results in

$$y = e^{x}(k_0 \cos(x) - \sin(x) k_0 + \sin(x) k_1)$$

Which simplifies to

$$y = ((k_1 - k_0)\sin(x) + k_0\cos(x))\,\mathrm{e}^{x}$$

Summary
The solution(s) found are the following

$$y = ((k_1 - k_0)\sin(x) + k_0\cos(x))\,\mathrm{e}^{x} \tag{1}$$

Verification of solutions

$$y = ((k_1 - k_0)\sin(x) + k_0\cos(x))\,\mathrm{e}^{x}$$

Verified OK.

8.3.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -1$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 354: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\, dx} \\ &= z_1 e^{x} \\ &= z_1(\mathrm{e}^{x}) \end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)\,\mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)\,\mathrm{e}^{x}) + c_2(\cos(x)\,\mathrm{e}^{x}(\tan(x))) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \cos(x)\,\mathrm{e}^{x} + c_2 \sin(x)\,\mathrm{e}^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = k_0$ and $x = 0$ in the above gives

$$k_0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -c_1 \sin(x) e^x + c_1 \cos(x) e^x + c_2 \cos(x) e^x + c_2 \sin(x) e^x$$

substituting $y' = k_1$ and $x = 0$ in the above gives

$$k_1 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= k_0 \\ c_2 &= k_1 - k_0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = k_0 \cos(x) e^x - \sin(x) e^x k_0 + \sin(x) e^x k_1$$

Which simplifies to

$$y = ((k_1 - k_0) \sin(x) + k_0 \cos(x)) e^x$$

Summary

The solution(s) found are the following

$$y = ((k_1 - k_0) \sin(x) + k_0 \cos(x)) e^x \tag{1}$$

Verification of solutions

$$y = ((k_1 - k_0) \sin(x) + k_0 \cos(x)) e^x$$

Verified OK.

8.3.4 Maple step by step solution

Let's solve

$$\left[y'' - 2y' + 2y = 0, y(0) = k_0, y'\Big|_{\{x=0\}} = k_1\right]$$

- Highest derivative means the order of the ODE is 2

y''

- Characteristic polynomial of ODE

  $r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

  $r = (1 - \mathrm{I}, 1 + \mathrm{I})$

- 1st solution of the ODE

  $y_1(x) = \cos(x)\,\mathrm{e}^x$

- 2nd solution of the ODE

  $y_2(x) = \sin(x)\,\mathrm{e}^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \cos(x)\,\mathrm{e}^x + c_2 \sin(x)\,\mathrm{e}^x$

☐ Check validity of solution $y = c_1 \cos(x)\,\mathrm{e}^x + c_2 \sin(x)\,\mathrm{e}^x$

  - Use initial condition $y(0) = k_0$

    $k_0 = c_1$

  - Compute derivative of the solution

    $y' = -c_1 \sin(x)\,\mathrm{e}^x + c_1 \cos(x)\,\mathrm{e}^x + c_2 \cos(x)\,\mathrm{e}^x + c_2 \sin(x)\,\mathrm{e}^x$

  - Use the initial condition $y'\Big|_{\{x=0\}} = k_1$

    $k_1 = c_1 + c_2$

  - Solve for c_1 and c_2

    $\{c_1 = k_0, c_2 = k_1 - k_0\}$

  - Substitute constant values into general solution and simplify

    $y = ((k_1 - k_0)\sin(x) + k_0 \cos(x))\,\mathrm{e}^x$

- Solution to the IVP

  $y = ((k_1 - k_0)\sin(x) + k_0 \cos(x))\,\mathrm{e}^x$

8.4.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 1 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 2y' + y = 0$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

8.4.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda\, e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)} \\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x\, e^x \tag{1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 e^x + c_2 x\, e^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 7$ and $x = 0$ in the above gives

$$7 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^x + c_2 e^x + c_2 x\, e^x$$

substituting $y' = 4$ and $x = 0$ in the above gives

$$4 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}c_1 &= 7 \\ c_2 &= -3\end{aligned}$$

Substituting these values back in above solution results in

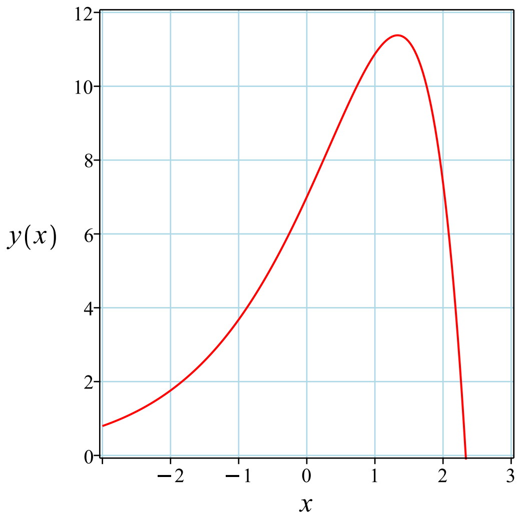
$$y = -3x\, e^x + 7\, e^x$$

Which simplifies to

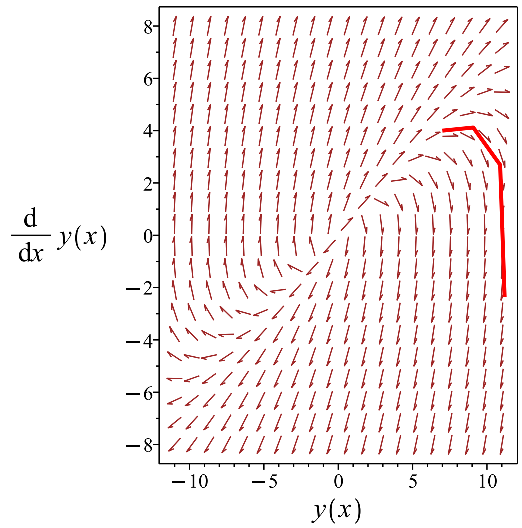
$$y = e^x(7 - 3x)$$

Summary
The solution(s) found are the following

$$y = e^x(7 - 3x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^x(7 - 3x)$$

Verified OK.

8.4.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2\, dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 0$$

$$\left(e^{-x}y\right)'' = 0$$

Integrating once gives

$$\left(e^{-x}y\right)' = c_1$$

Integrating again gives

$$\left(e^{-x}y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{e^{-x}}$$

Or

$$y = c_1x\,e^{x} + c_2e^{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1x\,e^{x} + c_2e^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 7$ and $x = 0$ in the above gives

$$7 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1e^{x} + c_1x\,e^{x} + c_2e^{x}$$

substituting $y' = 4$ and $x = 0$ in the above gives

$$4 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -3 \\ c_2 &= 7 \end{aligned}$$

Substituting these values back in above solution results in

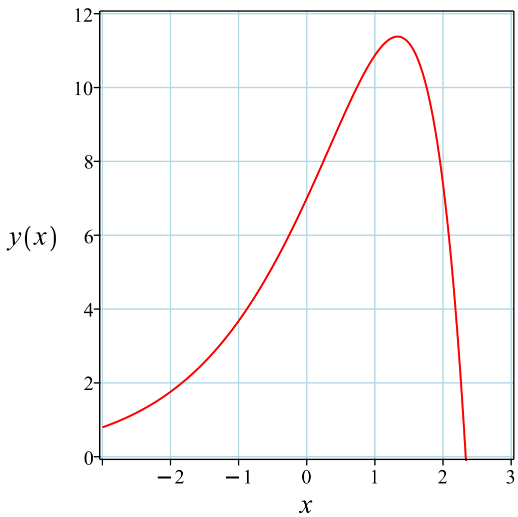
$$y = -3x\,e^{x} + 7\,e^{x}$$

Which simplifies to

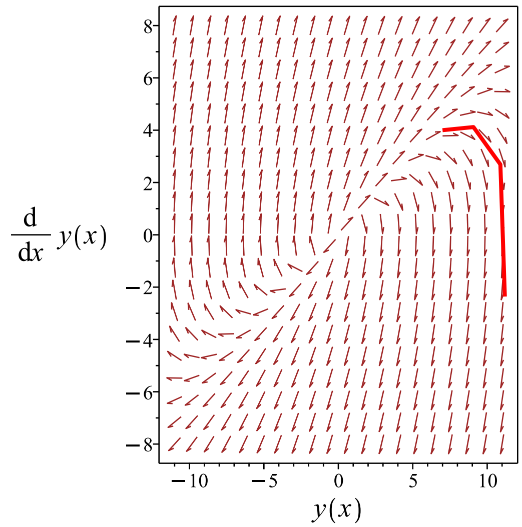
$$y = e^{x}(7 - 3x)$$

Summary
The solution(s) found are the following

$$y = e^{x}(7 - 3x) \tag{1}$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{x}(7 - 3x)$$

Verified OK.

8.4.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 356: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - -\infty\\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}\\ &= z_1 e^{x}\\ &= z_1(\mathrm{e}^{x})\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx\\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^x + c_2 x\,\mathrm{e}^x \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 7$ and $x = 0$ in the above gives

$$
7 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = c_1 \mathrm{e}^x + c_2 \mathrm{e}^x + c_2 x\,\mathrm{e}^x
$$

substituting $y' = 4$ and $x = 0$ in the above gives

$$
4 = c_1 + c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 7 \\
c_2 &= -3
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = -3x\,\mathrm{e}^x + 7\,\mathrm{e}^x
$$

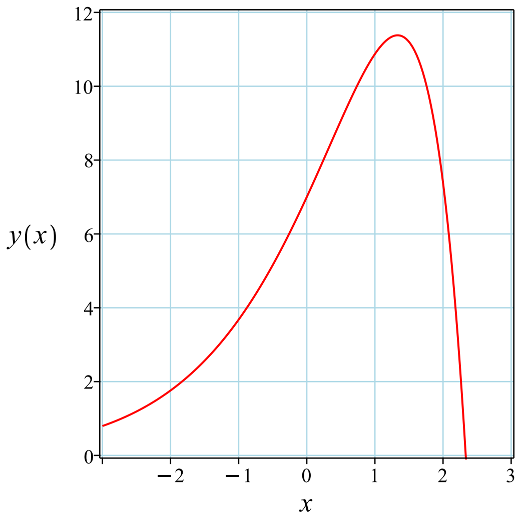
Which simplifies to

$$
y = \mathrm{e}^x(7 - 3x)
$$

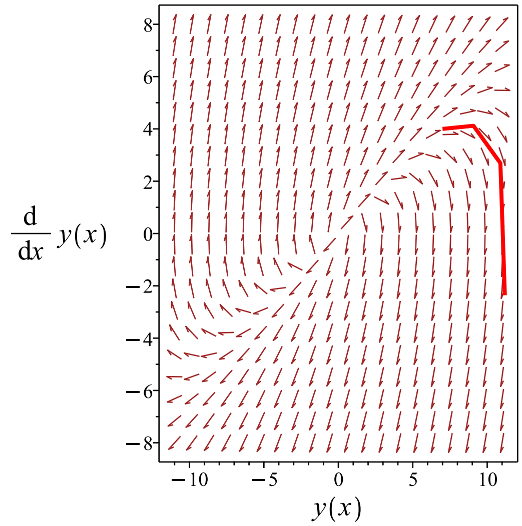
Summary

The solution(s) found are the following

$$
y = \mathrm{e}^x(7 - 3x) \tag{1}
$$



(a) Solution plot



(b) Slope field plot

Verification of solutions

$$y = e^{x}(7 - 3x)$$

Verified OK.

8.4.5 Maple step by step solution

Let's solve

$$\left[y'' - 2y' + y = 0, y(0) = 7, y'\Big|_{\{x=0\}} = 4\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)^2 = 0$

- Root of the characteristic polynomial

  $r = 1$

- 1st solution of the ODE

$y_1(x) = e^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\, e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^x + c_2 x\, e^x$

- ☐ Check validity of solution $y = c_1 e^x + c_2 x e^x$
  - Use initial condition $y(0) = 7$

    $7 = c_1$

  - Compute derivative of the solution

    $y' = c_1 e^x + c_2 e^x + c_2 x\, e^x$

  - Use the initial condition $y'\Big|_{\{x=0\}} = 4$

    $4 = c_1 + c_2$

  - Solve for c_1 and c_2

    $\{c_1 = 7, c_2 = -3\}$

  - Substitute constant values into general solution and simplify

    $y = e^x(7 - 3x)$

- Solution to the IVP

  $y = e^x(7 - 3x)$

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2y' + y = 0}$$

With initial conditions

$$[y(0) = k_0, y'(0) = k_1]$$

8.5.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -2 \\ q(x) &= 1 \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' - 2y' + y = 0$$

The domain of $p(x) = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

8.5.2 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\, \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\lambda_{1,2} = \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)}$$
$$= 1$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 \mathrm{e}^x + c_2 x\,\mathrm{e}^x \tag{1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^x + c_2 x\,\mathrm{e}^x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = k_0$ and $x = 0$ in the above gives

$$k_0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \mathrm{e}^x + c_2 \mathrm{e}^x + c_2 x\,\mathrm{e}^x$$

substituting $y' = k_1$ and $x = 0$ in the above gives

$$k_1 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = k_0$$
$$c_2 = k_1 - k_0$$

Substituting these values back in above solution results in

$$y = -x\,\mathrm{e}^x k_0 + x\,\mathrm{e}^x k_1 + k_0 \mathrm{e}^x$$

Which simplifies to

$$y = \mathrm{e}^x(-k_0 x + k_1 x + k_0)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^x(-k_0 x + k_1 x + k_0) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^x(-k_0 x + k_1 x + k_0)$$

Verified OK.

8.5.3 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -2\, dx} \\ &= \mathrm{e}^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ \left(\mathrm{e}^{-x} y\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-x} y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-x} y\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\mathrm{e}^{-x}}$$

Or

$$y = c_1 x\, \mathrm{e}^{x} + c_2 \mathrm{e}^{x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x\, \mathrm{e}^{x} + c_2 \mathrm{e}^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = k_0$ and $x = 0$ in the above gives

$$k_0 = c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^x + c_1 x\, e^x + c_2 e^x$$

substituting $y' = k_1$ and $x = 0$ in the above gives

$$k_1 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= k_1 - k_0 \\ c_2 &= k_0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = -x\, e^x k_0 + x\, e^x k_1 + k_0 e^x$$

Which simplifies to

$$y = e^x(-k_0 x + k_1 x + k_0)$$

Summary
The solution(s) found are the following

$$y = e^x(-k_0 x + k_1 x + k_0) \tag{1}$$

Verification of solutions

$$y = e^x(-k_0 x + k_1 x + k_0)$$

Verified OK.

8.5.4 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 358: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1 (\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\mathrm{e}^{x}) + c_2(\mathrm{e}^{x}(x)) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 \mathrm{e}^{x} + c_2 x\, \mathrm{e}^{x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = k_0$ and $x = 0$ in the above gives

$$k_0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{x} + c_2 x\, \mathrm{e}^{x}$$

substituting $y' = k_1$ and $x = 0$ in the above gives

$$k_1 = c_1 + c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= k_0 \\
c_2 &= k_1 - k_0
\end{aligned}
$$

Substituting these values back in above solution results in

$$y = -x\,\mathrm{e}^x k_0 + x\,\mathrm{e}^x k_1 + k_0 \mathrm{e}^x$$

Which simplifies to

$$y = \mathrm{e}^x(-k_0 x + k_1 x + k_0)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^x(-k_0 x + k_1 x + k_0) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^x(-k_0 x + k_1 x + k_0)$$

Verified OK.

8.5.5 Maple step by step solution

Let's solve

$\left[y'' - 2y' + y = 0, y(0) = k_0, y'\Big|_{\{x=0\}} = k_1\right]$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.1 Homogeneous linear equations. Page 203
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_y_method_1", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x^2-1)\,y''+4y'x+2y=0}$$

With initial conditions

$$[y(0)=-5, y'(0)=1]$$

8.6.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{4x}{x^2-1} \\ q(x) &= \frac{2}{x^2-1} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + \frac{4xy'}{x^2-1} + \frac{2y}{x^2-1} = 0$$

The domain of $p(x) = \frac{4x}{x^2-1}$ is

$$\{-\infty \le x < -1, -1 < x < 1, 1 < x \le \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{2}{x^2-1}$ is

$$\{-\infty \le x < -1, -1 < x < 1, 1 < x \le \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

8.6.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = \frac{4x}{x^2-1}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int \frac{4x}{x^2-1}\,dx} \\ &= x^2-1 \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 0$$
$$\left(\left(x^2-1\right)y\right)'' = 0$$

Integrating once gives

$$\left(\left(x^2-1\right)y\right)' = c_1$$

Integrating again gives

$$\left(\left(x^2-1\right)y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{x^2-1}$$

Or

$$y = \frac{c_1x}{x^2-1} + \frac{c_2}{x^2-1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1x}{x^2-1} + \frac{c_2}{x^2-1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -5$ and $x = 0$ in the above gives

$$-5 = -c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{2c_1x^2}{\left(x^2-1\right)^2} + \frac{c_1}{x^2-1} - \frac{2c_2x}{\left(x^2-1\right)^2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = -\frac{x-5}{x^2-1}$$

Summary

The solution(s) found are the following

$$y = -\frac{x-5}{x^2-1} \tag{1}$$

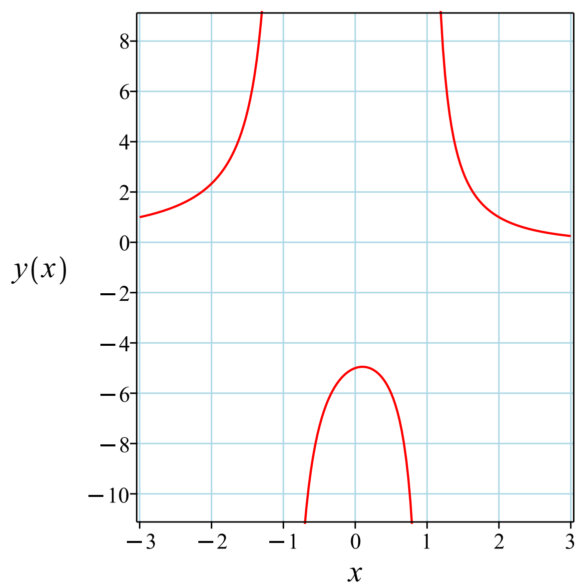

Figure 476: Solution plot

Verification of solutions

$$y = -\frac{x-5}{x^2-1}$$

Verified OK.

8.6.3 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{4x}{x^2-1}$$
$$q(x) = \frac{2}{x^2-1}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{2}{x^2-1} - \frac{\left(\frac{4x}{x^2-1}\right)'}{2} - \frac{\left(\frac{4x}{x^2-1}\right)^2}{4} \\
&= \frac{2}{x^2-1} - \frac{\left(\frac{4}{x^2-1} - \frac{8x^2}{(x^2-1)^2}\right)}{2} - \frac{\left(\frac{16x^2}{(x^2-1)^2}\right)}{4} \\
&= \frac{2}{x^2-1} - \left(\frac{2}{x^2-1} - \frac{4x^2}{(x^2-1)^2}\right) - \frac{4x^2}{(x^2-1)^2} \\
&= 0
\end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{4x}{x^2-1}}{2}} \\
&= \frac{1}{x^2-1}
\end{aligned} \tag{5}$$

Hence (3) becomes

$$y = \frac{v(x)}{x^2-1} \tag{4}$$

Applying this change of variable to the original ode results in

$$v''(x) = 0$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$v(x) = c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned}
y &= v(x)\, z(x) \\
&= (c_1 x + c_2)\,(z(x))
\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{1}{x^2 - 1}$$

Hence (7) becomes

$$y = \frac{c_1 x + c_2}{x^2 - 1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 x + c_2}{x^2 - 1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -5$ and $x = 0$ in the above gives

$$-5 = -c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1}{x^2 - 1} - \frac{2(c_1 x + c_2) x}{(x^2 - 1)^2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = -\frac{x - 5}{x^2 - 1}$$

Summary

The solution(s) found are the following

$$y = -\frac{x - 5}{x^2 - 1} \tag{1}$$

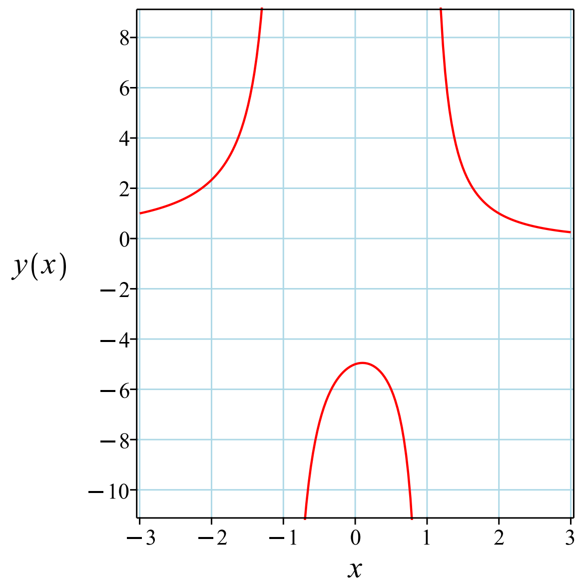

Figure 477: Solution plot

Verification of solutions

$$y = -\frac{x-5}{x^2-1}$$

Verified OK.

8.6.4 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(\left(x^2-1\right) y'' + 4y'x + 2y\right) dx = 0$$
$$2yx + \left(x^2-1\right) y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2x}{x^2-1}$$
$$q(x) = \frac{c_1}{x^2-1}$$

Hence the ode is

$$y' + \frac{2xy}{x^2 - 1} = \frac{c_1}{x^2 - 1}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2x}{x^2-1}dx} \\ &= e^{\ln(x-1)+\ln(x+1)}\end{aligned}$$

Which simplifies to

$$\mu = x^2 - 1$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2-1}\right) \\ \frac{d}{dx}\left(\left(x^2-1\right)y\right) &= \left(x^2-1\right)\left(\frac{c_1}{x^2-1}\right) \\ d\left(\left(x^2-1\right)y\right) &= c_1\, dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\left(x^2-1\right)y &= \int c_1\, dx \\ \left(x^2-1\right)y &= c_1 x + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2 - 1$ results in

$$y = \frac{c_1 x}{x^2-1} + \frac{c_2}{x^2-1}$$

which simplifies to

$$y = \frac{c_1 x + c_2}{x^2 - 1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 x + c_2}{x^2 - 1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -5$ and $x = 0$ in the above gives

$$-5 = -c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1}{x^2-1} - \frac{2(c_1x+c_2)\,x}{(x^2-1)^2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = -\frac{x-5}{x^2-1}$$

Summary

The solution(s) found are the following

$$y = -\frac{x-5}{x^2-1} \tag{1}$$

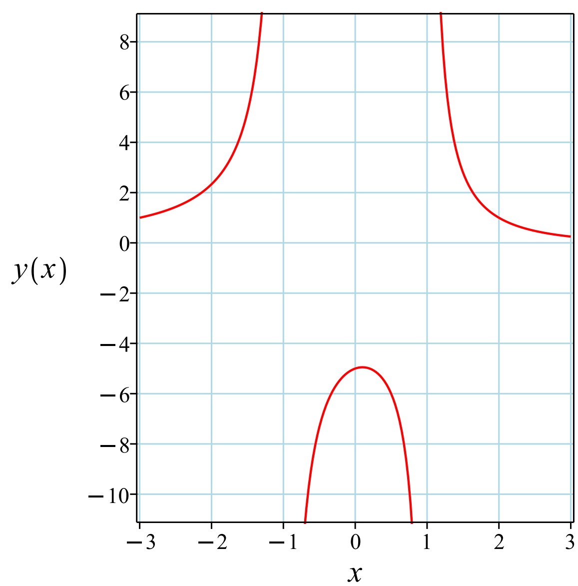

Figure 478: Solution plot

Verification of solutions

$$y = -\frac{x-5}{x^2-1}$$

Verified OK.

8.6.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x^2-1)\,y''+4y'x+2y=0$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}\int \left((x^2-1)\,y''+4y'x+2y\right)dx &= 0\\ 2yx+(x^2-1)\,y' &= c_1\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x) &= \frac{2x}{x^2-1}\\ q(x) &= \frac{c_1}{x^2-1}\end{aligned}$$

Hence the ode is

$$y'+\frac{2xy}{x^2-1}=\frac{c_1}{x^2-1}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int \frac{2x}{x^2-1}dx}\\ &= \mathrm{e}^{\ln(x-1)+\ln(x+1)}\end{aligned}$$

Which simplifies to

$$\mu=x^2-1$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x^2-1}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left((x^2-1)\,y\right) &= (x^2-1)\left(\frac{c_1}{x^2-1}\right)\\ \mathrm{d}\left((x^2-1)\,y\right) &= c_1\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\left(x^2-1\right)y = \int c_1\,\mathrm{d}x$$
$$\left(x^2-1\right)y = c_1x + c_2$$

Dividing both sides by the integrating factor $\mu = x^2 - 1$ results in

$$y = \frac{c_1x}{x^2-1} + \frac{c_2}{x^2-1}$$

which simplifies to

$$y = \frac{c_1x + c_2}{x^2-1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1x + c_2}{x^2-1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -5$ and $x = 0$ in the above gives

$$-5 = -c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1}{x^2-1} - \frac{2(c_1x + c_2)\,x}{\left(x^2-1\right)^2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = -\frac{x-5}{x^2-1}$$

Summary
The solution(s) found are the following

$$y = -\frac{x-5}{x^2-1} \tag{1}$$

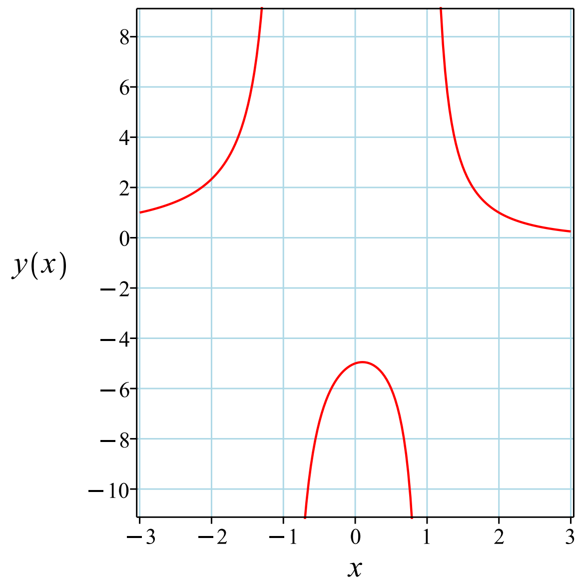

Figure 479: Solution plot

Verification of solutions

$$y = -\frac{x-5}{x^2-1}$$

Verified OK.

8.6.6 Solving using Kovacic algorithm

Writing the ode as

$$(x^2-1)\, y'' + 4y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 - 1 \\ B &= 4x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 360: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{x^2-1}\,dx} \\ &= z_1 e^{-\ln(x-1)-\ln(x+1)} \\ &= z_1\left(\frac{1}{x^2-1}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^2 - 1}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{x^2-1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-2\ln(x-1)-2\ln(x+1)}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^2 - 1}\right) + c_2 \left(\frac{1}{x^2 - 1}(x)\right)
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{x^2 - 1} + \frac{c_2 x}{x^2 - 1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -5$ and $x = 0$ in the above gives

$$-5 = -c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{2c_1 x}{(x^2 - 1)^2} + \frac{c_2}{x^2 - 1} - \frac{2c_2 x^2}{(x^2 - 1)^2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 5$$
$$c_2 = -1$$

Substituting these values back in above solution results in

$$y = -\frac{x-5}{x^2-1}$$

Summary
The solution(s) found are the following

$$y = -\frac{x-5}{x^2-1} \tag{1}$$

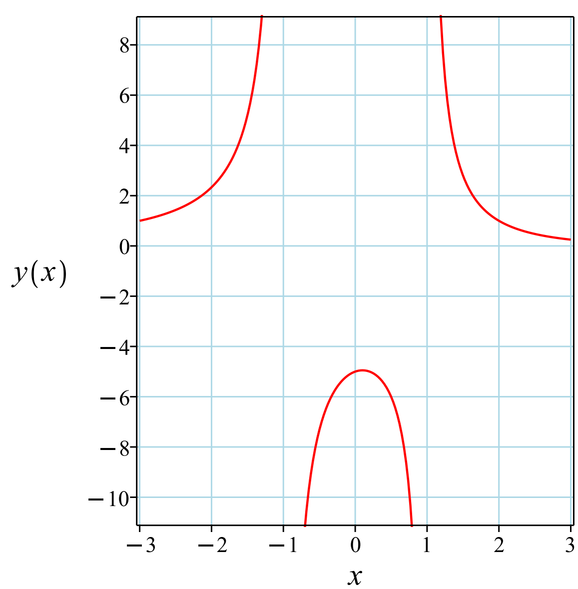

Figure 480: Solution plot

Verification of solutions

$$y = -\frac{x-5}{x^2-1}$$

Verified OK.

8.6.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x) &= x^2 - 1\\ q(x) &= 4x\\ r(x) &= 2\\ s(x) &= 0\end{aligned}$$

Hence

$$\begin{aligned}p''(x) &= 2\\ q'(x) &= 4\end{aligned}$$

Therefore (1) becomes

$$2 - (4) + (2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$2yx + \left(x^2 - 1\right) y' = c_1$$

We now have a first order ode to solve which is

$$2yx + \left(x^2 - 1\right) y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2x}{x^2-1}$$
$$q(x) = \frac{c_1}{x^2-1}$$

Hence the ode is

$$y' + \frac{2xy}{x^2-1} = \frac{c_1}{x^2-1}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int \frac{2x}{x^2-1}dx}$$
$$= \mathrm{e}^{\ln(x-1)+\ln(x+1)}$$

Which simplifies to

$$\mu = x^2 - 1$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{c_1}{x^2-1}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\left(x^2-1\right)y\right) = \left(x^2-1\right)\left(\frac{c_1}{x^2-1}\right)$$
$$\mathrm{d}\left(\left(x^2-1\right)y\right) = c_1\,\mathrm{d}x$$

Integrating gives

$$\left(x^2-1\right)y = \int c_1\,\mathrm{d}x$$
$$\left(x^2-1\right)y = c_1x + c_2$$

Dividing both sides by the integrating factor $\mu = x^2 - 1$ results in

$$y = \frac{c_1x}{x^2-1} + \frac{c_2}{x^2-1}$$

which simplifies to

$$y = \frac{c_1x + c_2}{x^2-1}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 x + c_2}{x^2 - 1} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = -5$ and $x = 0$ in the above gives

$$-5 = -c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1}{x^2 - 1} - \frac{2(c_1 x + c_2)\, x}{(x^2 - 1)^2}$$

substituting $y' = 1$ and $x = 0$ in the above gives

$$1 = -c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = 5$$

Substituting these values back in above solution results in

$$y = -\frac{x - 5}{x^2 - 1}$$

<u>Summary</u>

The solution(s) found are the following

$$y = -\frac{x - 5}{x^2 - 1} \tag{1}$$

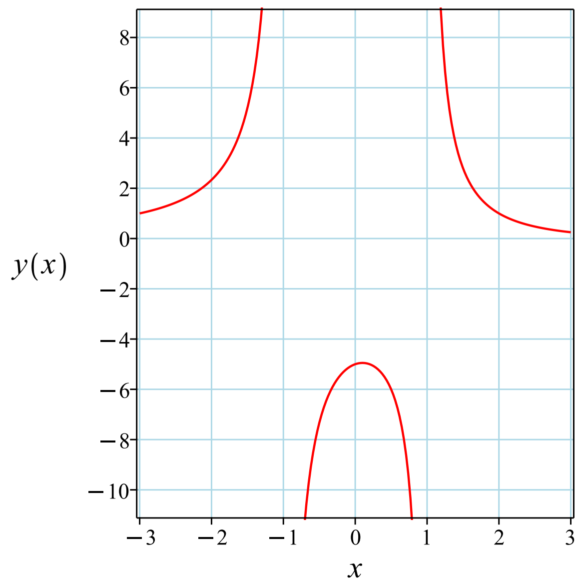

Figure 481: Solution plot

Verification of solutions

$$y = -\frac{x-5}{x^2-1}$$

Verified OK.

8.6.8 Maple step by step solution

Let's solve

$\left[(x^2-1)\,y''+4y'x+2y=0, y(0)=-5, y'\Big|_{\{x=0\}}=1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{4xy'}{x^2-1}-\frac{2y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{4xy'}{x^2-1}+\frac{2y}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

$\left[P_2(x) = \frac{4x}{x^2-1}, P_3(x) = \frac{2}{x^2-1}\right]$

- $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

  $$\left((x+1) \cdot P_2(x)\right)\Big|_{x=-1} = 2$$

- $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $$\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $$(x^2-1)\, y'' + 4y'x + 2y = 0$$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (4u-4)\left(\frac{d}{du}y(u)\right) + 2y(u) = 0$$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

$$-2a_0r(1+r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+r+1)\,(k+r+2)+a_k(k+r+2)\,(k+r+1)\right)u^{k+r}\right)=$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(1+r)=0$
- Values of r that satisfy the indicial equation

  $r\in\{-1,0\}$
- Each term in the series must be 0, giving the recursion relation

  $(k+r+2)\,(k+r+1)\,(-2a_{k+1}+a_k)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k}{2}$
- Recursion relation for $r=-1$

  $a_{k+1}=\frac{a_k}{2}$
- Solution for $r=-1$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k-1}, a_{k+1}=\frac{a_k}{2}\right]$
- Revert the change of variables $u=x+1$

  $\left[y=\sum_{k=0}^{\infty}a_k(x+1)^{k-1}, a_{k+1}=\frac{a_k}{2}\right]$
- Recursion relation for $r=0$

  $a_{k+1}=\frac{a_k}{2}$
- Solution for $r=0$

  $\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k}, a_{k+1}=\frac{a_k}{2}\right]$
- Revert the change of variables $u=x+1$

  $\left[y=\sum_{k=0}^{\infty}a_k(x+1)^{k}, a_{k+1}=\frac{a_k}{2}\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty}a_k(x+1)^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_k(x+1)^{k}\right), a_{1+k}=\frac{a_k}{2}, b_{1+k}=\frac{b_k}{2}\right]$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.1 Homogeneous linear equations. Page 203
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2y' - 3y = 0}$$

8.7.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = -3$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda\,\mathrm{e}^{\lambda x} - 3\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda - 3 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = -3$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{-2^2 - (4)(1)(-3)} \\ &= 1 \pm 2\end{aligned}$$

Hence

$$\lambda_1 = 1 + 2$$
$$\lambda_2 = 1 - 2$$

Which simplifies to

$$\lambda_1 = 3$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(3)x} + c_2 e^{(-1)x}$$

Or

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{-x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{3x} + c_2 \mathrm{e}^{-x} \tag{1}$$

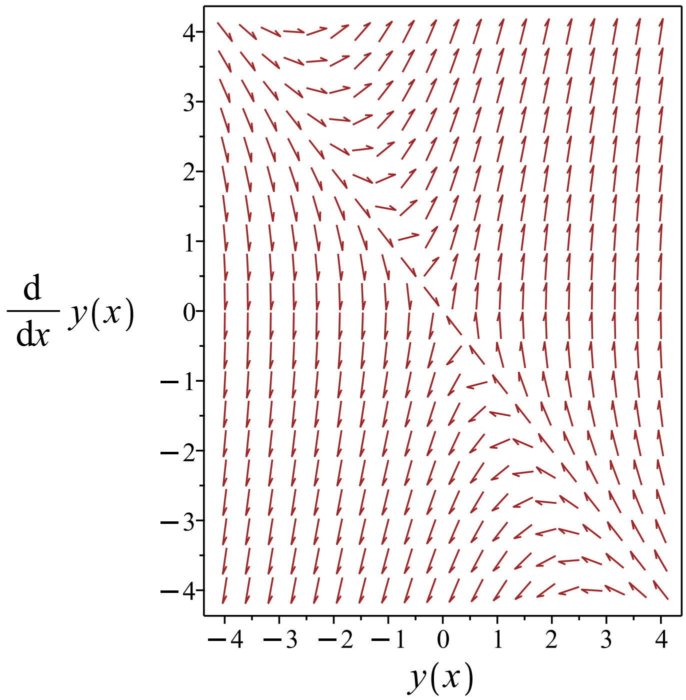

Figure 482: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 e^{-x}$$

Verified OK.

8.7.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 362: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - 0\\ &= 0\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}\\ &= z_1 e^{x}\\ &= z_1(\mathrm{e}^{x})\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx\\ &= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{3x}}{4} \tag{1}
$$

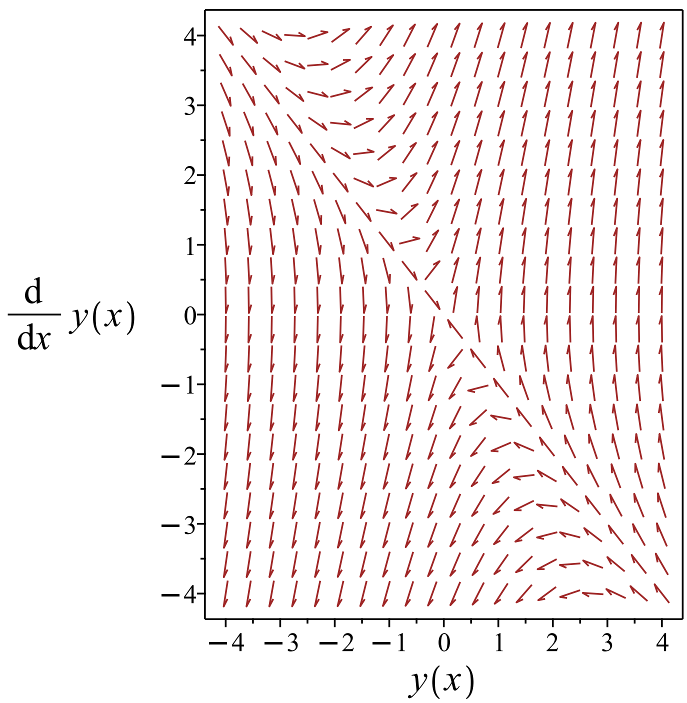

Figure 483: Slope field plot

Verification of solutions

$$
y = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{3x}}{4}
$$

Verified OK.

8.7.3 Maple step by step solution

Let's solve

$y'' - 2y' - 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 - 2r - 3 = 0$

- Factor the characteristic polynomial

  $(r+1)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 3)$

- 1st solution of the ODE

  $y_1(x) = e^{-x}$

- 2nd solution of the ODE

  $y_2(x) = e^{3x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{-x} + c_2 e^{3x}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 6y' + 9y = 0}$$

8.8.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -6, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 6\lambda\, e^{\lambda x} + 9\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 6\lambda + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -6, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{6}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-6)^2 - (4)(1)(9)} \\ &= 3\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -3$. Therefore the solution is

$$y = c_1 e^{3x} + c_2 x e^{3x} \tag{1}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{3x} + c_2 x e^{3x} \tag{1}$$

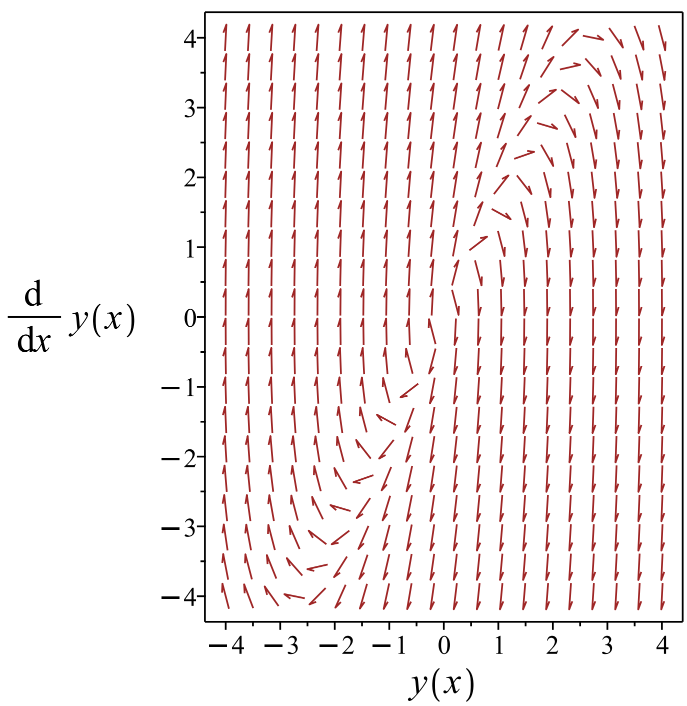

Figure 484: Slope field plot

Verification of solutions

$$y = c_1 e^{3x} + c_2 x e^{3x}$$

Verified OK.

8.8.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -6$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\, dx} \\ &= e^{\int -6\, dx} \\ &= \mathrm{e}^{-3x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= 0 \\ \left(\mathrm{e}^{-3x} y\right)'' &= 0 \end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-3x} y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-3x} y\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\mathrm{e}^{-3x}}$$

Or

$$y = c_1 x\, \mathrm{e}^{3x} + c_2 \mathrm{e}^{3x}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 x\, \mathrm{e}^{3x} + c_2 \mathrm{e}^{3x} \tag{1}$$

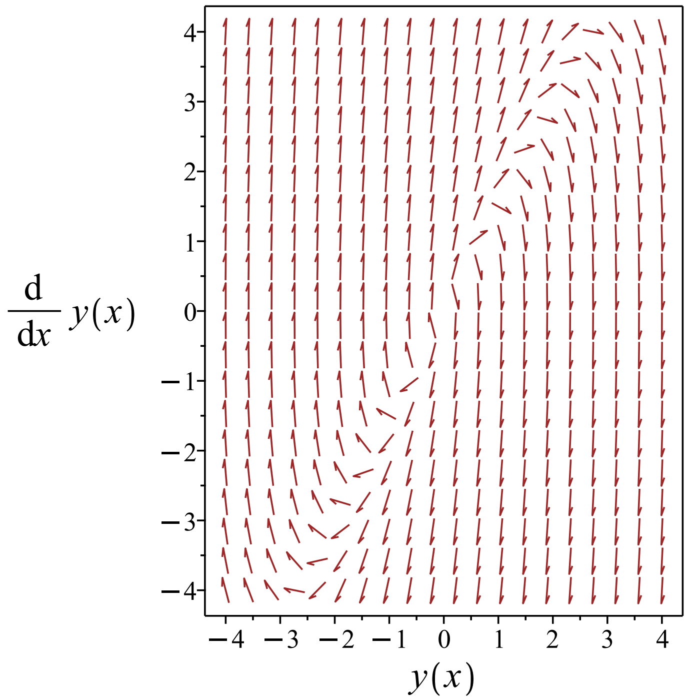

Figure 485: Slope field plot

Verification of solutions

$$y = c_1 x\, e^{3x} + c_2 e^{3x}$$

Verified OK.

8.8.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 6y' + 9y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -6 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 364: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-6}{1}\,dx} \\
&= z_1 e^{3x} \\
&= z_1 \left(\mathrm{e}^{3x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{3x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-6}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{6x}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{3x}\right) + c_2\left(e^{3x}(x)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{3x} + c_2 x\, e^{3x} \tag{1}
$$

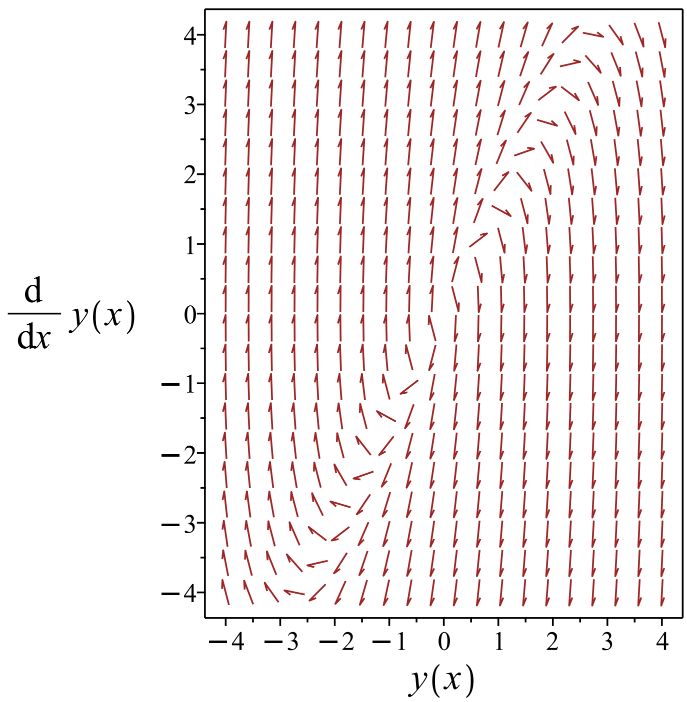

Figure 486: Slope field plot

Verification of solutions

$$
y = c_1 e^{3x} + c_2 x\, e^{3x}
$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' - 2ay' + a^2y = 0}$$

8.9.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2a, C = a^2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2a\lambda e^{\lambda x} + a^2 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$a^2 - 2a\lambda + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2a, C = a^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2a}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2a)^2 - (4)(1)(a^2)}\\ &= a\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -a$. Therefore the solution is

$$y = c_1 e^{ax} + c_2 x\, e^{ax} \tag{1}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{ax} + c_2 x\, e^{ax} \tag{1}$$

Verification of solutions

$$y = c_1 e^{ax} + c_2 x\, e^{ax}$$

Verified OK.

8.9.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{(p(x)^2 + p'(x))\, y}{2} = f(x)$$

Where $p(x) = -2a$. Therefore, there is an integrating factor given by

$$\begin{aligned}M(x) &= e^{\frac{1}{2}\int p\,dx}\\ &= e^{\int -2a\,dx}\\ &= e^{-ax}\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}(M(x)y)'' &= 0\\ (e^{-ax}y)'' &= 0\end{aligned}$$

Integrating once gives

$$\left(\mathrm{e}^{-ax}y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{-ax}y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{\mathrm{e}^{-ax}}$$

Or

$$y = c_1x\,\mathrm{e}^{ax} + c_2\mathrm{e}^{ax}$$

Summary

The solution(s) found are the following

$$y = c_1x\,\mathrm{e}^{ax} + c_2\mathrm{e}^{ax} \tag{1}$$

Verification of solutions

$$y = c_1x\,\mathrm{e}^{ax} + c_2\mathrm{e}^{ax}$$

Verified OK.

8.9.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2ay' + a^2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2a \\ C &= a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \qquad (5)$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \qquad (6)$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \qquad (7)$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 366: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2a}{1}\, dx} \\
&= z_1 e^{ax} \\
&= z_1(\mathrm{e}^{ax})
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{ax}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2a}{1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2ax}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (\mathrm{e}^{ax}) + c_2 (\mathrm{e}^{ax}(x))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{ax} + c_2 x\,\mathrm{e}^{ax} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{ax} + c_2 x\,\mathrm{e}^{ax}$$

Verified OK.

8.9.4 Maple step by step solution

Let's solve

$y'' - 2ay' + a^2 y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $a^2 - 2ar + r^2 = 0$

- Factor the characteristic polynomial

  $(a - r)^2 = 0$

- Root of the characteristic polynomial

  $r = a$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{ax}$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^{ax}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

$$y = c_1 e^{ax} + c_2 x \, e^{ax}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{x^2 y'' + y' x - y = 0}$$

8.10.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} - x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r - x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r - 1 = 0$$

Or

$$r^2 - 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -1 \\ r_2 &= 1 \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2 x$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + c_2 x \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + c_2 x$$

Verified OK.

8.10.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' + y'x - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{x} \\ q(x) &= -\frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\ &= \int e^{-\ln(x)}\,dx \\ &= \int \frac{1}{x}dx \\ &= \ln(x) \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{x^2}}{\frac{1}{x^2}} \\ &= -1 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - y(\tau) &= 0 \end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau} - \mathrm{e}^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1 \end{aligned}$$

Hence

$$\begin{aligned} \lambda_1 &= +1 \\ \lambda_2 &= -1 \end{aligned}$$

Which simplifies to

$$\lambda_1 = 1$$
$$\lambda_2 = -1$$

Since roots are real and distinct, then the solution is

$$y(\tau) = c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau}$$
$$y(\tau) = c_1 e^{(1)\tau} + c_2 e^{(-1)\tau}$$

Or

$$y(\tau) = c_1 \mathrm{e}^{\tau} + c_2 \mathrm{e}^{-\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 x^2 + c_2}{x}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 x^2 + c_2}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^2 + c_2}{x}$$

Verified OK.

8.10.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2 y'' + y'x - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = -\frac{1}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{-\frac{1}{x^2}}}{c} \\ \tau'' &= \frac{1}{c\sqrt{-\frac{1}{x^2}}\,x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{\frac{1}{c\sqrt{-\frac{1}{x^2}}\,x^3} + \frac{1}{x}\frac{\sqrt{-\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{-\frac{1}{x^2}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{-\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{-\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x} \tag{1}
$$

Verification of solutions

$$
y = \frac{(ic_2 + c_1)\, x^2 - ic_2 + c_1}{2x}
$$

Verified OK.

8.10.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$
x^2y'' + y'x - y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= -\frac{1}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n}{x^2} - \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{3}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= \mathrm{e}^{-3\ln(x) + c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x \\
&= \left(-\frac{c_1}{2x^2} + c_2\right) x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(-\frac{c_1}{2x^2} + c_2\right) x \tag{1}
$$

Verification of solutions

$$
y = \left(-\frac{c_1}{2x^2} + c_2\right) x
$$

Verified OK.

8.10.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\begin{aligned}
\int (x^2y'' + y'x - y)\,dx &= 0 \\
y'x^2 - yx &= c_1
\end{aligned}
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y' + p(x)y = q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{c_1}{x^2}
\end{aligned}
$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1}{x^2}\right) \\
\mathrm{d}\left(\frac{y}{x}\right) &= \left(\frac{c_1}{x^3}\right)\,\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{y}{x} &= \int \frac{c_1}{x^3}\,\mathrm{d}x \\
\frac{y}{x} &= -\frac{c_1}{2x^2} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -\frac{c_1}{2x} + c_2 x$$

Summary

The solution(s) found are the following

$$y = -\frac{c_1}{2x} + c_2 x \tag{1}$$

Verification of solutions

$$y = -\frac{c_1}{2x} + c_2 x$$

Verified OK.

8.10.6 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + \left(AB'' + BB' + CB\right) v &= 0
\end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= x^2 \\
B &= x \\
C &= -1 \\
F &= 0
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= \left(x^2\right)(0) + (x)(1) + (-1)(x) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$x^3v'' + (3x^2)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$x^2(u'(x)\, x + 3u(x)) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{3}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= e^{-3\ln(x)+c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= \frac{c_1}{x^3} \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int \frac{c_1}{x^3}\, \mathrm{d}x \\ &= -\frac{c_1}{2x^2} + c_2 \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (x)\left(-\frac{c_1}{2x^2} + c_2\right) \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x \tag{1}$$

Verification of solutions

$$y = \left(-\frac{c_1}{2x^2} + c_2\right) x$$

Verified OK.

8.10.7 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2 y'' + y'x - y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x^2 y'' + y'x - y\right) dx = 0$$
$$y'x^2 - yx = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{c_1}{x^2}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{c_1}{x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x} dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1}{x^2}\right)\\ \mathrm{d}\left(\frac{y}{x}\right) &= \left(\frac{c_1}{x^3}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x} &= \int \frac{c_1}{x^3}\,\mathrm{d}x\\ \frac{y}{x} &= -\frac{c_1}{2x^2} + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -\frac{c_1}{2x} + c_2 x$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{c_1}{2x} + c_2 x \tag{1}$$

<u>Verification of solutions</u>

$$y = -\frac{c_1}{2x} + c_2 x$$

Verified OK.

8.10.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + y'x - y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= x^2\\ B &= x\\ C &= -1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 368: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= e^{\int -\frac{1}{2x} dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2}\, dx} \\ &= z_1 e^{-\frac{\ln(x)}{2}} \\ &= z_1 \left(\frac{1}{\sqrt{x}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x} + \frac{c_2 x}{2} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1}{x} + \frac{c_2 x}{2}
$$

Verified OK.

8.10.9 Solving as exact linear second order ode ode

An ode of the form

$$
p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)
$$

is exact if

$$
p''(x) - q'(x) + r(x) = 0 \tag{1}
$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x^2 \\
q(x) &= x \\
r(x) &= -1 \\
s(x) &= 0
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 1
\end{aligned}
$$

Therefore (1) becomes

$$
2-(1)+(-1)=0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)
$$

Integrating gives

$$
p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\;dx
$$

Substituting the above values for p, q, r, s gives

$$
y'x^2-yx=c_1
$$

We now have a first order ode to solve which is

$$
y'x^2-yx=c_1
$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y'+p(x)y=q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{c_1}{x^2}
\end{aligned}
$$

Hence the ode is

$$
y'-\frac{y}{x}=\frac{c_1}{x^2}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{1}{x}dx} \\
&= \frac{1}{x}
\end{aligned}
$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x^2}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{c_1}{x^2}\right)\\ \mathrm{d}\left(\frac{y}{x}\right) &= \left(\frac{c_1}{x^3}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{y}{x} &= \int \frac{c_1}{x^3}\,\mathrm{d}x\\ \frac{y}{x} &= -\frac{c_1}{2x^2}+c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = -\frac{c_1}{2x}+c_2x$$

<u>Summary</u>
The solution(s) found are the following

$$y = -\frac{c_1}{2x}+c_2x \tag{1}$$

<u>Verification of solutions</u>

$$y = -\frac{c_1}{2x}+c_2x$$

Verified OK.

8.10.10 Maple step by step solution

Let's solve

$x^2y''+y'x-y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y'}{x}+\frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{y'}{x}-\frac{y}{x^2}=0$

- Multiply by denominators of the ODE

  $x^2y'' + y'x - y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) + \frac{d}{dt}y(t) - y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the ODE

  $y_1(t) = e^{-t}$

- 2nd solution of the ODE

  $y_2(t) = e^{t}$

- General solution of the ODE

$y(t) = c_1 y_1(t) + c_2 y_2(t)$

- Substitute in solutions

  $y(t) = c_1 e^{-t} + c_2 e^{t}$

- Change variables back using $t = \ln(x)$

  $y = \frac{c_1}{x} + c_2 x$

- Simplify

  $y = \frac{c_1}{x} + c_2 x$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' - y'x + y = 0}$$

8.11.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - xrx^{r-1} + x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - r\,x^r + x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - r + 1 = 0$$

Or

$$r^2 - 2r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 1$$

Since the roots are equal, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = c_1 x + \ln(x)\, c_2 x$$

Summary

The solution(s) found are the following

$$y = c_1 x + \ln(x)\, c_2 x \tag{1}$$

Verification of solutions

$$y = c_1 x + \ln(x)\, c_2 x$$

Verified OK.

8.11.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2y'' - y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{1}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\,(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\,(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{1}{x}dx\right)}dx \\ &= \int e^{\ln(x)}\,dx \\ &= \int x dx \\ &= \frac{x^2}{2} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{\frac{1}{x^2}}{x^2} \\ &= \frac{1}{x^4} \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned} \frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{x^4} &= 0 \end{aligned}$$

But in terms of τ

$$\frac{1}{x^4} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= \frac{1}{2} \\
r_2 &= \frac{1}{2}
\end{aligned}
$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{x\sqrt{2}\,(c_1 + 2c_2\ln(x) - c_2\ln(2))}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{x\sqrt{2}\,(c_1 + 2c_2\ln(x) - c_2\ln(2))}{2} \tag{1}$$

Verification of solutions

$$y = \frac{x\sqrt{2}\,(c_1 + 2c_2\ln(x) - c_2\ln(2))}{2}$$

Verified OK.

8.11.3 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x^2y'' - y'x + y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{1}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{1}{x}\frac{\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -2c\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) - 2c\left(\frac{d}{d\tau}y(\tau)\right) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = e^{c\tau}c_1$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\, dx \\
&= \frac{\int \sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 x
$$

Summary

The solution(s) found are the following

$$
y = c_1 x \tag{1}
$$

Verification of solutions

$$
y = c_1 x
$$

Verified OK.

8.11.4 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$
x^2 y'' - y'x + y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{1}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{n}{x^2} + \frac{1}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{v'(x)}{x} &= 0 \\ v''(x) + \frac{v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{1}{x}\, dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= e^{-\ln(x)+c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= (c_1 \ln(x) + c_2)\, x \\
&= (c_1 \ln(x) + c_2)\, x
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = (c_1 \ln(x) + c_2)\, x \tag{1}
$$

<u>Verification of solutions</u>

$$
y = (c_1 \ln(x) + c_2)\, x
$$

Verified OK.

8.11.5 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + (2AB' + B^2)\, v' + (AB'' + BB' + CB)\, v &= 0
\end{aligned} \tag{1}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 \\ B &= -x \\ C &= 1 \\ F &= 0 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= \left(x^2\right)(0) + (-x)(-1) + (1)(-x) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-x^3 v'' + \left(-x^2\right) v' = 0$$

Now by applying $v' = u$ the above becomes

$$-x^2 (u'(x)\, x + u(x)) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x) g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{1}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{1}{x}\, dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= e^{-\ln(x) + c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{x}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{x}\, \mathrm{d}x \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (-x)\,(c_1 \ln(x) + c_2) \\
&= -(c_1 \ln(x) + c_2)\, x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -(c_1 \ln(x) + c_2)\, x \tag{1}
$$

Verification of solutions

$$
y = -(c_1 \ln(x) + c_2)\, x
$$

Verified OK.

8.11.6 Solving using Kovacic algorithm

Writing the ode as

$$
x^2 y'' - y'x + y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= -x \\
C &= 1
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 370: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-x}{x^2} \, dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1 \left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2} \, dx \\ &= y_1(\ln(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(x) + c_2(x(\ln(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x + \ln(x) c_2 x \tag{1}$$

Verification of solutions

$$y = c_1 x + \ln(x) c_2 x$$

Verified OK.

8.11.7 Maple step by step solution

Let's solve

$x^2 y'' - y' x + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{y'}{x} - \frac{y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} + \frac{y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2 y'' - y' x + y = 0$

- Make a change of variables

$t = \ln(x)$

- ☐ Substitute the change of variables back into the ODE
  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$
  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$
  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$
  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2 \left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) - \frac{d}{dt}y(t) + y(t) = 0$
- Simplify

  $\frac{d^2}{dt^2}y(t) - 2\frac{d}{dt}y(t) + y(t) = 0$
- Characteristic polynomial of ODE

  $r^2 - 2r + 1 = 0$
- Factor the characteristic polynomial

  $(r-1)^2 = 0$
- Root of the characteristic polynomial

  $r = 1$
- 1st solution of the ODE

  $y_1(t) = e^t$
- Repeated root, multiply $y_1(t)$ by t to ensure linear independence

  $y_2(t) = t\,e^t$
- General solution of the ODE

  $y(t) = c_1 y_1(t) + c_2 y_2(t)$
- Substitute in solutions

  $y(t) = c_1 e^t + c_2 t\,e^t$

- Change variables back using $t = \ln(x)$

  $y = c_1 x + \ln(x) c_2 x$
- Simplify

  $y = x(c_1 + c_2 \ln(x))$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' - (2a-1)\,xy' + a^2y = 0}$$

8.12.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2}(-2a+1)\,xrx^{r-1} + a^2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r(-2a+1)\,r\,x^r + a^2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1)\,(-2a+1)\,r + a^2 = 0$$

Or

$$a^2 - 2ra + r^2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = a$$
$$r_2 = a$$

Since the roots are equal, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = c_1 x^a + c_2 x^a \ln(x)$$

Summary
The solution(s) found are the following

$$y = c_1 x^a + c_2 x^a \ln(x) \tag{1}$$

Verification of solutions

$$y = c_1 x^a + c_2 x^a \ln(x)$$

Verified OK.

8.12.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^2 y'' + (-2ax + x) y' + a^2 y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$p(x) = \frac{-2a + 1}{x}$$
$$q(x) = \frac{a^2}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau) \right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-(\int p(x)dx)} dx \\
&= \int \mathrm{e}^{-(\int \frac{-2a+1}{x} dx)} dx \\
&= \int e^{(2a-1)\ln(x)}\, dx \\
&= \int x^{2a-1} dx \\
&= \frac{x^{2a}}{2a}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{a^2}{x^2}}{x^{4a-2}} \\
&= a^2 x^{-4a}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2} y(\tau) + a^2 x^{-4a} y(\tau) = 0$$

But in terms of τ

$$a^2 x^{-4a} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\left(c_1 + c_2\ln\left(\frac{x^{2a}}{a}\right) - c_2\ln(2)\right)}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\left(c_1 + c_2 \ln\left(\frac{x^{2a}}{a}\right) - c_2 \ln(2)\right)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\left(c_1 + c_2 \ln\left(\frac{x^{2a}}{a}\right) - c_2 \ln(2)\right)}{2}$$

Verified OK.

8.12.3 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + (-2ax + x)\,y' + a^2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{-2a + 1}{x}$$
$$q(x) = \frac{a^2}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(-2a + 1)}{x^2} + \frac{a^2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = a \tag{6}$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \left(\frac{2a}{x} + \frac{-2a+1}{x}\right) v'(x) &= 0 \\
v''(x) + \frac{v'(x)}{x} &= 0 \qquad (7)
\end{aligned}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \frac{u(x)}{x} = 0 \qquad (8)
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x) g(u) \\
&= -\frac{u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u} \, du &= -\frac{1}{x} \, dx \\
\int \frac{1}{u} \, du &= \int -\frac{1}{x} \, dx \\
\ln(u) &= -\ln(x) + c_1 \\
u &= \mathrm{e}^{-\ln(x) + c_1} \\
&= \frac{c_1}{x}
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x) \, dx + c_2 \\
&= c_1 \ln(x) + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= (c_1 \ln(x) + c_2)\, x^a \\
&= (c_1 \ln(x) + c_2)\, x^a
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = (c_1 \ln(x) + c_2)\, x^a \tag{1}
$$

Verification of solutions

$$
y = (c_1 \ln(x) + c_2)\, x^a
$$

Verified OK.

8.12.4 Solving using Kovacic algorithm

Writing the ode as

$$
x^2 y'' + (-2ax + x)\, y' + a^2 y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= -2ax + x \\
C &= a^2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 372: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{1}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{1}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{1}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = \frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= \frac{1}{2} - \left(\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{2x} + (-)\,(0) \\ &= \frac{1}{2x} \\ &= \frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1}{2x} dx} \\ &= \sqrt{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-2ax+x}{x^2} \, dx} \\ &= z_1 e^{\frac{(2a-1)\ln(x)}{2}} \\ &= z_1 \left(x^{a-\frac{1}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^a$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2ax+x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{(2a-1)\ln(x)}}{(y_1)^2} \, dx \\ &= y_1(\ln(x)) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x^a) + c_2(x^a(\ln(x)))
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 x^a + c_2 x^a \ln(x) \tag{1}$$

Verification of solutions

$$y = c_1 x^a + c_2 x^a \ln(x)$$

Verified OK.

8.12.5 Maple step by step solution

Let's solve

$x^2 y'' + (-2ax + x) y' + a^2 y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{a^2 y}{x^2} + \frac{(2a-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(2a-1)y'}{x} + \frac{a^2 y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = -\frac{2a-1}{x}, P_3(x) = \frac{a^2}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -2a + 1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = a^2$

  ◦ $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$x^2 y'' - (2a - 1)\, x y' + a^2 y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite DE with series expansions

- ○ Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- ○ Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite DE with series expansions

$$\sum_{k=0}^{\infty} a_k (a-k-r)^2\, x^{k+r} = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r = 0$

- Each term in the series must be 0, giving the recursion relation

$a_k (a-k)^2 = 0$

- Recursion relation that defines series solution to ODE

$a_k = 0$

- Recursion relation for $r = 0$

$a_k = 0$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_k = 0\right]$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^2y'' - 4y'x + (-16x^2 + 3)\, y = 0}$$

8.13.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{-16x^2 + 3}{4x^2}
\end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{-16x^2+3}{4x^2} - \frac{\left(-\frac{1}{x}\right)'}{2} - \frac{\left(-\frac{1}{x}\right)^2}{4} \\
&= \frac{-16x^2+3}{4x^2} - \frac{\left(\frac{1}{x^2}\right)}{2} - \frac{\left(\frac{1}{x^2}\right)}{4} \\
&= \frac{-16x^2+3}{4x^2} - \left(\frac{1}{2x^2}\right) - \frac{1}{4x^2} \\
&= -4
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{1}{x}}{2}} \\
&= \sqrt{x}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\sqrt{x} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
4x^{\frac{5}{2}}(v''(x) - 4v(x)) = 0
$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = 0
$$

Where in the above $A = 1, B = 0, C = -4$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$
\lambda^2 \mathrm{e}^{\lambda x} - 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$
\lambda^2 - 4 = 0 \tag{2}
$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-4)} \\ &= \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2 \\ \lambda_2 &= -2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2 \\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ v(x) &= c_1 e^{(2)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$v(x) = c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x) \\ &= \left(c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x}\right)(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \sqrt{x}$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x}\right)\sqrt{x}$$

Summary
The solution(s) found are the following

$$y = \left(c_1 e^{2x} + c_2 e^{-2x}\right) \sqrt{x} \tag{1}$$

Verification of solutions

$$y = \left(c_1 e^{2x} + c_2 e^{-2x}\right) \sqrt{x}$$

Verified OK.

8.13.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' - y'x + \left(-4x^2 + \frac{3}{4}\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha) x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta x^\gamma) + c_2 \operatorname{BesselY}(n, \beta x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= 1 \\
\beta &= 2i \\
n &= -\frac{1}{2} \\
\gamma &= 1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x \cosh(2x)}{\sqrt{\pi}\, \sqrt{ix}} + \frac{i c_2 x \sinh(2x)}{\sqrt{\pi}\, \sqrt{ix}}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 x \cosh(2x)}{\sqrt{\pi}\, \sqrt{ix}} + \frac{i c_2 x \sinh(2x)}{\sqrt{\pi}\, \sqrt{ix}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x \cosh(2x)}{\sqrt{\pi}\,\sqrt{ix}} + \frac{i c_2 x \sinh(2x)}{\sqrt{\pi}\,\sqrt{ix}}$$

Verified OK.

8.13.3 Solving using Kovacic algorithm

Writing the ode as

$$4x^2 y'' - 4y'x + (-16x^2 + 3)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= -16x^2 + 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 374: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-2x}\sqrt{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-2x}\sqrt{x}\right) + c_2\left(\mathrm{e}^{-2x}\sqrt{x}\left(\frac{\mathrm{e}^{4x}}{4}\right)\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-2x}\sqrt{x} + \frac{c_2 \mathrm{e}^{2x}\sqrt{x}}{4} \tag{1}
$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-2x}\sqrt{x} + \frac{c_2 \mathrm{e}^{2x}\sqrt{x}}{4}$$

Verified OK.

8.13.4 Maple step by step solution

Let's solve

$4x^2 y'' - 4y'x + (-16x^2 + 3)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(16x^2-3)y}{4x^2} + \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{y'}{x} - \frac{(16x^2-3)y}{4x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = -\frac{1}{x}, P_3(x) = -\frac{16x^2-3}{4x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = -1$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = \frac{3}{4}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $4x^2 y'' - 4y'x + (-16x^2 + 3)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot y'$ to series expansion

  $$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+2r)\,(-3+2r)\, x^r + a_1(1+2r)\,(-1+2r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(2k+2r-1)\,(2k+2r-3) - 1\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$(-1+2r)\,(-3+2r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{\frac{1}{2}, \frac{3}{2}\right\}$$

- Each term must be 0

  $$a_1(1+2r)\,(-1+2r) = 0$$

- Solve for the dependent coefficient(s)

  $$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$4\left(k+r-\frac{1}{2}\right)\left(k+r-\frac{3}{2}\right) a_k - 16a_{k-2} = 0$$

- Shift index using $k- >k + 2$

  $$4\left(k+\frac{3}{2}+r\right)\left(k+\frac{1}{2}+r\right) a_{k+2} - 16a_k = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = \frac{16a_k}{(2k+3+2r)(2k+1+2r)}$$

- Recursion relation for $r = \frac{1}{2}$

$a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}, a_1 = 0\right]$$

- Recursion relation for $r = \frac{3}{2}$

$a_{k+2} = \frac{16a_k}{(2k+6)(2k+4)}$

- Solution for $r = \frac{3}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{3}{2}}, a_{k+2} = \frac{16a_k}{(2k+6)(2k+4)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{3}{2}}\right), a_{k+2} = \frac{16a_k}{(2k+4)(2k+2)}, a_1 = 0, b_{k+2} = \frac{16b_k}{(2k+6)(2k+4)}, b_1 = 0\right]$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(x-1)\,y''-y'x+y=0}$$

8.14.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$(x-1)\,y''-y'x+y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=-\frac{x}{x-1}$$
$$q(x)=\frac{1}{x-1}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{n}{x-1} + \frac{1}{x-1} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) v'(x) &= 0 \\ v''(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) v'(x) &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u(x^2 - 2x + 2)}{x\,(x-1)} \end{aligned}$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{x^2-2x+2}{x\,(x-1)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{x^2-2x+2}{x\,(x-1)}\,dx \\
\ln(u) &= x - 2\ln(x) + \ln(x-1) + c_1 \\
u &= \mathrm{e}^{x-2\ln(x)+\ln(x-1)+c_1} \\
&= c_1 \mathrm{e}^{x-2\ln(x)+\ln(x-1)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = c_1\left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2}\right)
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{c_1 \mathrm{e}^x}{x} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{c_1 \mathrm{e}^x}{x} + c_2\right)x \\
&= c_1 \mathrm{e}^x + c_2 x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(\frac{c_1 \mathrm{e}^x}{x} + c_2\right)x \tag{1}
$$

Verification of solutions

$$
y = \left(\frac{c_1 \mathrm{e}^x}{x} + c_2\right)x
$$

Verified OK.

8.14.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + (2AB' + B^2)\, v' + (AB'' + BB' + CB)\, v &= 0 \qquad (1)
\end{aligned}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + (2AB' + B^2)\, v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + (2AB' + B^2)\, u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= x - 1 \\
B &= -x \\
C &= 1 \\
F &= 0
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= (x - 1)\,(0) + (-x)\,(-1) + (1)\,(-x) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-x(x-1)\,v''+\left(x^2-2x+2\right)v'=0$$

Now by applying $v'=u$ the above becomes

$$\left(-x^2+x\right)u'(x)+\left(x^2-2x+2\right)u(x)=0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u)\\
&= f(x)g(u)\\
&= \frac{u(x^2-2x+2)}{x\,(x-1)}
\end{aligned}$$

Where $f(x)=\frac{x^2-2x+2}{x(x-1)}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{x^2-2x+2}{x\,(x-1)}\,dx\\
\int \frac{1}{u}\,du &= \int \frac{x^2-2x+2}{x\,(x-1)}\,dx\\
\ln(u) &= x-2\ln(x)+\ln(x-1)+c_1\\
u &= \mathrm{e}^{x-2\ln(x)+\ln(x-1)+c_1}\\
&= c_1\mathrm{e}^{x-2\ln(x)+\ln(x-1)}
\end{aligned}$$

Which simplifies to

$$u(x)=c_1\left(\frac{\mathrm{e}^x}{x}-\frac{\mathrm{e}^x}{x^2}\right)$$

The ode for v now becomes

$$\begin{aligned}
v' &= u\\
&= c_1\left(\frac{\mathrm{e}^x}{x}-\frac{\mathrm{e}^x}{x^2}\right)
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{(x-1)\,c_1\mathrm{e}^x}{x^2}\,\mathrm{d}x\\
&= \frac{c_1\mathrm{e}^x}{x}+c_2
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (-x)\left(\frac{c_1 e^x}{x} + c_2\right) \\
&= -c_1 e^x - c_2 x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = -c_1 e^x - c_2 x \tag{1}
$$

Verification of solutions

$$
y = -c_1 e^x - c_2 x
$$

Verified OK.

8.14.3 Solving using Kovacic algorithm

Writing the ode as

$$
(x-1)\, y'' - y'x + y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x - 1 \\
B &= -x \\
C &= 1
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^2 - 4x + 6}{4(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= x^2 - 4x + 6 \\ t &= 4(x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^2 - 4x + 6}{4(x-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 376: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2\,(x-1)} + \frac{3}{4\,(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{1}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2 - 4x + 6}{4x^2 - 8x + 4} \\ &= Q + \frac{R}{4x^2 - 8x + 4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x + 5}{4x^2 - 8x + 4}\right) \\ &= \frac{1}{4} + \frac{-2x + 5}{4x^2 - 8x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &&= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^2 - 4x + 6}{4\left(x-1\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2\left(x-1\right)} + \left(\frac{1}{2}\right) \\
&= -\frac{1}{2\left(x-1\right)} + \frac{1}{2} \\
&= \frac{-2+x}{2x-2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x-1\right)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2\left(x-1\right)^2}\right) + \left(-\frac{1}{2\left(x-1\right)} + \frac{1}{2}\right)^2 - \left(\frac{x^2 - 4x + 6}{4\left(x-1\right)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right) dx} \\
&= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{-x}{x-1} \, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x-1)}{2}} \\
&= z_1 \left(\sqrt{x-1}\, \mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x-1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\, dx \\
&= y_1\left(-x\,\mathrm{e}^{-x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2\left(\mathrm{e}^{x}\left(-x\,\mathrm{e}^{-x}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{x} - c_2 x \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{x} - c_2 x$$

Verified OK.

8.14.4 Maple step by step solution

Let's solve

$(x-1)\, y'' - y' x + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{y}{x-1} + \frac{xy'}{x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' - \frac{xy'}{x-1} + \frac{y}{x-1} = 0$

□ Check to see if $x_0 = 1$ is a regular singular point

- Define functions

$\left[P_2(x) = -\frac{x}{x-1}, P_3(x) = \frac{1}{x-1}\right]$

- $(x-1) \cdot P_2(x)$ is analytic at $x = 1$

$\left((x-1) \cdot P_2(x)\right)\bigg|_{x=1} = -1$

- $(x-1)^2 \cdot P_3(x)$ is analytic at $x = 1$

$\left((x-1)^2 \cdot P_3(x)\right)\bigg|_{x=1} = 0$

- $x = 1$is a regular singular point

Check to see if $x_0 = 1$ is a regular singular point

$x_0 = 1$

- Multiply by denominators

$(x-1)\, y'' - y'x + y = 0$

- Change variables using $x = u + 1$ so that the regular singular point is at $u = 0$

$u\left(\frac{d^2}{du^2}y(u)\right) + (-u-1)\left(\frac{d}{du}y(u)\right) + y(u) = 0$

- Assume series solution for $y(u)$

$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-1}$$

- Shift index using $k- > k+1$

  $$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-2+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} (a_{k+1}(k+1+r)(k+r-1) - a_k(k+r-1))\,u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\,(a_{k+1}(k+1+r) - a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k}{k+1+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k}{k+1}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Revert the change of variables $u = x - 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x-1)^k, a_{k+1} = \frac{a_k}{k+1}\right]$

- Recursion relation for $r = 2$

  $a_{k+1} = \frac{a_k}{k+3}$

- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Revert the change of variables $u = x - 1$

  $\left[y = \sum_{k=0}^{\infty} a_k (x-1)^{k+2}, a_{k+1} = \frac{a_k}{k+3}\right]$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k(x-1)^k\right)+\left(\sum_{k=0}^{\infty} b_k(x-1)^{k+2}\right), a_{1+k}=\frac{a_k}{1+k}, b_{1+k}=\frac{b_k}{k+3}\right]$$

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' - 2y'x + (x^2 + 2)\, y = 0}$$

8.15.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = -\frac{2}{x}$$
$$q(x) = \frac{x^2 + 2}{x^2}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x^2+2}{x^2} - \frac{\left(-\frac{2}{x}\right)'}{2} - \frac{\left(-\frac{2}{x}\right)^2}{4} \\
&= \frac{x^2+2}{x^2} - \frac{\left(\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\
&= \frac{x^2+2}{x^2} - \left(\frac{1}{x^2}\right) - \frac{1}{x^2} \\
&= 1
\end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2}{x}}{2}} \\
&= x
\end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, x \tag{4}$$

Applying this change of variable to the original ode results in

$$x^3(v''(x) + v(x)) = 0$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$v(x) = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$v(x) = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$v(x) = c_1 \cos(x) + c_2 \sin(x)$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x) \\ &= (c_1 \cos(x) + c_2 \sin(x))\,(z(x)) \qquad (7)\end{aligned}$$

But from (5)

$$z(x) = x$$

Hence (7) becomes

$$y = (c_1 \cos(x) + c_2 \sin(x))\, x$$

Summary
The solution(s) found are the following

$$y = (c_1 \cos(x) + c_2 \sin(x))\, x \tag{1}$$

Verification of solutions

$$y = (c_1 \cos(x) + c_2 \sin(x))\, x$$

Verified OK.

8.15.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' - 2y' x + (x^2 + 2)\, y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + (-n^2 + x^2)\, y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, x y' + (\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2)\, y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned} \alpha &= \frac{3}{2} \\ \beta &= 1 \\ n &= -\frac{1}{2} \\ \gamma &= 1 \end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x \sqrt{2}\, \cos(x)}{\sqrt{\pi}} + \frac{c_2 x \sqrt{2}\, \sin(x)}{\sqrt{\pi}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x \sqrt{2}\, \cos(x)}{\sqrt{\pi}} + \frac{c_2 x \sqrt{2}\, \sin(x)}{\sqrt{\pi}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x \sqrt{2}\, \cos(x)}{\sqrt{\pi}} + \frac{c_2 x \sqrt{2}\, \sin(x)}{\sqrt{\pi}}$$

Verified OK.

8.15.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 2y'x + (x^2 + 2)\, y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 378: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx} \\
&= z_1 e^{\ln(x)} \\
&= z_1(x)
\end{aligned}$$

Which simplifies to

$$y_1 = x\cos(x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\cos(x)) + c_2(x\cos(x)(\tan(x)))
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 x \cos(x) + c_2 \sin(x) x \tag{1}$$

Verification of solutions

$$y = c_1 x \cos(x) + c_2 \sin(x) x$$

Verified OK.

8.15.4 Maple step by step solution

Let's solve

$x^2 y'' - 2y'x + (x^2+2) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2+2)y}{x^2} + \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{x} + \frac{(x^2+2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{2}{x}, P_3(x) = \frac{x^2+2}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -2$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 2$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2 y'' - 2y'x + (x^2+2) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-1+r)\,(-2+r)\, x^r + a_1 r(-1+r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)\,(k+r-2) + a_{k-2}\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-1+r)\,(-2+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, 2\}$

- Each term must be 0

  $a_1 r(-1+r) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r-1)\,(k+r-2) + a_{k-2} = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(k+1+r)\,(k+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{a_k}{(k+1+r)(k+r)}$

- Recursion relation for $r = 1$

  $a_{k+2} = -\frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 1$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$$

- Recursion relation for $r = 2$

  $a_{k+2} = -\frac{a_k}{(k+3)(k+2)}$

- Solution for $r = 2$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{1+k}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2} = -\frac{a_k}{(k+2)(1+k)}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$$

Problem number: 19.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{4x^{2} \sin \left(x \right) y^{\prime \prime}-4 x \left(x \cos \left(x \right)+\sin \left(x \right)\right) y^{\prime}+\left(2 x \cos \left(x \right)+3 \sin \left(x \right)\right) y=0}$$

8.16.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$4x^{2} \sin \left(x \right) y^{\prime \prime}-4 x \left(x \cos \left(x \right)+\sin \left(x \right)\right) y^{\prime}+\left(2 x \cos \left(x \right)+3 \sin \left(x \right)\right) y=0 \tag{1}$$

Becomes

$$y^{\prime \prime}+p(x) y^{\prime}+q(x) y=0 \tag{2}$$

Where

$$p(x) = \frac{-1-x \cot \left(x \right)}{x}$$
$$q(x) = \frac{2 x \cot \left(x \right)+3}{4 x^{2}}$$

Applying change of variables on the depndent variable $y = v(x) x^{n}$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v^{\prime \prime}(x)+\left(\frac{2 n}{x}+p \right) v^{\prime}(x)+\left(\frac{n \left(n -1\right)}{x^{2}}+\frac{n p}{x}+q \right) v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(-1-x\cot(x))}{x^2}+\frac{2x\cot(x)+3}{4x^2}=0 \tag{5}$$

Solving (5) for n gives

$$n=\frac{1}{2} \tag{6}$$

Substituting this value in (3) gives

$$v''(x)+\left(\frac{1}{x}+\frac{-1-x\cot(x)}{x}\right)v'(x)=0$$
$$v''(x)-\cot(x)\,v'(x)=0 \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)-\cot(x)\,u(x)=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\&=f(x)g(u)\\&=\cot(x)\,u\end{aligned}$$

Where $f(x)=\cot(x)$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du&=\cot(x)\,dx\\\int\frac{1}{u}\,du&=\int\cot(x)\,dx\\\ln(u)&=\ln(\sin(x))+c_1\\u&=e^{\ln(\sin(x))+c_1}\\&=\sin(x)\,c_1\end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= -c_1 \cos(x) + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= (-c_1 \cos(x) + c_2) \sqrt{x} \\
&= (-c_1 \cos(x) + c_2) \sqrt{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = (-c_1 \cos(x) + c_2) \sqrt{x} \tag{1}
$$

Verification of solutions

$$
y = (-c_1 \cos(x) + c_2) \sqrt{x}
$$

Verified OK.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$(3x-1)\,y''-(3x+2)\,y'+(6x-8)\,y=0$$

8.17.1 Maple step by step solution

Let's solve

$(3x-1)\,y''+(-3x-2)\,y'+(6x-8)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{2(3x-4)y}{3x-1}+\frac{(3x+2)y'}{3x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(3x+2)y'}{3x-1}+\frac{2(3x-4)y}{3x-1}=0$

□ Check to see if $x_0=\frac{1}{3}$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{3x+2}{3x-1}, P_3(x) = \frac{2(3x-4)}{3x-1}\right]$

- $\left(x-\frac{1}{3}\right) \cdot P_2(x)$ is analytic at $x = \frac{1}{3}$

  $\left(\left(x-\frac{1}{3}\right) \cdot P_2(x)\right)\Big|_{x=\frac{1}{3}} = -1$

- $\left(x-\frac{1}{3}\right)^2 \cdot P_3(x)$ is analytic at $x = \frac{1}{3}$

  $\left(\left(x-\frac{1}{3}\right)^2 \cdot P_3(x)\right)\Big|_{x=\frac{1}{3}} = 0$

- $x = \frac{1}{3}$is a regular singular point

  Check to see if $x_0 = \frac{1}{3}$ is a regular singular point

  $x_0 = \frac{1}{3}$

- Multiply by denominators

  $(3x-1)\,y'' + (-3x-2)\,y' + (6x-8)\,y = 0$

- Change variables using $x = u + \frac{1}{3}$ so that the regular singular point is at $u = 0$

  $3u\left(\frac{d^2}{du^2}y(u)\right) + (-3u-3)\left(\frac{d}{du}y(u)\right) + (6u-6)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-1}$$

- Shift index using $k- >k+1$

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0r(-2+r)\, u^{-1+r} + (3a_1(1+r)(-1+r) - 3a_0(2+r))\, u^r + \left(\sum_{k=1}^{\infty} (3a_{k+1}(k+1+r)(k+r-1\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$3r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term must be 0

$$3a_1(1+r)(-1+r) - 3a_0(2+r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$3a_{k+1}(k+1+r)(k+r-1) + a_k(-3k-3r-6) + 6a_{k-1} = 0$$

- Shift index using $k- >k+1$

$$3a_{k+2}(k+r+2)(k+r) + a_{k+1}(-3k-9-3r) + 6a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{ka_{k+1}+ra_{k+1}-2a_k+3a_{k+1}}{(k+r+2)(k+r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{ka_{k+1}-2a_k+3a_{k+1}}{(k+2)k}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

$$a_{k+2} = \frac{ka_{k+1}-2a_k+3a_{k+1}}{(k+2)k}$$

- Recursion relation for $r = 2$

$$a_{k+2} = \frac{ka_{k+1}-2a_k+5a_{k+1}}{(k+4)(k+2)}$$

- Solution for $r = 2$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{ka_{k+1}-2a_k+5a_{k+1}}{(k+4)(k+2)}, 9a_1 - 12a_0 = 0\right]$$

- Revert the change of variables $u = x - \frac{1}{3}$

$$\left[y=\sum_{k=0}^{\infty} a_k\left(x-\frac{1}{3}\right)^{k+2}, a_{k+2}=\frac{k a_{k+1}-2 a_k+5 a_{k+1}}{(k+4)(k+2)}, 9 a_1-12 a_0=0\right]$$

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_y_method_1", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x^2-4)\, y''+4y'x+2y=0}$$

8.18.1 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = \frac{4x}{x^2-4}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int \frac{4x}{x^2-4}\,dx} \\ &= x^2 - 4 \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 0$$
$$\left(\left(x^2-4\right)y\right)'' = 0$$

Integrating once gives

$$\left(\left(x^2-4\right)y\right)' = c_1$$

Integrating again gives

$$\left(\left(x^2-4\right)y\right) = c_1x + c_2$$

Hence the solution is

$$y = \frac{c_1x + c_2}{x^2-4}$$

Or

$$y = \frac{c_1x}{x^2-4} + \frac{c_2}{x^2-4}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1x}{x^2-4} + \frac{c_2}{x^2-4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1x}{x^2-4} + \frac{c_2}{x^2-4}$$

Verified OK.

8.18.2 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{4x}{x^2 - 4} \\ q(x) &= \frac{2}{x^2 - 4} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{2}{x^2 - 4} - \frac{\left(\frac{4x}{x^2-4}\right)'}{2} - \frac{\left(\frac{4x}{x^2-4}\right)^2}{4} \\ &= \frac{2}{x^2 - 4} - \frac{\left(\frac{4}{x^2-4} - \frac{8x^2}{(x^2-4)^2}\right)}{2} - \frac{\left(\frac{16x^2}{(x^2-4)^2}\right)}{4} \\ &= \frac{2}{x^2 - 4} - \left(\frac{2}{x^2 - 4} - \frac{4x^2}{(x^2 - 4)^2}\right) - \frac{4x^2}{(x^2 - 4)^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\ &= e^{-\int \frac{\frac{4x}{x^2-4}}{2}} \\ &= \frac{1}{x^2 - 4} \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = \frac{v(x)}{x^2 - 4} \tag{4}$$

Applying this change of variable to the original ode results in

$$v''(x) = 0$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$v(x) = c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= (c_1 x + c_2)\, (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{1}{x^2 - 4}$$

Hence (7) becomes

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x + c_2}{x^2 - 4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Verified OK.

8.18.3 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\begin{gathered} \int \left(\left(x^2 - 4\right) y'' + 4y'x + 2y\right) dx = 0 \\ 2yx + \left(x^2 - 4\right) y' = c_1 \end{gathered}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2x}{x^2 - 4}$$
$$q(x) = \frac{c_1}{x^2 - 4}$$

Hence the ode is

$$y' + \frac{2xy}{x^2 - 4} = \frac{c_1}{x^2 - 4}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2x}{x^2-4}dx}$$
$$= x^2 - 4$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{x^2 - 4}\right)$$
$$\frac{d}{dx}\left(\left(x^2 - 4\right)y\right) = \left(x^2 - 4\right)\left(\frac{c_1}{x^2 - 4}\right)$$
$$d\left(\left(x^2 - 4\right)y\right) = c_1\, dx$$

Integrating gives

$$\left(x^2 - 4\right)y = \int c_1\, dx$$
$$\left(x^2 - 4\right)y = c_1 x + c_2$$

Dividing both sides by the integrating factor $\mu = x^2 - 4$ results in

$$y = \frac{c_1 x}{x^2 - 4} + \frac{c_2}{x^2 - 4}$$

which simplifies to

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x + c_2}{x^2 - 4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Verified OK.

8.18.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x^2-4)\,y''+4y'x+2y=0$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}\int \left((x^2-4)\,y''+4y'x+2y\right)dx &= 0\\ 2yx+(x^2-4)\,y' &= c_1\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x) &= \frac{2x}{x^2-4}\\ q(x) &= \frac{c_1}{x^2-4}\end{aligned}$$

Hence the ode is

$$y'+\frac{2xy}{x^2-4}=\frac{c_1}{x^2-4}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \frac{2x}{x^2-4}dx}\\ &= x^2-4\end{aligned}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2-4}\right)\\ \frac{d}{dx}\left((x^2-4)\,y\right) &= (x^2-4)\left(\frac{c_1}{x^2-4}\right)\\ d\left((x^2-4)\,y\right) &= c_1\,dx\end{aligned}$$

Integrating gives

$$\begin{aligned}(x^2-4)\,y &= \int c_1\,dx\\ (x^2-4)\,y &= c_1x+c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2 - 4$ results in

$$y = \frac{c_1 x}{x^2 - 4} + \frac{c_2}{x^2 - 4}$$

which simplifies to

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x + c_2}{x^2 - 4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Verified OK.

8.18.5 Solving using Kovacic algorithm

Writing the ode as

$$(x^2 - 4) y'' + 4y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 - 4 \\ B &= 4x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 381: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x}{x^2-4}\,dx} \\
&= z_1 e^{-\ln(x^2-4)} \\
&= z_1\left(\frac{1}{x^2-4}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^2-4}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{x^2-4}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x^2-4)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^2 - 4}\right) + c_2 \left(\frac{1}{x^2 - 4}(x)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x^2 - 4} + \frac{c_2 x}{x^2 - 4} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1}{x^2 - 4} + \frac{c_2 x}{x^2 - 4}
$$

Verified OK.

8.18.6 Solving as exact linear second order ode ode

An ode of the form

$$
p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)
$$

is exact if

$$
p''(x) - q'(x) + r(x) = 0 \tag{1}
$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x^2 - 4 \\
q(x) &= 4x \\
r(x) &= 2 \\
s(x) &= 0
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 4
\end{aligned}
$$

Therefore (1) becomes

$$
2 - (4) + (2) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$
\left(p(x)\, y' + (q(x) - p'(x))\, y\right)' = s(x)
$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$2yx + \left(x^2 - 4\right) y' = c_1$$

We now have a first order ode to solve which is

$$2yx + \left(x^2 - 4\right) y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= \frac{2x}{x^2 - 4} \\ q(x) &= \frac{c_1}{x^2 - 4} \end{aligned}$$

Hence the ode is

$$y' + \frac{2xy}{x^2 - 4} = \frac{c_1}{x^2 - 4}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int \frac{2x}{x^2 - 4} dx} \\ &= x^2 - 4 \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu) \left(\frac{c_1}{x^2 - 4}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\left(x^2 - 4\right) y\right) &= \left(x^2 - 4\right) \left(\frac{c_1}{x^2 - 4}\right) \\ \mathrm{d}\left(\left(x^2 - 4\right) y\right) &= c_1\, \mathrm{d}x \end{aligned}$$

Integrating gives

$$\begin{aligned} \left(x^2 - 4\right) y &= \int c_1\, \mathrm{d}x \\ \left(x^2 - 4\right) y &= c_1 x + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^2 - 4$ results in

$$y = \frac{c_1 x}{x^2 - 4} + \frac{c_2}{x^2 - 4}$$

which simplifies to

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 x + c_2}{x^2 - 4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x + c_2}{x^2 - 4}$$

Verified OK.

8.18.7 Maple step by step solution

Let's solve

$(x^2 - 4)\, y'' + 4y'x + 2y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{4xy'}{x^2-4} - \frac{2y}{x^2-4}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{4xy'}{x^2-4} + \frac{2y}{x^2-4} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{4x}{x^2-4}, P_3(x) = \frac{2}{x^2-4}\right]$

  ◦ $(2+x) \cdot P_2(x)$ is analytic at $x = -2$

  $\left((2+x) \cdot P_2(x)\right)\Big|_{x=-2} = 2$

  ◦ $(2+x)^2 \cdot P_3(x)$ is analytic at $x = -2$

$$\left((2+x)^2 \cdot P_3(x)\right)\Bigg|_{x=-2} = 0$$

- $x = -2$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -2$

- Multiply by denominators

  $(x^2-4)\,y'' + 4y'x + 2y = 0$

- Change variables using $x = u-2$ so that the regular singular point is at $u = 0$

  $(u^2-4u)\left(\frac{d^2}{du^2}y(u)\right) + (4u-8)\left(\frac{d}{du}y(u)\right) + 2y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum\limits_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum\limits_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum\limits_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum\limits_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum\limits_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-4a_0r(1+r)\,u^{-1+r} + \left(\sum\limits_{k=0}^{\infty}\left(-4a_{k+1}(k+r+1)\,(k+r+2) + a_k(k+r+2)\,(k+r+1)\right)u^{k+r}\right) =$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-4r(1+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{-1, 0\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r+2)(k+r+1)(-4a_{k+1}+a_k)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=\frac{a_k}{4}$

- Recursion relation for $r=-1$

  $a_{k+1}=\frac{a_k}{4}$

- Solution for $r=-1$

  $$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k-1}, a_{k+1}=\frac{a_k}{4}\right]$$

- Revert the change of variables $u=2+x$

  $$\left[y=\sum_{k=0}^{\infty} a_k(2+x)^{k-1}, a_{k+1}=\frac{a_k}{4}\right]$$

- Recursion relation for $r=0$

  $a_{k+1}=\frac{a_k}{4}$

- Solution for $r=0$

  $$\left[y(u)=\sum_{k=0}^{\infty} a_k u^k, a_{k+1}=\frac{a_k}{4}\right]$$

- Revert the change of variables $u=2+x$

  $$\left[y=\sum_{k=0}^{\infty} a_k(2+x)^k, a_{k+1}=\frac{a_k}{4}\right]$$

- Combine solutions and rename parameters

  $$\left[y=\left(\sum_{k=0}^{\infty} a_k(2+x)^{k-1}\right)+\left(\sum_{k=0}^{\infty} b_k(2+x)^k\right), a_{1+k}=\frac{a_k}{4}, b_{1+k}=\frac{b_k}{4}\right]$$

Let's solve

$(1+2x)\,y''+(-4x^2+2)\,y'+(-4x-4)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{4(x+1)y}{1+2x}+\frac{2(2x^2-1)y'}{1+2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{2(2x^2-1)y'}{1+2x}-\frac{4(x+1)y}{1+2x}=0$

□ Check to see if $x_0=-\frac{1}{2}$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{2(2x^2-1)}{1+2x}, P_3(x) = -\frac{4(x+1)}{1+2x}\right]$

- $\left(x+\frac{1}{2}\right) \cdot P_2(x)$ is analytic at $x = -\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right) \cdot P_2(x)\right)\bigg|_{x=-\frac{1}{2}} = \frac{1}{2}$

- $\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)$ is analytic at $x = -\frac{1}{2}$

  $\left(\left(x+\frac{1}{2}\right)^2 \cdot P_3(x)\right)\bigg|_{x=-\frac{1}{2}} = 0$

- $x = -\frac{1}{2}$is a regular singular point

  Check to see if $x_0 = -\frac{1}{2}$ is a regular singular point

  $x_0 = -\frac{1}{2}$

- Multiply by denominators

  $(1+2x)\, y'' + (-4x^2+2)\, y' + (-4x-4)\, y = 0$

- Change variables using $x = u - \frac{1}{2}$ so that the regular singular point is at $u = 0$

  $2u\left(\frac{d^2}{du^2}y(u)\right) + (-4u^2+4u+1)\left(\frac{d}{du}y(u)\right) + (-4u-2)\, y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) u^{k+r-1}$$

- Shift index using $k- >k+1$

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+2r) u^{-1+r} + (a_1(1+r)(1+2r) + 2a_0(-1+2r)) u^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(2k+1+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term must be 0

$$a_1(1+r)(1+2r) + 2a_0(-1+2r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$2(k+1+r)\left(k+\frac{1}{2}+r\right) a_{k+1} + (4a_k - 4a_{k-1}) k + (4a_k - 4a_{k-1}) r - 2a_k = 0$$

- Shift index using $k- >k+1$

$$2(k+2+r)\left(k+\frac{3}{2}+r\right) a_{k+2} + (4a_{k+1} - 4a_k)(k+1) + (4a_{k+1} - 4a_k) r - 2a_{k+1} = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{2(2a_k k - 2k a_{k+1} + 2a_k r - 2r a_{k+1} + 2a_k - a_{k+1})}{(k+2+r)(2k+3+2r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{2(2a_k k - 2k a_{k+1} + 2a_k - a_{k+1})}{(k+2)(2k+3)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = \frac{2(2a_k k - 2k a_{k+1} + 2a_k - a_{k+1})}{(k+2)(2k+3)}, a_1 - 2a_0 = 0\right]$$

- Revert the change of variables $u = x + \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x+\frac{1}{2}\right)^k, a_{k+2} = \frac{2(2a_k k - 2k a_{k+1} + 2a_k - a_{k+1})}{(k+2)(2k+3)}, a_1 - 2a_0 = 0\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+2} = \frac{2(2a_k k - 2k a_{k+1} + 3a_k - 2a_{k+1})}{\left(k+\frac{5}{2}\right)(2k+4)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y(u)=\sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+2}=\frac{2(2a_k k-2k a_{k+1}+3a_k-2a_{k+1})}{\left(k+\frac{5}{2}\right)(2k+4)}, 3a_1=0\right]$$

- Revert the change of variables $u=x+\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty} a_k \left(x+\frac{1}{2}\right)^{k+\frac{1}{2}}, a_{k+2}=\frac{2(2a_k k-2k a_{k+1}+3a_k-2a_{k+1})}{\left(k+\frac{5}{2}\right)(2k+4)}, 3a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} a_k \left(x+\frac{1}{2}\right)^{k}\right)+\left(\sum_{k=0}^{\infty} b_k \left(x+\frac{1}{2}\right)^{k+\frac{1}{2}}\right), a_{k+2}=\frac{2(2k a_k-2k a_{1+k}+2a_k-a_{1+k})}{(k+2)(2k+3)}, a_1-2a_0=0, b_{k+}\right.$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(x^{2}-2x\right) y''+\left(-x^{2}+2\right) y'+\left(2x-2\right) y=0}$$

8.20.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$\left(x^{2}-2x\right) y''+\left(-x^{2}+2\right) y'+\left(2x-2\right) y=0 \tag{1}$$

Becomes

$$y''+p(x)\, y'+q(x)\, y=0 \tag{2}$$

Where

$$p(x)=\frac{-x^{2}+2}{x\left(-2+x\right)}$$
$$q(x)=\frac{2x-2}{x\left(-2+x\right)}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(-x^2+2)}{x^2\,(-2+x)} + \frac{2x-2}{x\,(-2+x)} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4}{x} + \frac{-x^2+2}{x\,(-2+x)}\right) v'(x) &= 0 \\ v''(x) + \frac{(-x^2+4x-6)\, v'(x)}{x\,(-2+x)} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(-x^2+4x-6)\, u(x)}{x\,(-2+x)} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u(x^2-4x+6)}{x\,(-2+x)} \end{aligned}$$

Where $f(x) = \frac{x^2-4x+6}{x(-2+x)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{x^2-4x+6}{x(-2+x)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{x^2-4x+6}{x(-2+x)}\,dx \\
\ln(u) &= x - 3\ln(x) + \ln(-2+x) + c_1 \\
u &= \mathrm{e}^{x-3\ln(x)+\ln(-2+x)+c_1} \\
&= c_1 \mathrm{e}^{x-3\ln(x)+\ln(-2+x)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(-\frac{2\,\mathrm{e}^x}{x^3} + \frac{\mathrm{e}^x}{x^2}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \frac{\mathrm{e}^x c_1}{x^2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\frac{\mathrm{e}^x c_1}{x^2} + c_2\right)x^2 \\
&= c_2 x^2 + c_1 \mathrm{e}^x
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(\frac{\mathrm{e}^x c_1}{x^2} + c_2\right)x^2 \tag{1}$$

Verification of solutions

$$y = \left(\frac{\mathrm{e}^x c_1}{x^2} + c_2\right)x^2$$

Verified OK.

8.20.2 Solving using Kovacic algorithm

Writing the ode as

$$(x^2-2x)\,y''+(-x^2+2)\,y'+(2x-2)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x^2-2x\\B&=-x^2+2\\C&=2x-2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^4-8x^3+24x^2-24x+12}{4\,(x^2-2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^4-8x^3+24x^2-24x+12\\t&=4\big(x^2-2x\big)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^4-8x^3+24x^2-24x+12}{4\,(x^2-2x)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y=z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 384: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 4 \\
&= 0
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2 - 2x)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = 2$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{4(-2+x)} + \frac{3}{4x^2} - \frac{3}{4x} + \frac{3}{4(-2+x)^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

For the pole at $x = 2$ let b be the coefficient of $\frac{1}{(-2+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$
v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{1}{2} - \frac{1}{x} + \frac{2}{x^3} + \frac{11}{x^4} + \frac{42}{x^5} + \frac{132}{x^6} + \frac{348}{x^7} + \frac{711}{x^8} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{1}{2}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2} \\
&= Q + \frac{R}{4x^4 - 16x^3 + 16x^2} \\
&= \left(\frac{1}{4}\right) + \left(\frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}\right) \\
&= \frac{1}{4} + \frac{-4x^3 + 20x^2 - 24x + 12}{4x^4 - 16x^3 + 16x^2}
\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is -4. Dividing this by leading coefficient in t which is 4 gives -1. Now b can be found.

$$\begin{aligned}
b &= (-1) - (0) \\
&= -1
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-1}{\frac{1}{2}} - 0\right) &= -1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-1}{\frac{1}{2}} - 0\right) &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^4 - 8x^3 + 24x^2 - 24x + 12}{4\left(x^2 - 2x\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$
2	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{1}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -1$ then

$$\begin{aligned} d &= \alpha_\infty^+ - \left(\alpha_{c_1}^- + \alpha_{c_2}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((-)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^-}{x - c_2} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} - \frac{1}{2(-2 + x)} + \left(\frac{1}{2}\right) \\ &= -\frac{1}{2x} - \frac{1}{2(-2 + x)} + \frac{1}{2} \\ &= -\frac{1}{2x} - \frac{1}{-4 + 2x} + \frac{1}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - \frac{1}{2(-2+x)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2x^2} + \frac{1}{2(-2+x)^2}\right) + \left(-\frac{1}{2x} - \frac{1}{2(-2+x)} + \frac{1}{2}\right)^2 - \left(\frac{x^4 -}{}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(-\frac{1}{2x} - \frac{1}{2(-2+x)} + \frac{1}{2}\right) dx} \\
&= \frac{e^{\frac{x}{2}}}{\sqrt{x}\,\sqrt{-2+x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2+2}{x^2-2x}\, dx} \\
&= z_1 e^{\frac{x}{2} + \frac{\ln(x)}{2} + \frac{\ln(-2+x)}{2}} \\
&= z_1 \left(\sqrt{x}\,\sqrt{-2+x}\, e^{\frac{x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{e^x \sqrt{x}\,\sqrt{-2+x}}{\sqrt{x(-2+x)}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2+2}{x^2-2x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x+\ln(x)+\ln(-2+x)}}{(y_1)^2}\,dx \\
&= y_1\left(-x^2 \mathrm{e}^{-x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{\mathrm{e}^{x}\sqrt{x}\,\sqrt{-2+x}}{\sqrt{x\,(-2+x)}}\right) + c_2\left(\frac{\mathrm{e}^{x}\sqrt{x}\,\sqrt{-2+x}}{\sqrt{x\,(-2+x)}}\left(-x^2\mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1\mathrm{e}^{x}\sqrt{x}\,\sqrt{-2+x}}{\sqrt{x\,(-2+x)}} - \frac{c_2 x^{\frac{5}{2}}\sqrt{-2+x}}{\sqrt{x\,(-2+x)}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1\mathrm{e}^{x}\sqrt{x}\,\sqrt{-2+x}}{\sqrt{x\,(-2+x)}} - \frac{c_2 x^{\frac{5}{2}}\sqrt{-2+x}}{\sqrt{x\,(-2+x)}}
$$

Verified OK.

8.20.3 Maple step by step solution

Let's solve

$(x^2-2x)\,y'' + (-x^2+2)\,y' + (2x-2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(x^2-2)y'}{x(-2+x)} - \frac{2y(x-1)}{x(-2+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$$y'' - \frac{(x^2-2)y'}{x(-2+x)} + \frac{2y(x-1)}{x(-2+x)} = 0$$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $$\left[P_2(x) = -\frac{x^2-2}{x(-2+x)}, P_3(x) = \frac{2(x-1)}{x(-2+x)}\right]$$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -1$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$y''x(-2+x) + (-x^2+2)\,y' + (2x-2)\,y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

$$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0 r(-2+r)\, x^{-1+r} + (-2a_1(1+r)(-1+r) + a_0(1+r)(-2+r))\, x^r + \left(\sum_{k=1}^{\infty} (-2a_{k+1}(k+r+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term must be 0

$$-2a_1(1+r)(-1+r) + a_0(1+r)(-2+r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+r+1)(k+r-2) - 2k^2 a_{k+1} + (-4r a_{k+1} - a_{k-1})\, k - 2r^2 a_{k+1} - a_{k-1} r + 3a_{k-1} + 2a_{k+1} =$$

- Shift index using $k- > k+1$

$$a_{k+1}(k+2+r)(k+r-1) - 2(k+1)^2 a_{k+2} + (-4r a_{k+2} - a_k)(k+1) - 2r^2 a_{k+2} - r a_k + 3a_k +$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{k^2 a_{k+1} + 2kr a_{k+1} + r^2 a_{k+1} - k a_k + k a_{k+1} - r a_k + r a_{k+1} + 2a_k - 2a_{k+1}}{2(k^2 + 2kr + r^2 + 2k + 2r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{k^2 a_{k+1} - k a_k + k a_{k+1} + 2a_k - 2a_{k+1}}{2(k^2 + 2k)}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

$$a_{k+2} = \frac{k^2 a_{k+1} - k a_k + k a_{k+1} + 2a_k - 2a_{k+1}}{2(k^2 + 2k)}$$

- Recursion relation for $r = 2$

$$a_{k+2} = \frac{k^2 a_{k+1} - k a_k + 5k a_{k+1} + 4a_{k+1}}{2(k^2 + 6k + 8)}$$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{k^2 a_{k+1} - k a_k + 5k a_{k+1} + 4a_{k+1}}{2(k^2 + 6k + 8)}, -6a_1 = 0\right]$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(1+2x)\, y''-2y'-(2x+3)\, y=(1+2x)^{2}}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{-x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1+2x, B = -2, C = -3-2x, f(x) = 4\left(x+\frac{1}{2}\right)^{2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$(1+2x)\, y''-2y'+(-3-2x)\, y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^{2}}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{2}{1+2x}$$

Therefore

$$\begin{aligned}
y_2(x) &= \mathrm{e}^{-x}\left(\int \mathrm{e}^{-\left(\int -\frac{2}{1+2x}dx\right)}\mathrm{e}^{2x}dx\right)\\
y_2(x) &= \mathrm{e}^{-x}\int \frac{1+2x}{\mathrm{e}^{-2x}},dx\\
y_2(x) &= \mathrm{e}^{-x}\left(\int (1+2x)\,\mathrm{e}^{2x}dx\right)\\
y_2(x) &= \mathrm{e}^{-x}x\,\mathrm{e}^{2x}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1y_1(x) + c_2y_2(x)\\
&= c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{-x}x\,\mathrm{e}^{2x}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1\mathrm{e}^{-x} + c_2\mathrm{e}^{-x}x\,\mathrm{e}^{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \mathrm{e}^{-x}\\
y_2 &= \mathrm{e}^{-x}x\,\mathrm{e}^{2x}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-x} x\, \mathrm{e}^{2x} \\ \frac{d}{dx}\left(\mathrm{e}^{-x}\right) & \frac{d}{dx}\left(\mathrm{e}^{-x} x\, \mathrm{e}^{2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \mathrm{e}^{-x} x\, \mathrm{e}^{2x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{-x} x\, \mathrm{e}^{2x} + \mathrm{e}^{-x} \mathrm{e}^{2x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x}\right)\left(\mathrm{e}^{-x} x\, \mathrm{e}^{2x} + \mathrm{e}^{-x} \mathrm{e}^{2x}\right) - \left(\mathrm{e}^{-x} x\, \mathrm{e}^{2x}\right)\left(-\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = 2\,\mathrm{e}^{-2x} x\, \mathrm{e}^{2x} + \mathrm{e}^{-2x} \mathrm{e}^{2x}$$

Which simplifies to

$$W = 1 + 2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\,\mathrm{e}^{-x} x\, \mathrm{e}^{2x} \left(x + \frac{1}{2}\right)^2}{\left(1 + 2x\right)^2}\, dx$$

Which simplifies to

$$u_1 = -\int x\, \mathrm{e}^{x} dx$$

Hence

$$u_1 = -(x - 1)\, \mathrm{e}^{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\,\mathrm{e}^{-x} \left(x + \frac{1}{2}\right)^2}{\left(1+2x\right)^2}\, dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{-x} dx$$

Hence

$$u_2 = -\mathrm{e}^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -(x-1)\,\mathrm{e}^{x}\mathrm{e}^{-x} - \mathrm{e}^{-2x} x\,\mathrm{e}^{2x}$$

Which simplifies to

$$y_p(x) = 1 - 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{-x} x\,\mathrm{e}^{2x}\right) + (1 - 2x) \end{aligned}$$

Which simplifies to

$$y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{x} + 1 - 2x$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{x} + 1 - 2x \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-x} + c_2 x\,\mathrm{e}^{x} + 1 - 2x$$

Verified OK.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "exact linear second order ode", "second_order_integrable_as_is", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' + y'x - y = \frac{4}{x^2}}$$

Given that one solution of the ode is

$$y_1 = x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = \frac{4}{x^2}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + y'x - y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{1}{x}$$

Therefore

$$y_2(x) = x\left(\int \frac{\mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}}{x^2}dx\right)$$

$$y_2(x) = x \int \frac{\frac{1}{x}}{x^2},\, dx$$

$$y_2(x) = x\left(\int \frac{1}{x^3}dx\right)$$

$$y_2(x) = -\frac{1}{2x}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x - \frac{c_2}{2x} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x - \frac{c_2}{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = -\frac{1}{2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & -\frac{1}{2x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(-\frac{1}{2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & -\frac{1}{2x} \\ 1 & \frac{1}{2x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(\frac{1}{2x^2}\right) - \left(-\frac{1}{2x}\right)(1)$$

Which simplifies to

$$W = \frac{1}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{2}{x^3}}{x}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{2}{x^4} dx$$

Hence

$$u_1 = -\frac{2}{3x^3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4}{x}}{x} dx$$

Which simplifies to

$$u_2 = \int \frac{4}{x^2} dx$$

Hence

$$u_2 = -\frac{4}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{4}{3x^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x - \frac{c_2}{2x}\right) + \left(\frac{4}{3x^2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x - \frac{c_2}{2x} + \frac{4}{3x^2} \tag{1}$$

Verification of solutions

$$y = c_1 x - \frac{c_2}{2x} + \frac{4}{3x^2}$$

Verified OK.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - y'x + y = x}$$

Given that one solution of the ode is

$$y_1 = x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = 1, f(x) = x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - y'x + y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{1}{x}$$

Therefore

$$\begin{aligned}
y_2(x) &= x \left(\int \frac{e^{-\left(\int -\frac{1}{x} dx\right)}}{x^2} dx \right) \\
y_2(x) &= x \int \frac{x}{x^2}, dx \\
y_2(x) &= x \left(\int \frac{1}{x} dx \right) \\
y_2(x) &= x \ln(x)
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x + \ln(x)\, c_2 x
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x + \ln(x)\, c_2 x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x \ln(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x \ln(x) \\ \frac{d}{dx}(x) & \frac{d}{dx}(x \ln(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x \ln(x) \\ 1 & \ln(x) + 1 \end{vmatrix}$$

Therefore

$$W = (x)(\ln(x) + 1) - (x \ln(x))(1)$$

Which simplifies to

$$W = x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\ln(x) x^2}{x^3} dx$$

Which simplifies to

$$u_1 = -\int \frac{\ln(x)}{x} dx$$

Hence

$$u_1 = -\frac{\ln(x)^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2}{x^3} \, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x} dx$$

Hence

$$u_2 = \ln(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x \ln(x)^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 x + \ln(x) c_2 x) + \left(\frac{x \ln(x)^2}{2}\right) \end{aligned}$$

Which simplifies to

$$y = x(c_1 + c_2 \ln(x)) + \frac{x \ln(x)^2}{2}$$

Summary

The solution(s) found are the following

$$y = x(c_1 + c_2 \ln(x)) + \frac{x \ln(x)^2}{2} \tag{1}$$

Verification of solutions

$$y = x(c_1 + c_2 \ln(x)) + \frac{x \ln(x)^2}{2}$$

Verified OK.

Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 3y' + 2y = \frac{1}{1 + e^{-x}}}$$

Given that one solution of the ode is

$$y_1 = e^{2x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = \frac{1}{1+e^{-x}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -3$$

Therefore

$$\begin{aligned}
y_2(x) &= \mathrm{e}^{2x}\left(\int \mathrm{e}^{-\left(\int(-3)dx\right)}\mathrm{e}^{-4x}dx\right) \\
y_2(x) &= \mathrm{e}^{2x}\int \frac{\mathrm{e}^{3x}}{\mathrm{e}^{4x}}, dx \\
y_2(x) &= \mathrm{e}^{2x}\left(\int \mathrm{e}^{-x}dx\right) \\
y_2(x) &= -\mathrm{e}^{-x}\mathrm{e}^{2x}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1y_1(x) + c_2y_2(x) \\
&= c_1\mathrm{e}^{2x} - c_2\mathrm{e}^{-x}\mathrm{e}^{2x}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1\mathrm{e}^{2x} - c_2\mathrm{e}^{-x}\mathrm{e}^{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \mathrm{e}^{2x} \\
y_2 &= -\mathrm{e}^{-x}\mathrm{e}^{2x}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & -e^{-x}e^{2x} \\ \frac{d}{dx}(e^{2x}) & \frac{d}{dx}(-e^{-x}e^{2x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & -e^{-x}e^{2x} \\ 2\,e^{2x} & -e^{-x}e^{2x} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\right)\left(-e^{-x}e^{2x}\right) - \left(-e^{-x}e^{2x}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = e^{4x}e^{-x}$$

Which simplifies to

$$W = e^{3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{e^{-x}e^{2x}}{1+e^{-x}}}{e^{3x}}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{e^{-2x}}{1+e^{-x}} dx$$

Hence

$$u_1 = -e^{-x} - \ln\left(e^{x}\right) + \ln\left(1+e^{x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{e^{2x}}{1+e^{-x}}}{e^{3x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{e^{-x}}{1+e^{-x}} dx$$

Hence

$$u_2 = -\ln\left(1+e^{-x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-e^{-x} - \ln\left(e^{x}\right) + \ln\left(1+e^{x}\right)\right) e^{2x} + \ln\left(1+e^{-x}\right) e^{-x} e^{2x}$$

Which simplifies to

$$y_p(x) = e^{x}\left(-\ln\left(e^{x}\right) e^{x} + \ln\left(1+e^{x}\right) e^{x} + \ln\left(1+e^{-x}\right) - 1\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} - c_2 e^{-x} e^{2x}\right) + \left(e^{x}\left(-\ln\left(e^{x}\right) e^{x} + \ln\left(1+e^{x}\right) e^{x} + \ln\left(1+e^{-x}\right) - 1\right)\right) \end{aligned}$$

Which simplifies to

$$y = c_1 e^{2x} - c_2 e^{x} + e^{x}\left(-\ln\left(e^{x}\right) e^{x} + \ln\left(1+e^{x}\right) e^{x} + \ln\left(1+e^{-x}\right) - 1\right)$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} - c_2 e^{x} + e^{x}\left(-\ln\left(e^{x}\right) e^{x} + \ln\left(1+e^{x}\right) e^{x} + \ln\left(1+e^{-x}\right) - 1\right) \tag{1}$$

Verification of solutions

$$y = c_1 e^{2x} - c_2 e^{x} + e^{x}\left(-\ln\left(e^{x}\right) e^{x} + \ln\left(1+e^{x}\right) e^{x} + \ln\left(1+e^{-x}\right) - 1\right)$$

Verified OK.

9.4.1 Maple step by step solution

Let's solve

$y'' - 3y' + 2y = \frac{1}{1+e^{-x}}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = e^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 e^x + c_2 e^{2x} + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \frac{1}{1+e^{-x}}\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{2x} \\ e^x & 2\,e^{2x} \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = e^{3x}$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -e^x \left(\int \frac{e^{-x}}{1+e^{-x}} dx\right) + e^{2x} \left(\int \frac{e^{-2x}}{1+e^{-x}} dx\right)$$

- Compute integrals

$$y_p(x) = e^x(-\ln(e^x) e^x + \ln(1+e^x) e^x + \ln(1+e^{-x}) - 1)$$

- Substitute particular solution into general solution to ODE

$$y = c_1 e^x + c_2 e^{2x} + e^x(-\ln(e^x) e^x + \ln(1+e^x) e^x + \ln(1+e^{-x}) - 1)$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = 7x^{\frac{3}{2}}\mathrm{e}^{x}}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = 7x^{\frac{3}{2}}\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -2$$

Therefore

$$\begin{aligned} y_2(x) &= e^x \left(\int e^{-\left(\int (-2)dx\right)} e^{-2x} dx \right) \\ y_2(x) &= e^x \int \frac{e^{2x}}{e^{2x}}, dx \\ y_2(x) &= e^x \left(\int 1 dx \right) \\ y_2(x) &= x e^x \end{aligned}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 e^x + c_2 x e^x \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^x + c_2 x e^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^x$$
$$y_2 = x\,\mathrm{e}^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^x & x\,\mathrm{e}^x \\ \frac{d}{dx}(\mathrm{e}^x) & \frac{d}{dx}(x\,\mathrm{e}^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^x & x\,\mathrm{e}^x \\ \mathrm{e}^x & x\,\mathrm{e}^x + \mathrm{e}^x \end{vmatrix}$$

Therefore

$$W = (\mathrm{e}^x)(x\,\mathrm{e}^x + \mathrm{e}^x) - (x\,\mathrm{e}^x)(\mathrm{e}^x)$$

Which simplifies to

$$W = \mathrm{e}^{2x}$$

Which simplifies to

$$W = \mathrm{e}^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{7x^{\frac{5}{2}}\mathrm{e}^{2x}}{\mathrm{e}^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int 7x^{\frac{5}{2}}dx$$

Hence

$$u_1 = -2x^{\frac{7}{2}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{7\,\mathrm{e}^{2x} x^{\frac{3}{2}}}{\mathrm{e}^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int 7x^{\frac{3}{2}}dx$$

Hence

$$u_2 = \frac{14x^{\frac{5}{2}}}{5}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{4x^{\frac{7}{2}}\mathrm{e}^{x}}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \mathrm{e}^{x} + c_2 x\,\mathrm{e}^{x}) + \left(\frac{4x^{\frac{7}{2}}\mathrm{e}^{x}}{5}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{x}(c_2 x + c_1) + \frac{4x^{\frac{7}{2}}\mathrm{e}^{x}}{5}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x}(c_2 x + c_1) + \frac{4x^{\frac{7}{2}}\mathrm{e}^{x}}{5} \tag{1}$$

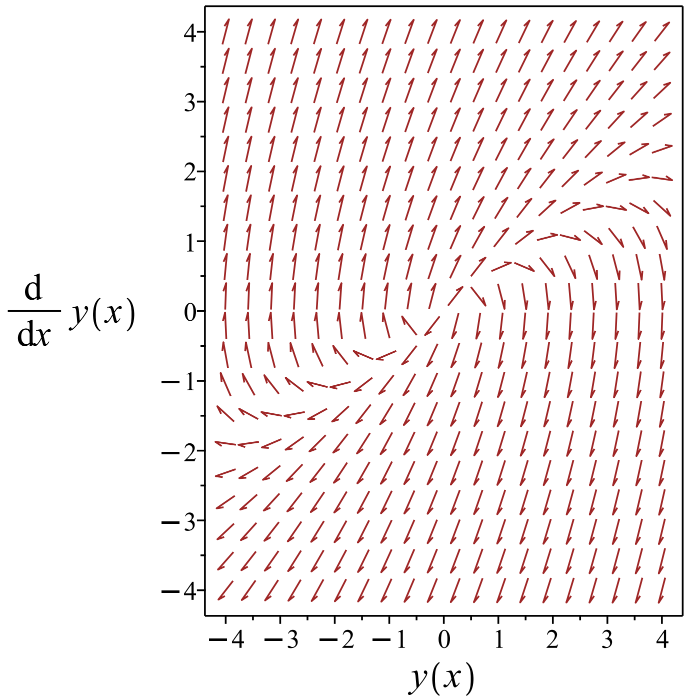

Figure 487: Slope field plot

Verification of solutions

$$y = e^x(c_2x + c_1) + \frac{4x^{\frac{7}{2}}e^x}{5}$$

Verified OK.

9.5.1 Maple step by step solution

Let's solve

$y'' - 2y' + y = 7x^{\frac{3}{2}}e^x$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r - 1)^2 = 0$

- Root of the characteristic polynomial

$r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^x + c_2 x\,\mathrm{e}^x + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  - Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 7x^{\frac{3}{2}}\mathrm{e}^x\right]$

  - Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^x & x\,\mathrm{e}^x \\ \mathrm{e}^x & x\,\mathrm{e}^x + \mathrm{e}^x \end{bmatrix}$

  - Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$

  - Substitute functions into equation for $y_p(x)$

    $y_p(x) = -7\,\mathrm{e}^x\left(-\left(\int x^{\frac{3}{2}} dx\right) x + \int x^{\frac{5}{2}} dx\right)$

  - Compute integrals

    $y_p(x) = \frac{4x^{\frac{7}{2}}\mathrm{e}^x}{5}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,\mathrm{e}^x + c_1 \mathrm{e}^x + \frac{4x^{\frac{7}{2}}\mathrm{e}^x}{5}$

The type(s) of ODE detected by this program : **"reduction_of_order", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{4x^2y'' + (-8x^2+4x)\, y' + (4x^2-4x-1)\, y = 4\sqrt{x}\, e^x(4x+1)}$$

Given that one solution of the ode is

$$y_1 = \sqrt{x}\, e^x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4x^2, B = -8x^2+4x, C = 4x^2-4x-1, f(x) = -(-16x-4)\, e^x\sqrt{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$4x^2y'' + (-8x^2+4x)\, y' + (4x^2-4x-1)\, y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-8x^2 + 4x}{4x^2}$$

Therefore

$$y_2(x) = \sqrt{x}\, e^{x} \left(\int \frac{e^{-\left(\int \frac{-8x^2+4x}{4x^2} dx\right)} e^{-2x}}{x} dx\right)$$

$$y_2(x) = \sqrt{x}\, e^{x} \int \frac{e^{2x-\ln(x)}}{x\, e^{2x}}, dx$$

$$y_2(x) = \sqrt{x}\, e^{x} \left(\int \frac{1}{x^2} dx\right)$$

$$y_2(x) = -\frac{e^{x}}{\sqrt{x}}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \sqrt{x}\, e^{x} c_1 - \frac{c_2 e^{x}}{\sqrt{x}} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \sqrt{x}\, e^{x} c_1 - \frac{c_2 e^{x}}{\sqrt{x}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{x}\, e^{x}$$
$$y_2 = -\frac{e^{x}}{\sqrt{x}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x}\, e^{x} & -\frac{e^{x}}{\sqrt{x}} \\ \frac{d}{dx}\left(\sqrt{x}\, e^{x}\right) & \frac{d}{dx}\left(-\frac{e^{x}}{\sqrt{x}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x}\, e^{x} & -\frac{e^{x}}{\sqrt{x}} \\ \frac{e^{x}}{2\sqrt{x}} + \sqrt{x}\, e^{x} & \frac{e^{x}}{2x^{\frac{3}{2}}} - \frac{e^{x}}{\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x}\, e^{x}\right)\left(\frac{e^{x}}{2x^{\frac{3}{2}}} - \frac{e^{x}}{\sqrt{x}}\right) - \left(-\frac{e^{x}}{\sqrt{x}}\right)\left(\frac{e^{x}}{2\sqrt{x}} + \sqrt{x}\, e^{x}\right)$$

Which simplifies to

$$W = \frac{e^{2x}}{x}$$

Which simplifies to

$$W = \frac{e^{2x}}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{2x}(-16x-4)}{4x\, e^{2x}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{-4x-1}{x} dx$$

Hence

$$u_1 = 4x + \ln(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{-x\, e^{2x}(-16x-4)}{4x\, e^{2x}}\, dx$$

Which simplifies to

$$u_2 = \int (4x+1)\, dx$$

Hence

$$u_2 = 2x^2 + x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (4x + \ln(x))\sqrt{x}\, e^{x} - \frac{(2x^2+x)\, e^{x}}{\sqrt{x}}$$

Which simplifies to

$$y_p(x) = e^{x}\sqrt{x}\,(\ln(x) + 2x - 1)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\sqrt{x}\, e^{x} c_1 - \frac{c_2 e^{x}}{\sqrt{x}}\right) + \left(e^{x}\sqrt{x}\,(\ln(x) + 2x - 1)\right) \end{aligned}$$

Which simplifies to

$$y = \frac{e^{x}(c_1 x - c_2)}{\sqrt{x}} + e^{x}\sqrt{x}\,(\ln(x) + 2x - 1)$$

Summary
The solution(s) found are the following

$$y = \frac{e^{x}(c_1 x - c_2)}{\sqrt{x}} + e^{x}\sqrt{x}\,(\ln(x) + 2x - 1) \tag{1}$$

Verification of solutions

$$y = \frac{e^{x}(c_1 x - c_2)}{\sqrt{x}} + e^{x}\sqrt{x}\,(\ln(x) + 2x - 1)$$

Verified OK.

Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 2y = e^x \sec(x)}$$

Given that one solution of the ode is

$$y_1 = \cos(x) e^x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 2, f(x) = e^x \sec(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -2$$

Therefore

$$y_2(x) = \cos(x)\,\mathrm{e}^{x}\left(\int \frac{\mathrm{e}^{-\left(\int(-2)dx\right)}\,\mathrm{e}^{-2x}}{\cos(x)^2}dx\right)$$

$$y_2(x) = \cos(x)\,\mathrm{e}^{x}\int \frac{\mathrm{e}^{2x}}{\cos(x)^2\,\mathrm{e}^{2x}},dx$$

$$y_2(x) = \cos(x)\,\mathrm{e}^{x}\left(\int \sec(x)^2\,dx\right)$$

$$y_2(x) = \cos(x)\,\mathrm{e}^{x}\tan(x)$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= \cos(x)\,\mathrm{e}^{x}c_1 + c_2\cos(x)\,\mathrm{e}^{x}\tan(x) \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \cos(x)\,\mathrm{e}^{x}c_1 + c_2\cos(x)\,\mathrm{e}^{x}\tan(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(x)\,\mathrm{e}^{x} \\ y_2 &= \cos(x)\,\mathrm{e}^{x}\tan(x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\,e^{x} & \cos(x)\,e^{x}\tan(x) \\ \frac{d}{dx}(\cos(x)\,e^{x}) & \frac{d}{dx}(\cos(x)\,e^{x}\tan(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\,e^{x} & \cos(x)\,e^{x}\tan(x) \\ -\sin(x)\,e^{x} + \cos(x)\,e^{x} & -\sin(x)\,e^{x}\tan(x) + \cos(x)\,e^{x}\tan(x) + \cos(x)\,e^{x}(1+\tan(x)^2) \end{vmatrix}$$

Therefore

$$\begin{aligned} W = {} & (\cos(x)\,e^{x})\left(-\sin(x)\,e^{x}\tan(x) + \cos(x)\,e^{x}\tan(x) + \cos(x)\,e^{x}(1+\tan(x)^2)\right) \\ & - (\cos(x)\,e^{x}\tan(x))(-\sin(x)\,e^{x} + \cos(x)\,e^{x}) \end{aligned}$$

Which simplifies to

$$W = \tan(x)^2\,e^{2x}\cos(x)^2 + \cos(x)^2\,e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\cos(x)\,e^{2x}\tan(x)\sec(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int \tan(x)\,dx$$

Hence

$$u_1 = \ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(x)\,\mathrm{e}^{2x}\sec(x)}{\mathrm{e}^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int 1dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln(\cos(x))\cos(x)\,\mathrm{e}^x + x\cos(x)\,\mathrm{e}^x\tan(x)$$

Which simplifies to

$$y_p(x) = \mathrm{e}^x(\ln(\cos(x))\cos(x) + \sin(x)\,x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (\cos(x)\,\mathrm{e}^x c_1 + c_2\cos(x)\,\mathrm{e}^x\tan(x)) + (\mathrm{e}^x(\ln(\cos(x))\cos(x) + \sin(x)\,x)) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^x(c_1\cos(x) + c_2\sin(x)) + \mathrm{e}^x(\ln(\cos(x))\cos(x) + \sin(x)\,x)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^x(c_1\cos(x) + c_2\sin(x)) + \mathrm{e}^x(\ln(\cos(x))\cos(x) + \sin(x)\,x) \tag{1}$$

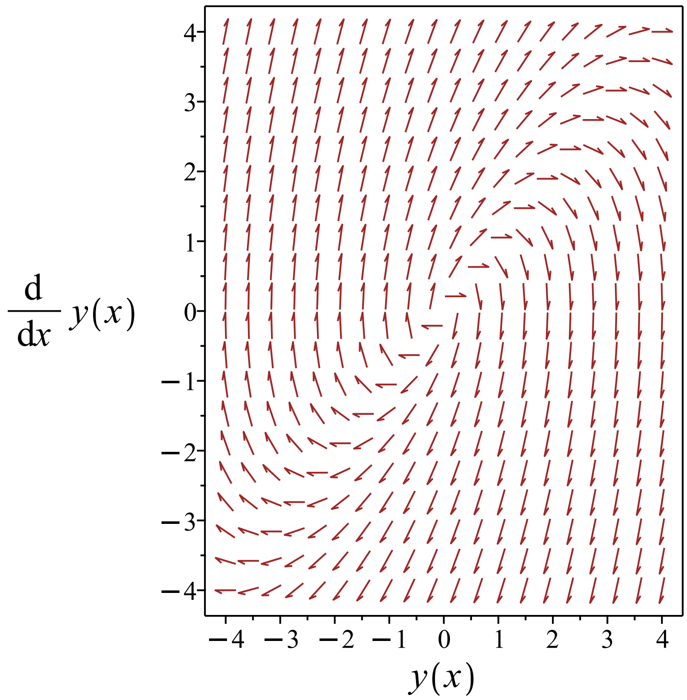

Figure 488: Slope field plot

Verification of solutions

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + e^{x}(\ln(\cos(x)) \cos(x) + \sin(x)\, x)$$

Verified OK.

9.7.1 Maple step by step solution

Let's solve

$y'' - 2y' + 2y = e^{x} \sec(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2 \pm (\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (1 - I, 1 + I)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)\, e^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)\, e^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \cos(x)\, e^x c_1 + e^x \sin(x)\, c_2 + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = e^x \sec(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x)\, e^x & \sin(x)\, e^x \\ -\sin(x)\, e^x + \cos(x)\, e^x & \cos(x)\, e^x + \sin(x)\, e^x \end{bmatrix}$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = e^{2x}$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x) = -e^x\left(\cos(x)\left(\int \tan(x)\, dx\right) - \sin(x)\left(\int 1 dx\right)\right)$

  ◦ Compute integrals

    $y_p(x) = e^x(\ln(\cos(x))\cos(x) + \sin(x)\, x)$

- Substitute particular solution into general solution to ODE

  $y = \cos(x)\, e^x c_1 + e^x \sin(x)\, c_2 + e^x(\ln(\cos(x))\cos(x) + \sin(x)\, x)$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y'x + (4x^2 + 2)\, y = 8\,\mathrm{e}^{-x(2+x)}}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{-x^2}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 4x, C = 4x^2 + 2, f(x) = 8\,\mathrm{e}^{-x(2+x)}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y'x + (4x^2 + 2)\, y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = 4x$$

Therefore

$$\begin{aligned}
y_2(x) &= \mathrm{e}^{-x^2} \left(\int \mathrm{e}^{-\left(\int 4x dx\right)} \mathrm{e}^{2x^2} dx \right) \\
y_2(x) &= \mathrm{e}^{-x^2} \int \frac{\mathrm{e}^{-2x^2}}{\mathrm{e}^{-2x^2}}, dx \\
y_2(x) &= \mathrm{e}^{-x^2} \left(\int 1 dx \right) \\
y_2(x) &= x\, \mathrm{e}^{-x^2}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \mathrm{e}^{-x^2} + c_2 x\, \mathrm{e}^{-x^2}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x^2} + c_2 x\, \mathrm{e}^{-x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \mathrm{e}^{-x^2} \\
y_2 &= x\, \mathrm{e}^{-x^2}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x^2} & x\,e^{-x^2} \\ \frac{d}{dx}\left(e^{-x^2}\right) & \frac{d}{dx}\left(x\,e^{-x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x^2} & x\,e^{-x^2} \\ -2x\,e^{-x^2} & e^{-x^2} - 2x^2 e^{-x^2} \end{vmatrix}$$

Therefore

$$W = \left(e^{-x^2}\right)\left(e^{-x^2} - 2x^2 e^{-x^2}\right) - \left(x\,e^{-x^2}\right)\left(-2x\,e^{-x^2}\right)$$

Which simplifies to

$$W = e^{-2x^2}$$

Which simplifies to

$$W = e^{-2x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{8x\,e^{-x^2} e^{-x(2+x)}}{e^{-2x^2}}\,dx$$

Which simplifies to

$$u_1 = -\int 8\,e^{-2x} x dx$$

Hence

$$u_1 = 2(1 + 2x)\,\mathrm{e}^{-2x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,\mathrm{e}^{-x^2}\mathrm{e}^{-x(2+x)}}{\mathrm{e}^{-2x^2}}\,dx$$

Which simplifies to

$$u_2 = \int 8\,\mathrm{e}^{-2x}dx$$

Hence

$$u_2 = -4\,\mathrm{e}^{-2x}$$

Which simplifies to

$$\begin{aligned} u_1 &= (4x + 2)\,\mathrm{e}^{-2x} \\ u_2 &= -4\,\mathrm{e}^{-2x} \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (4x + 2)\,\mathrm{e}^{-2x}\mathrm{e}^{-x^2} - 4\,\mathrm{e}^{-2x}x\,\mathrm{e}^{-x^2}$$

Which simplifies to

$$y_p(x) = 2\,\mathrm{e}^{-x(2+x)}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x^2} + c_2x\,\mathrm{e}^{-x^2}\right) + \left(2\,\mathrm{e}^{-x(2+x)}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x^2}(c_2x + c_1) + 2\,\mathrm{e}^{-x(2+x)}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x^2}(c_2x + c_1) + 2\,\mathrm{e}^{-x(2+x)} \tag{1}$$

Verification of solutions

$$y = e^{-x^2}(c_2x + c_1) + 2\,e^{-x(2+x)}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + y'x - 4y = -6x - 4}$$

Given that one solution of the ode is

$$y_1 = x^2$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -4, f(x) = -6x - 4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + y'x - 4y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{1}{x}$$

Therefore

$$y_2(x) = x^2\left(\int \frac{e^{-\left(\int \frac{1}{x}dx\right)}}{x^4}dx\right)$$

$$y_2(x) = x^2 \int \frac{\frac{1}{x}}{x^4}, dx$$

$$y_2(x) = x^2\left(\int \frac{1}{x^5}dx\right)$$

$$y_2(x) = -\frac{1}{4x^2}$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= c_1x^2 - \frac{c_2}{4x^2} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1x^2 - \frac{c_2}{4x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$

$$y_2 = -\frac{1}{4x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & -\frac{1}{4x^2} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(-\frac{1}{4x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & -\frac{1}{4x^2} \\ 2x & \frac{1}{2x^3} \end{vmatrix}$$

Therefore

$$W = (x^2)\left(\frac{1}{2x^3}\right) - \left(-\frac{1}{4x^2}\right)(2x)$$

Which simplifies to

$$W = \frac{1}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{-6x-4}{4x^2}}{x}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{3x+2}{2x^3}dx$$

Hence

$$u_1 = \frac{3}{2x} + \frac{1}{2x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^2(-6x-4)}{x}\,dx$$

Which simplifies to

$$u_2 = \int \left(-6x^2 - 4x\right) dx$$

Hence

$$u_2 = -2x^3 - 2x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{3}{2x} + \frac{1}{2x^2}\right) x^2 - \frac{-2x^3 - 2x^2}{4x^2}$$

Which simplifies to

$$y_p(x) = 1 + 2x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^2 - \frac{c_2}{4x^2}\right) + (1 + 2x) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 x^2 - \frac{c_2}{4x^2} + 1 + 2x \tag{1}$$

Verification of solutions

$$y = c_1x^2 - \frac{c_2}{4x^2} + 1 + 2x$$

Verified OK.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' + 2x(x-1)\,y' + \left(x^2-2x+2\right)y = \mathrm{e}^{2x}x^3}$$

Given that one solution of the ode is

$$y_1 = x\,\mathrm{e}^{-x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 2x^2 - 2x, C = x^2 - 2x + 2, f(x) = \mathrm{e}^{2x}x^3$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + \left(2x^2-2x\right)y' + \left(x^2-2x+2\right)y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{2x^2 - 2x}{x^2}$$

Therefore

$$\begin{aligned}
y_2(x) &= x\,\mathrm{e}^{-x} \left(\int \frac{\mathrm{e}^{-\left(\int \frac{2x^2-2x}{x^2} dx\right)}\mathrm{e}^{2x}}{x^2} dx \right) \\
y_2(x) &= x\,\mathrm{e}^{-x} \int \frac{\mathrm{e}^{-2x+2\ln(x)}}{x^2\mathrm{e}^{-2x}}, dx \\
y_2(x) &= x\,\mathrm{e}^{-x} \left(\int 1 dx \right) \\
y_2(x) &= x^2\mathrm{e}^{-x}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= x\,\mathrm{e}^{-x} c_1 + c_2 x^2\mathrm{e}^{-x}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = x\,\mathrm{e}^{-x} c_1 + c_2 x^2\mathrm{e}^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= x\,\mathrm{e}^{-x} \\
y_2 &= x^2\mathrm{e}^{-x}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,\mathrm{e}^{-x} & x^2\mathrm{e}^{-x} \\ \frac{d}{dx}(x\,\mathrm{e}^{-x}) & \frac{d}{dx}(x^2\mathrm{e}^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,\mathrm{e}^{-x} & x^2\mathrm{e}^{-x} \\ \mathrm{e}^{-x} - x\,\mathrm{e}^{-x} & 2x\,\mathrm{e}^{-x} - x^2\mathrm{e}^{-x} \end{vmatrix}$$

Therefore

$$W = \left(x\,\mathrm{e}^{-x}\right)\left(2x\,\mathrm{e}^{-x} - x^2\mathrm{e}^{-x}\right) - \left(x^2\mathrm{e}^{-x}\right)\left(\mathrm{e}^{-x} - x\,\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = x^2\mathrm{e}^{-2x}$$

Which simplifies to

$$W = x^2\mathrm{e}^{-2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5\mathrm{e}^{-x}\mathrm{e}^{2x}}{x^4\mathrm{e}^{-2x}}\,dx$$

Which simplifies to

$$u_1 = -\int x\,\mathrm{e}^{3x}dx$$

Hence

$$u_1 = -\frac{(3x-1)\,\mathrm{e}^{3x}}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4 \mathrm{e}^{-x} \mathrm{e}^{2x}}{x^4 \mathrm{e}^{-2x}}\, dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{3x} dx$$

Hence

$$u_2 = \frac{\mathrm{e}^{3x}}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{(3x-1)\, \mathrm{e}^{3x} x\, \mathrm{e}^{-x}}{9} + \frac{\mathrm{e}^{3x} x^2 \mathrm{e}^{-x}}{3}$$

Which simplifies to

$$y_p(x) = \frac{x\, \mathrm{e}^{2x}}{9}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x\, \mathrm{e}^{-x} c_1 + c_2 x^2 \mathrm{e}^{-x}\right) + \left(\frac{x\, \mathrm{e}^{2x}}{9}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x} x (c_2 x + c_1) + \frac{x\, \mathrm{e}^{2x}}{9}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x} x (c_2 x + c_1) + \frac{x\, \mathrm{e}^{2x}}{9} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-x} x (c_2 x + c_1) + \frac{x\, \mathrm{e}^{2x}}{9}$$

Verified OK.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - x(2x-1)\,y' + \left(x^2 - x - 1\right)y = x^2\mathrm{e}^x}$$

Given that one solution of the ode is

$$y_1 = x\,\mathrm{e}^x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2x^2 + x, C = x^2 - x - 1, f(x) = x^2\mathrm{e}^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + \left(-2x^2 + x\right)y' + \left(x^2 - x - 1\right)y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-2x^2 + x}{x^2}$$

Therefore

$$\begin{aligned}
y_2(x) &= x\,\mathrm{e}^x \left(\int \frac{\mathrm{e}^{-\left(\int \frac{-2x^2+x}{x^2}dx\right)}\mathrm{e}^{-2x}}{x^2} dx\right) \\
y_2(x) &= x\,\mathrm{e}^x \int \frac{\mathrm{e}^{2x-\ln(x)}}{x^2 \mathrm{e}^{2x}}, dx \\
y_2(x) &= x\,\mathrm{e}^x \left(\int \frac{1}{x^3} dx\right) \\
y_2(x) &= -\frac{\mathrm{e}^x}{2x}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x\,\mathrm{e}^x - \frac{c_2 \mathrm{e}^x}{2x}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x\,\mathrm{e}^x - \frac{c_2 \mathrm{e}^x}{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x\,e^x$$
$$y_2 = -\frac{e^x}{2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,e^x & -\frac{e^x}{2x} \\ \frac{d}{dx}(x\,e^x) & \frac{d}{dx}\left(-\frac{e^x}{2x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,e^x & -\frac{e^x}{2x} \\ x\,e^x + e^x & -\frac{e^x}{2x} + \frac{e^x}{2x^2} \end{vmatrix}$$

Therefore

$$W = (x\,e^x)\left(-\frac{e^x}{2x} + \frac{e^x}{2x^2}\right) - \left(-\frac{e^x}{2x}\right)(x\,e^x + e^x)$$

Which simplifies to

$$W = \frac{e^{2x}}{x}$$

Which simplifies to

$$W = \frac{e^{2x}}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{x\,e^{2x}}{2}}{x\,e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{1}{2} dx$$

Hence

$$u_1 = \frac{x}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} x^3}{x\, e^{2x}} dx$$

Which simplifies to

$$u_2 = \int x^2 dx$$

Hence

$$u_2 = \frac{x^3}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2 e^x}{3}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x\, e^x - \frac{c_2 e^x}{2x}\right) + \left(\frac{x^2 e^x}{3}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x\, e^x - \frac{c_2 e^x}{2x} + \frac{x^2 e^x}{3} \tag{1}$$

Verification of solutions

$$y = c_1 x\, e^x - \frac{c_2 e^x}{2x} + \frac{x^2 e^x}{3}$$

Verified OK.

Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{(1-2x)\,y''+2y'+(-3+2x)\,y=\left(4x^2-4x+1\right)\mathrm{e}^x}$$

Given that one solution of the ode is

$$y_1=\mathrm{e}^x$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=1-2x, B=2, C=-3+2x, f(x)=(2x-1)^2\,\mathrm{e}^x$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$(1-2x)\,y''+2y'+(-3+2x)\,y=0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x)=y_1\left(\int\frac{\mathrm{e}^{-(\int p dx)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{2}{1 - 2x}$$

Therefore

$$\begin{aligned}
y_2(x) &= \mathrm{e}^{x} \left(\int \mathrm{e}^{-\left(\int \frac{2}{1-2x}dx\right)} \mathrm{e}^{-2x} dx\right) \\
y_2(x) &= \mathrm{e}^{x} \int \frac{1 - 2x}{\mathrm{e}^{2x}}, dx \\
y_2(x) &= \mathrm{e}^{x} \left(\int (1 - 2x)\, \mathrm{e}^{-2x} dx\right) \\
y_2(x) &= \mathrm{e}^{x} \mathrm{e}^{-2x} x
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{x} \mathrm{e}^{-2x} x
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{x} \mathrm{e}^{-2x} x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \mathrm{e}^{x} \\
y_2 &= \mathrm{e}^{x} \mathrm{e}^{-2x} x
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & e^x e^{-2x} x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(e^x e^{-2x} x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & e^x e^{-2x} x \\ e^x & -e^x e^{-2x} x + e^{-2x} e^x \end{vmatrix}$$

Therefore

$$W = (e^x)\left(-e^x e^{-2x} x + e^{-2x} e^x\right) - \left(e^x e^{-2x} x\right)(e^x)$$

Which simplifies to

$$W = -2\, e^{-2x} x\, e^{2x} + e^{2x} e^{-2x}$$

Which simplifies to

$$W = 1 - 2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{2x} e^{-2x} x (2x-1)^2}{(1-2x)^2}\, dx$$

Which simplifies to

$$u_1 = -\int x dx$$

Hence

$$u_1 = -\frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x}(2x-1)^2}{(1-2x)^2}\, dx$$

Which simplifies to

$$u_2 = \int e^{2x} dx$$

Hence

$$u_2 = \frac{e^{2x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2 e^x}{2} + \frac{e^{2x} e^x e^{-2x} x}{2}$$

Which simplifies to

$$y_p(x) = -\frac{e^x x(x-1)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^x + c_2 e^x e^{-2x} x\right) + \left(-\frac{e^x x(x-1)}{2}\right) \end{aligned}$$

Which simplifies to

$$y = c_1 e^x + x\, e^{-x} c_2 - \frac{e^x x(x-1)}{2}$$

Summary

The solution(s) found are the following

$$y = c_1 e^x + x\, e^{-x} c_2 - \frac{e^x x(x-1)}{2} \tag{1}$$

Verification of solutions

$$y = c_1 e^x + x\,e^{-x} c_2 - \frac{e^x x(x-1)}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 3y'x + 4y = 4x^4}$$

Given that one solution of the ode is

$$y_1 = x^2$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 4, f(x) = 4x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 3y'x + 4y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{3}{x}$$

Therefore

$$\begin{aligned}
y_2(x) &= x^2 \left(\int \frac{e^{-\left(\int -\frac{3}{x} dx\right)}}{x^4} dx \right) \\
y_2(x) &= x^2 \int \frac{x^3}{x^4}, dx \\
y_2(x) &= x^2 \left(\int \frac{1}{x} dx \right) \\
y_2(x) &= \ln(x) x^2
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2 + c_2 \ln(x) x^2
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x^2 + c_2 \ln(x) x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = \ln(x)\, x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\ln(x)\, x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ 2x & x + 2x\ln(x) \end{vmatrix}$$

Therefore

$$W = (x^2)\,(x + 2x\ln(x)) - (\ln(x)\, x^2)\,(2x)$$

Which simplifies to

$$W = x^3$$

Which simplifies to

$$W = x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\ln(x)\, x^6}{x^5}\, dx$$

Which simplifies to

$$u_1 = -\int 4x \ln(x)\, dx$$

Hence

$$u_1 = -2\ln(x)\, x^2 + x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x^6}{x^5}\, dx$$

Which simplifies to

$$u_2 = \int 4x dx$$

Hence

$$u_2 = 2x^2$$

Which simplifies to

$$\begin{aligned} u_1 &= x^2(1 - 2\ln(x)) \\ u_2 &= 2x^2 \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^4(1 - 2\ln(x)) + 2x^4 \ln(x)$$

Which simplifies to

$$y_p(x) = x^4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^2 + c_2 \ln(x)\, x^2\right) + \left(x^4\right) \end{aligned}$$

Which simplifies to

$$y = x^2(c_1 + c_2 \ln(x)) + x^4$$

Summary

The solution(s) found are the following

$$y = x^2(c_1 + c_2 \ln(x)) + x^4 \tag{1}$$

Verification of solutions

$$y = x^2(c_1 + c_2 \ln(x)) + x^4$$

Verified OK.

Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{2xy'' + (4x+1)\,y' + (1+2x)\,y = 3\sqrt{x}\,\mathrm{e}^{-x}}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{-x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 2x, B = 4x+1, C = 1+2x, f(x) = 3\sqrt{x}\,\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$2xy'' + (4x+1)\,y' + (1+2x)\,y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{4x+1}{2x}$$

Therefore

$$y_2(x) = \mathrm{e}^{-x} \left(\int \mathrm{e}^{-\left(\int \frac{4x+1}{2x}dx\right)} \mathrm{e}^{2x} dx \right)$$

$$y_2(x) = \mathrm{e}^{-x} \int \frac{\mathrm{e}^{-2x-\frac{\ln(x)}{2}}}{\mathrm{e}^{-2x}}, dx$$

$$y_2(x) = \mathrm{e}^{-x} \left(\int \frac{1}{\sqrt{x}} dx \right)$$

$$y_2(x) = 2\sqrt{x}\, \mathrm{e}^{-x}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \mathrm{e}^{-x} + 2c_2 \sqrt{x}\, \mathrm{e}^{-x} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \mathrm{e}^{-x} + 2c_2 \sqrt{x}\, \mathrm{e}^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^{-x} \\ y_2 &= 2\sqrt{x}\, \mathrm{e}^{-x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & 2\sqrt{x}\,\mathrm{e}^{-x} \\ \frac{d}{dx}(\mathrm{e}^{-x}) & \frac{d}{dx}(2\sqrt{x}\,\mathrm{e}^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & 2\sqrt{x}\,\mathrm{e}^{-x} \\ -\mathrm{e}^{-x} & \frac{\mathrm{e}^{-x}}{\sqrt{x}} - 2\sqrt{x}\,\mathrm{e}^{-x} \end{vmatrix}$$

Therefore

$$W = (\mathrm{e}^{-x})\left(\frac{\mathrm{e}^{-x}}{\sqrt{x}} - 2\sqrt{x}\,\mathrm{e}^{-x}\right) - (2\sqrt{x}\,\mathrm{e}^{-x})(-\mathrm{e}^{-x})$$

Which simplifies to

$$W = \frac{\mathrm{e}^{-2x}}{\sqrt{x}}$$

Which simplifies to

$$W = \frac{\mathrm{e}^{-2x}}{\sqrt{x}}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{6\,\mathrm{e}^{-2x} x}{2\,\mathrm{e}^{-2x}\sqrt{x}}\,dx$$

Which simplifies to

$$u_1 = -\int 3\sqrt{x}dx$$

Hence

$$u_1 = -2x^{\frac{3}{2}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{3\,\mathrm{e}^{-2x}\sqrt{x}}{2\,\mathrm{e}^{-2x}\sqrt{x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{3}{2}dx$$

Hence

$$u_2 = \frac{3x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^{\frac{3}{2}}\mathrm{e}^{-x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \mathrm{e}^{-x} + 2c_2\sqrt{x}\,\mathrm{e}^{-x}\right) + \left(x^{\frac{3}{2}}\mathrm{e}^{-x}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{-x}\left(c_1 + 2\sqrt{x}\,c_2\right) + x^{\frac{3}{2}}\mathrm{e}^{-x}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-x}\left(c_1 + 2\sqrt{x}\,c_2\right) + x^{\frac{3}{2}}\mathrm{e}^{-x} \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-x}\left(c_1 + 2\sqrt{x}\,c_2\right) + x^{\frac{3}{2}}\mathrm{e}^{-x}$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{xy'' - (1+2x)\,y' + (x+1)\,y = -\mathrm{e}^{-x}}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x, B = -1-2x, C = x+1, f(x) = -\mathrm{e}^{-x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$xy'' + (-1-2x)\,y' + (x+1)\,y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-1 - 2x}{x}$$

Therefore

$$y_2(x) = \mathrm{e}^{x}\left(\int \mathrm{e}^{-\left(\int \frac{-1-2x}{x}dx\right)}\mathrm{e}^{-2x}dx\right)$$

$$y_2(x) = \mathrm{e}^{x}\int \frac{\mathrm{e}^{2x+\ln(x)}}{\mathrm{e}^{2x}}, dx$$

$$y_2(x) = \mathrm{e}^{x}\left(\int x dx\right)$$

$$y_2(x) = \frac{x^{2}\mathrm{e}^{x}}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1\mathrm{e}^{x} + \frac{c_2 x^{2}\mathrm{e}^{x}}{2} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1\mathrm{e}^{x} + \frac{c_2 x^{2}\mathrm{e}^{x}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{x}$$

$$y_2 = \frac{x^{2}\mathrm{e}^{x}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & \frac{x^2 e^x}{2} \\ \frac{d}{dx}(e^x) & \frac{d}{dx}\left(\frac{x^2 e^x}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & \frac{x^2 e^x}{2} \\ e^x & x\,e^x + \frac{x^2 e^x}{2} \end{vmatrix}$$

Therefore

$$W = (e^x)\left(x\,e^x + \frac{x^2 e^x}{2}\right) - \left(\frac{x^2 e^x}{2}\right)(e^x)$$

Which simplifies to

$$W = x\,e^{2x}$$

Which simplifies to

$$W = x\,e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{x^2 e^x e^{-x}}{2}}{x^2 e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{e^{-2x}}{2}dx$$

Hence

$$u_1 = -\frac{e^{-2x}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-e^{-x}e^{x}}{x^2 e^{2x}}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{e^{-2x}}{x^2} dx$$

Hence

$$u_2 = \frac{e^{-2x}}{x} - 2\ \mathrm{expIntegral}_1\left(2x\right)$$

Which simplifies to

$$u_1 = -\frac{e^{-2x}}{4}$$
$$u_2 = \frac{-2\ \mathrm{expIntegral}_1\left(2x\right) x + e^{-2x}}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{e^{-2x}e^{x}}{4} + \frac{\left(-2\ \mathrm{expIntegral}_1\left(2x\right) x + e^{-2x}\right) x\, e^{x}}{2}$$

Which simplifies to

$$y_p(x) = -e^{x}\ \mathrm{expIntegral}_1\left(2x\right) x^2 + \frac{e^{-x}(2x-1)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{x} + \frac{c_2 x^2 e^{x}}{2}\right) + \left(-e^{x}\ \mathrm{expIntegral}_1\left(2x\right) x^2 + \frac{e^{-x}(2x-1)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = e^{x}\left(c_1 + \frac{c_2 x^2}{2}\right) - e^{x}\ \mathrm{expIntegral}_1\left(2x\right) x^2 + \frac{e^{-x}(2x-1)}{4}$$

Summary
The solution(s) found are the following

$$y = e^{x}\left(c_1 + \frac{c_2 x^2}{2}\right) - e^{x} \operatorname{expIntegral}_1(2x)\, x^2 + \frac{e^{-x}(2x-1)}{4} \tag{1}$$

Verification of solutions

$$y = e^{x}\left(c_1 + \frac{c_2 x^2}{2}\right) - e^{x} \operatorname{expIntegral}_1(2x)\, x^2 + \frac{e^{-x}(2x-1)}{4}$$

Verified OK.

```

$$\boxed{4x^2y'' - 4x(x+1)\,y' + (2x+3)\,y = 4x^{\frac{5}{2}}\mathrm{e}^{2x}}$$

Given that one solution of the ode is

$$y_1 = \sqrt{x}$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4x^2, B = -4x^2 - 4x, C = 2x + 3, f(x) = 4x^{\frac{5}{2}}\mathrm{e}^{2x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$4x^2y'' + \left(-4x^2 - 4x\right)y' + (2x+3)\,y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-4x^2 - 4x}{4x^2}$$

Therefore

$$y_2(x) = \sqrt{x}\left(\int \frac{\mathrm{e}^{-\left(\int \frac{-4x^2-4x}{4x^2}dx\right)}}{x}dx\right)$$

$$y_2(x) = \sqrt{x}\int \frac{\mathrm{e}^{x+\ln(x)}}{x}, dx$$

$$y_2(x) = \sqrt{x}\left(\int \mathrm{e}^x dx\right)$$

$$y_2(x) = \sqrt{x}\,\mathrm{e}^x$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \sqrt{x}\,c_1 + c_2\sqrt{x}\,\mathrm{e}^x \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \sqrt{x}\,c_1 + c_2\sqrt{x}\,\mathrm{e}^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \sqrt{x} \\ y_2 &= \sqrt{x}\,\mathrm{e}^x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x} & \sqrt{x}\,\mathrm{e}^{x} \\ \frac{d}{dx}\left(\sqrt{x}\right) & \frac{d}{dx}\left(\sqrt{x}\,\mathrm{e}^{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x} & \sqrt{x}\,\mathrm{e}^{x} \\ \frac{1}{2\sqrt{x}} & \frac{\mathrm{e}^{x}}{2\sqrt{x}} + \sqrt{x}\,\mathrm{e}^{x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x}\right)\left(\frac{\mathrm{e}^{x}}{2\sqrt{x}} + \sqrt{x}\,\mathrm{e}^{x}\right) - \left(\sqrt{x}\,\mathrm{e}^{x}\right)\left(\frac{1}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x\,\mathrm{e}^{x}$$

Which simplifies to

$$W = x\,\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4x^3 \mathrm{e}^{x} \mathrm{e}^{2x}}{4\,\mathrm{e}^{x} x^3}\,dx$$

Which simplifies to

$$u_1 = -\int \mathrm{e}^{2x} dx$$

Hence

$$u_1 = -\frac{\mathrm{e}^{2x}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\,e^{2x} x^3}{4\,e^{x} x^3}\, dx$$

Which simplifies to

$$u_2 = \int e^{x} dx$$

Hence

$$u_2 = e^{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^{2x}\sqrt{x}}{2}$$

Which simplifies to

$$y_p(x) = \frac{e^{2x}\sqrt{x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\sqrt{x}\, c_1 + c_2\sqrt{x}\, e^{x}\right) + \left(\frac{e^{2x}\sqrt{x}}{2}\right) \end{aligned}$$

Which simplifies to

$$y = (c_1 + c_2 e^{x})\sqrt{x} + \frac{e^{2x}\sqrt{x}}{2}$$

Summary

The solution(s) found are the following

$$y = (c_1 + c_2 e^{x})\sqrt{x} + \frac{e^{2x}\sqrt{x}}{2} \tag{1}$$

Verification of solutions

$$y = (c_1 + c_2 e^{x})\sqrt{x} + \frac{e^{2x}\sqrt{x}}{2}$$

Verified OK.

Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 17.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 5y'x + 8y = 4x^2}$$

Given that one solution of the ode is

$$y_1 = x^2$$

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -5x, C = 8, f(x) = 4x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 5y'x + 8y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{5}{x}$$

Therefore

$$y_2(x) = x^2 \left(\int \frac{e^{-(\int -\frac{5}{x} dx)}}{x^4} dx \right)$$

$$y_2(x) = x^2 \int \frac{x^5}{x^4}, dx$$

$$y_2(x) = x^2 \left(\int x dx \right)$$

$$y_2(x) = \frac{x^4}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 x^2 + \frac{1}{2} c_2 x^4 \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 x^2 + \frac{1}{2} c_2 x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$

$$y_2 = \frac{x^4}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \frac{x^4}{2} \\ \frac{d}{dx}(x^2) & \frac{d}{dx}\left(\frac{x^4}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \frac{x^4}{2} \\ 2x & 2x^3 \end{vmatrix}$$

Therefore

$$W = (x^2)(2x^3) - \left(\frac{x^4}{2}\right)(2x)$$

Which simplifies to

$$W = x^5$$

Which simplifies to

$$W = x^5$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^6}{x^7}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{2}{x} dx$$

Hence

$$u_1 = -2\ln(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x^4}{x^7}\, dx$$

Which simplifies to

$$u_2 = \int \frac{4}{x^3} dx$$

Hence

$$u_2 = -\frac{2}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2\ln(x)\, x^2 - x^2$$

Which simplifies to

$$y_p(x) = x^2(-1 - 2\ln(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^2 + \frac{1}{2} c_2 x^4\right) + \left(x^2(-1 - 2\ln(x))\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^2 + \frac{c_2 x^4}{2} + x^2(-1 - 2\ln(x)) \tag{1}$$

Verification of solutions

$$y = c_1 x^2 + \frac{c_2 x^4}{2} + x^2(-1 - 2\ln(x))$$

Verified OK.

Verified OK.

9.18.1 Maple step by step solution

Let's solve

$y''x + (-2x + 2) y' + (-2 + x) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(-2+x)y}{x} + \frac{2(x-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2(x-1)y'}{x} + \frac{(-2+x)y}{x} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{2(x-1)}{x}, P_3(x) = \frac{-2+x}{x}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 2$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $y''x + (-2x+2)\,y' + (-2+x)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r-1}$$

- Shift index using $k- > k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(1+r) x^{-1+r} + (a_1(1+r)(2+r) - 2a_0(1+r)) x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k+2+r) - 2a_k\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- Each term must be 0

$$a_1(1+r)(2+r) - 2a_0(1+r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+2+r) - 2a_k k - 2a_k r - 2a_k + a_{k-1} = 0$$

- Shift index using $k- > k+1$

$$a_{k+2}(k+2+r)(k+3+r) - 2a_{k+1}(k+1) - 2r a_{k+1} - 2a_{k+1} + a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{2k a_{k+1} + 2r a_{k+1} - a_k + 4a_{k+1}}{(k+2+r)(k+3+r)}$$

- Recursion relation for $r = -1$

$$a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+1)(k+2)}$$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = \frac{2k a_{k+1} - a_k + 2a_{k+1}}{(k+1)(k+2)}, 0 = 0\right]$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{2k a_{k+1} - a_k + 4a_{k+1}}{(k+2)(k+3)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{2k a_{k+1} - a_k + 4a_{k+1}}{(k+2)(k+3)}, 2a_1 - 2a_0 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = \frac{2k a_{1+k} - a_k + 2a_{1+k}}{(1+k)(k+2)}, 0 = 0, b_{k+2} = \frac{2k b_{1+k} - b_k + 4b_{1+k}}{(k+2)(k+3)}, 2b_1 - 2b\right.$$

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{x^2y'' - 4y'x + 6y = 0}$$

Given that one solution of the ode is

$$y_1 = x^2$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{4}{x}$$

Therefore

$$y_2(x) = x^2 \left(\int \frac{e^{-(\int -\frac{4}{x} dx)}}{x^4} dx \right)$$

$$y_2(x) = x^2 \int \frac{x^4}{x^4}, dx$$

$$y_2(x) = x^2 \left(\int 1 dx \right)$$

$$y_2(x) = x^3$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_2 x^3 + c_1 x^2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_2 x^3 + c_1 x^2 \tag{1}$$

Verification of solutions

$$y = c_2 x^3 + c_1 x^2$$

Verified OK.

9.19.1 Maple step by step solution

Let's solve

$x^2 y'' - 4y'x + 6y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4y'}{x} - \frac{6y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{4y'}{x} + \frac{6y}{x^2} = 0$

- Multiply by denominators of the ODE

  $x^2y'' - 4y'x + 6y = 0$

- Make a change of variables

  $t = \ln(x)$

☐ Substitute the change of variables back into the ODE

  - Calculate the 1st derivative of y with respect to x , using the chain rule

    $y' = \left(\frac{d}{dt}y(t)\right) t'(x)$

  - Compute derivative

    $y' = \frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y'' = \left(\frac{d^2}{dt^2}y(t)\right) t'(x)^2 + t''(x) \left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y'' = \frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $x^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2} - \frac{\frac{d}{dt}y(t)}{x^2}\right) - 4\frac{d}{dt}y(t) + 6y(t) = 0$

- Simplify

  $\frac{d^2}{dt^2}y(t) - 5\frac{d}{dt}y(t) + 6y(t) = 0$

- Characteristic polynomial of ODE

  $r^2 - 5r + 6 = 0$

- Factor the characteristic polynomial

  $(r-2)(r-3) = 0$

- Roots of the characteristic polynomial

  $r = (2, 3)$

- 1st solution of the ODE

  $y_1(t) = e^{2t}$

- 2nd solution of the ODE

$$y_2(t) = e^{3t}$$

- General solution of the ODE

$$y(t) = c_1 y_1(t) + c_2 y_2(t)$$

- Substitute in solutions

$$y(t) = c_1 e^{2t} + c_2 e^{3t}$$

- Change variables back using $t = \ln(x)$

$$y = c_2 x^3 + c_1 x^2$$

- Simplify

$$y = x^2(c_2 x + c_1)$$

9.20 problem 20

Internal problem ID [1126]
Internal file name [`OUTPUT/1127_Sunday_June_05_2022_02_03_11_AM_7309673/index.tex`]

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 20.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_1", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2 \ln(x)^2 y'' - 2x \ln(x) y' + (2 + \ln(x)) y = 0}$$

Given that one solution of the ode is

$$y_1 = \ln(x)$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{2}{x \ln(x)}$$

Therefore

$$y_2(x) = \ln(x)\left(\int \frac{e^{-\left(\int -\frac{2}{x\ln(x)}dx\right)}}{\ln(x)^2}dx\right)$$

$$y_2(x) = \ln(x)\int \frac{\ln(x)^2}{\ln(x)^2}, dx$$

$$y_2(x) = \ln(x)\left(\int 1dx\right)$$

$$y_2(x) = x\ln(x)$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= c_1\ln(x) + \ln(x)\,c_2x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\ln(x) + \ln(x)\,c_2x \tag{1}$$

Verification of solutions

$$y = c_1\ln(x) + \ln(x)\,c_2x$$

Verified OK.

9.21 problem 21

Internal problem ID [1127]
Internal file name [`OUTPUT/1128_Sunday_June_05_2022_02_03_11_AM_90055498/index.tex`]

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_bessel_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{4xy''+2y'+y=0}$$

Given that one solution of the ode is

$$y_1=\sin\left(\sqrt{x}\right)$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x)=y_1\left(\int\frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y''+p(x)\,y'+q(x)\,y=f(x)$$

Looking at the ode to solve shows that

$$p(x)=\frac{1}{2x}$$

Therefore

$$y_2(x) = \sin\left(\sqrt{x}\right)\left(\int \frac{e^{-\left(\int \frac{1}{2x}dx\right)}}{\sin\left(\sqrt{x}\right)^2}dx\right)$$

$$y_2(x) = \sin\left(\sqrt{x}\right)\int \frac{\frac{1}{\sqrt{x}}}{\sin\left(\sqrt{x}\right)^2}, dx$$

$$y_2(x) = \sin\left(\sqrt{x}\right)\left(\int \frac{\csc\left(\sqrt{x}\right)^2}{\sqrt{x}}dx\right)$$

$$y_2(x) = -2\sin\left(\sqrt{x}\right)\cot\left(\sqrt{x}\right)$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= \sin\left(\sqrt{x}\right)c_1 - 2c_2\sin\left(\sqrt{x}\right)\cot\left(\sqrt{x}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sin\left(\sqrt{x}\right)c_1 - 2c_2\sin\left(\sqrt{x}\right)\cot\left(\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = \sin\left(\sqrt{x}\right)c_1 - 2c_2\sin\left(\sqrt{x}\right)\cot\left(\sqrt{x}\right)$$

Verified OK.

9.21.1 Maple step by step solution

Let's solve

$4y''x + 2y' + y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y}{4x} - \frac{y'}{2x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{2x} + \frac{y}{4x} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{1}{4x}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = \frac{1}{2}$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $4y''x + 2y' + y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert y' to series expansion

    $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$
  - Shift index using $k- > k+1$

    $y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$
  - Shift index using $k- > k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

    Rewrite ODE with series expansions

$$2a_0 r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(2a_{k+1}(k+1+r)\,(2k+1+2r)+a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $2r(-1+2r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $4\left(k+\frac{1}{2}+r\right)(k+1+r)\, a_{k+1} + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a_k}{2(2k+1+2r)(k+1+r)}$
- Recursion relation for $r = 0$

  $a_{k+1} = -\frac{a_k}{2(2k+1)(k+1)}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{a_k}{2(2k+1)(k+1)}\right]$
- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = -\frac{a_k}{2(2k+2)\left(k+\frac{3}{2}\right)}$
- Solution for $r = \frac{1}{2}$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k}{2(2k+2)\left(k+\frac{3}{2}\right)}\right]$
- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k x^k\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+\frac{1}{2}}\right), a_{1+k} = -\frac{a_k}{2(2k+1)(1+k)}, b_{1+k} = -\frac{b_k}{2(2k+2)\left(k+\frac{3}{2}\right)}\right]$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 22.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' - (2+2x)\,y' + (2+x)\,y = 0}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{x}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-2x-2}{x}$$

Therefore

$$y_2(x) = e^x \left(\int e^{-\left(\int \frac{-2x-2}{x} dx\right)} e^{-2x} dx \right)$$

$$y_2(x) = e^x \int \frac{e^{2x+2\ln(x)}}{e^{2x}}, dx$$

$$y_2(x) = e^x \left(\int x^2 dx \right)$$

$$y_2(x) = \frac{e^x x^3}{3}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 e^x + \frac{c_2 e^x x^3}{3} \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x + \frac{c_2 e^x x^3}{3} \tag{1}$$

Verification of solutions

$$y = c_1 e^x + \frac{c_2 e^x x^3}{3}$$

Verified OK.

9.22.1 Maple step by step solution

Let's solve

$y''x + (-2x-2)\, y' + (2+x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 2y'x + (x^2 + 2)\, y = 0}$$

Given that one solution of the ode is

$$y_1 = \sin(x)\, x$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{2}{x}$$

Therefore

$$y_2(x) = \sin(x)\,x\left(\int \frac{\mathrm{e}^{-\left(\int -\frac{2}{x}dx\right)}}{\sin(x)^2\,x^2}dx\right)$$

$$y_2(x) = \sin(x)\,x\int \frac{x^2}{x^2\sin(x)^2},dx$$

$$y_2(x) = \sin(x)\,x\left(\int \csc(x)^2\,dx\right)$$

$$y_2(x) = -\sin(x)\cot(x)\,x$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= \sin(x)\,xc_1 - c_2\sin(x)\cot(x)\,x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sin(x)\,xc_1 - c_2\sin(x)\cot(x)\,x \tag{1}$$

Verification of solutions

$$y = \sin(x)\,xc_1 - c_2\sin(x)\cot(x)\,x$$

Verified OK.

9.24.1 Maple step by step solution

Let's solve

$x^2y'' - 2y'x + (x^2+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2+2)y}{x^2} + \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2y'}{x} + \frac{(x^2+2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$$\left[P_2(x) = -\frac{2}{x}, P_3(x) = \frac{x^2+2}{x^2}\right]$$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = -2$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 2$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$x^2 y'' - 2y'x + (x^2 + 2) y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot y'$ to series expansion

  $$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r) x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(-1+r)(-2+r)x^r + a_1 r(-1+r)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r-1)(k+r-2) + a_{k-2}\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$(-1+r)(-2+r) = 0$

- Values of r that satisfy the indicial equation

$r \in \{1, 2\}$

- Each term must be 0

$a_1 r(-1+r) = 0$

- Solve for the dependent coefficient(s)

$a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

$a_k(k+r-1)(k+r-2) + a_{k-2} = 0$

- Shift index using $k- > k+2$

$a_{k+2}(k+1+r)(k+r) + a_k = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{a_k}{(k+1+r)(k+r)}$

- Recursion relation for $r = 1$

$a_{k+2} = -\frac{a_k}{(k+2)(k+1)}$

- Solution for $r = 1$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = -\frac{a_k}{(k+2)(k+1)}, a_1 = 0\right]$

- Recursion relation for $r = 2$

$a_{k+2} = -\frac{a_k}{(k+3)(k+2)}$

- Solution for $r = 2$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = -\frac{a_k}{(k+3)(k+2)}, a_1 = 0\right]$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{1+k}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k+2}\right), a_{k+2} = -\frac{a_k}{(k+2)(1+k)}, a_1 = 0, b_{k+2} = -\frac{b_k}{(k+3)(k+2)}, b_1 = 0\right]$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' - (4x+1)\, y' + (4x+2)\, y = 0}$$

Given that one solution of the ode is

$$y_1 = e^{2x}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-4x-1}{x}$$

Therefore

$$y_2(x) = e^{2x}\left(\int e^{-\left(\int \frac{-4x-1}{x}dx\right)} e^{-4x} dx\right)$$

$$y_2(x) = e^{2x}\int \frac{e^{4x+\ln(x)}}{e^{4x}}, dx$$

$$y_2(x) = e^{2x}\left(\int x dx\right)$$

$$y_2(x) = \frac{x^2 e^{2x}}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 e^{2x} + \frac{c_2 x^2 e^{2x}}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{2x} + \frac{c_2 x^2 e^{2x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 e^{2x} + \frac{c_2 x^2 e^{2x}}{2}$$

Verified OK.

9.25.1 Maple step by step solution

Let's solve

$y''x + (-4x-1)\,y' + (4x+2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2(1+2x)y}{x} + \frac{(4x+1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(4x+1)y'}{x} + \frac{2(1+2x)y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ○ Define functions

  $\left[P_2(x) = -\frac{4x+1}{x}, P_3(x) = \frac{2(1+2x)}{x}\right]$

- ○ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = -1$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (-4x - 1)\, y' + (4x + 2)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$

- ○ Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$

- ○ Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r-1}$$

- Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-2+r) x^{-1+r} + (a_1(1+r)(-1+r) - 2a_0(-1+2r)) x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k+r-1)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term must be 0

$$a_1(1+r)(-1+r) - 2a_0(-1+2r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+r-1) + a_k(-4k-4r+2) + 4a_{k-1} = 0$$

- Shift index using $k->k+1$

$$a_{k+2}(k+2+r)(k+r) + a_{k+1}(-4k-2-4r) + 4a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{2(2ka_{k+1} + 2ra_{k+1} - 2a_k + a_{k+1})}{(k+2+r)(k+r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + a_{k+1})}{(k+2)k}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

$$a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + a_{k+1})}{(k+2)k}$$

- Recursion relation for $r = 2$

$$a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + 5a_{k+1})}{(k+4)(k+2)}$$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + 5a_{k+1})}{(k+4)(k+2)}, 3a_1 - 6a_0 = 0\right]$$

9.26 problem 26

Internal problem ID [1132]
Internal file name [`OUTPUT/1133_Sunday_June_05_2022_02_03_16_AM_33275409/index.tex`]

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$4x^2 \sin(x) y'' - 4x(x\cos(x) + \sin(x)) y' + (2x\cos(x) + 3\sin(x)) y = 0$$

Given that one solution of the ode is

$$y_1 = \sqrt{x}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x) y' + q(x) y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-4x^2\cos(x) - 4\sin(x) x}{4\sin(x) x^2}$$

Therefore

$$y_2(x) = \sqrt{x}\left(\int \frac{e^{-\left(\int \frac{-4x^2\cos(x)-4\sin(x)x}{4\sin(x)x^2}dx\right)}}{x}dx\right)$$

$$y_2(x) = \sqrt{x}\int \frac{e^{\ln(\sin(x))+\ln(x)}}{x}, dx$$

$$y_2(x) = \sqrt{x}\left(\int \sin(x)\,dx\right)$$

$$y_2(x) = -\cos(x)\sqrt{x}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= \sqrt{x}\,c_1 - c_2\cos(x)\sqrt{x} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \sqrt{x}\,c_1 - c_2\cos(x)\sqrt{x} \tag{1}$$

Verification of solutions

$$y = \sqrt{x}\,c_1 - c_2\cos(x)\sqrt{x}$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 28.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(1+2x)\,xy''-2(2x^2-1)\,y'-4(x+1)\,y=0}$$

Given that one solution of the ode is

$$y_1=\frac{1}{x}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x)=y_1\left(\int\frac{e^{-(\int p dx)}}{y_1^2}dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y''+p(x)\,y'+q(x)\,y=f(x)$$

Looking at the ode to solve shows that

$$p(x)=\frac{-4x^2+2}{2x^2+x}$$

Therefore

$$
\begin{aligned}
y_2(x) &= \frac{\int e^{-\left(\int \frac{-4x^2+2}{2x^2+x}dx\right)} x^2 dx}{x} \\
y_2(x) &= \frac{1}{x} \int \frac{e^{2x-2\ln(x)+\ln(1+2x)}}{\frac{1}{x^2}}, dx \\
y_2(x) &= \frac{\int (1+2x)\, e^{2x} dx}{x} \\
y_2(x) &= e^{2x}
\end{aligned}
$$

Hence the solution is

$$
\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= \frac{c_1}{x} + c_2 e^{2x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1}{x} + c_2 e^{2x} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1}{x} + c_2 e^{2x}
$$

Verified OK.

9.28.1 Maple step by step solution

Let's solve

$(2x^2 + x)\, y'' + (-4x^2 + 2)\, y' + (-4x - 4)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{4(x+1)y}{(1+2x)x} + \frac{2(2x^2-1)y'}{(1+2x)x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2(2x^2-1)y'}{(1+2x)x} - \frac{4(x+1)y}{(1+2x)x} = 0$

- ☐ Check to see if x_0 is a regular singular point
  - Define functions

    $\left[P_2(x) = -\frac{2(2x^2-1)}{(1+2x)x}, P_3(x) = -\frac{4(x+1)}{(1+2x)x}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 2$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $(1+2x)\, xy'' + (-4x^2+2)\, y' + (-4x-4)\, y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

$$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(1+r)\, x^{-1+r} + (a_1(1+r)(2+r) + 2a_0(1+r)(-2+r))\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)(k+2+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- Each term must be 0

$$a_1(1+r)(2+r) + 2a_0(1+r)(-2+r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+r+1)(k+2+r) + 2a_k(k+r+1)(k+r-2) - 4a_{k-1}(k+r) = 0$$

- Shift index using $k- >k+1$

$$a_{k+2}(k+2+r)(k+3+r) + 2a_{k+1}(k+2+r)(k+r-1) - 4a_k(k+r+1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2(k^2 a_{k+1} + 2kra_{k+1} + r^2 a_{k+1} - 2ka_k + ka_{k+1} - 2ra_k + ra_{k+1} - 2a_k - 2a_{k+1})}{(k+2+r)(k+3+r)}$$

- Recursion relation for $r = -1$

$$a_{k+2} = -\frac{2(k^2 a_{k+1} - 2ka_k - ka_{k+1} - 2a_{k+1})}{(k+1)(k+2)}$$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{2(k^2 a_{k+1} - 2ka_k - ka_{k+1} - 2a_{k+1})}{(k+1)(k+2)}, 0 = 0\right]$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{2(k^2 a_{k+1} - 2ka_k + ka_{k+1} - 2a_k - 2a_{k+1})}{(k+2)(k+3)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{2(k^2 a_{k+1} - 2ka_k + ka_{k+1} - 2a_k - 2a_{k+1})}{(k+2)(k+3)}, 2a_1 - 4a_0 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{k+2} = -\frac{2(k^2 a_{1+k} - 2k a_k - k a_{1+k} - 2a_{1+k})}{(1+k)(k+2)}, 0 = 0, b_{k+2} = -\frac{2(k^2 b_{1+k} - 2k$$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.6 Reduction or order. Page 253
Problem number: 30.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' - (4x+1)\,y' + (4x+2)\,y = 0}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{2x}$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-4x-1}{x}$$

Therefore

$$y_2(x) = \mathrm{e}^{2x} \left(\int \mathrm{e}^{-\left(\int \frac{-4x-1}{x} dx\right)} \mathrm{e}^{-4x} dx \right)$$

$$y_2(x) = \mathrm{e}^{2x} \int \frac{\mathrm{e}^{4x+\ln(x)}}{\mathrm{e}^{4x}}, dx$$

$$y_2(x) = \mathrm{e}^{2x} \left(\int x dx \right)$$

$$y_2(x) = \frac{x^2 \mathrm{e}^{2x}}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= c_1 \mathrm{e}^{2x} + \frac{c_2 x^2 \mathrm{e}^{2x}}{2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{2x} + \frac{c_2 x^2 \mathrm{e}^{2x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{2x} + \frac{c_2 x^2 \mathrm{e}^{2x}}{2}$$

Verified OK.

    $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$$
  - ◦ Shift index using $k- >k + 1 - m$

    $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$$
  - ◦ Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r-1}$$

- Shift index using $k- > k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-2+r) x^{-1+r} + (a_1(1+r)(-1+r) - 2a_0(-1+2r)) x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k+r-1)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 2\}$$

- Each term must be 0

$$a_1(1+r)(-1+r) - 2a_0(-1+2r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+r-1) + a_k(-4k-4r+2) + 4a_{k-1} = 0$$

- Shift index using $k- > k+1$

$$a_{k+2}(k+2+r)(k+r) + a_{k+1}(-4k-2-4r) + 4a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{2(2ka_{k+1} + 2ra_{k+1} - 2a_k + a_{k+1})}{(k+2+r)(k+r)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + a_{k+1})}{(k+2)k}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

$$a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + a_{k+1})}{(k+2)k}$$

- Recursion relation for $r = 2$

$$a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + 5a_{k+1})}{(k+4)(k+2)}$$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+2} = \frac{2(2ka_{k+1} - 2a_k + 5a_{k+1})}{(k+4)(k+2)}, 3a_1 - 6a_0 = 0\right]$$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 3y'x + 4y = 4x^4}$$

Given that one solution of the ode is

$$y_1 = x^2$$

With initial conditions

$$[y(-1) = 7, y'(-1) = -8]$$

9.31.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{4}{x^2} \\ F &= 4x^2 \end{aligned}$$

Hence the ode is

$$y'' - \frac{3y'}{x} + \frac{4y}{x^2} = 4x^2$$

The domain of $p(x) = -\frac{3}{x}$ is

$$\{x < 0 \vee 0 < x\}$$

And the point $x_0 = -1$ is inside this domain. The domain of $q(x) = \frac{4}{x^2}$ is

$$\{x < 0 \vee 0 < x\}$$

And the point $x_0 = -1$ is also inside this domain. The domain of $F = 4x^2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = -1$ is also inside this domain. Hence solution exists and is unique.

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 4, f(x) = 4x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 3y'x + 4y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = -\frac{3}{x}$$

Therefore

$$
\begin{aligned}
y_2(x) &= x^2 \left(\int \frac{e^{-\left(\int -\frac{3}{x} dx\right)}}{x^4} dx \right) \\
y_2(x) &= x^2 \int \frac{x^3}{x^4}, dx \\
y_2(x) &= x^2 \left(\int \frac{1}{x} dx \right) \\
y_2(x) &= \ln(x)\, x^2
\end{aligned}
$$

Hence the solution is

$$
\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2 + c_2 \ln(x)\, x^2
\end{aligned}
$$

Therefore the homogeneous solution y_h is

$$
y_h = c_1 x^2 + c_2 \ln(x)\, x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= \ln(x)\, x^2
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(\ln(x)\, x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & \ln(x)\, x^2 \\ 2x & x + 2x\ln(x) \end{vmatrix}$$

Therefore

$$W = (x^2)(x + 2x\ln(x)) - (\ln(x)\, x^2)(2x)$$

Which simplifies to

$$W = x^3$$

Which simplifies to

$$W = x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\ln(x)\, x^6}{x^5}\, dx$$

Which simplifies to

$$u_1 = -\int 4x\ln(x)\, dx$$

Hence

$$u_1 = -2\ln(x)\, x^2 + x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{4x^6}{x^5}\, dx$$

Which simplifies to

$$u_2 = \int 4x dx$$

Hence

$$u_2 = 2x^2$$

Which simplifies to

$$\begin{aligned} u_1 &= x^2(1 - 2\ln(x)) \\ u_2 &= 2x^2 \end{aligned}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x^4(1 - 2\ln(x)) + 2x^4 \ln(x)$$

Which simplifies to

$$y_p(x) = x^4$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^2 + c_2 \ln(x) x^2\right) + \left(x^4\right) \end{aligned}$$

Which simplifies to

$$y = x^2(c_1 + c_2 \ln(x)) + x^4$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = x^2(c_1 + c_2 \ln(x)) + x^4 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 7$ and $x = -1$ in the above gives

$$7 = \pi c_2 i + c_1 + 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2x(c_1 + c_2 \ln(x)) + c_2 x + 4x^3$$

substituting $y' = -8$ and $x = -1$ in the above gives

$$-8 = -2\pi c_2 i - 2c_1 - c_2 - 4 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 8i\pi + 6$$
$$c_2 = -8$$

Substituting these values back in above solution results in

$$y = 8ix^2\pi + x^4 - 8\ln(x)\,x^2 + 6x^2$$

Summary

The solution(s) found are the following

$$y = \left(-8\ln(x) + 8i\pi + x^2 + 6\right)x^2 \tag{1}$$

Verification of solutions

$$y = \left(-8\ln(x) + 8i\pi + x^2 + 6\right)x^2$$

Verified OK.

Problem number: 32.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"reduction_of_order"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(3x-1)\,y''-(3x+2)\,y'-(6x-8)\,y=0}$$

Given that one solution of the ode is

$$y_1 = \mathrm{e}^{2x}$$

With initial conditions

$$[y(0)=2, y'(0)=3]$$

9.32.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$\begin{aligned} p(x) &= \frac{-3x-2}{3x-1} \\ q(x) &= \frac{-6x+8}{3x-1} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + \frac{(-3x-2)\, y'}{3x-1} + \frac{(-6x+8)\, y}{3x-1} = 0$$

The domain of $p(x) = \frac{-3x-2}{3x-1}$ is

$$\left\{x < \frac{1}{3} \vee \frac{1}{3} < x\right\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{-6x+8}{3x-1}$ is

$$\left\{x < \frac{1}{3} \vee \frac{1}{3} < x\right\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-\left(\int p dx\right)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-3x-2}{3x-1}$$

Therefore

$$y_2(x) = \mathrm{e}^{2x} \left(\int \mathrm{e}^{-\left(\int \frac{-3x-2}{3x-1} dx\right)} \mathrm{e}^{-4x} dx \right)$$

$$y_2(x) = \mathrm{e}^{2x} \int \frac{\mathrm{e}^{x+\ln(3x-1)}}{\mathrm{e}^{4x}}, dx$$

$$y_2(x) = \mathrm{e}^{2x} \left(\int (3x-1)\, \mathrm{e}^{-3x} dx \right)$$

$$y_2(x) = -\mathrm{e}^{2x} x\, \mathrm{e}^{-3x}$$

Hence the solution is

$$
\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \mathrm{e}^{2x} - c_2 \mathrm{e}^{2x} x \,\mathrm{e}^{-3x}
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{2x} - c_2 \mathrm{e}^{2x} x \,\mathrm{e}^{-3x} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 2$ and $x = 0$ in the above gives

$$
2 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{2x} x \,\mathrm{e}^{-3x} - c_2 \mathrm{e}^{2x} \mathrm{e}^{-3x}
$$

substituting $y' = 3$ and $x = 0$ in the above gives

$$
3 = 2c_1 - c_2 \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 2 \\
c_2 &= 1
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = -\mathrm{e}^{2x} x \,\mathrm{e}^{-3x} + 2\,\mathrm{e}^{2x}
$$

Which simplifies to

$$
y = -x \,\mathrm{e}^{-x} + 2\,\mathrm{e}^{2x}
$$

Summary

The solution(s) found are the following

$$
y = -x \,\mathrm{e}^{-x} + 2\,\mathrm{e}^{2x} \tag{1}
$$

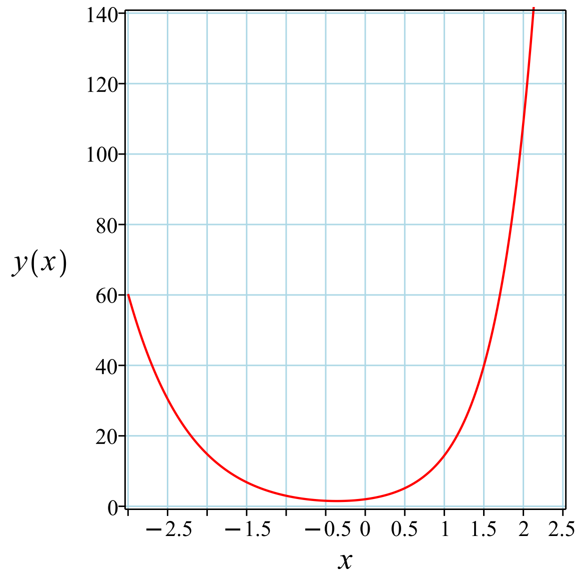

Figure 489: Solution plot

Verification of solutions

$$y = -x\,e^{-x} + 2\,e^{2x}$$

Verified OK.

9.32.2 Maple step by step solution

Let's solve

$$\left[(3x-1)\,y'' + (-3x-2)\,y' + (-6x+8)\,y = 0, y(0) = 2, y'\Big|_{\{x=0\}} = 3\right]$$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{2(3x-4)y}{3x-1} + \frac{(3x+2)y'}{3x-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(3x+2)y'}{3x-1} - \frac{2(3x-4)y}{3x-1} = 0$

□ Check to see if $x_0 = \frac{1}{3}$ is a regular singular point

- ◦ Define functions

$\left[P_2(x) = -\frac{3x+2}{3x-1}, P_3(x) = -\frac{2(3x-4)}{3x-1}\right]$

- $\left(x - \frac{1}{3}\right) \cdot P_2(x)$ is analytic at $x = \frac{1}{3}$

  $\left(\left(x - \frac{1}{3}\right) \cdot P_2(x)\right) \bigg|_{x=\frac{1}{3}} = -1$

- $\left(x - \frac{1}{3}\right)^2 \cdot P_3(x)$ is analytic at $x = \frac{1}{3}$

  $\left(\left(x - \frac{1}{3}\right)^2 \cdot P_3(x)\right) \bigg|_{x=\frac{1}{3}} = 0$

- $x = \frac{1}{3}$is a regular singular point

  Check to see if $x_0 = \frac{1}{3}$ is a regular singular point

  $x_0 = \frac{1}{3}$

- Multiply by denominators

  $(3x-1)\, y'' + (-3x-2)\, y' + (-6x+8)\, y = 0$

- Change variables using $x = u + \frac{1}{3}$ so that the regular singular point is at $u = 0$

  $3u\left(\frac{d^2}{du^2}y(u)\right) + (-3u-3)\left(\frac{d}{du}y(u)\right) + (-6u+6)\, y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k- >k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\, u^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-1}$$

◦ Shift index using $k- > k+1$

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$3a_0 r(-2+r)\, u^{-1+r} + (3a_1(1+r)(-1+r) - 3a_0(-2+r))\, u^r + \left(\sum_{k=1}^{\infty} (3a_{k+1}(k+1+r)(k+r-\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $3r(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$
- Each term must be 0

  $3a_1(1+r)(-1+r) - 3a_0(-2+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $3a_{k+1}(k+1+r)(k+r-1) + a_k(-3k-3r+6) - 6a_{k-1} = 0$
- Shift index using $k- > k+1$

  $3a_{k+2}(k+2+r)(k+r) + a_{k+1}(-3k+3-3r) - 6a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{k a_{k+1} + r a_{k+1} + 2a_k - a_{k+1}}{(k+2+r)(k+r)}$
- Recursion relation for $r = 0$

  $a_{k+2} = \frac{k a_{k+1} + 2a_k - a_{k+1}}{(k+2)k}$
- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 0$

  $a_{k+2} = \frac{k a_{k+1} + 2a_k - a_{k+1}}{(k+2)k}$
- Recursion relation for $r = 2$

  $a_{k+2} = \frac{k a_{k+1} + 2a_k + a_{k+1}}{(k+4)(k+2)}$
- Solution for $r = 2$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+2}, a_{k+2} = \frac{k a_{k+1} + 2a_k + a_{k+1}}{(k+4)(k+2)}, 9a_1 = 0\right]$
- Revert the change of variables $u = x - \frac{1}{3}$

$$\left[y=\sum_{k=0}^{\infty} a_k \left(x-\frac{1}{3}\right)^{k+2}, a_{k+2}=\frac{k a_{k+1}+2 a_k+a_{k+1}}{(k+4)(k+2)}, 9 a_1=0\right]$$

$$y_1 = (x+1) e^x$$

With initial conditions

$$[y(0) = 1, y'(0) = -1]$$

9.33.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{-2x-2}{(x+1)^2} \\ q(x) &= \frac{-x^2-2x+1}{(x+1)^2} \\ F &= (x+1) e^x \end{aligned}$$

Hence the ode is

$$y'' + \frac{(-2x-2)\,y'}{(x+1)^2} + \frac{(-x^2-2x+1)\,y}{(x+1)^2} = (x+1)\,e^x$$

The domain of $p(x) = \frac{-2x-2}{(x+1)^2}$ is

$$\{x < -1 \lor -1 < x\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{-x^2-2x+1}{(x+1)^2}$ is

$$\{x < -1 \lor -1 < x\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = (x+1)\,e^x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2 + 2x + 1, B = -2x - 2, C = -x^2 - 2x + 1, f(x) = (x+1)^3\,e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$(x^2 + 2x + 1)\,y'' + (-2x-2)\,y' + (-x^2 - 2x + 1)\,y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1\left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx\right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\,y' + q(x)\,y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{-2x - 2}{x^2 + 2x + 1}$$

Therefore

$$y_2(x) = (x+1)\,\mathrm{e}^{x} \left(\int \frac{\mathrm{e}^{-\left(\int \frac{-2x-2}{x^2+2x+1}dx\right)}\mathrm{e}^{-2x}}{(x+1)^2}dx\right)$$

$$y_2(x) = (x+1)\,\mathrm{e}^{x} \int \frac{(x+1)^2}{(x+1)^2\,\mathrm{e}^{2x}}, dx$$

$$y_2(x) = (x+1)\,\mathrm{e}^{x} \left(\int \mathrm{e}^{-2x}dx\right)$$

$$y_2(x) = -\frac{(x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}$$

Hence the solution is

$$\begin{aligned} y &= c_1 y_1(x) + c_2 y_2(x) \\ &= (x+1)\,\mathrm{e}^{x} c_1 - \frac{c_2 (x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = (x+1)\,\mathrm{e}^{x} c_1 - \frac{c_2 (x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x+1)\,\mathrm{e}^{x}$$

$$y_2 = -\frac{(x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x+1)\,\mathrm{e}^{x} & -\frac{(x+1)\mathrm{e}^{x}\mathrm{e}^{-2x}}{2} \\ \frac{d}{dx}\left((x+1)\,\mathrm{e}^{x}\right) & \frac{d}{dx}\left(-\frac{(x+1)\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x+1)\,\mathrm{e}^{x} & -\frac{(x+1)\mathrm{e}^{x}\mathrm{e}^{-2x}}{2} \\ \mathrm{e}^{x} + (x+1)\,\mathrm{e}^{x} & -\frac{\mathrm{e}^{-2x}\mathrm{e}^{x}}{2} + \frac{(x+1)\mathrm{e}^{x}\mathrm{e}^{-2x}}{2} \end{vmatrix}$$

Therefore

$$W = \left((x+1)\,\mathrm{e}^{x}\right)\left(-\frac{\mathrm{e}^{-2x}\mathrm{e}^{x}}{2} + \frac{(x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}\right) - \left(-\frac{(x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}\right)\left(\mathrm{e}^{x} + (x+1)\,\mathrm{e}^{x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-2x}\mathrm{e}^{2x}x^{2} + 2\,\mathrm{e}^{-2x}x\,\mathrm{e}^{2x} + \mathrm{e}^{2x}\mathrm{e}^{-2x}$$

Which simplifies to

$$W = (x+1)^{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{(x+1)^{4}\mathrm{e}^{2x}\mathrm{e}^{-2x}}{2}}{(x^{2}+2x+1)\,(x+1)^{2}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{1}{2}dx$$

Hence

$$u_1 = \frac{x}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x+1)^4 \mathrm{e}^{2x}}{(x^2+2x+1)(x+1)^2}\,dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{2x} dx$$

Hence

$$u_2 = \frac{\mathrm{e}^{2x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x(x+1)\,\mathrm{e}^{x}}{2} - \frac{\mathrm{e}^{2x}(x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{4}$$

Which simplifies to

$$y_p(x) = \frac{\mathrm{e}^{x}(2x^2+x-1)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left((x+1)\,\mathrm{e}^{x} c_1 - \frac{c_2(x+1)\,\mathrm{e}^{x}\mathrm{e}^{-2x}}{2}\right) + \left(\frac{\mathrm{e}^{x}(2x^2+x-1)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{(x+1)\,(2c_1\mathrm{e}^{x} - c_2\mathrm{e}^{-x})}{2} + \frac{\mathrm{e}^{x}(2x^2+x-1)}{4}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{(x+1)\,(2c_1\mathrm{e}^{x} - c_2\mathrm{e}^{-x})}{2} + \frac{\mathrm{e}^{x}(2x^2+x-1)}{4} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$1 = -\frac{1}{4} + c_1 - \frac{c_2}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 e^x - \frac{c_2 e^{-x}}{2} + \frac{(x+1)(2c_1 e^x + c_2 e^{-x})}{2} + \frac{e^x(2x^2 + x - 1)}{4} + \frac{e^x(4x+1)}{4}$$

substituting $y' = -1$ and $x = 0$ in the above gives

$$-1 = 2c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{1}{2}$$
$$c_2 = -\frac{7}{2}$$

Substituting these values back in above solution results in

$$y = \frac{7x\, e^{-x}}{4} - \frac{x\, e^x}{4} + \frac{7\, e^{-x}}{4} - \frac{3\, e^x}{4} + \frac{x^2 e^x}{2}$$

Which simplifies to

$$y = \frac{(2x\, e^x - 3\, e^x + 7\, e^{-x})(x+1)}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{(2x\, e^x - 3\, e^x + 7\, e^{-x})(x+1)}{4} \tag{1}$$

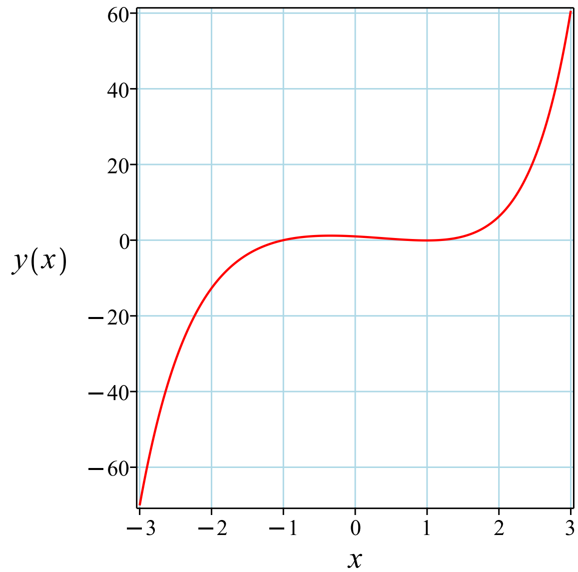

Figure 490: Solution plot

Verification of solutions

$$y = \frac{(2x\,e^{x} - 3\,e^{x} + 7\,e^{-x})\,(x+1)}{4}$$

Verified OK.

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + 2y'x - 2y = x^2}$$

Given that one solution of the ode is

$$y_1 = x$$

With initial conditions

$$\left[y(1) = \frac{5}{4}, y'(1) = \frac{3}{2}\right]$$

9.34.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$p(x) = \frac{2}{x}$$
$$q(x) = -\frac{2}{x^2}$$
$$F = 1$$

Hence the ode is

$$y'' + \frac{2y'}{x} - \frac{2y}{x^2} = 1$$

The domain of $p(x) = \frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = -\frac{2}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. The domain of $F = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

This is second order nonhomogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 2x, C = -2, f(x) = x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 2y'x - 2y = 0$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$y_2(x) = y_1 \left(\int \frac{e^{-(\int p dx)}}{y_1^2} dx \right)$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{2}{x}$$

Therefore

$$y_2(x) = x\left(\int \frac{e^{-\left(\int \frac{2}{x}dx\right)}}{x^2}dx\right)$$

$$y_2(x) = x\int \frac{\frac{1}{x^2}}{x^2}, dx$$

$$y_2(x) = x\left(\int \frac{1}{x^4}dx\right)$$

$$y_2(x) = -\frac{1}{3x^2}$$

Hence the solution is

$$\begin{aligned} y &= c_1y_1(x) + c_2y_2(x) \\ &= c_1x - \frac{c_2}{3x^2} \end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1x - \frac{c_2}{3x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = -\frac{1}{3x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & -\frac{1}{3x^2} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(-\frac{1}{3x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & -\frac{1}{3x^2} \\ 1 & \frac{2}{3x^3} \end{vmatrix}$$

Therefore

$$W = (x)\left(\frac{2}{3x^3}\right) - \left(-\frac{1}{3x^2}\right)(1)$$

Which simplifies to

$$W = \frac{1}{x^2}$$

Which simplifies to

$$W = \frac{1}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{1}{3}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{1}{3}dx$$

Hence

$$u_1 = \frac{x}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^3}{1}\,dx$$

Which simplifies to

$$u_2 = \int x^3 dx$$

Hence

$$u_2 = \frac{x^4}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x - \frac{c_2}{3x^2}\right) + \left(\frac{x^2}{4}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = c_1 x - \frac{c_2}{3x^2} + \frac{x^2}{4} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = \frac{5}{4}$ and $x = 1$ in the above gives

$$\frac{5}{4} = c_1 - \frac{c_2}{3} + \frac{1}{4} \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_1 + \frac{2c_2}{3x^3} + \frac{x}{2}$$

substituting $y' = \frac{3}{2}$ and $x = 1$ in the above gives

$$\frac{3}{2} = c_1 + \frac{2c_2}{3} + \frac{1}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= 1 \\ c_2 &= 0 \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{x(x+4)}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{x(x+4)}{4} \tag{1}$$

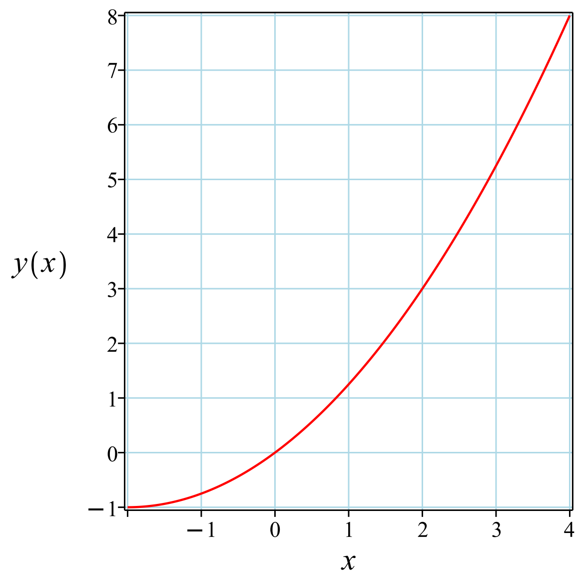

Figure 491: Solution plot

Verification of solutions

$$y = \frac{x(x+4)}{4}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{(x^2-4)\,y''+4y'x+2y=2+x}$$

Given that one solution of the ode is

$$y_1=\frac{1}{-2+x}$$

With initial conditions

$$\left[y(0)=-\frac{1}{3},y'(0)=-1\right]$$

9.35.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$
\begin{aligned}
p(x) &= \frac{4x}{x^2-4} \\
q(x) &= \frac{2}{x^2-4} \\
F &= \frac{2+x}{x^2-4}
\end{aligned}
$$

Hence the ode is

$$
y'' + \frac{4xy'}{x^2-4} + \frac{2y}{x^2-4} = \frac{2+x}{x^2-4}
$$

The domain of $p(x) = \frac{4x}{x^2-4}$ is

$$
\{-\infty \leq x < -2, -2 < x < 2, 2 < x \leq \infty\}
$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{2}{x^2-4}$ is

$$
\{-\infty \leq x < -2, -2 < x < 2, 2 < x \leq \infty\}
$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = \frac{2+x}{x^2-4}$ is

$$
\{-\infty \leq x < -2, -2 < x < 2, 2 < x \leq \infty\}
$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

This is second order nonhomogeneous ODE. In standard form the ODE is

$$
Ay''(x) + By'(x) + Cy(x) = f(x)
$$

Where $A = x^2 - 4, B = 4x, C = 2, f(x) = 2 + x$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the inhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
(x^2 - 4)\, y'' + 4y'x + 2y = 0
$$

Given one basis solution $y_1(x)$, then the second basis solution is given by

$$
y_2(x) = y_1 \left(\int \frac{\mathrm{e}^{-(\int p dx)}}{y_1^2} dx \right)
$$

Where $p(x)$ is the coefficient of y' when the ode is written in the normal form

$$y'' + p(x)\, y' + q(x)\, y = f(x)$$

Looking at the ode to solve shows that

$$p(x) = \frac{4x}{x^2 - 4}$$

Therefore

$$\begin{aligned}
y_2(x) &= \frac{\int \mathrm{e}^{-\left(\int \frac{4x}{x^2-4}dx\right)} (-2+x)^2\, dx}{-2+x} \\
y_2(x) &= \frac{1}{-2+x} \int \frac{\frac{1}{(x^2-4)^2}}{\frac{1}{(-2+x)^2}},\, dx \\
y_2(x) &= \frac{\int \frac{1}{(2+x)^2} dx}{-2+x} \\
y_2(x) &= -\frac{1}{(-2+x)\,(2+x)}
\end{aligned}$$

Hence the solution is

$$\begin{aligned}
y &= c_1 y_1(x) + c_2 y_2(x) \\
&= \frac{c_1}{-2+x} - \frac{c_2}{(-2+x)\,(2+x)}
\end{aligned}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1}{-2+x} - \frac{c_2}{(-2+x)\,(2+x)}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{-2+x}$$

$$y_2 = -\frac{1}{(-2+x)(2+x)}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{-2+x} & -\frac{1}{(-2+x)(2+x)} \\ \frac{d}{dx}\left(\frac{1}{-2+x}\right) & \frac{d}{dx}\left(-\frac{1}{(-2+x)(2+x)}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{-2+x} & -\frac{1}{(-2+x)(2+x)} \\ -\frac{1}{(-2+x)^2} & \frac{1}{(-2+x)^2(2+x)} + \frac{1}{(-2+x)(2+x)^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{-2+x}\right)\left(\frac{1}{(-2+x)^2(2+x)} + \frac{1}{(-2+x)(2+x)^2}\right) - \left(-\frac{1}{(-2+x)(2+x)}\right)\left(-\frac{1}{(-2+x)^2}\right)$$

Which simplifies to

$$W = \frac{1}{(-2+x)^2(2+x)^2}$$

Which simplifies to

$$W = \frac{1}{(-2+x)^2(2+x)^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{1}{-2+x}}{\frac{x^2-4}{(-2+x)^2(2+x)^2}} \, dx$$

Which simplifies to

$$u_1 = -\int (-x-2) \, dx$$

Hence

$$u_1 = \frac{1}{2}x^2 + 2x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2+x}{-2+x}}{\frac{x^2-4}{(-2+x)^2(2+x)^2}} \, dx$$

Which simplifies to

$$u_2 = \int (2+x)^2 \, dx$$

Hence

$$u_2 = \frac{(2+x)^3}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\frac{1}{2}x^2 + 2x}{-2+x} - \frac{(2+x)^2}{3(-2+x)}$$

Which simplifies to

$$y_p(x) = \frac{x^2 + 4x - 8}{-12 + 6x}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{-2+x} - \frac{c_2}{(-2+x)(2+x)}\right) + \left(\frac{x^2 + 4x - 8}{-12 + 6x}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{c_1(2+x)-c_2}{x^2-4}+\frac{x^2+4x-8}{-12+6x}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1(2+x)-c_2}{x^2-4}+\frac{x^2+4x-8}{-12+6x} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=-\frac{1}{3}$ and $x=0$ in the above gives

$$-\frac{1}{3} = \frac{c_2}{4}+\frac{2}{3}-\frac{c_1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1}{x^2-4}-\frac{2(c_1(2+x)-c_2)\,x}{(x^2-4)^2}+\frac{2x+4}{-12+6x}-\frac{6(x^2+4x-8)}{(-12+6x)^2}$$

substituting $y'=-1$ and $x=0$ in the above gives

$$-1 = -\frac{c_1}{4} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 4$$
$$c_2 = 4$$

Substituting these values back in above solution results in

$$y = \frac{x^3+6x^2+24x+8}{6\,(-2+x)\,(2+x)}$$

Which simplifies to

$$y = \frac{x^3+6x^2+24x+8}{6x^2-24}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3+6x^2+24x+8}{6x^2-24} \tag{1}$$

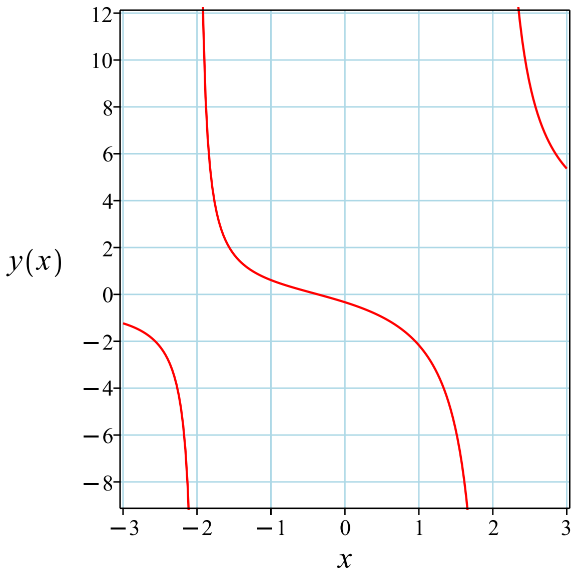

Figure 492: Solution plot

Verification of solutions

$$y = \frac{x^3 + 6x^2 + 24x + 8}{6x^2 - 24}$$

Verified OK.

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x),G(x)]`],
   _Riccati]
```

$$\boxed{x^2(y'+y^2)-x(2+x)\,y=-x-2}$$

9.43.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{x^2y^2-y\,x^2-2yx+x+2}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y'=-y^2+y+\frac{2y}{x}-\frac{1}{x}-\frac{2}{x^2}$$

With Riccati ODE standard form

$$y'=f_0(x)+f_1(x)y+f_2(x)y^2$$

Shows that $f_0(x)=-\frac{2+x}{x^2}$, $f_1(x)=-\frac{-x^2-2x}{x^2}$ and $f_2(x)=-1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2u} \\ &= \frac{-u'}{-u} \qquad (1) \end{aligned}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= \frac{-x^2-2x}{x^2} \\ f_2^2f_0 &= -\frac{2+x}{x^2} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x) - \frac{(-x^2-2x)\,u'(x)}{x^2} - \frac{(2+x)\,u(x)}{x^2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = x(c_1 + c_2\mathrm{e}^x)$$

The above shows that

$$u'(x) = (x+1)\,c_2\mathrm{e}^x + c_1$$

Using the above in (1) gives the solution

$$y = \frac{(x+1)\,c_2\mathrm{e}^x + c_1}{x\,(c_1 + c_2\mathrm{e}^x)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{x\,\mathrm{e}^x + \mathrm{e}^x + c_3}{x\,(c_3 + \mathrm{e}^x)}$$

Summary

The solution(s) found are the following

$$y = \frac{x\,\mathrm{e}^x + \mathrm{e}^x + c_3}{x\,(c_3 + \mathrm{e}^x)} \tag{1}$$

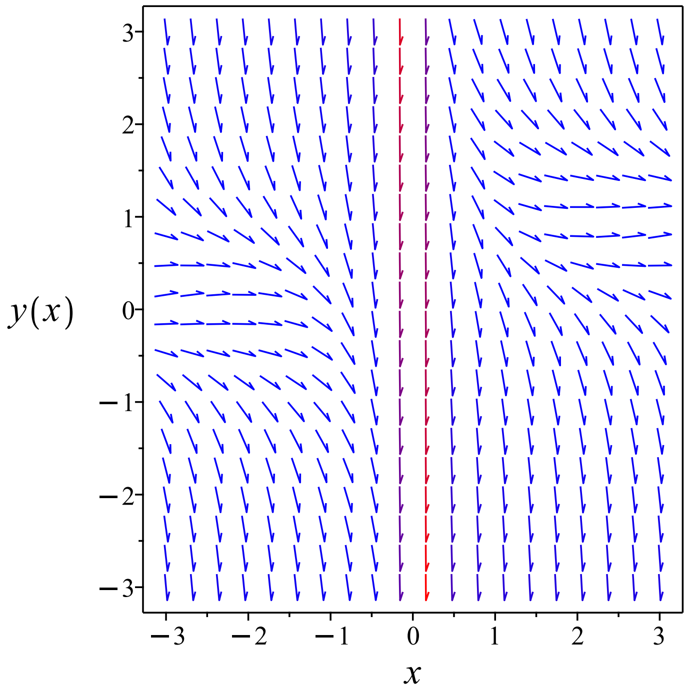

Figure 499: Slope field plot

Verification of solutions

$$y = \frac{x\,\mathrm{e}^{x} + \mathrm{e}^{x} + c_3}{x\,(c_3 + \mathrm{e}^{x})}$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _Riccati]
```

$$\boxed{y' + y^2 + 4yx = -4x^2 - 2}$$

9.44.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -4x^2 - 4yx - y^2 - 2$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + (-4x^2 - 4yx - y^2 - 2)(b_3 - a_2) - (-4x^2 - 4yx - y^2 - 2)^2 a_3 - (-8x - 4y)(xa_2 + ya_3 + a_1) - (-4x - 2y)(xb_2 + yb_3 + b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-16x^4a_3 - 32x^3ya_3 - 24x^2y^2a_3 - 8x\,y^3a_3 - y^4a_3 + 12x^2a_2 - 16x^2a_3 + 4x^2b_2 - 4x^2b_3 + 8xya_2 - 8xya_3 + 2xyb_2 + y^2a_2 + y^2b_3 + 8xa_1 + 4xb_1 + 4ya_1 + 2yb_1 + 2a_2 - 4a_3 + b_2 - 2b_3 = 0$$

Setting the numerator to zero gives

$$-16x^4a_3 - 32x^3ya_3 - 24x^2y^2a_3 - 8x\,y^3a_3 - y^4a_3 + 12x^2a_2 - 16x^2a_3 + 4x^2b_2 - 4x^2b_3 + 8xya_2 - 8xya_3 + 2xyb_2 + y^2a_2 + y^2b_3 + 8xa_1 + 4xb_1 + 4ya_1 + 2yb_1 + 2a_2 - 4a_3 + b_2 - 2b_3 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-16a_3v_1^4 - 32a_3v_1^3v_2 - 24a_3v_1^2v_2^2 - 8a_3v_1v_2^3 - a_3v_2^4 + 12a_2v_1^2 + 8a_2v_1v_2 + a_2v_2^2 - 16a_3v_1^2 - 8a_3v_1v_2 + 4b_2v_1^2 + 2b_2v_1v_2 - 4b_3v_1^2 + b_3v_2^2 + 8a_1v_1 + 4a_1v_2 + 4b_1v_1 + 2b_1v_2 + 2a_2 - 4a_3 + b_2 - 2b_3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$
\begin{aligned}
-16a_3v_1^4 - 32a_3v_1^3v_2 - 24a_3v_1^2v_2^2 + (12a_2 - 16a_3 + 4b_2 - 4b_3)\, v_1^2 \\
- 8a_3v_1v_2^3 + (8a_2 - 8a_3 + 2b_2)\, v_1v_2 + (8a_1 + 4b_1)\, v_1 - a_3v_2^4 \\
+ (a_2 + b_3)\, v_2^2 + (4a_1 + 2b_1)\, v_2 + 2a_2 - 4a_3 + b_2 - 2b_3 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-32a_3 &= 0 \\
-24a_3 &= 0 \\
-16a_3 &= 0 \\
-8a_3 &= 0 \\
-a_3 &= 0 \\
4a_1 + 2b_1 &= 0 \\
8a_1 + 4b_1 &= 0 \\
a_2 + b_3 &= 0 \\
8a_2 - 8a_3 + 2b_2 &= 0 \\
2a_2 - 4a_3 + b_2 - 2b_3 &= 0 \\
12a_2 - 16a_3 + 4b_2 - 4b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= a_1 \\
a_2 &= -b_3 \\
a_3 &= 0 \\
b_1 &= -2a_1 \\
b_2 &= 4b_3 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 1 \\
\eta &= -2
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= -2 - \left(-4x^2 - 4yx - y^2 - 2\right)(1) \\
&= 4x^2 + 4yx + y^2 \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{4x^2 + 4yx + y^2} dy
\end{aligned}$$

Which results in

$$S = -\frac{1}{2x + y}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -4x^2 - 4yx - y^2 - 2$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{2}{(2x+y)^2} \\
S_y &= \frac{1}{(2x+y)^2}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -1 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -1
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -R + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\frac{1}{2x+y} = -x + c_1
$$

Which simplifies to

$$
-\frac{1}{2x+y} = -x + c_1
$$

Which gives

$$
y = -\frac{2c_1 x - 2x^2 + 1}{-x + c_1}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -4x^2 - 4yx - y^2 - 2$ 	$R = x$ $S = -\frac{1}{2x+y}$	$\frac{dS}{dR} = -1$ 
Summary

The solution(s) found are the following

$$y = -\frac{2c_1x - 2x^2 + 1}{-x + c_1} \tag{1}$$

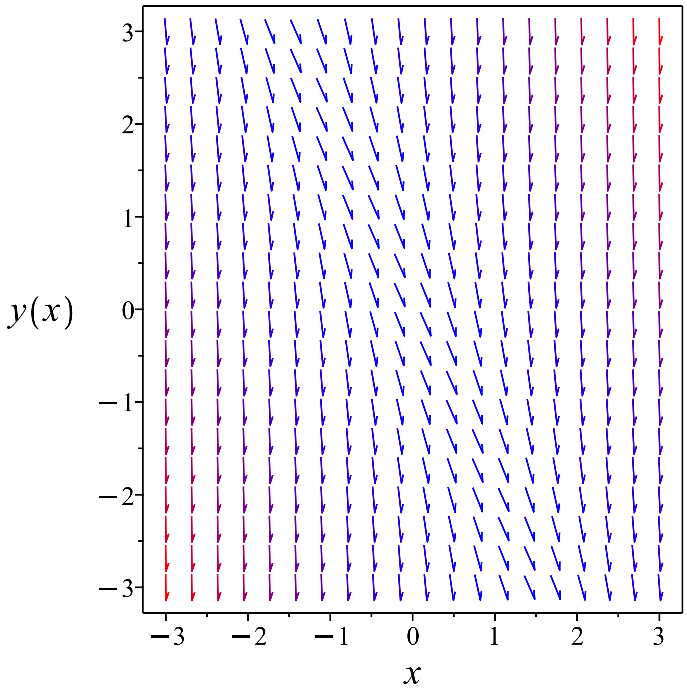

Figure 500: Slope field plot

Verification of solutions

$$y = -\frac{2c_1x - 2x^2 + 1}{-x + c_1}$$

Verified OK.

9.44.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -4x^2 - 4yx - y^2 - 2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -4x^2 - 4yx - y^2 - 2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -4x^2 - 2$, $f_1(x) = -4x$ and $f_2(x) = -1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= 4x \\ f_2^2 f_0 &= -4x^2 - 2 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x) - 4xu'(x) + (-4x^2 - 2) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = e^{-x^2}(c_2 x + c_1)$$

The above shows that

$$u'(x) = e^{-x^2}(-2c_2 x^2 - 2c_1 x + c_2)$$

Using the above in (1) gives the solution

$$y = \frac{-2c_2 x^2 - 2c_1 x + c_2}{c_2 x + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-2c_3 x - 2x^2 + 1}{c_3 + x}$$

Summary

The solution(s) found are the following

$$y = \frac{-2c_3x - 2x^2 + 1}{c_3 + x} \tag{1}$$

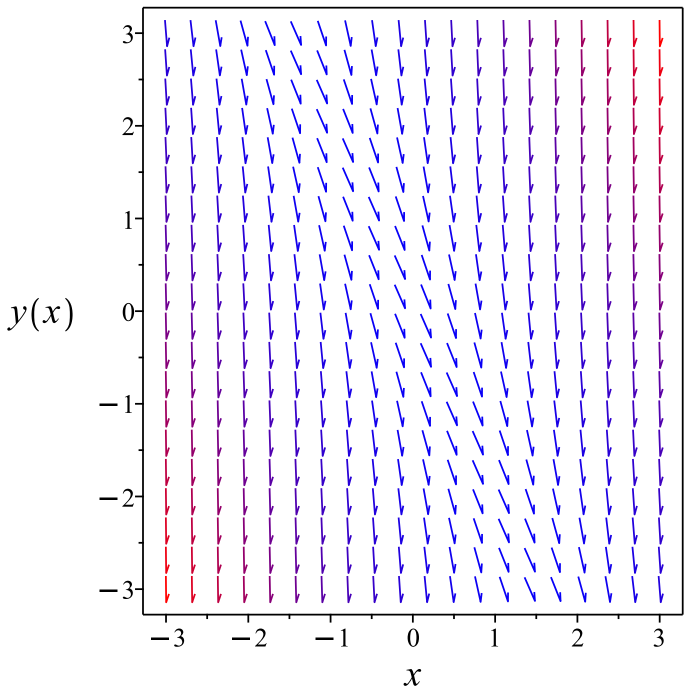

Figure 501: Slope field plot

Verification of solutions

$$y = \frac{-2c_3x - 2x^2 + 1}{c_3 + x}$$

Verified OK.

Maple gives the following as the ode type

```
[_rational, _Riccati]
```

$$\boxed{(1+2x)\left(y'+y^2\right)-2y=2x+3}$$

9.45.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{2x\,y^2+y^2-2x-2y-3}{1+2x}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 3 to use as anstaz gives

$$\xi = x^3a_7+y\,x^2a_8+x\,y^2a_9+y^3a_{10}+x^2a_4+yxa_5+y^2a_6+xa_2+ya_3+a_1 \tag{1E}$$
$$\eta = x^3b_7+y\,x^2b_8+x\,y^2b_9+y^3b_{10}+x^2b_4+yxb_5+y^2b_6+xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9, a_{10}, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9, b_{10}\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} &3x^2b_7 + 2xyb_8 + y^2b_9 + 2xb_4 + yb_5 + b_2 \\ &- \frac{(2x\,y^2 + y^2 - 2x - 2y - 3)\,(-3x^2a_7 + x^2b_8 - 2xya_8 + 2xyb_9 - y^2a_9 + 3y^2b_{10} - 2xa_4 + xb_5 - ya_5 + 2yb_6}{1+2x} \\ &- \frac{(2x\,y^2 + y^2 - 2x - 2y - 3)^2\,(x^2a_8 + 2xya_9 + 3y^2a_{10} + xa_5 + 2ya_6 + a_3)}{(1+2x)^2} \\ &- \left(-\frac{2y^2-2}{1+2x} + \frac{4x\,y^2 + 2y^2 - 4x - 4y - 6}{(1+2x)^2}\right)(x^3a_7 + y\,x^2a_8 \\ &+ x\,y^2a_9 + y^3a_{10} + x^2a_4 + yxa_5 + y^2a_6 + xa_2 + ya_3 + a_1) \\ &+ \frac{(4yx + 2y - 2)\,(x^3b_7 + y\,x^2b_8 + x\,y^2b_9 + y^3b_{10} + x^2b_4 + yxb_5 + y^2b_6 + xb_2 + yb_3 + b_1)}{1+2x} \\ &= 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

Expression too large to display (6E)

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

Expression too large to display (7E)

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(4b_5+16a_8+12a_7+4b_8+8a_4+8a_5)\,v_2^2v_1^3\\
&+(12a_5+16a_6+32a_9+12a_8)\,v_2^3v_1^2\\

8b_7 - 12a_7 + 4b_8 - 4a_8 &= 0 \\
8a_6 - a_3 + a_9 - b_{10} + 10a_{10} &= 0 \\
4a_1 - 3a_2 - 9a_3 - 2b_1 + b_2 + 3b_3 &= 0 \\
4a_3 - 2a_9 + a_5 + 8a_6 - 32a_{10} + 4b_{10} &= 0 \\
-a_5 + 16a_6 + 48a_{10} + 12a_9 - 4b_{10} - 4a_3 &= 0 \\
-a_8 + 24a_{10} + 20a_9 - 4b_{10} - 4a_5 - 4a_3 &= 0 \\
4b_5 + 16a_8 + 12a_7 + 4b_8 + 8a_4 + 8a_5 &= 0 \\
8a_5 + 32a_6 - 24a_{10} + 2a_8 + 4a_9 + 8b_{10} + 8a_3 &= 0 \\
4a_1 - 2a_2 - 8a_3 - 3a_5 - 18a_6 + 2b_1 + b_5 + 6b_6 &= 0 \\
-8a_4 - 4a_5 + 8b_8 - 12a_8 + 4b_4 + 4b_5 - 20a_7 + 10b_7 &= 0 \\
8b_4 - 8a_9 + 2b_7 + 8b_8 - 8a_7 - 16a_8 + 8b_9 + 8b_2 &= 0 \\
-4a_2 - 12a_3 - 6a_4 - 9a_5 - 4b_1 + 2b_2 + 8b_3 + 2b_4 + 3b_5 &= 0 \\
b_9 + a_2 + 6a_3 + b_3 - 20a_6 + 2b_6 - 3a_9 + 9b_{10} - 27a_{10} - 2a_5 &= 0 \\
3b_7 - 4a_2 - 4a_3 + 4b_3 - 12a_4 + 6b_4 - 9a_7 + 3b_8 - 9a_8 - 12a_5 + 8b_5 &= 0 \\
-4a_4 - 24a_6 + 16b_6 - 16a_5 + 4b_5 - 6a_8 + 6b_9 - 18a_9 + 2b_8 - 8a_3 + 8b_1 + 2b_2 &= 0 \\
-4a_4 - 12a_5 - 8a_6 + 2b_4 + 4b_5 + 8b_6 - 24a_8 + 8b_8 - 6a_7 + 16b_9 - 24a_9 + 8b_1 + 8b_2 &= 0 \\
2a_4 + 2a_5 - 16a_6 + b_5 + 4b_6 - 28a_9 + 6b_9 - 4a_8 + 24b_{10} - 36a_{10} + 4a_2 + 16a_3 + 4b_3 &= 0 \\
8a_4 + 16a_5 + 4b_5 - 12a_{10} + 8b_9 + 3a_7 - 2a_8 - 20a_9 + b_8 + 12b_{10} + 4a_2 + 8a_3 + 4b_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= -\frac{b_9}{2} - b_{10} \\
a_2 &= -b_9 \\
a_3 &= -b_{10} \\
a_4 &= 0 \\
a_5 &= 0 \\
a_6 &= 0 \\
a_7 &= 0 \\
a_8 &= 0 \\
a_9 &= 0 \\
a_{10} &= 0 \\
b_1 &= -\frac{3b_9}{2} + b_{10} \\
b_2 &= -b_9 \\
b_3 &= -b_9 - b_{10} \\
b_4 &= 0 \\
b_5 &= 0 \\
b_6 &= \frac{b_9}{2} - b_{10} \\
b_7 &= 0 \\
b_8 &= 0 \\
b_9 &= b_9 \\
b_{10} &= b_{10}
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -y - 1 \\
\eta &= y^3 - y^2 - y + 1
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y^3 - y^2 - y + 1 - \left(-\frac{2x\,y^2 + y^2 - 2x - 2y - 3}{1+2x}\right)(-y-1) \\
&= \frac{-4x\,y^2 + 4x + 4y + 4}{1+2x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-4x\,y^2+4x+4y+4}{1+2x}} dy
\end{aligned}
$$

Which results in

$$
S = \left(\frac{1}{4} + \frac{x}{2}\right)\left(\frac{\ln(y+1)}{1+2x} - \frac{\ln(yx - x - 1)}{1+2x}\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{2x\,y^2 + y^2 - 2x - 2y - 3}{1+2x}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{-y+1}{-4+(4y-4)\,x} \\
S_y &= \frac{-1-2x}{4\,(-1+(y-1)\,x)\,(y+1)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{2} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{2}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \frac{R}{2} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
\frac{\ln(1+y)}{4} - \frac{\ln(-1+(y-1)\,x)}{4} = \frac{x}{2} + c_1
$$

Which simplifies to

$$
\frac{\ln(1+y)}{4} - \frac{\ln(-1+(y-1)\,x)}{4} = \frac{x}{2} + c_1
$$

Which gives

$$
y = \frac{x\,\mathrm{e}^{2x+4c_1} + \mathrm{e}^{2x+4c_1} + 1}{-1 + x\,\mathrm{e}^{2x+4c_1}}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{2x\,y^2+y^2-2x-2y-3}{1+2x}$ 	$R = x$ $S = \frac{\ln(y+1)}{4} - \ln(-1+$	$\frac{dS}{dR} = \frac{1}{2}$ 
Summary

The solution(s) found are the following

$$y = \frac{x\,\mathrm{e}^{2x+4c_1} + \mathrm{e}^{2x+4c_1} + 1}{-1 + x\,\mathrm{e}^{2x+4c_1}} \tag{1}$$

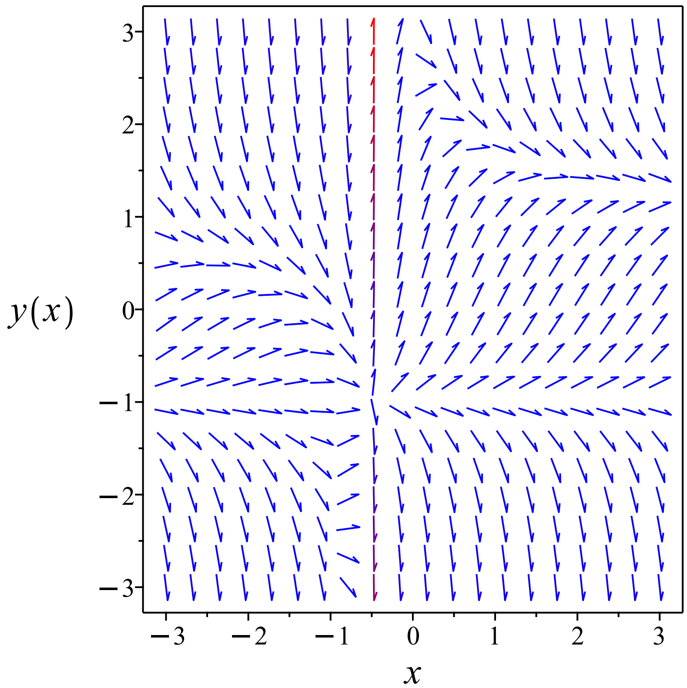

Figure 502: Slope field plot

Verification of solutions

$$y = \frac{x\,\mathrm{e}^{2x+4c_1} + \mathrm{e}^{2x+4c_1} + 1}{-1 + x\,\mathrm{e}^{2x+4c_1}}$$

Verified OK.

9.45.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{2x\,y^2 + y^2 - 2x - 2y - 3}{1+2x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{2x\,y^2}{1+2x} - \frac{y^2}{1+2x} + \frac{2x}{1+2x} + \frac{2y}{1+2x} + \frac{3}{1+2x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -\frac{-3-2x}{1+2x}$, $f_1(x) = \frac{2}{1+2x}$ and $f_2(x) = -1$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{-u}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= 0 \\
f_1 f_2 &= -\frac{2}{1+2x} \\
f_2^2 f_0 &= -\frac{-3-2x}{1+2x}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
-u''(x) + \frac{2u'(x)}{1+2x} - \frac{(-3-2x)\, u(x)}{1+2x} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = c_1 \mathrm{e}^{-x} + c_2 x\, \mathrm{e}^{x}
$$

The above shows that

$$
u'(x) = -c_1 \mathrm{e}^{-x} + (x+1)\, c_2 \mathrm{e}^{x}
$$

Using the above in (1) gives the solution

$$
y = \frac{-c_1 \mathrm{e}^{-x} + (x+1)\, c_2 \mathrm{e}^{x}}{c_1 \mathrm{e}^{-x} + c_2 x\, \mathrm{e}^{x}}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$
y = \frac{x\, \mathrm{e}^{2x} + \mathrm{e}^{2x} - c_3}{x\, \mathrm{e}^{2x} + c_3}
$$

Summary

The solution(s) found are the following

$$y = \frac{x\,e^{2x} + e^{2x} - c_3}{x\,e^{2x} + c_3} \tag{1}$$

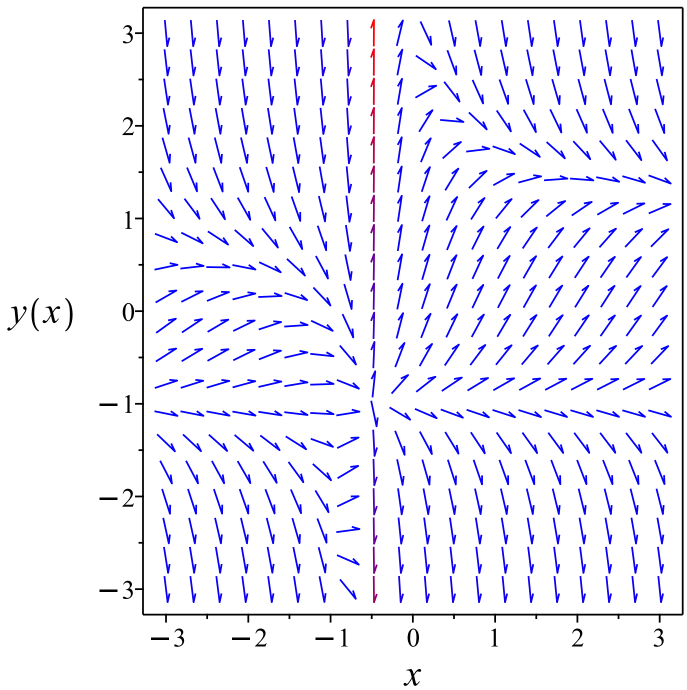

Figure 503: Slope field plot

Verification of solutions

$$y = \frac{x\,e^{2x} + e^{2x} - c_3}{x\,e^{2x} + c_3}$$

Verified OK.

Maple gives the following as the ode type

```
[_rational, _Riccati]
```

$$\boxed{(3x-1)\left(y'+y^2\right)-y(3x+2)=6x-8}$$

9.46.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{3x\,y^2-3yx-y^2-6x-2y+8}{3x-1}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 3 to use as anstaz gives

$$\xi = x^3a_7+y\,x^2a_8+x\,y^2a_9+y^3a_{10}+x^2a_4+yxa_5+y^2a_6+xa_2+ya_3+a_1 \tag{1E}$$
$$\eta = x^3b_7+y\,x^2b_8+x\,y^2b_9+y^3b_{10}+x^2b_4+yxb_5+y^2b_6+xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9, a_{10}, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9, b_{10}\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&3x^2b_7 + 2xyb_8 + y^2b_9 + 2xb_4 + yb_5 + b_2 \\
&- \frac{(3x\,y^2 - 3yx - y^2 - 6x - 2y + 8)\,(-3x^2a_7 + x^2b_8 - 2xya_8 + 2xyb_9 - y^2a_9 + 3y^2b_{10} - 2xa_4 + xb_5 - ya_5}{3x-1} \\
&- \frac{(3x\,y^2 - 3yx - y^2 - 6x - 2y + 8)^2\,(x^2a_8 + 2xya_9 + 3y^2a_{10} + xa_5 + 2ya_6 + a_3)}{(3x-1)^2} \\
&- \left(-\frac{3y^2 - 3y - 6}{3x-1} + \frac{9x\,y^2 - 9yx - 3y^2 - 18x - 6y + 24}{(3x-1)^2}\right)\big(x^3a_7 \\
&+ y\,x^2a_8 + x\,y^2a_9 + y^3a_{10} + x^2a_4 + yxa_5 + y^2a_6 + xa_2 + ya_3 + a_1\big) \\
&+ \frac{(6yx - 3x - 2y - 2)\,(x^3b_7 + y\,x^2b_8 + x\,y^2b_9 + y^3b_{10} + x^2b_4 + yxb_5 + y^2b_6 + xb_2 + yb_3 + b_1)}{3x-1} \\
&= 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

$$\text{Expression too large to display} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\text{Expression too large to display} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(24a_8 + 54a_9 + 18a_5)\, v_2^3 v_1^3 + (21a_9 - 9b_{10} - a_8 + 81a_{10} - 9a_3 + 6a_5 + 36a_6)\, v_2^4 v_1^2 \\
&+ (6a_8 + 36a_9 - 9a_5)\, v_2^4 v_1^3 + (12a_9 + 54a_{10} - 18a_6)\, v_2^5 v_1^2 \\
&+ (18a_{10} - 2a_9 + 12a_6)\, v_2^5 v_1 + (-36a_8 - 12b_7 - 27a_7 + 18b_4)\, v_2 v_1^4 \\
&+ (-72a_9 - 18a_7 - 90a_8 - 6b_8 + 9b_9 + 18a_4 + 27a_5 + 9b_5)\, v_2^2 v_1^3 \\

$$9a_1 + 2a_2 + 14a_3 - 8a_5 - 128a_6 + 2b_1 + b_5 + 16b_6 =$$
$$-72a_9 - 18a_7 - 90a_8 - 6b_8 + 9b_9 + 18a_4 + 27a_5 + 9b_5 =$$
$$12a_2 + 96a_3 - 16a_4 - 64a_5 - 3b_1 - 4b_2 - 30b_3 + 2b_4 + 8b_5 =$$
$$-72a_9 + 2b_7 - 18a_4 - 36a_5 - 12b_4 + 18b_8 - 12a_8 + 36b_9 + 18b_2 =$$
$$-30b_8 + 96a_8 + 72a_7 - 16b_7 - 9b_2 - 36a_4 - 36a_5 + 15b_4 + 18b_5 =$$
$$b_9 - 8a_9 + 24b_{10} - 192a_{10} + a_2 + 21a_3 + b_3 + 2a_5 + 46a_6 - 2b_6 =$$
$$-128a_9 + 6a_2 + 24a_3 - 12b_1 + 2b_2 + 2b_8 - 16a_8 + 16b_9 + 4a_4 + 192a_6 - 60b_6 + 44a_5 - 6b_5 =$$
$$288a_{10} - 6a_2 - 72a_3 - 6b_3 + 4a_8 - 90b_{10} + 2a_4 + 18a_5 + 48a_6 + b_5 + 3b_6 + 76a_9 - 8b_9 =$$
$$3b_7 - 24a_7 + 8b_8 - 64a_8 - 18a_2 - 36a_3 - 9b_1 + 6b_2 + 18b_3 + 96a_5 - 30b_5 + 42a_4 - 10b_4 =$$
$$192a_9 + 3a_4 - 9a_2 - 36a_3 + 18b_1 - 12b_2 + 6a_7 - 60b_9 + 6a_5 - 72a_6 + 2b_4 + 9b_5 + 36b_6 + 74a_8 - 12b_8 =$$
$$-108a_{10} - 12a_4 - 81a_5 - 72a_6 - 6b_5 + 9b_6 + 9a_2 + 27a_3 + 9b_3 + 12b_9 + 3a_7 + 15a_8 + 30a_9 + b_8 + 54b_{10} =$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= \frac{b_9}{3} + 2b_{10} \\
a_2 &= -b_9 \\
a_3 &= -b_{10} \\
a_4 &= 0 \\
a_5 &= 0 \\
a_6 &= 0 \\
a_7 &= 0 \\
a_8 &= 0 \\
a_9 &= 0 \\
a_{10} &= 0 \\
b_1 &= \frac{8b_9}{3} - 2b_{10} \\
b_2 &= -2b_9 \\
b_3 &= -\frac{2b_9}{3} - 3b_{10} \\
b_4 &= 0 \\
b_5 &= -b_9 \\
b_6 &= -\frac{b_9}{3} \\
b_7 &= 0 \\
b_8 &= 0 \\
b_9 &= b_9 \\
b_{10} &= b_{10}
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -y + 2 \\
\eta &= y^3 - 3y - 2
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y^3 - 3y - 2 - \left(-\frac{3x\,y^2 - 3yx - y^2 - 6x - 2y + 8}{3x - 1}\right)(-y+2) \\
&= \frac{9x\,y^2 - 9yx - 18x - 9y + 18}{3x - 1} \\
\xi &= 0
\end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{9x\,y^2 - 9yx - 18x - 9y + 18}{3x - 1}} dy
\end{aligned}$$

Which results in

$$S = \left(\frac{x}{3} - \frac{1}{9}\right)\left(-\frac{\ln(yx + x - 1)}{3x - 1} + \frac{\ln(y - 2)}{3x - 1}\right)$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y) S_y}{R_x + \omega(x,y) R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = -\frac{3x\,y^2 - 3yx - y^2 - 6x - 2y + 8}{3x - 1}$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1\\
R_y &= 0\\
S_x &= \frac{-y-1}{-9+(9y+9)\,x}\\
S_y &= \frac{3x-1}{9\,(y-2)\,(yx+x-1)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = -\frac{1}{3} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = -\frac{1}{3}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = -\frac{R}{3} + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\frac{\ln(yx+x-1)}{9} + \frac{\ln(y-2)}{9} = -\frac{x}{3} + c_1
$$

Which simplifies to

$$
-\frac{\ln(yx+x-1)}{9} + \frac{\ln(y-2)}{9} = -\frac{x}{3} + c_1
$$

Which gives

$$
y = -\frac{x\,\mathrm{e}^{-3x+9c_1} - \mathrm{e}^{-3x+9c_1} + 2}{-1 + x\,\mathrm{e}^{-3x+9c_1}}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{3x\,y^2-3yx-y^2-6x-2y+8}{3x-1}$ 	$R = x$ $S = -\frac{\ln(yx+x-1)}{9} +$	$\frac{dS}{dR} = -\frac{1}{3}$ 
Summary

The solution(s) found are the following

$$y = -\frac{x\,\mathrm{e}^{-3x+9c_1} - \mathrm{e}^{-3x+9c_1} + 2}{-1 + x\,\mathrm{e}^{-3x+9c_1}} \tag{1}$$

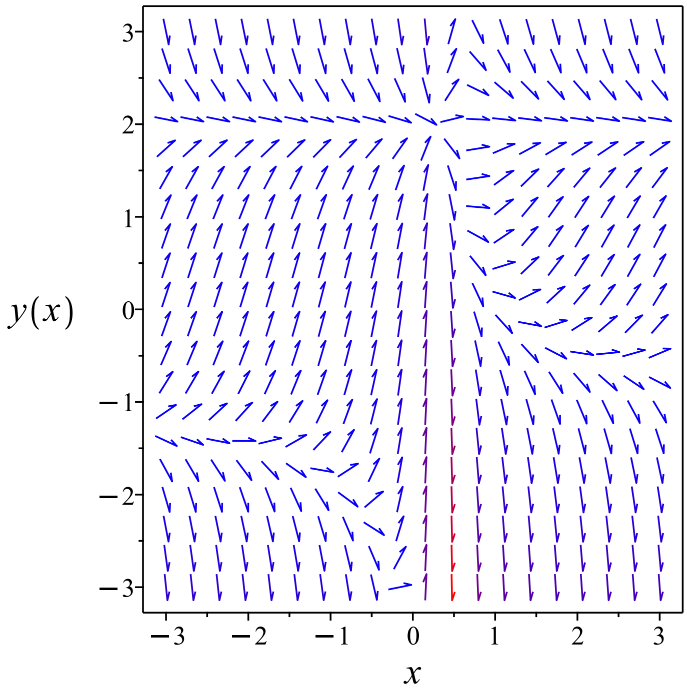

Figure 504: Slope field plot

Verification of solutions

$$y = -\frac{x\,\mathrm{e}^{-3x+9c_1} - \mathrm{e}^{-3x+9c_1} + 2}{-1 + x\,\mathrm{e}^{-3x+9c_1}}$$

Verified OK.

9.46.2 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{3x\,y^2 - 3yx - y^2 - 6x - 2y + 8}{3x - 1} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{3x\,y^2}{3x-1} + \frac{3yx}{3x-1} + \frac{y^2}{3x-1} + \frac{6x}{3x-1} + \frac{2y}{3x-1} - \frac{8}{3x-1}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -\frac{-6x+8}{3x-1}$, $f_1(x) = -\frac{-3x-2}{3x-1}$ and $f_2(x) = -1$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{-u}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= 0 \\
f_1 f_2 &= \frac{-3x-2}{3x-1} \\
f_2^2 f_0 &= -\frac{-6x+8}{3x-1}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
-u''(x) - \frac{(-3x-2) u'(x)}{3x-1} - \frac{(-6x+8) u(x)}{3x-1} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = c_1 \mathrm{e}^{2x} + x\,\mathrm{e}^{-x} c_2
$$

The above shows that

$$
u'(x) = -c_2(x-1)\,\mathrm{e}^{-x} + 2c_1 \mathrm{e}^{2x}
$$

Using the above in (1) gives the solution

$$
y = \frac{-c_2(x-1)\,\mathrm{e}^{-x} + 2c_1 \mathrm{e}^{2x}}{c_1 \mathrm{e}^{2x} + x\,\mathrm{e}^{-x} c_2}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$
y = \frac{2c_3 \mathrm{e}^{3x} - x + 1}{c_3 \mathrm{e}^{3x} + x}
$$

Summary

The solution(s) found are the following

$$y = \frac{2c_3 e^{3x} - x + 1}{c_3 e^{3x} + x} \tag{1}$$

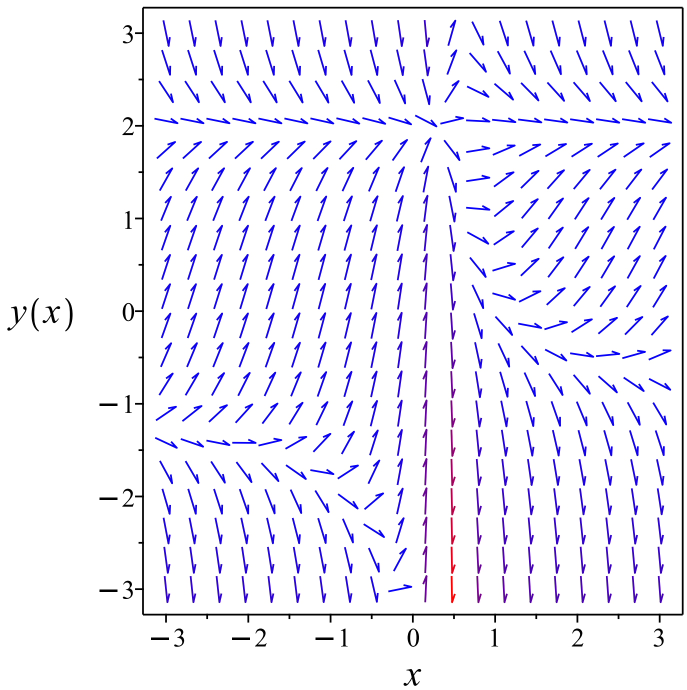

Figure 505: Slope field plot

Verification of solutions

$$y = \frac{2c_3 e^{3x} - x + 1}{c_3 e^{3x} + x}$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_rational, [_1st_order, `_with_symmetry_[F(x),G(x)]`],
   _Riccati]
```

$$\boxed{x^2(y'+y^2)+yx=-x^2+\frac{1}{4}}$$

9.47.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{4x^2y^2+4x^2+4yx-1}{4x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -y^2-1-\frac{y}{x}+\frac{1}{4x^2}$$

With Riccati ODE standard form

$$y' = f_0(x)+f_1(x)y+f_2(x)y^2$$

Shows that $f_0(x) = -\frac{4x^2-1}{4x^2}$, $f_1(x) = -\frac{1}{x}$ and $f_2(x) = -1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= \frac{1}{x} \\ f_2^2f_0 &= -\frac{4x^2-1}{4x^2} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x) - \frac{u'(x)}{x} - \frac{(4x^2-1)\,u(x)}{4x^2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \frac{\sin(x)\,c_1 + c_2\cos(x)}{\sqrt{x}}$$

The above shows that

$$u'(x) = \frac{\left(c_1x - \frac{c_2}{2}\right)\cos(x) - \left(c_2x + \frac{c_1}{2}\right)\sin(x)}{x^{\frac{3}{2}}}$$

Using the above in (1) gives the solution

$$y = \frac{\left(c_1x - \frac{c_2}{2}\right)\cos(x) - \left(c_2x + \frac{c_1}{2}\right)\sin(x)}{x\,(\sin(x)\,c_1 + c_2\cos(x))}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{(2c_3x - 1)\cos(x) - 2\left(x + \frac{c_3}{2}\right)\sin(x)}{2\,(c_3\sin(x) + \cos(x))\,x}$$

Summary

The solution(s) found are the following

$$y = \frac{(2c_3x - 1)\cos(x) - 2\left(x + \frac{c_3}{2}\right)\sin(x)}{2\,(c_3\sin(x) + \cos(x))\,x} \tag{1}$$

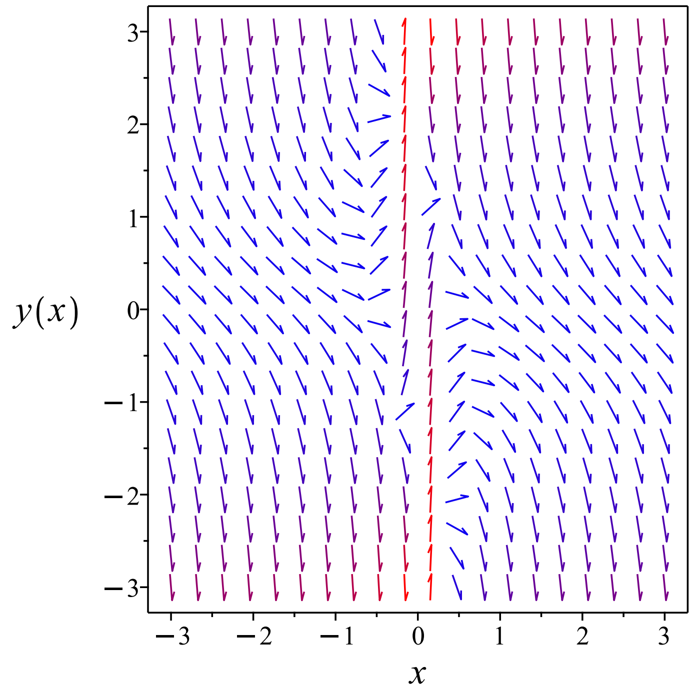

Figure 506: Slope field plot

Verification of solutions

$$y = \frac{(2c_3x - 1)\cos(x) - 2\left(x + \frac{c_3}{2}\right)\sin(x)}{2\left(c_3 \sin(x) + \cos(x)\right)x}$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati", "exactWithIntegrationFactor", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class G`], _rational, _Riccati]
```

$$\boxed{x^2(y'+y^2)-7yx=-7}$$

9.48.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{x^2y^2-7yx+7}{x^2}$$
$$y' = \omega(x,y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x+\omega(\eta_y-\xi_x)-\omega^2\xi_y-\omega_x\xi-\omega_y\eta=0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2+ya_3+a_1 \tag{1E}$$
$$\eta = xb_2+yb_3+b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(x^2y^2 - 7yx + 7)(b_3 - a_2)}{x^2} - \frac{(x^2y^2 - 7yx + 7)^2 a_3}{x^4} - \left(-\frac{2x\,y^2 - 7y}{x^2} + \frac{2x^2y^2 - 14yx + 14}{x^3}\right)(xa_2 + ya_3 + a_1) + \frac{(2y\,x^2 - 7x)(xb_2 + yb_3 + b_1)}{x^2} = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{-x^4y^4a_3 + 2x^5yb_2 + x^4y^2a_2 + x^4y^2b_3 + 14x^3y^3a_3 + 2x^4yb_1 - 6b_2x^4 - 56x^2y^2a_3 - 7x^3b_1 + 7x^2ya_1 - 7x^2a_2}{x^4} = 0$$

Setting the numerator to zero gives

$$-x^4y^4a_3 + 2x^5yb_2 + x^4y^2a_2 + x^4y^2b_3 + 14x^3y^3a_3 + 2x^4yb_1 - 6b_2x^4 - 56x^2y^2a_3 - 7x^3b_1 + 7x^2ya_1 - 7x^2a_2 - 7x^2b_3 + 84xya_3 - 14xa_1 - 49a_3 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-a_3v_1^4v_2^4 + a_2v_1^4v_2^2 + 14a_3v_1^3v_2^3 + 2b_2v_1^5v_2 + b_3v_1^4v_2^2 + 2b_1v_1^4v_2 - 56a_3v_1^2v_2^2 - 6b_2v_1^4 + 7a_1v_1^2v_2 - 7b_1v_1^3 - 7a_2v_1^2 + 84a_3v_1v_2 - 7b_3v_1^2 - 14a_1v_1 - 49a_3 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned} 2b_2v_1^5v_2 - a_3v_1^4v_2^4 + (a_2 + b_3)\, v_1^4v_2^2 + 2b_1v_1^4v_2 - 6b_2v_1^4 + 14a_3v_1^3v_2^3 - 7b_1v_1^3 \\ - 56a_3v_1^2v_2^2 + 7a_1v_1^2v_2 + (-7a_2 - 7b_3)\, v_1^2 + 84a_3v_1v_2 - 14a_1v_1 - 49a_3 = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} -14a_1 &= 0 \\ 7a_1 &= 0 \\ -56a_3 &= 0 \\ -49a_3 &= 0 \\ -a_3 &= 0 \\ 14a_3 &= 0 \\ 84a_3 &= 0 \\ -7b_1 &= 0 \\ 2b_1 &= 0 \\ -6b_2 &= 0 \\ 2b_2 &= 0 \\ -7a_2 - 7b_3 &= 0 \\ a_2 + b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= -b_3 \\ a_3 &= 0 \\ b_1 &= 0 \\ b_2 &= 0 \\ b_3 &= b_3 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= -x \\ \eta &= y \end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= y - \left(-\frac{x^2y^2 - 7yx + 7}{x^2}\right)(-x) \\
&= \frac{-x^2y^2 + 8yx - 7}{x} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-x^2y^2+8yx-7}{x}} dy
\end{aligned}
$$

Which results in

$$
S = -\frac{\ln(yx-7)}{6} + \frac{\ln(yx-1)}{6}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x, y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{x^2y^2 - 7yx + 7}{x^2}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= -\frac{y}{(yx-1)(yx-7)} \\
S_y &= -\frac{x}{(yx-1)(yx-7)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = \frac{1}{x} \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = \frac{1}{R}
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$
S(R) = \ln(R) + c_1 \tag{4}
$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$
-\frac{\ln(yx-7)}{6} + \frac{\ln(yx-1)}{6} = \ln(x) + c_1
$$

Which simplifies to

$$
-\frac{\ln(yx-7)}{6} + \frac{\ln(yx-1)}{6} = \ln(x) + c_1
$$

Which gives

$$
y = \frac{7x^6 e^{6c_1} - 1}{x\left(x^6 e^{6c_1} - 1\right)}
$$

The following diagram shows solution curves of the original ode and how they transform in the canonical coordinates space using the mapping shown.

Original ode in x, y coordinates	Canonical coordinates transformation	ODE in canonical coordinates (R, S)
$\frac{dy}{dx} = -\frac{x^2y^2-7yx+7}{x^2}$ 	$R = x$ $S = -\frac{\ln(yx-7)}{6} + \frac{\ln(y}{}$	$\frac{dS}{dR} = \frac{1}{R}$ 
Summary
The solution(s) found are the following

$$y = \frac{7x^6 e^{6c_1} - 1}{x\left(x^6 e^{6c_1} - 1\right)} \tag{1}$$

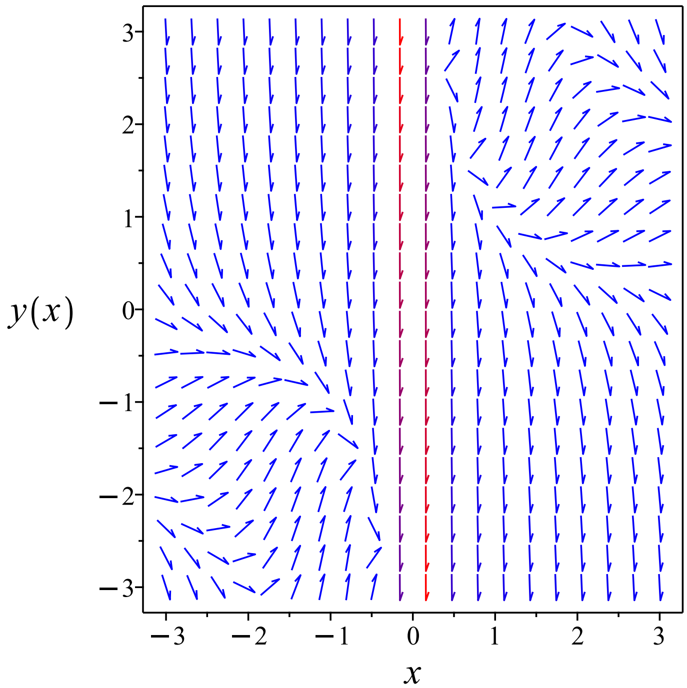

Figure 507: Slope field plot

Verification of solutions

$$y = \frac{7x^6 e^{6c_1} - 1}{x\left(x^6 e^{6c_1} - 1\right)}$$

Verified OK.

9.48.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}$$

Therefore

$$\begin{aligned} (x^2) \, \mathrm{d}y &= (-x^2y^2 + 7yx - 7) \, \mathrm{d}x \\ (x^2y^2 - 7yx + 7) \, \mathrm{d}x + (x^2) \, \mathrm{d}y &= 0 \end{aligned} \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = x^2y^2 - 7yx + 7$$
$$N(x, y) = x^2$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned} \frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(x^2y^2 - 7yx + 7) \\ &= 2y\,x^2 - 7x \end{aligned}$$

And

$$\begin{aligned} \frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(x^2) \\ &= 2x \end{aligned}$$

Since $\frac{\partial M}{\partial y} \neq \frac{\partial N}{\partial x}$, then the ODE is not exact. Since the ODE is not exact, we will try to find an integrating factor to make it exact. Let

$$\begin{aligned}
A &= \frac{1}{N}\left(\frac{\partial M}{\partial y} - \frac{\partial N}{\partial x}\right) \\
&= \frac{1}{x^2}\left(\left(2y\,x^2 - 7x\right) - (2x)\right) \\
&= \frac{2yx - 9}{x}
\end{aligned}$$

Since A depends on y, it can not be used to obtain an integrating factor. We will now try a second method to find an integrating factor. Let

$$\begin{aligned}
B &= \frac{1}{M}\left(\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}\right) \\
&= \frac{1}{x^2y^2 - 7yx + 7}\left((2x) - \left(2y\,x^2 - 7x\right)\right) \\
&= \frac{-2y\,x^2 + 9x}{x^2y^2 - 7yx + 7}
\end{aligned}$$

Since B depends on x, it can not be used to obtain an integrating factor.We will now try a third method to find an integrating factor. Let

$$R = \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN}$$

R is now checked to see if it is a function of only $t = xy$. Therefore

$$\begin{aligned}
R &= \frac{\frac{\partial N}{\partial x} - \frac{\partial M}{\partial y}}{xM - yN} \\
&= \frac{(2x) - \left(2y\,x^2 - 7x\right)}{x\left(x^2y^2 - 7yx + 7\right) - y\left(x^2\right)} \\
&= \frac{-2yx + 9}{x^2y^2 - 8yx + 7}
\end{aligned}$$

Replacing all powers of terms xy by t gives

$$R = \frac{-2t + 9}{t^2 - 8t + 7}$$

Since R depends on t only, then it can be used to find an integrating factor. Let the integrating factor be μ then

$$\begin{aligned}
\mu &= e^{\int R \,\mathrm{d}t} \\
&= e^{\int \left(\frac{-2t+9}{t^2-8t+7}\right) \mathrm{d}t}
\end{aligned}$$

The result of integrating gives

$$\begin{aligned}\mu &= e^{-\frac{7\ln(t-1)}{6}-\frac{5\ln(t-7)}{6}}\\ &= \frac{1}{(t-1)^{\frac{7}{6}}(t-7)^{\frac{5}{6}}}\end{aligned}$$

Now t is replaced back with xy giving

$$\mu = \frac{1}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}$$

Multiplying M and N by this integrating factor gives new M and new N which are called $\overline{M}$ and $\overline{N}$ so not to confuse them with the original M and N

$$\begin{aligned}\overline{M} &= \mu M\\ &= \frac{1}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}\left(x^2y^2-7yx+7\right)\\ &= \frac{x^2y^2-7yx+7}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}\end{aligned}$$

And

$$\begin{aligned}\overline{N} &= \mu N\\ &= \frac{1}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}\left(x^2\right)\\ &= \frac{x^2}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}\end{aligned}$$

A modified ODE is now obtained from the original ODE, which is exact and can solved. The modified ODE is

$$\begin{aligned}\overline{M}+\overline{N}\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\\ \left(\frac{x^2y^2-7yx+7}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}\right)+\left(\frac{x^2}{(yx-1)^{\frac{7}{6}}(yx-7)^{\frac{5}{6}}}\right)\frac{\mathrm{d}y}{\mathrm{d}x} &= 0\end{aligned}$$

The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial\phi}{\partial x} = \overline{M} \tag{1}$$

$$\frac{\partial\phi}{\partial y} = \overline{N} \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \overline{M} \mathrm{d}x$$

$$\int \frac{\partial \phi}{\partial x} \mathrm{d}x = \int \frac{x^2y^2 - 7yx + 7}{(yx-1)^{\frac{7}{6}} (yx-7)^{\frac{5}{6}}} \mathrm{d}x$$

$$\phi = \frac{(yx-7)^{\frac{1}{6}} x}{(yx-1)^{\frac{1}{6}}} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = -\frac{(yx-7)^{\frac{1}{6}} x^2}{6(yx-1)^{\frac{7}{6}}} + \frac{x^2}{6(yx-1)^{\frac{1}{6}} (yx-7)^{\frac{5}{6}}} + f'(y) \tag{4}$$

$$= \frac{x^2}{(yx-1)^{\frac{7}{6}} (yx-7)^{\frac{5}{6}}} + f'(y)$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = \frac{x^2}{(yx-1)^{\frac{7}{6}} (yx-7)^{\frac{5}{6}}}$. Therefore equation (4) becomes

$$\frac{x^2}{(yx-1)^{\frac{7}{6}} (yx-7)^{\frac{5}{6}}} = \frac{x^2}{(yx-1)^{\frac{7}{6}} (yx-7)^{\frac{5}{6}}} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = 0$$

Therefore

$$f(y) = c_1$$

Where c_1 is constant of integration. Substituting this result for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{(yx-7)^{\frac{1}{6}} x}{(yx-1)^{\frac{1}{6}}} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{(yx-7)^{\frac{1}{6}} x}{(yx-1)^{\frac{1}{6}}}$$

The solution becomes

$$y = \frac{c_1^6 - 7x^6}{(c_1^6 - x^6)\, x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1^6 - 7x^6}{(c_1^6 - x^6)\, x} \tag{1}$$

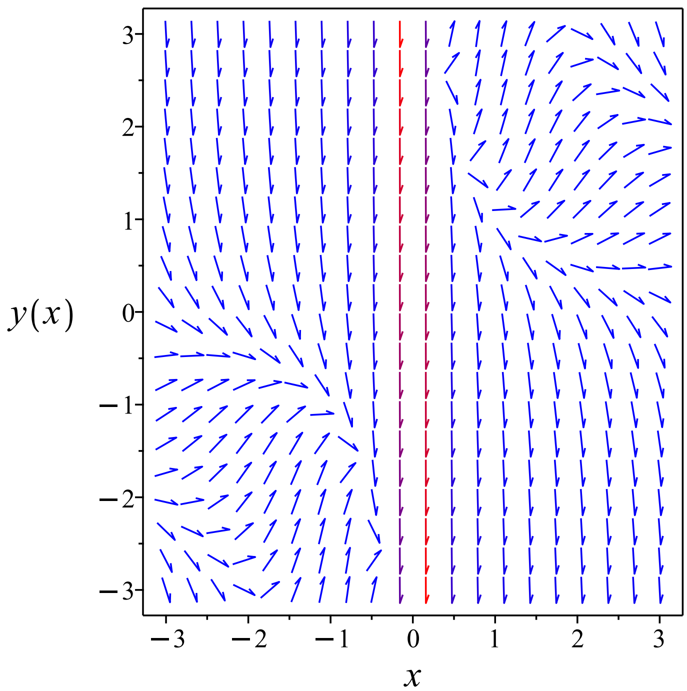

Figure 508: Slope field plot

Verification of solutions

$$y = \frac{c_1^6 - 7x^6}{(c_1^6 - x^6)\, x}$$

Verified OK.

9.48.3 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -\frac{x^2y^2-7yx+7}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -y^2+\frac{7y}{x}-\frac{7}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x)+f_1(x)y+f_2(x)y^2$$

Shows that $f_0(x) = -\frac{7}{x^2}$, $f_1(x) = \frac{7}{x}$ and $f_2(x) = -1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x)-(f_2'+f_1f_2)\,u'(x)+f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= -\frac{7}{x} \\ f_2^2f_0 &= -\frac{7}{x^2} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-u''(x)+\frac{7u'(x)}{x}-\frac{7u(x)}{x^2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = x(c_1x^6+c_2)$$

The above shows that

$$u'(x) = 7c_1x^6 + c_2$$

Using the above in (1) gives the solution

$$y = \frac{7c_1x^6 + c_2}{x\,(c_1x^6 + c_2)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{7c_3x^6 + 1}{x\,(c_3x^6 + 1)}$$

Summary

The solution(s) found are the following

$$y = \frac{7c_3x^6 + 1}{x\,(c_3x^6 + 1)} \tag{1}$$

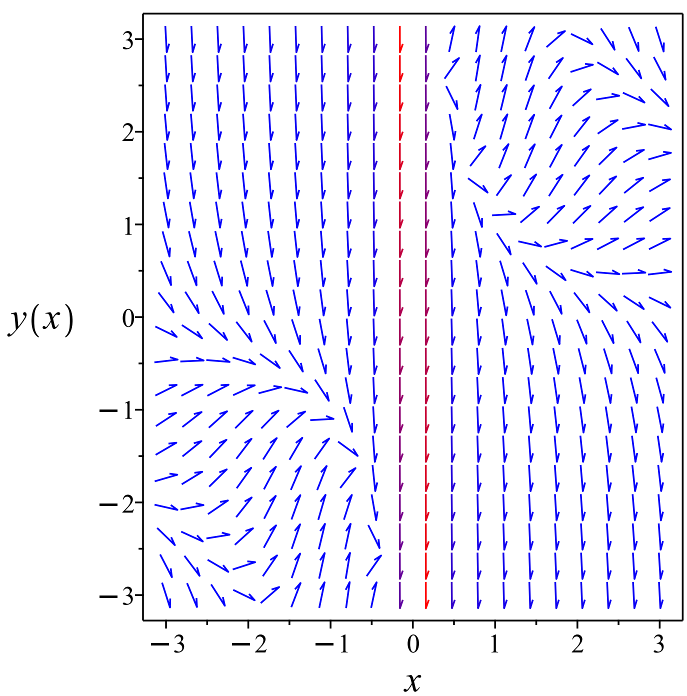

Figure 509: Slope field plot

Verification of solutions

$$y = \frac{7c_3x^6 + 1}{x(c_3x^6 + 1)}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 9y = \tan(3x)}$$

10.1.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 9, f(x) = \tan(3x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 9y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 9$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 9 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 9 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 9$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(9)} \\ &= \pm 3i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +3i \\ \lambda_2 &= -3i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 3i \\ \lambda_2 &= -3i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 3$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(3x) + c_2 \sin(3x))$$

Or

$$y = c_1 \cos(3x) + c_2 \sin(3x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(3x) + c_2 \sin(3x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(3x)$$
$$y_2 = \sin(3x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(3x) & \sin(3x) \\ \frac{d}{dx}(\cos(3x)) & \frac{d}{dx}(\sin(3x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{vmatrix}$$

Therefore

$$W = (\cos(3x))(3\cos(3x)) - (\sin(3x))(-3\sin(3x))$$

Which simplifies to

$$W = 3\cos(3x)^2 + 3\sin(3x)^2$$

Which simplifies to

$$W = 3$$

Therefore Eq. (2) becomes

$$u_1 = -\left(\int \frac{\sin(3x)\tan(3x)}{3}dx\right)$$

Which simplifies to

$$u_1 = -\left(\int \frac{\sin(3x)\tan(3x)}{3}dx\right)$$

Hence

$$u_1 = \frac{\sin(3x)}{9} - \frac{\ln(\sec(3x) + \tan(3x))}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(3x)\tan(3x)}{3}dx$$

Which simplifies to

$$u_2 = \int \frac{\sin(3x)}{3}dx$$

Hence

$$u_2 = -\frac{\cos(3x)}{9}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\sin(3x)}{9} - \frac{\ln(\sec(3x) + \tan(3x))}{9}\right)\cos(3x) - \frac{\cos(3x)\sin(3x)}{9}$$

Which simplifies to

$$y_p(x) = -\frac{\cos(3x)\ln(\sec(3x) + \tan(3x))}{9}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 \cos(3x) + c_2 \sin(3x)) + \left(-\frac{\cos(3x)\ln(\sec(3x) + \tan(3x))}{9}\right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
y = c_1 \cos(3x) + c_2 \sin(3x) - \frac{\cos(3x)\ln(\sec(3x) + \tan(3x))}{9} \tag{1}
$$

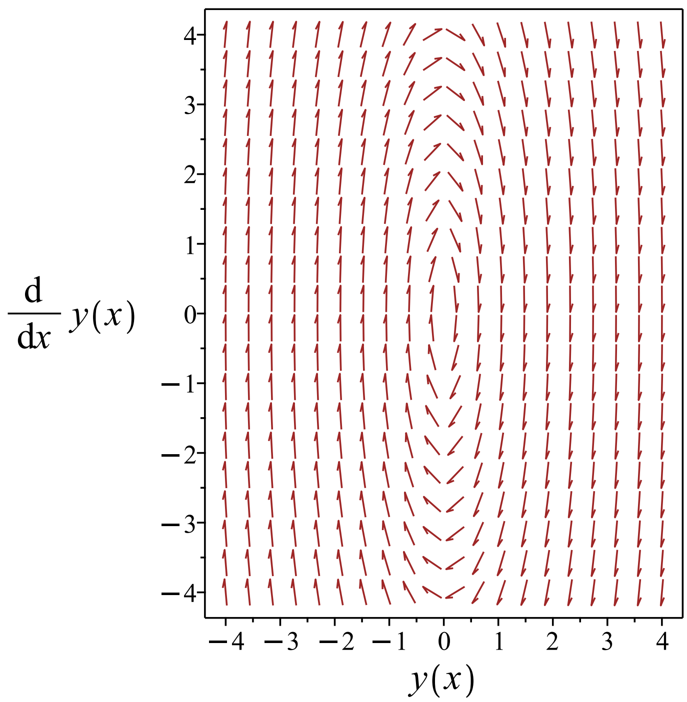

Figure 510: Slope field plot

<u>Verification of solutions</u>

$$
y = c_1 \cos(3x) + c_2 \sin(3x) - \frac{\cos(3x)\ln(\sec(3x) + \tan(3x))}{9}
$$

Verified OK.

10.1.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + 9y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= 9 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-9}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -9 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -9z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 408: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -9$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(3x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \cos(3x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \cos(3x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \cos(3x) \int \frac{1}{\cos(3x)^2}\, dx \\
&= \cos(3x) \left(\frac{\tan(3x)}{3}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\cos(3x)) + c_2\left(\cos(3x) \left(\frac{\tan(3x)}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' + 9y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(3x) + \frac{c_2 \sin(3x)}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(3x)$$
$$y_2 = \frac{\sin(3x)}{3}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(3x) & \frac{\sin(3x)}{3} \\ \frac{d}{dx}(\cos(3x)) & \frac{d}{dx}\left(\frac{\sin(3x)}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(3x) & \frac{\sin(3x)}{3} \\ -3\sin(3x) & \cos(3x) \end{vmatrix}$$

Therefore

$$W = (\cos(3x))(\cos(3x)) - \left(\frac{\sin(3x)}{3}\right)(-3\sin(3x))$$

Which simplifies to

$$W = \cos(3x)^2 + \sin(3x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(3x)\tan(3x)}{3}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(3x)\tan(3x)}{3}dx$$

Hence

$$u_1 = \frac{\sin(3x)}{9} - \frac{\ln(\sec(3x) + \tan(3x))}{9}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(3x)\tan(3x)}{1}\,dx$$

Which simplifies to

$$u_2 = \int \sin(3x)\,dx$$

Hence

$$u_2 = -\frac{\cos(3x)}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{\sin(3x)}{9} - \frac{\ln(\sec(3x) + \tan(3x))}{9}\right)\cos(3x) - \frac{\cos(3x)\sin(3x)}{9}$$

Which simplifies to

$$y_p(x) = -\frac{\cos(3x)\ln(\sec(3x)+\tan(3x))}{9}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(3x) + \frac{c_2\sin(3x)}{3}\right) + \left(-\frac{\cos(3x)\ln(\sec(3x)+\tan(3x))}{9}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\cos(3x) + \frac{c_2\sin(3x)}{3} - \frac{\cos(3x)\ln(\sec(3x)+\tan(3x))}{9} \tag{1}$$

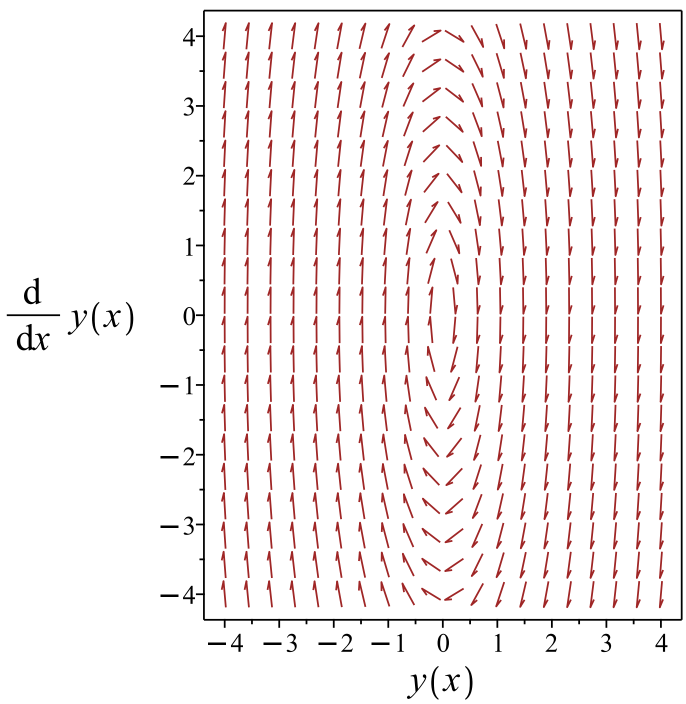

Figure 511: Slope field plot

Verification of solutions

$$y = c_1\cos(3x) + \frac{c_2\sin(3x)}{3} - \frac{\cos(3x)\ln(\sec(3x)+\tan(3x))}{9}$$

Verified OK.

10.1.3 Maple step by step solution

Let's solve

$y'' + 9y = \tan(3x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 9 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-36})}{2}$

- Roots of the characteristic polynomial

  $r = (-3\,\mathrm{I}, 3\,\mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(3x)$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(3x)$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \cos(3x) + c_2 \sin(3x) + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

- ○ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = \tan(3x)\right]$

- ○ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(3x) & \sin(3x) \\ -3\sin(3x) & 3\cos(3x) \end{bmatrix}$

- ○ Compute Wronskian

  $W(y_1(x), y_2(x)) = 3$

- ○ Substitute functions into equation for $y_p(x)$

$$y_p(x) = -\frac{\cos(3x)\left(\int \sin(3x)\tan(3x)dx\right)}{3} + \frac{\sin(3x)\left(\int \sin(3x)dx\right)}{3}$$

- Compute integrals

$$y_p(x) = -\frac{\cos(3x)\ln(\sec(3x)+\tan(3x))}{9}$$

- Substitute particular solution into general solution to ODE

$$y = c_1\cos(3x) + c_2\sin(3x) - \frac{\cos(3x)\ln(\sec(3x)+\tan(3x))}{9}$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' + 4y = \sin(2x)\sec(2x)^2}$$

10.2.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = 4, f(x) = \tan(2x)\sec(2x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = 4$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + 4 e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(4)} \\ &= \pm 2i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2i \\ \lambda_2 &= -2i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2i \\ \lambda_2 &= -2i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 2$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^0(c_1 \cos(2x) + c_2 \sin(2x))$$

Or

$$y = c_1 \cos(2x) + c_2 \sin(2x)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \cos(2x) + c_2 \sin(2x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(2x)$$
$$y_2 = \sin(2x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2x) & \sin(2x) \\ \frac{d}{dx}(\cos(2x)) & \frac{d}{dx}(\sin(2x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2x) & \sin(2x) \\ -2\sin(2x) & 2\cos(2x) \end{vmatrix}$$

Therefore

$$W = (\cos(2x))(2\cos(2x)) - (\sin(2x))(-2\sin(2x))$$

Which simplifies to

$$W = 2\cos(2x)^2 + 2\sin(2x)^2$$

Which simplifies to

$$W = 2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(2x)\tan(2x)\sec(2x)}{2}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\tan(2x)^2}{2}dx$$

Hence

$$u_1 = -\frac{\tan(2x)}{4} + \frac{x}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(2x)\tan(2x)\sec(2x)}{2}\,dx$$

Which simplifies to

$$u_2 = \int \frac{\tan(2x)}{2}dx$$

Hence

$$u_2 = \frac{\ln\left(1+\tan(2x)^2\right)}{8}$$

Which simplifies to

$$u_1 = -\frac{\tan(2x)}{4} + \frac{x}{2}$$

$$u_2 = \frac{\ln\left(\sec(2x)^2\right)}{8}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\tan(2x)}{4} + \frac{x}{2}\right)\cos(2x) + \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8}$$

Which simplifies to

$$y_p(x) = \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\cos(2x) + c_2\sin(2x)) + \left(\frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(2x) + c_2\sin(2x) + \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2} \tag{1}$$

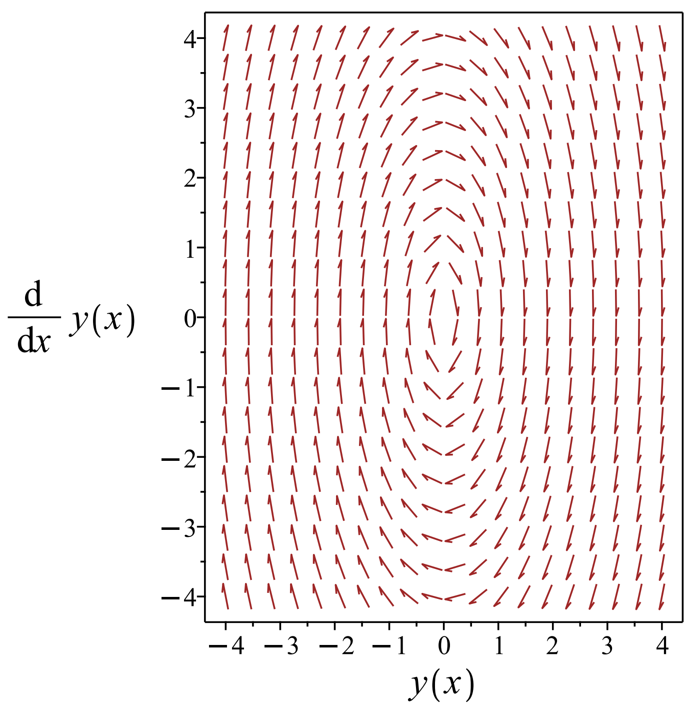

Figure 512: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + c_2 \sin(2x) + \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2}$$

Verified OK.

10.2.2 Solving using Kovacic algorithm

Writing the ode as

$$\begin{align*} y'' + 4y &= 0 \tag{1} \\ Ay'' + By' + Cy &= 0 \tag{2} \end{align*}$$

Comparing (1) and (2) shows that

$$\begin{align*} A &= 1 \\ B &= 0 \tag{3} \\ C &= 4 \end{align*}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{align*} r &= \frac{s}{t} \tag{5} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{align*}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{align*} s &= -4 \\ t &= 1 \end{align*}$$

Therefore eq. (4) becomes

$$z''(x) = -4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 410: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(2x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1 \\ &= \cos(2x)\end{aligned}$$

Which simplifies to

$$y_1 = \cos(2x)$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \cos(2x) \int \frac{1}{\cos(2x)^2}\,dx \\ &= \cos(2x)\left(\frac{\tan(2x)}{2}\right)\end{aligned}$$

Therefore the solution is

$$\begin{aligned}y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(2x)) + c_2\left(\cos(2x)\left(\frac{\tan(2x)}{2}\right)\right)\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''+4y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(2x)$$
$$y_2 = \frac{\sin(2x)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(2x) & \frac{\sin(2x)}{2} \\ \frac{d}{dx}(\cos(2x)) & \frac{d}{dx}\left(\frac{\sin(2x)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(2x) & \frac{\sin(2x)}{2} \\ -2\sin(2x) & \cos(2x) \end{vmatrix}$$

Therefore

$$W = (\cos(2x))(\cos(2x)) - \left(\frac{\sin(2x)}{2}\right)(-2\sin(2x))$$

Which simplifies to

$$W = \cos(2x)^2 + \sin(2x)^2$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(2x)\tan(2x)\sec(2x)}{2}}{1} dx$$

Which simplifies to

$$u_1 = -\int \frac{\tan(2x)^2}{2} dx$$

Hence

$$u_1 = -\frac{\tan(2x)}{4} + \frac{x}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\cos(2x)\tan(2x)\sec(2x)}{1} dx$$

Which simplifies to

$$u_2 = \int \tan(2x)\, dx$$

Hence

$$u_2 = \frac{\ln\left(1 + \tan(2x)^2\right)}{4}$$

Which simplifies to

$$u_1 = -\frac{\tan(2x)}{4} + \frac{x}{2}$$
$$u_2 = \frac{\ln\left(\sec(2x)^2\right)}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\tan(2x)}{4} + \frac{x}{2}\right)\cos(2x) + \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8}$$

Which simplifies to

$$y_p(x) = \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\cos(2x) + \frac{c_2\sin(2x)}{2}\right) + \left(\frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1\cos(2x) + \frac{c_2\sin(2x)}{2} + \frac{\ln\left(\sec(2x)^2\right)\sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x\cos(2x)}{2} \tag{1}$$

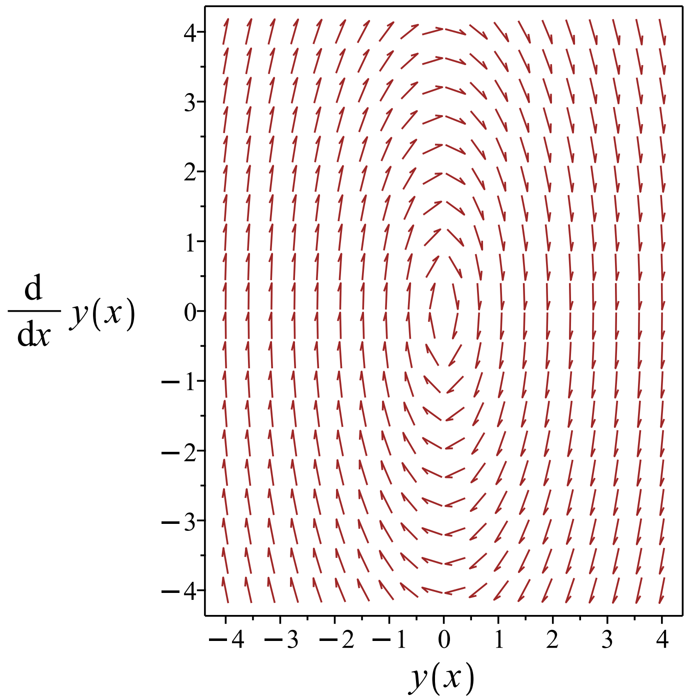

Figure 513: Slope field plot

Verification of solutions

$$y = c_1 \cos(2x) + \frac{c_2 \sin(2x)}{2} + \frac{\ln(\sec(2x)^2) \sin(2x)}{8} - \frac{\sin(2x)}{4} + \frac{x \cos(2x)}{2}$$

Verified OK.

10.2.3 Maple step by step solution

Let's solve

$y'' + 4y = \tan(2x) \sec(2x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 + 4 = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-16})}{2}$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 3y' + 2y = \frac{4}{1 + \mathrm{e}^{-x}}}$$

10.3.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -3, C = 2, f(x) = \frac{4}{1+\mathrm{e}^{-x}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -3, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 3\lambda\, e^{\lambda x} + 2\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 3\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -3, C = 2$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{3}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-3^2 - (4)\,(1)\,(2)} \\ &= \frac{3}{2} \pm \frac{1}{2} \end{aligned}$$

Hence

$$\lambda_1 = \frac{3}{2} + \frac{1}{2}$$
$$\lambda_2 = \frac{3}{2} - \frac{1}{2}$$

Which simplifies to

$$\lambda_1 = 2$$
$$\lambda_2 = 1$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{(2)x} + c_2 e^{(1)x}$$

Or

$$y = c_1 e^{2x} + c_2 e^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{2x} + c_2 e^{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{2x}$$
$$y_2 = e^{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & e^{x} \\ \frac{d}{dx}\left(e^{2x}\right) & \frac{d}{dx}\left(e^{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & e^{x} \\ 2\,e^{2x} & e^{x} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\right)\left(e^{x}\right) - \left(e^{x}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = -e^x e^{2x}$$

Which simplifies to

$$W = -e^{3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4\,e^x}{1+e^{-x}}}{-e^{3x}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{4\,e^{-2x}}{1+e^{-x}}dx$$

Hence

$$u_1 = -4\,e^{-x} - 4\ln\left(e^x\right) + 4\ln\left(1+e^x\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\,e^{2x}}{1+e^{-x}}}{-e^{3x}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{4\,e^{-x}}{1+e^{-x}}dx$$

Hence

$$u_2 = 4\ln\left(1+e^{-x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-4\,e^{-x} - 4\ln\left(e^x\right) + 4\ln\left(1+e^x\right)\right)e^{2x} + 4\ln\left(1+e^{-x}\right)e^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{2x} + c_2 e^x\right) + \left(\left(-4\,e^{-x} - 4\ln\left(e^x\right) + 4\ln\left(1+e^x\right)\right)e^{2x} + 4\ln\left(1+e^{-x}\right)e^x\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{2x} + c_2 e^{x} + \left(-4\,e^{-x} - 4\ln\left(e^{x}\right) + 4\ln\left(1+e^{x}\right)\right) e^{2x} + 4\ln\left(1+e^{-x}\right) e^{x} \tag{1}$$

Verification of solutions

$$y = c_1 e^{2x} + c_2 e^{x} + \left(-4\,e^{-x} - 4\ln\left(e^{x}\right) + 4\ln\left(1+e^{x}\right)\right) e^{2x} + 4\ln\left(1+e^{-x}\right) e^{x}$$

Verified OK.

10.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 3y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -3 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 412: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3}{1}\,dx} \\
&= z_1 e^{\frac{3x}{2}} \\
&= z_1\left(\mathrm{e}^{\frac{3x}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{3x}}{(y_1)^2}\,dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^{x}) + c_2(\mathrm{e}^{x}(\mathrm{e}^{x}))
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 3y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^x + c_2 e^{2x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^x$$
$$y_2 = e^{2x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & e^{2x} \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(e^{2x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{x} & e^{2x} \\ e^{x} & 2\,e^{2x} \end{vmatrix}$$

Therefore

$$W = (e^{x})\left(2\,e^{2x}\right) - \left(e^{2x}\right)(e^{x})$$

Which simplifies to

$$W = e^{x} e^{2x}$$

Which simplifies to

$$W = e^{3x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4\,e^{2x}}{1+e^{-x}}}{e^{3x}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{4\,e^{-x}}{1+e^{-x}} dx$$

Hence

$$u_1 = 4\ln\left(1+e^{-x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\,e^{x}}{1+e^{-x}}}{e^{3x}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{4\,e^{-2x}}{1+e^{-x}} dx$$

Hence

$$u_2 = -4\,e^{-x} - 4\ln(e^{x}) + 4\ln(1+e^{x})$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-4\,e^{-x} - 4\ln(e^{x}) + 4\ln(1+e^{x})\right)e^{2x} + 4\ln\left(1+e^{-x}\right)e^{x}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^x + c_2 \mathrm{e}^{2x}\right) + \left(\left(-4\,\mathrm{e}^{-x} - 4\ln\left(\mathrm{e}^x\right) + 4\ln\left(1+\mathrm{e}^x\right)\right)\mathrm{e}^{2x} + 4\ln\left(1+\mathrm{e}^{-x}\right)\mathrm{e}^x\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^x + c_2 \mathrm{e}^{2x} + \left(-4\,\mathrm{e}^{-x} - 4\ln\left(\mathrm{e}^x\right) + 4\ln\left(1+\mathrm{e}^x\right)\right)\mathrm{e}^{2x} + 4\ln\left(1+\mathrm{e}^{-x}\right)\mathrm{e}^x \tag{1}
$$

Verification of solutions

$$
y = c_1 \mathrm{e}^x + c_2 \mathrm{e}^{2x} + \left(-4\,\mathrm{e}^{-x} - 4\ln\left(\mathrm{e}^x\right) + 4\ln\left(1+\mathrm{e}^x\right)\right)\mathrm{e}^{2x} + 4\ln\left(1+\mathrm{e}^{-x}\right)\mathrm{e}^x
$$

Verified OK.

10.3.3 Maple step by step solution

Let's solve

$y'' - 3y' + 2y = \frac{4}{1+\mathrm{e}^{-x}}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 3r + 2 = 0$

- Factor the characteristic polynomial

  $(r-1)(r-2) = 0$

- Roots of the characteristic polynomial

  $r = (1, 2)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{2x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

$$y = c_1 e^x + c_2 e^{2x} + y_p(x)$$

☐ Find a particular solution $y_p(x)$ of the ODE

- Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $$\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x)f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x)f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = \frac{4}{1+e^{-x}}\right]$$

- Wronskian of solutions of the homogeneous equation

  $$W(y_1(x), y_2(x)) = \begin{bmatrix} e^x & e^{2x} \\ e^x & 2e^{2x} \end{bmatrix}$$

- Compute Wronskian

  $$W(y_1(x), y_2(x)) = e^{3x}$$

- Substitute functions into equation for $y_p(x)$

  $$y_p(x) = -4e^x\left(\int \frac{e^{-x}}{1+e^{-x}}dx\right) + 4e^{2x}\left(\int \frac{e^{-2x}}{1+e^{-x}}dx\right)$$

- Compute integrals

  $$y_p(x) = -4e^x(\ln(e^x)e^x - \ln(1+e^x)e^x - \ln(1+e^{-x}) + 1)$$

- Substitute particular solution into general solution to ODE

  $$y = c_1 e^x + c_2 e^{2x} - 4e^x(\ln(e^x)e^x - \ln(1+e^x)e^x - \ln(1+e^{-x}) + 1)$$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + 2y = 3\,\mathrm{e}^{x} \sec(x)}$$

10.4.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 2, f(x) = 3\,\mathrm{e}^{x} \sec(x)$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 2$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 2\lambda \,\mathrm{e}^{\lambda x} + 2\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{-2^2 - (4)\,(1)\,(2)}\\ &= 1 \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= 1 + i\\ \lambda_2 &= 1 - i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 + i\\ \lambda_2 &= 1 - i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 1$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$y = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$y = e^{x}(c_1 \cos{(x)} + c_2 \sin{(x)})$$

Therefore the homogeneous solution y_h is

$$y_h = \mathrm{e}^{x}(c_1 \cos{(x)} + c_2 \sin{(x)})$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)\,\mathrm{e}^{x}$$
$$y_2 = \sin(x)\,\mathrm{e}^{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\,\mathrm{e}^{x} & \sin(x)\,\mathrm{e}^{x} \\ \frac{d}{dx}(\cos(x)\,\mathrm{e}^{x}) & \frac{d}{dx}(\sin(x)\,\mathrm{e}^{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\,\mathrm{e}^{x} & \sin(x)\,\mathrm{e}^{x} \\ -\sin(x)\,\mathrm{e}^{x} + \cos(x)\,\mathrm{e}^{x} & \cos(x)\,\mathrm{e}^{x} + \sin(x)\,\mathrm{e}^{x} \end{vmatrix}$$

Therefore

$$W = (\cos(x)\,\mathrm{e}^{x})(\cos(x)\,\mathrm{e}^{x} + \sin(x)\,\mathrm{e}^{x}) - (\sin(x)\,\mathrm{e}^{x})(-\sin(x)\,\mathrm{e}^{x} + \cos(x)\,\mathrm{e}^{x})$$

Which simplifies to

$$W = \mathrm{e}^{2x}\cos(x)^2 + \mathrm{e}^{2x}\sin(x)^2$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{3\sin(x)\,e^{2x}\sec(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int 3\tan(x)\,dx$$

Hence

$$u_1 = 3\ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{3\cos(x)\,e^{2x}\sec(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int 3dx$$

Hence

$$u_2 = 3x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 3\ln(\cos(x))\cos(x)\,e^{x} + 3\,e^{x}\sin(x)\,x$$

Which simplifies to

$$y_p(x) = 3\,e^{x}(\ln(\cos(x))\cos(x) + \sin(x)\,x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^{x}(c_1\cos(x) + c_2\sin(x))) + (3\,e^{x}(\ln(\cos(x))\cos(x) + \sin(x)\,x)) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + 3\,e^{x}(\ln(\cos(x)) \cos(x) + \sin(x)\, x) \tag{1}$$

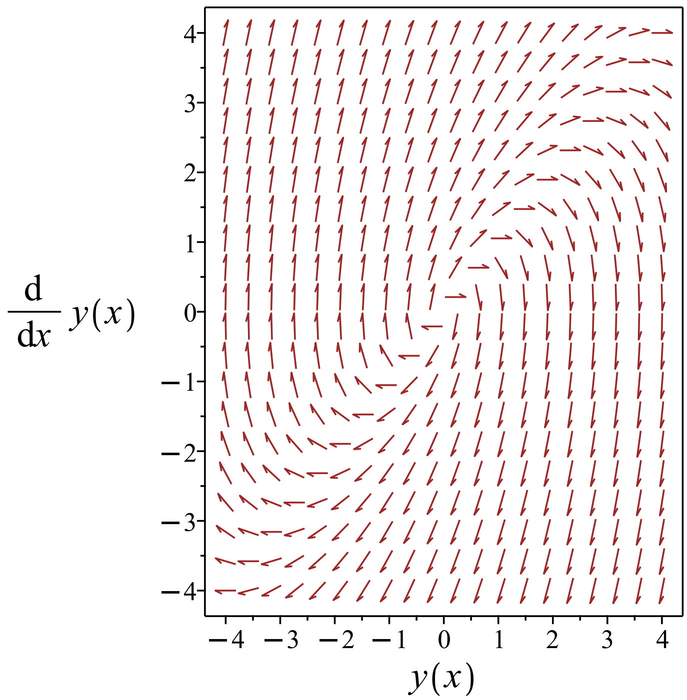

Figure 514: Slope field plot

Verification of solutions

$$y = e^{x}(c_1 \cos(x) + c_2 \sin(x)) + 3\,e^{x}(\ln(\cos(x)) \cos(x) + \sin(x)\, x)$$

Verified OK.

10.4.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 414: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx} \\
&= z_1 e^{x} \\
&= z_1(\mathrm{e}^{x})
\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)\, e^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\, dx \\ &= y_1(\tan(x)) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1(\cos(x)\, e^{x}) + c_2(\cos(x)\, e^{x}(\tan(x))) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = e^{x} \cos(x)\, c_1 + e^{x} \sin(x)\, c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)\,e^x$$
$$y_2 = \sin(x)\,e^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\,e^x & \sin(x)\,e^x \\ \frac{d}{dx}(\cos(x)\,e^x) & \frac{d}{dx}(\sin(x)\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\,e^x & \sin(x)\,e^x \\ -\sin(x)\,e^x + \cos(x)\,e^x & \cos(x)\,e^x + \sin(x)\,e^x \end{vmatrix}$$

Therefore

$$W = (\cos(x)\,e^x)(\cos(x)\,e^x + \sin(x)\,e^x) - (\sin(x)\,e^x)(-\sin(x)\,e^x + \cos(x)\,e^x)$$

Which simplifies to

$$W = e^{2x}\cos(x)^2 + e^{2x}\sin(x)^2$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{3\sin(x)\,e^{2x}\sec(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int 3\tan(x)\,dx$$

Hence

$$u_1 = 3\ln(\cos(x))$$

And Eq. (3) becomes

$$u_2 = \int \frac{3\cos(x)\,e^{2x}\sec(x)}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int 3dx$$

Hence

$$u_2 = 3x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = 3\ln(\cos(x))\cos(x)\,e^x + 3\,e^x\sin(x)\,x$$

Which simplifies to

$$y_p(x) = 3\,e^x(\ln(\cos(x))\cos(x) + \sin(x)\,x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (e^x\cos(x)\,c_1 + e^x\sin(x)\,c_2) + (3\,e^x(\ln(\cos(x))\cos(x) + \sin(x)\,x)) \end{aligned}$$

Which simplifies to

$$y = e^x(c_1\cos(x) + c_2\sin(x)) + 3\,e^x(\ln(\cos(x))\cos(x) + \sin(x)\,x)$$

Summary

The solution(s) found are the following

$$y = e^x(c_1\cos(x) + c_2\sin(x)) + 3\,e^x(\ln(\cos(x))\cos(x) + \sin(x)\,x) \tag{1}$$

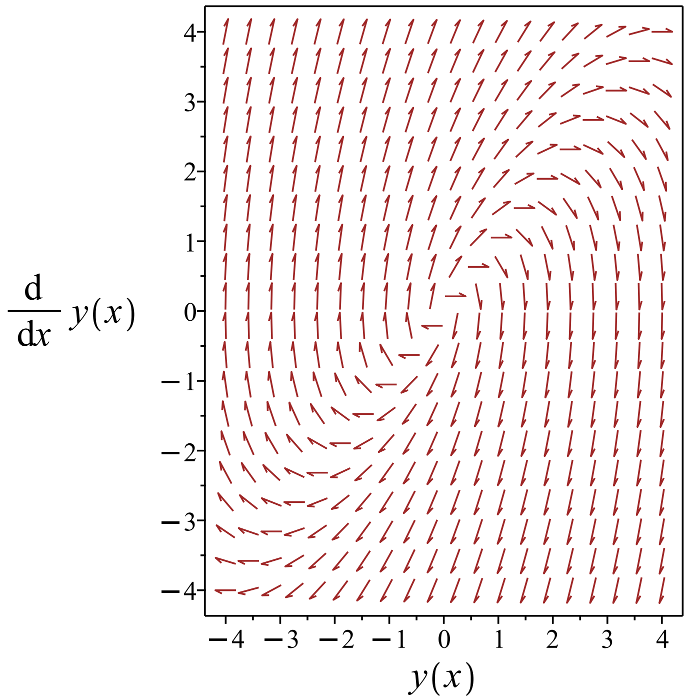

Figure 515: Slope field plot

Verification of solutions

$$y = e^x(c_1\cos(x) + c_2\sin(x)) + 3e^x(\ln(\cos(x))\cos(x) + \sin(x)x)$$

Verified OK.

10.4.3 Maple step by step solution

Let's solve

$y'' - 2y' + 2y = 3e^x\sec(x)$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 2 = 0$

- Use quadratic formula to solve for r

  $r = \frac{2\pm(\sqrt{-4})}{2}$

- Roots of the characteristic polynomial

$r = (1 - \mathrm{I}, 1 + \mathrm{I})$

- 1st solution of the homogeneous ODE

  $y_1(x) = \cos(x)\, \mathrm{e}^x$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \sin(x)\, \mathrm{e}^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = \mathrm{e}^x \cos(x)\, c_1 + \mathrm{e}^x \sin(x)\, c_2 + y_p(x)$

□ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

    $\left[y_p(x) = -y_1(x) \left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x) \left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = 3\, \mathrm{e}^x \sec(x)\right]$

  ◦ Wronskian of solutions of the homogeneous equation

    $$W(y_1(x), y_2(x)) = \begin{bmatrix} \cos(x)\, \mathrm{e}^x & \sin(x)\, \mathrm{e}^x \\ -\sin(x)\, \mathrm{e}^x + \cos(x)\, \mathrm{e}^x & \cos(x)\, \mathrm{e}^x + \sin(x)\, \mathrm{e}^x \end{bmatrix}$$

  ◦ Compute Wronskian

    $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$

  ◦ Substitute functions into equation for $y_p(x)$

    $y_p(x) = -3\, \mathrm{e}^x \left(\cos(x) \left(\int \tan(x)\, dx\right) - \sin(x) \left(\int 1 dx\right)\right)$

  ◦ Compute integrals

    $y_p(x) = 3\, \mathrm{e}^x (\ln(\cos(x)) \cos(x) + \sin(x)\, x)$

- Substitute particular solution into general solution to ODE

  $y = \mathrm{e}^x \cos(x)\, c_1 + \mathrm{e}^x \sin(x)\, c_2 + 3\, \mathrm{e}^x (\ln(\cos(x)) \cos(x) + \sin(x)\, x)$

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - 2y' + y = 14x^{\frac{3}{2}}\mathrm{e}^{x}}$$

10.5.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = -2, C = 1, f(x) = 14x^{\frac{3}{2}}\mathrm{e}^{x}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - 2y' + y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = -2, C = 1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - 2\lambda e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 2\lambda + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = -2, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{2}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{(-2)^2 - (4)(1)(1)}\\ &= 1\end{aligned}$$

Hence this is the case of a double root $\lambda_{1,2} = -1$. Therefore the solution is

$$y = c_1 e^x + c_2 x\, e^x \tag{1}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^x + c_2 x\, e^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= e^x\\ y_2 &= x\, e^x\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{x} & x\,e^{x} \\ \frac{d}{dx}(e^{x}) & \frac{d}{dx}(x\,e^{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{x} & x\,e^{x} \\ e^{x} & x\,e^{x} + e^{x} \end{vmatrix}$$

Therefore

$$W = (e^{x})(x\,e^{x} + e^{x}) - (x\,e^{x})(e^{x})$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{14x^{\frac{5}{2}} e^{2x}}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int 14x^{\frac{5}{2}}\,dx$$

Hence

$$u_1 = -4x^{\frac{7}{2}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{14\,\mathrm{e}^{2x} x^{\frac{3}{2}}}{\mathrm{e}^{2x}}\, dx$$

Which simplifies to

$$u_2 = \int 14 x^{\frac{3}{2}} dx$$

Hence

$$u_2 = \frac{28 x^{\frac{5}{2}}}{5}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{8 x^{\frac{7}{2}} \mathrm{e}^{x}}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \mathrm{e}^{x} + c_2 x\, \mathrm{e}^{x}) + \left(\frac{8 x^{\frac{7}{2}} \mathrm{e}^{x}}{5}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{x} (c_2 x + c_1) + \frac{8 x^{\frac{7}{2}} \mathrm{e}^{x}}{5}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x} (c_2 x + c_1) + \frac{8 x^{\frac{7}{2}} \mathrm{e}^{x}}{5} \tag{1}$$

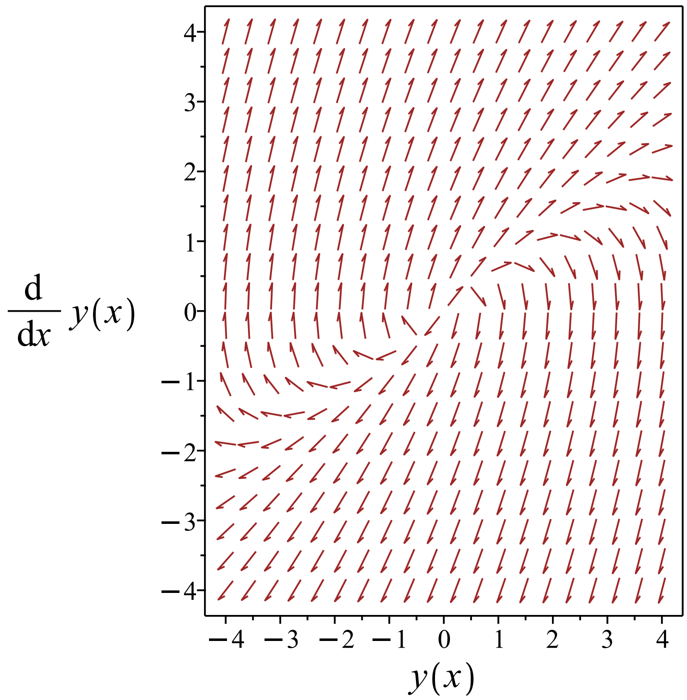

Figure 516: Slope field plot

Verification of solutions

$$y = e^{x}(c_2 x + c_1) + \frac{8x^{\frac{7}{2}} e^{x}}{5}$$

Verified OK.

10.5.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = -2$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -2\,dx} \\ &= e^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= 14\,\mathrm{e}^{-x} x^{\frac{3}{2}} \mathrm{e}^{x} \\
\left(\mathrm{e}^{-x} y\right)'' &= 14\,\mathrm{e}^{-x} x^{\frac{3}{2}} \mathrm{e}^{x}
\end{aligned}
$$

Integrating once gives

$$
\left(\mathrm{e}^{-x} y\right)' = \frac{28x^{\frac{5}{2}}}{5} + c_1
$$

Integrating again gives

$$
\left(\mathrm{e}^{-x} y\right) = c_1 x + \frac{8x^{\frac{7}{2}}}{5} + c_2
$$

Hence the solution is

$$
y = \frac{c_1 x + \frac{8x^{\frac{7}{2}}}{5} + c_2}{\mathrm{e}^{-x}}
$$

Or

$$
y = \frac{8x^{\frac{7}{2}} \mathrm{e}^{x}}{5} + c_1 x\,\mathrm{e}^{x} + c_2 \mathrm{e}^{x}
$$

Summary

The solution(s) found are the following

$$
y = \frac{8x^{\frac{7}{2}} \mathrm{e}^{x}}{5} + c_1 x\,\mathrm{e}^{x} + c_2 \mathrm{e}^{x} \tag{1}
$$

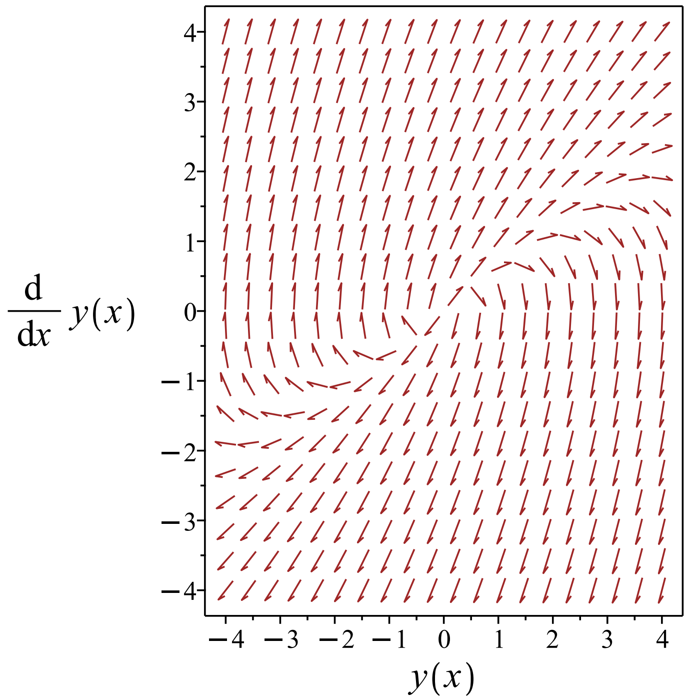

Figure 517: Slope field plot

Verification of solutions

$$y = \frac{8x^{\frac{7}{2}} e^{x}}{5} + c_1 x \,e^{x} + c_2 e^{x}$$

Verified OK.

10.5.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' - 2y' + y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= -2 \\ C &= 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 416: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 0 - -\infty\\ &= \infty\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-2}{1}\,dx}\\ &= z_1 e^{x}\\ &= z_1(\mathrm{e}^{x})\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1}\,dx}}{(y_1)^2}\,dx\\ &= y_1 \int \frac{e^{2x}}{(y_1)^2}\,dx\\ &= y_1(x)\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2(\mathrm{e}^x(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' - 2y' + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^x + c_2 x \,\mathrm{e}^x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^x \\
y_2 &= x \,\mathrm{e}^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & x\,e^x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(x\,e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & x\,e^x \\ e^x & x\,e^x + e^x \end{vmatrix}$$

Therefore

$$W = (e^x)(x\,e^x + e^x) - (x\,e^x)(e^x)$$

Which simplifies to

$$W = e^{2x}$$

Which simplifies to

$$W = e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{14x^{\frac{5}{2}}\,e^{2x}}{e^{2x}}\,dx$$

Which simplifies to

$$u_1 = -\int 14x^{\frac{5}{2}}\,dx$$

Hence

$$u_1 = -4x^{\frac{7}{2}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{14\,e^{2x}x^{\frac{3}{2}}}{e^{2x}}\,dx$$

Which simplifies to

$$u_2 = \int 14x^{\frac{3}{2}}\,dx$$

Hence

$$u_2 = \frac{28x^{\frac{5}{2}}}{5}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{8x^{\frac{7}{2}} \mathrm{e}^{x}}{5}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 \mathrm{e}^{x} + c_2 x \, \mathrm{e}^{x}) + \left(\frac{8x^{\frac{7}{2}} \mathrm{e}^{x}}{5}\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^{x}(c_2 x + c_1) + \frac{8x^{\frac{7}{2}} \mathrm{e}^{x}}{5}$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{x}(c_2 x + c_1) + \frac{8x^{\frac{7}{2}} \mathrm{e}^{x}}{5} \tag{1}$$

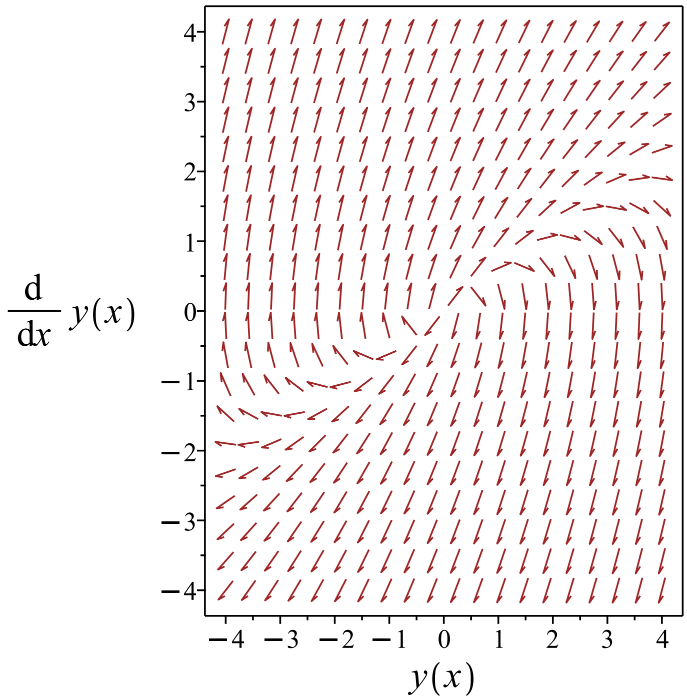

Figure 518: Slope field plot

Verification of solutions

$$y = e^{x}(c_2x + c_1) + \frac{8x^{\frac{7}{2}}e^{x}}{5}$$

Verified OK.

10.5.4 Maple step by step solution

Let's solve

$y'' - 2y' + y = 14x^{\frac{3}{2}}e^{x}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

  $r^2 - 2r + 1 = 0$

- Factor the characteristic polynomial

  $(r-1)^2 = 0$

- Root of the characteristic polynomial

$r = 1$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^x$

- Repeated root, multiply $y_1(x)$ by x to ensure linear independence

  $y_2(x) = x\,\mathrm{e}^x$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^x + c_2 x\,\mathrm{e}^x + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x),y_2(x))}dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x),y_2(x))}dx\right), f(x) = 14x^{\frac{3}{2}}\mathrm{e}^x\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^x & x\,\mathrm{e}^x \\ \mathrm{e}^x & x\,\mathrm{e}^x + \mathrm{e}^x \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = \mathrm{e}^{2x}$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = -14\,\mathrm{e}^x\left(-\left(\int x^{\frac{3}{2}}dx\right)x + \int x^{\frac{5}{2}}dx\right)$

  ◦ Compute integrals

  $y_p(x) = \frac{8x^{\frac{7}{2}}\mathrm{e}^x}{5}$

- Substitute particular solution into general solution to ODE

  $y = c_2 x\,\mathrm{e}^x + c_1 \mathrm{e}^x + \frac{8x^{\frac{7}{2}}\mathrm{e}^x}{5}$

Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y'' - y = \frac{4\,\mathrm{e}^{-x}}{1 - \mathrm{e}^{-2x}}}$$

10.6.1 Solving as second order linear constant coeff ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 1, B = 0, C = -1, f(x) = -\frac{4\,\mathrm{e}^{-x}}{-1+\mathrm{e}^{-2x}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$y = c_1 e^{x} + c_2 e^{-x}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{x} + c_2 e^{-x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^x$$
$$y_2 = e^{-x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & e^{-x} \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(e^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & e^{-x} \\ e^x & -e^{-x} \end{vmatrix}$$

Therefore

$$W = (e^x)\left(-e^{-x}\right) - \left(e^{-x}\right)(e^x)$$

Which simplifies to

$$W = -2\,e^{-x} e^x$$

Which simplifies to

$$W = -2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{4\,e^{-2x}}{-1+e^{-2x}}}{-2}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{2\,e^{-2x}}{-1+e^{-2x}}dx$$

Hence

$$u_1 = \ln\left(-1+e^{-2x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{-\frac{4\,e^{x}e^{-x}}{-1+e^{-2x}}}{-2}\,dx$$

Which simplifies to

$$u_2 = \int \frac{2}{-1+e^{-2x}}dx$$

Hence

$$u_2 = \ln\left(e^{-2x}\right) - \ln\left(-1+e^{-2x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln\left(-1+e^{-2x}\right)e^{x} + \left(\ln\left(e^{-2x}\right) - \ln\left(-1+e^{-2x}\right)\right)e^{-x}$$

Which simplifies to

$$y_p(x) = \left(e^{x}-e^{-x}\right)\ln\left(-1+e^{-2x}\right) + e^{-x}\ln\left(e^{-2x}\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{x} + c_2 e^{-x}\right) + \left(\left(e^{x}-e^{-x}\right)\ln\left(-1+e^{-2x}\right) + e^{-x}\ln\left(e^{-2x}\right)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^x + c_2 e^{-x} + \left(e^x - e^{-x}\right) \ln\left(-1 + e^{-2x}\right) + e^{-x} \ln\left(e^{-2x}\right) \tag{1}$$

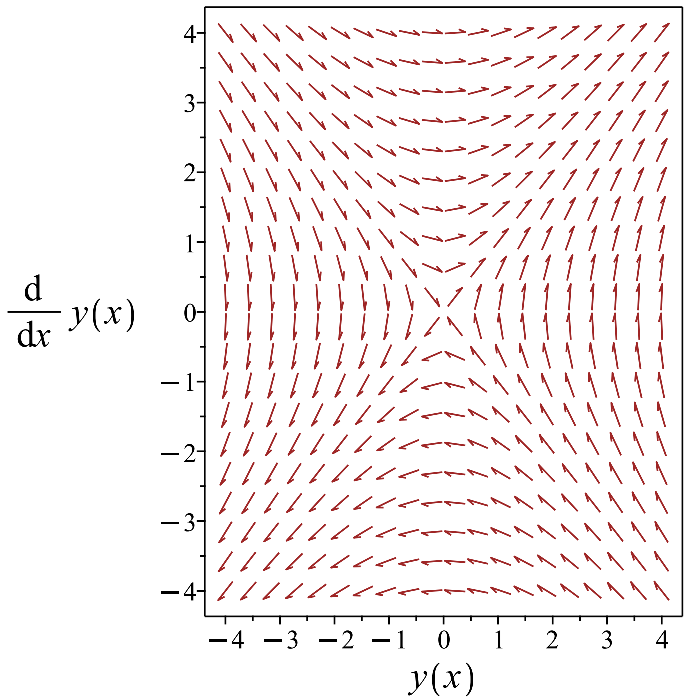

Figure 519: Slope field plot

Verification of solutions

$$y = c_1 e^x + c_2 e^{-x} + \left(e^x - e^{-x}\right) \ln\left(-1 + e^{-2x}\right) + e^{-x} \ln\left(e^{-2x}\right)$$

Verified OK.

10.6.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 418: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{-x}
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{\mathrm{e}^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{-x} \int \frac{1}{\mathrm{e}^{-2x}}\, dx \\ &= \mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' - y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x} + \frac{c_2 \mathrm{e}^{x}}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = \frac{\mathrm{e}^{x}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \frac{\mathrm{e}^{x}}{2} \\ \frac{d}{dx}(\mathrm{e}^{-x}) & \frac{d}{dx}\left(\frac{\mathrm{e}^{x}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & \frac{\mathrm{e}^{x}}{2} \\ -\mathrm{e}^{-x} & \frac{\mathrm{e}^{x}}{2} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x}\right)\left(\frac{\mathrm{e}^{x}}{2}\right) - \left(\frac{\mathrm{e}^{x}}{2}\right)\left(-\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-x}\mathrm{e}^{x}$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{2\,e^{x} e^{-x}}{-1+e^{-2x}}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{2}{-1+e^{-2x}}dx$$

Hence

$$u_1 = \ln\left(e^{-2x}\right) - \ln\left(-1+e^{-2x}\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{-\frac{4\,e^{-2x}}{-1+e^{-2x}}}{1}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{4\,e^{-2x}}{-1+e^{-2x}}dx$$

Hence

$$u_2 = 2\ln\left(-1+e^{-2x}\right)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \ln\left(-1+e^{-2x}\right)e^{x} + \left(\ln\left(e^{-2x}\right) - \ln\left(-1+e^{-2x}\right)\right)e^{-x}$$

Which simplifies to

$$y_p(x) = \left(e^{x} - e^{-x}\right)\ln\left(-1+e^{-2x}\right) + e^{-x}\ln\left(e^{-2x}\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x} + \frac{c_2 e^{x}}{2}\right) + \left(\left(e^{x} - e^{-x}\right)\ln\left(-1+e^{-2x}\right) + e^{-x}\ln\left(e^{-2x}\right)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} + \left(e^{x} - e^{-x}\right) \ln \left(-1 + e^{-2x}\right) + e^{-x} \ln \left(e^{-2x}\right) \tag{1}$$

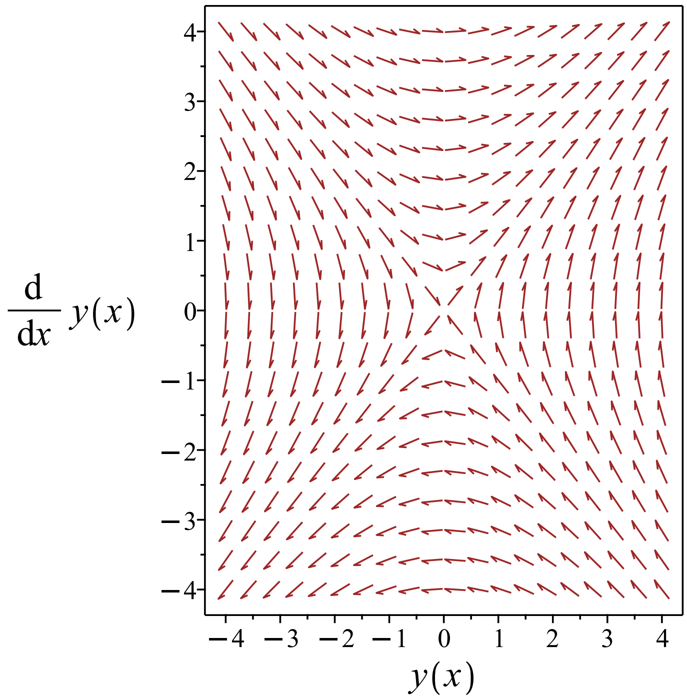

Figure 520: Slope field plot

Verification of solutions

$$y = c_1 e^{-x} + \frac{c_2 e^{x}}{2} + \left(e^{x} - e^{-x}\right) \ln \left(-1 + e^{-2x}\right) + e^{-x} \ln \left(e^{-2x}\right)$$

Verified OK.

10.6.3 Maple step by step solution

Let's solve

$y'' - y = -\frac{4 e^{-x}}{-1+e^{-2x}}$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of homogeneous ODE

$r^2 - 1 = 0$

- Factor the characteristic polynomial

  $(r-1)(r+1) = 0$

- Roots of the characteristic polynomial

  $r = (-1, 1)$

- 1st solution of the homogeneous ODE

  $y_1(x) = \mathrm{e}^{-x}$

- 2nd solution of the homogeneous ODE

  $y_2(x) = \mathrm{e}^{x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x) + y_p(x)$

- Substitute in solutions of the homogeneous ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + y_p(x)$

☐ Find a particular solution $y_p(x)$ of the ODE

  ◦ Use variation of parameters to find y_p here $f(x)$ is the forcing function

  $\left[y_p(x) = -y_1(x)\left(\int \frac{y_2(x) f(x)}{W(y_1(x), y_2(x))} dx\right) + y_2(x)\left(\int \frac{y_1(x) f(x)}{W(y_1(x), y_2(x))} dx\right), f(x) = -\frac{4\,\mathrm{e}^{-x}}{-1+\mathrm{e}^{-2x}}\right]$

  ◦ Wronskian of solutions of the homogeneous equation

  $W(y_1(x), y_2(x)) = \begin{bmatrix} \mathrm{e}^{-x} & \mathrm{e}^{x} \\ -\mathrm{e}^{-x} & \mathrm{e}^{x} \end{bmatrix}$

  ◦ Compute Wronskian

  $W(y_1(x), y_2(x)) = 2$

  ◦ Substitute functions into equation for $y_p(x)$

  $y_p(x) = 2\,\mathrm{e}^{-x}\left(\int \frac{1}{-1+\mathrm{e}^{-2x}} dx\right) - 2\,\mathrm{e}^{x}\left(\int \frac{\mathrm{e}^{-2x}}{-1+\mathrm{e}^{-2x}} dx\right)$

  ◦ Compute integrals

  $y_p(x) = (\mathrm{e}^{x} - \mathrm{e}^{-x}) \ln(-1 + \mathrm{e}^{-2x}) + \mathrm{e}^{-x} \ln(\mathrm{e}^{-2x})$

- Substitute particular solution into general solution to ODE

  $y = c_1 \mathrm{e}^{-x} + c_2 \mathrm{e}^{x} + (\mathrm{e}^{x} - \mathrm{e}^{-x}) \ln(-1 + \mathrm{e}^{-2x}) + \mathrm{e}^{-x} \ln(\mathrm{e}^{-2x})$

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' + y'x - y = 2x^2 + 2}$$

10.7.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = 2x^2 + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x - y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + xrx^{r-1} - x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + r\,x^r - x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + r - 1 = 0$$

Or

$$r^2 - 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 1$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2x$$

Next, we find the particular solution to the ODE

$$x^2y'' + y'x - y = 2x^2 + 2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x \\ -\frac{1}{x^2} & 1 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(1) - (x)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{2}{x}$$

Which simplifies to

$$W = \frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x(2x^2+2)}{2x}\,dx$$

Which simplifies to

$$u_1 = -\int \left(x^2+1\right) dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2x^2+2}{x}}{2x}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x^2+1}{x^2}dx$$

Hence

$$u_2 = x - \frac{1}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - x}{x} + \left(x - \frac{1}{x}\right)x$$

Which simplifies to

$$y_p(x) = \frac{2x^2}{3} - 2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \frac{2x^2}{3} - 2 + \frac{c_1}{x} + c_2 x
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{2x^2}{3} - 2 + \frac{c_1}{x} + c_2 x \tag{1}
$$

Verification of solutions

$$
y = \frac{2x^2}{3} - 2 + \frac{c_1}{x} + c_2 x
$$

Verified OK.

10.7.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + y'x - y = 0
$$

In normal form the ode

$$
x^2y'' + y'x - y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{1}{x} \\
q(x) &= -\frac{1}{x^2}
\end{aligned}
$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'\left(x\right)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'\left(x\right)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{1}{x}dx\right)}dx \\ &= \int e^{-\ln(x)}\,dx \\ &= \int \frac{1}{x}dx \\ &= \ln\left(x\right)\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'\left(x\right)^2} \\ &= \frac{-\frac{1}{x^2}}{\frac{1}{x^2}} \\ &= -1\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) - y(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} - e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-1)}\\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1\\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1\\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1\tau} + c_2 e^{\lambda_2\tau}\\ y(\tau) &= c_1 e^{(1)\tau} + c_2 e^{(-1)\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\tau} + c_2 e^{-\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 x^2 + c_2}{x}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 x^2 + c_2}{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = \frac{1}{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2x^2+2}{x}}{-2x}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{-x^2-1}{x^2} dx$$

Hence

$$u_1 = x - \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(2x^2+2)}{-2x}\, dx$$

Which simplifies to

$$u_2 = \int \left(-x^2 - 1\right) dx$$

Hence

$$u_2 = -\frac{1}{3}x^3 - x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - x}{x} + \left(x - \frac{1}{x}\right)x$$

Which simplifies to

$$y_p(x) = \frac{2x^2}{3} - 2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1x^2 + c_2}{x}\right) + \left(\frac{2x^2}{3} - 2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1x^2 + c_2}{x} + \frac{2x^2}{3} - 2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1x^2 + c_2}{x} + \frac{2x^2}{3} - 2$$

Verified OK.

10.7.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = 2x^2 + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x - y = 0$$

In normal form the ode

$$x^2y'' + y'x - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{1}{x}\\
q(x) &= -\frac{1}{x^2}
\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q}\\
&= \frac{\sqrt{-\frac{1}{x^2}}}{c} \\
\tau'' &= \frac{1}{c\sqrt{-\frac{1}{x^2}}\, x^3}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2}\\
&= \frac{\frac{1}{c\sqrt{-\frac{1}{x^2}}\, x^3} + \frac{1}{x}\frac{\sqrt{-\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{-\frac{1}{x^2}}}{c}\right)^2}\\
&= 0
\end{aligned}$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c} \sqrt{q}\, dx \\
&= \frac{\int \sqrt{-\frac{1}{x^2}} dx}{c} \\
&= \frac{\sqrt{-\frac{1}{x^2}}\, x \ln(x)}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = \frac{(ic_2 + c_1) x^2 - ic_2 + c_1}{2x}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + y' x - y = 2x^2 + 2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= \frac{1}{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2x^2+2}{x}}{-2x} dx$$

Which simplifies to

$$u_1 = -\int \frac{-x^2 - 1}{x^2} dx$$

Hence

$$u_1 = x - \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(2x^2+2)}{-2x}\,dx$$

Which simplifies to

$$u_2 = \int (-x^2 - 1)\,dx$$

Hence

$$u_2 = -\frac{1}{3}x^3 - x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - x}{x} + \left(x - \frac{1}{x}\right)x$$

Which simplifies to

$$y_p(x) = \frac{2x^2}{3} - 2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{(ic_2 + c_1)\,x^2 - ic_2 + c_1}{2x}\right) + \left(\frac{2x^2}{3} - 2\right) \\ &= \frac{2x^2}{3} - 2 + \frac{(ic_2 + c_1)\,x^2 - ic_2 + c_1}{2x} \end{aligned}$$

Which simplifies to

$$y = \frac{3c_2x^2i + 3c_1x^2 + 4x^3 - 3ic_2 + 3c_1 - 12x}{6x}$$

Summary
The solution(s) found are the following

$$y = \frac{3c_2x^2i + 3c_1x^2 + 4x^3 - 3ic_2 + 3c_1 - 12x}{6x} \tag{1}$$

Verification of solutions

$$y = \frac{3c_2x^2i + 3c_1x^2 + 4x^3 - 3ic_2 + 3c_1 - 12x}{6x}$$

Verified OK.

10.7.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = x, C = -1, f(x) = 2x^2 + 2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + y'x - y = 0$$

In normal form the ode

$$x^2y'' + y'x - y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{1}{x}$$
$$q(x) = -\frac{1}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n}{x^2}-\frac{1}{x^2}=0 \tag{5}$$

Solving (5) for n gives

$$n=1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x)+\frac{3v'(x)}{x}=0$$

$$v''(x)+\frac{3v'(x)}{x}=0 \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\frac{3u(x)}{x}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x)=-\frac{3}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{3}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{3}{x}\,dx \\ \ln(u) &= -3\ln(x)+c_1 \\ u &= \mathrm{e}^{-3\ln(x)+c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1}{2x^2} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + y'x - y = 2x^2 + 2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x \\ y_2 &= \frac{1}{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2x^2+2}{x}}{-2x}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{-x^2-1}{x^2}dx$$

Hence

$$u_1 = x - \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(2x^2+2)}{-2x}\,dx$$

Which simplifies to

$$u_2 = \int \left(-x^2 - 1\right) dx$$

Hence

$$u_2 = -\frac{1}{3}x^3 - x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - x}{x} + \left(x - \frac{1}{x}\right) x$$

Which simplifies to

$$y_p(x) = \frac{2x^2}{3} - 2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{2x^2} + c_2\right) x\right) + \left(\frac{2x^2}{3} - 2\right) \\ &= \frac{2x^2}{3} - 2 + \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

Which simplifies to

$$y = -\frac{-6c_2x^2 - 4x^3 + 3c_1 + 12x}{6x}$$

Summary

The solution(s) found are the following

$$y = -\frac{-6c_2x^2 - 4x^3 + 3c_1 + 12x}{6x} \tag{1}$$

Verification of solutions

$$y = -\frac{-6c_2x^2 - 4x^3 + 3c_1 + 12x}{6x}$$

Verified OK.

10.7.5 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' + y'x - y)\,dx = \int (2x^2 + 2)\,dx$$
$$y'x^2 - yx = \frac{2}{3}x^3 + 2x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$
$$q(x) = \frac{2x^3 + 3c_1 + 6x}{3x^2}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{2x^3 + 3c_1 + 6x}{3x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$
$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2x^3 + 3c_1 + 6x}{3x^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x}\right) = \left(\frac{1}{x}\right)\left(\frac{2x^3 + 3c_1 + 6x}{3x^2}\right)$$
$$d\left(\frac{y}{x}\right) = \left(\frac{2x^3 + 3c_1 + 6x}{3x^3}\right)\,dx$$

Integrating gives

$$\frac{y}{x} = \int \frac{2x^3 + 3c_1 + 6x}{3x^3}\,dx$$
$$\frac{y}{x} = \frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x$$

Summary

The solution(s) found are the following

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x \tag{1}$$

Verification of solutions

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x$$

Verified OK.

10.7.6 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right)u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -1 \\ F &= 2x^2 + 2 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= \left(x^2\right)(0) + (x)(1) + (-1)(x) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$x^3 v'' + \left(3x^2\right) v' = 0$$

Now by applying $v' = u$ the above becomes

$$x^2 (u'(x)\, x + 3u(x)) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{3}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{3}{x}\, dx \\ \ln(u) &= -3\ln(x) + c_1 \\ u &= \mathrm{e}^{-3\ln(x) + c_1} \\ &= \frac{c_1}{x^3} \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= \frac{c_1}{x^3} \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int \frac{c_1}{x^3}\,\mathrm{d}x \\ &= -\frac{c_1}{2x^2} + c_2 \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= Bv \\ &= (x)\left(-\frac{c_1}{2x^2} + c_2\right) \\ &= \left(-\frac{c_1}{2x^2} + c_2\right) x \end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x \\ y_2 &= \frac{1}{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x} \\ 1 & -\frac{1}{x^2} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{1}{x^2}\right) - \left(\frac{1}{x}\right)(1)$$

Which simplifies to

$$W = -\frac{2}{x}$$

Which simplifies to

$$W = -\frac{2}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2x^2+2}{x}}{-2x}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{-x^2-1}{x^2} dx$$

Hence

$$u_1 = x - \frac{1}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x(2x^2+2)}{-2x}\, dx$$

Which simplifies to

$$u_2 = \int \left(-x^2 - 1\right) dx$$

Hence

$$u_2 = -\frac{1}{3}x^3 - x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - x}{x} + \left(x - \frac{1}{x}\right) x$$

Which simplifies to

$$y_p(x) = \frac{2x^2}{3} - 2$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{2x^2} + c_2\right) x\right) + \left(\frac{2x^2}{3} - 2\right) \\ &= \frac{6c_2x^2 + 4x^3 - 3c_1 - 12x}{6x} \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{6c_2x^2 + 4x^3 - 3c_1 - 12x}{6x} \tag{1}$$

Verification of solutions

$$y = \frac{6c_2x^2 + 4x^3 - 3c_1 - 12x}{6x}$$

Verified OK.

10.7.7 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' + y'x - y = 2x^2 + 2$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' + y'x - y)\, dx = \int (2x^2 + 2)\, dx$$

$$y'x^2 - yx = \frac{2}{3}x^3 + 2x + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1}{x}$$

$$q(x) = \frac{2x^3 + 3c_1 + 6x}{3x^2}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{2x^3 + 3c_1 + 6x}{3x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1}{x}dx}$$

$$= \frac{1}{x}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2x^3 + 3c_1 + 6x}{3x^2}\right)$$

$$\frac{d}{dx}\left(\frac{y}{x}\right) = \left(\frac{1}{x}\right)\left(\frac{2x^3 + 3c_1 + 6x}{3x^2}\right)$$

$$d\left(\frac{y}{x}\right) = \left(\frac{2x^3 + 3c_1 + 6x}{3x^3}\right) dx$$

Integrating gives

$$\frac{y}{x} = \int \frac{2x^3 + 3c_1 + 6x}{3x^3} \, dx$$
$$\frac{y}{x} = \frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x$$

Summary

The solution(s) found are the following

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x \tag{1}$$

Verification of solutions

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x$$

Verified OK.

10.7.8 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + y'x - y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= x \\ C &= -1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 3$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 420: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{gathered}(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) = 0\\ 0 = 0\end{gathered}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega \, dx}\\ &= e^{\int -\frac{1}{2x} dx}\\ &= \frac{1}{\sqrt{x}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2} \, dx}\\ &= z_1 e^{-\frac{\ln(x)}{2}}\\ &= z_1 \left(\frac{1}{\sqrt{x}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^2}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + y'x - y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1}{x} + \frac{c_2 x}{2}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$

$$y_2 = \frac{x}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x}{2} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x}{2} \\ -\frac{1}{x^2} & \frac{1}{2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{1}{2}\right) - \left(\frac{x}{2}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = \frac{1}{x}$$

Which simplifies to

$$W = \frac{1}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x(2x^2+2)}{2}}{x}\, dx$$

Which simplifies to

$$u_1 = -\int (x^2+1)\, dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2x^2+2}{x}}{x}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2x^2+2}{x^2} dx$$

Hence

$$u_2 = 2x - \frac{2}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - x}{x} + \frac{\left(2x - \frac{2}{x}\right)x}{2}$$

Which simplifies to

$$y_p(x) = \frac{2x^2}{3} - 2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x}{2}\right) + \left(\frac{2x^2}{3} - 2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x}{2} + \frac{2x^2}{3} - 2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x}{2} + \frac{2x^2}{3} - 2$$

Verified OK.

10.7.9 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 \\ q(x) &= x \\ r(x) &= -1 \\ s(x) &= 2x^2 + 2 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 2 \\ q'(x) &= 1 \end{aligned}$$

Therefore (1) becomes

$$2 - (1) + (-1) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + (q(x) - p'(x))\, y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y'x^2 - yx = \int 2x^2 + 2\,dx$$

We now have a first order ode to solve which is

$$y'x^2 - yx = \frac{2}{3}x^3 + 2x + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= \frac{2x^3 + 3c_1 + 6x}{3x^2} \end{aligned}$$

Hence the ode is

$$y' - \frac{y}{x} = \frac{2x^3 + 3c_1 + 6x}{3x^2}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{1}{x}dx} \\ &= \frac{1}{x} \end{aligned}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{2x^3 + 3c_1 + 6x}{3x^2}\right) \\ \frac{d}{dx}\left(\frac{y}{x}\right) &= \left(\frac{1}{x}\right)\left(\frac{2x^3 + 3c_1 + 6x}{3x^2}\right) \\ d\left(\frac{y}{x}\right) &= \left(\frac{2x^3 + 3c_1 + 6x}{3x^3}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} \frac{y}{x} &= \int \frac{2x^3 + 3c_1 + 6x}{3x^3}\,dx \\ \frac{y}{x} &= \frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2} + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x}$ results in

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x$$

Summary

The solution(s) found are the following

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x \tag{1}$$

Verification of solutions

$$y = x\left(\frac{2x}{3} - \frac{2}{x} - \frac{c_1}{2x^2}\right) + c_2 x$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{4x^2y'' + \left(-8x^2 + 4x\right) y' + \left(4x^2 - 4x - 1\right) y = 4\sqrt{x}\,\mathrm{e}^x}$$

10.9.1 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\, y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = \frac{1-2x}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int \frac{1-2x}{x}\,dx} \\ &= \sqrt{x}\,\mathrm{e}^{-x} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= \frac{e^{-x}e^{x}}{x} \\
\left(\sqrt{x}\,e^{-x}y\right)'' &= \frac{e^{-x}e^{x}}{x}
\end{aligned}
$$

Integrating once gives

$$
\left(\sqrt{x}\,e^{-x}y\right)' = \ln(x) + c_1
$$

Integrating again gives

$$
\left(\sqrt{x}\,e^{-x}y\right) = x(\ln(x) + c_1 - 1) + c_2
$$

Hence the solution is

$$
y = \frac{x(\ln(x) + c_1 - 1) + c_2}{\sqrt{x}\,e^{-x}}
$$

Or

$$
y = c_1\sqrt{x}\,e^{x} + \sqrt{x}\,e^{x}\ln(x) + \frac{c_2 e^{x}}{\sqrt{x}} - \sqrt{x}\,e^{x}
$$

Summary

The solution(s) found are the following

$$
y = c_1\sqrt{x}\,e^{x} + \sqrt{x}\,e^{x}\ln(x) + \frac{c_2 e^{x}}{\sqrt{x}} - \sqrt{x}\,e^{x} \tag{1}
$$

Verification of solutions

$$
y = c_1\sqrt{x}\,e^{x} + \sqrt{x}\,e^{x}\ln(x) + \frac{c_2 e^{x}}{\sqrt{x}} - \sqrt{x}\,e^{x}
$$

Verified OK.

10.9.2 Solving using Kovacic algorithm

Writing the ode as

$$4x^2y'' + (-8x^2 + 4x)\,y' + (4x^2 - 4x - 1)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -8x^2 + 4x \\ C &= 4x^2 - 4x - 1 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 421: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2} \frac{-8x^2+4x}{4x^2}\, dx} \\
&= z_1 e^{x-\frac{\ln(x)}{2}} \\
&= z_1 \left(\frac{\mathrm{e}^x}{\sqrt{x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\mathrm{e}^x}{\sqrt{x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-8x^2+4x}{4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2x-\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\mathrm{e}^x}{\sqrt{x}}\right) + c_2 \left(\frac{\mathrm{e}^x}{\sqrt{x}}(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
4x^2y'' + \left(-8x^2 + 4x\right) y' + \left(4x^2 - 4x - 1\right) y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1 e^x}{\sqrt{x}} + c_2 \sqrt{x}\, e^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{e^x}{\sqrt{x}}$$

$$y_2 = \sqrt{x}\, e^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{e^x}{\sqrt{x}} & \sqrt{x}\, e^x \\ \frac{d}{dx}\left(\frac{e^x}{\sqrt{x}}\right) & \frac{d}{dx}\left(\sqrt{x}\, e^x\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{e^x}{\sqrt{x}} & \sqrt{x}\, e^x \\ -\frac{e^x}{2x^{\frac{3}{2}}} + \frac{e^x}{\sqrt{x}} & \frac{e^x}{2\sqrt{x}} + \sqrt{x}\, e^x \end{vmatrix}$$

Therefore

$$W = \left(\frac{e^{x}}{\sqrt{x}}\right)\left(\frac{e^{x}}{2\sqrt{x}} + \sqrt{x}\, e^{x}\right) - \left(\sqrt{x}\, e^{x}\right)\left(-\frac{e^{x}}{2x^{\frac{3}{2}}} + \frac{e^{x}}{\sqrt{x}}\right)$$

Which simplifies to

$$W = \frac{e^{2x}}{x}$$

Which simplifies to

$$W = \frac{e^{2x}}{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4x\, e^{2x}}{4x\, e^{2x}}\, dx$$

Which simplifies to

$$u_1 = -\int 1 dx$$

Hence

$$u_1 = -x$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\, e^{2x}}{4x\, e^{2x}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x} dx$$

Hence

$$u_2 = \ln (x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \sqrt{x}\, e^{x} \ln (x) - \sqrt{x}\, e^{x}$$

Which simplifies to

$$y_p(x) = \sqrt{x}\, e^{x} (\ln(x) - 1)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 e^{x}}{\sqrt{x}} + c_2 \sqrt{x}\, e^{x}\right) + \left(\sqrt{x}\, e^{x} (\ln(x) - 1)\right) \end{aligned}$$

Which simplifies to

$$y = \frac{e^{x} (c_2 x + c_1)}{\sqrt{x}} + \sqrt{x}\, e^{x} (\ln(x) - 1)$$

Summary

The solution(s) found are the following

$$y = \frac{e^{x} (c_2 x + c_1)}{\sqrt{x}} + \sqrt{x}\, e^{x} (\ln(x) - 1) \tag{1}$$

Verification of solutions

$$y = \frac{e^{x} (c_2 x + c_1)}{\sqrt{x}} + \sqrt{x}\, e^{x} (\ln(x) - 1)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{y''+4y'x+\left(4x^2+2\right)y=4\,\mathrm{e}^{-x(2+x)}}$$

10.10.1 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y''+p(x)\,y'+\frac{\left(p(x)^2+p'(x)\right)y}{2}=f(x)$$

Where $p(x)=4x$. Therefore, there is an integrating factor given by

$$\begin{aligned}M(x)&=e^{\frac{1}{2}\int p\,dx}\\&=e^{\int 4x\,dx}\\&=\mathrm{e}^{x^2}\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= 4\,\mathrm{e}^{x^2}\mathrm{e}^{-x(2+x)} \\
\left(\mathrm{e}^{x^2}y\right)'' &= 4\,\mathrm{e}^{x^2}\mathrm{e}^{-x(2+x)}
\end{aligned}
$$

Integrating once gives

$$
\left(\mathrm{e}^{x^2}y\right)' = -2\,\mathrm{e}^{-2x} + c_1
$$

Integrating again gives

$$
\left(\mathrm{e}^{x^2}y\right) = c_1x + \mathrm{e}^{-2x} + c_2
$$

Hence the solution is

$$
y = \frac{c_1x + \mathrm{e}^{-2x} + c_2}{\mathrm{e}^{x^2}}
$$

Or

$$
y = c_1x\,\mathrm{e}^{-x^2} + c_2\mathrm{e}^{-x^2} + \mathrm{e}^{-x^2}\mathrm{e}^{-2x}
$$

Summary

The solution(s) found are the following

$$
y = c_1x\,\mathrm{e}^{-x^2} + c_2\mathrm{e}^{-x^2} + \mathrm{e}^{-x^2}\mathrm{e}^{-2x} \tag{1}
$$

Verification of solutions

$$
y = c_1x\,\mathrm{e}^{-x^2} + c_2\mathrm{e}^{-x^2} + \mathrm{e}^{-x^2}\mathrm{e}^{-2x}
$$

Verified OK.

10.10.2 Solving using Kovacic algorithm

Writing the ode as

$$
y'' + 4y'x + \left(4x^2+2\right)y = 0 \tag{1}
$$
$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 1 \\
B &= 4x \\
C &= 4x^2+2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 422: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{4x}{1}\,dx} \\ &= z_1 e^{-x^2} \\ &= z_1\left(\mathrm{e}^{-x^2}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-2x^2}}{(y_1)^2}\, dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-x^2}\right) + c_2\left(\mathrm{e}^{-x^2}(x)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$y'' + 4y'x + \left(4x^2 + 2\right) y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x^2} + c_2 x\, \mathrm{e}^{-x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x^2}$$
$$y_2 = x\,\mathrm{e}^{-x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x^2} & x\,\mathrm{e}^{-x^2} \\ \frac{d}{dx}\left(\mathrm{e}^{-x^2}\right) & \frac{d}{dx}\left(x\,\mathrm{e}^{-x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x^2} & x\,\mathrm{e}^{-x^2} \\ -2x\,\mathrm{e}^{-x^2} & \mathrm{e}^{-x^2} - 2x^2\mathrm{e}^{-x^2} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x^2}\right)\left(\mathrm{e}^{-x^2} - 2x^2\mathrm{e}^{-x^2}\right) - \left(x\,\mathrm{e}^{-x^2}\right)\left(-2x\,\mathrm{e}^{-x^2}\right)$$

Which simplifies to

$$W = \mathrm{e}^{-2x^2}$$

Which simplifies to

$$W = e^{-2x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4x\, e^{-x^2} e^{-x(2+x)}}{e^{-2x^2}} \, dx$$

Which simplifies to

$$u_1 = -\int 4\, e^{-2x} x dx$$

Hence

$$u_1 = (1 + 2x)\, e^{-2x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{4\, e^{-x^2} e^{-x(2+x)}}{e^{-2x^2}} \, dx$$

Which simplifies to

$$u_2 = \int 4\, e^{-2x} dx$$

Hence

$$u_2 = -2\, e^{-2x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (1 + 2x)\, e^{-2x} e^{-x^2} - 2\, e^{-2x} x\, e^{-x^2}$$

Which simplifies to

$$y_p(x) = e^{-x(2+x)}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-x^2} + c_2 x\, e^{-x^2}\right) + \left(e^{-x(2+x)}\right) \end{aligned}$$

Which simplifies to

$$y = e^{-x^2}(c_2 x + c_1) + e^{-x(2+x)}$$

Summary

The solution(s) found are the following

$$y = e^{-x^2}(c_2 x + c_1) + e^{-x(2+x)} \tag{1}$$

Verification of solutions

$$y = e^{-x^2}(c_2 x + c_1) + e^{-x(2+x)}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - 4y'x + 6y = x^{\frac{5}{2}}}$$

10.11.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 6, f(x) = x^{\frac{5}{2}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 6y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 4xrx^{r-1} + 6x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - 4r\,x^r + 6x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 4r + 6 = 0$$

Or

$$r^2 - 5r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 2$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^3 + c_1x^2$$

Next, we find the particular solution to the ODE

$$x^2y'' - 4y'x + 6y = x^{\frac{5}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^3 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^3 \\ 2x & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x^2)(3x^2) - (x^3)(2x)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{11}{2}}}{x^6}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{\sqrt{x}}dx$$

Hence

$$u_1 = -2\sqrt{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{9}{2}}}{x^6}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^{\frac{3}{2}}}dx$$

Hence

$$u_2 = -\frac{2}{\sqrt{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -4x^{\frac{5}{2}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -4x^{\frac{5}{2}} + c_2x^3 + c_1x^2 \end{aligned}$$

Summary
The solution(s) found are the following

$$y = -4x^{\frac{5}{2}} + c_2x^3 + c_1x^2 \tag{1}$$

Verification of solutions

$$y = -4x^{\frac{5}{2}} + c_2x^3 + c_1x^2$$

Verified OK.

10.11.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = -\frac{4}{x}$. Therefore, there is an integrating factor given by

$$\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\,dx} \\
&= e^{\int -\frac{4}{x}\,dx} \\
&= \frac{1}{x^2}
\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned}
(M(x)y)'' &= \frac{1}{x^{\frac{3}{2}}} \\
\left(\frac{y}{x^2}\right)'' &= \frac{1}{x^{\frac{3}{2}}}
\end{aligned}$$

Integrating once gives

$$\left(\frac{y}{x^2}\right)' = -\frac{2}{\sqrt{x}} + c_1$$

Integrating again gives

$$\left(\frac{y}{x^2}\right) = c_1x - 4\sqrt{x} + c_2$$

Hence the solution is

$$y = \frac{c_1x - 4\sqrt{x} + c_2}{\frac{1}{x^2}}$$

Or

$$y = c_1x^3 + c_2x^2 - 4x^{\frac{5}{2}}$$

Summary
The solution(s) found are the following

$$y = c_1x^3 + c_2x^2 - 4x^{\frac{5}{2}} \tag{1}$$

Verification of solutions

$$y = c_1x^3 + c_2x^2 - 4x^{\frac{5}{2}}$$

Verified OK.

10.11.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}\,dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{4}{x}dx\right)}\,dx \\
&= \int e^{4\ln(x)}\,dx \\
&= \int x^4 dx \\
&= \frac{x^5}{5} \qquad (6)
\end{aligned}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{6}{x^2}}{x^8} \\
&= \frac{6}{x^{10}} \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{x^{10}} &= 0
\end{aligned}$$

But in terms of τ

$$\frac{6}{x^{10}} = \frac{6}{25\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{6y(\tau)}{25\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$25\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 6y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$25\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 6\tau^r = 0$$

Simplifying gives

$$25r(r-1)\,\tau^r + 0\,\tau^r + 6\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$25r(r-1) + 0 + 6 = 0$$

Or

$$25r^2 - 25r + 6 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= \frac{2}{5} \\ r_2 &= \frac{3}{5} \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{2}{5}} + c_2\tau^{\frac{3}{5}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^5\right)^{\frac{2}{5}}$$

$$y_2 = \left(x^5\right)^{\frac{3}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^5\right)^{\frac{2}{5}} & \left(x^5\right)^{\frac{3}{5}} \\ \frac{d}{dx}\left(\left(x^5\right)^{\frac{2}{5}}\right) & \frac{d}{dx}\left(\left(x^5\right)^{\frac{3}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^5\right)^{\frac{2}{5}} & \left(x^5\right)^{\frac{3}{5}} \\ \frac{2x^4}{\left(x^5\right)^{\frac{3}{5}}} & \frac{3x^4}{\left(x^5\right)^{\frac{2}{5}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^5\right)^{\frac{2}{5}}\right)\left(\frac{3x^4}{\left(x^5\right)^{\frac{2}{5}}}\right) - \left(\left(x^5\right)^{\frac{3}{5}}\right)\left(\frac{2x^4}{\left(x^5\right)^{\frac{3}{5}}}\right)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}} x^{\frac{5}{2}}}{x^6} dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}}{x^{\frac{7}{2}}} dx$$

Hence

$$u_1 = -\frac{2(x^5)^{\frac{3}{5}}}{x^{\frac{5}{2}}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}} x^{\frac{5}{2}}}{x^6} dx$$

Which simplifies to

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}}}{x^{\frac{7}{2}}} dx$$

Hence

$$u_2 = -\frac{2(x^5)^{\frac{2}{5}}}{x^{\frac{5}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -4x^{\frac{5}{2}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5}\right) + \left(-4x^{\frac{5}{2}}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5} - 4x^{\frac{5}{2}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 5^{\frac{3}{5}} (x^5)^{\frac{2}{5}}}{5} + \frac{c_2 5^{\frac{2}{5}} (x^5)^{\frac{3}{5}}}{5} - 4x^{\frac{5}{2}}$$

Verified OK.

10.11.4 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 6, f(x) = x^{\frac{5}{2}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c} \\
\tau'' &= -\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{\sqrt{6}}{c\sqrt{\frac{1}{x^2}}\,x^3} - \frac{4}{x}\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\
&= -\frac{5c\sqrt{6}}{6}
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - \frac{5c\sqrt{6}\left(\frac{d}{d\tau}y(\tau)\right)}{6} + c^2 y(\tau) &= 0
\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{5\sqrt{6}\,c\tau}{12}}\left(c_1\cosh\left(\frac{\sqrt{6}\,c\tau}{12}\right) + ic_2\sinh\left(\frac{\sqrt{6}\,c\tau}{12}\right)\right)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{6}\,\sqrt{\frac{1}{x^2}}dx}{c} \\
&= \frac{\sqrt{6}\,\sqrt{\frac{1}{x^2}}\,x\ln(x)}{c}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = x^{\frac{5}{2}} \left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + i c_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)$$

Now the particular solution to this ODE is found

$$x^2 y'' - 4y'x + 6y = x^{\frac{5}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = (x^5)^{\frac{2}{5}}$$
$$y_2 = (x^5)^{\frac{3}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{d}{dx}\left((x^5)^{\frac{2}{5}}\right) & \frac{d}{dx}\left((x^5)^{\frac{3}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{2x^4}{(x^5)^{\frac{3}{5}}} & \frac{3x^4}{(x^5)^{\frac{2}{5}}} \end{vmatrix}$$

Therefore

$$W = \left((x^5)^{\frac{2}{5}}\right)\left(\frac{3x^4}{(x^5)^{\frac{2}{5}}}\right) - \left((x^5)^{\frac{3}{5}}\right)\left(\frac{2x^4}{(x^5)^{\frac{3}{5}}}\right)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}\, x^{\frac{5}{2}}}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}}{x^{\frac{7}{2}}} dx$$

Hence

$$u_1 = -\frac{2(x^5)^{\frac{3}{5}}}{x^{\frac{5}{2}}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}}\, x^{\frac{5}{2}}}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}}}{x^{\frac{7}{2}}} dx$$

Hence

$$u_2 = -\frac{2(x^5)^{\frac{2}{5}}}{x^{\frac{5}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -4x^{\frac{5}{2}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^{\frac{5}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)\right) + \left(-4x^{\frac{5}{2}}\right) \\ &= -4x^{\frac{5}{2}} + x^{\frac{5}{2}}\left(c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \end{aligned}$$

Which simplifies to

$$y = x^{\frac{5}{2}}\left(-4 + c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)$$

Summary

The solution(s) found are the following

$$y = x^{\frac{5}{2}}\left(-4 + c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right) \tag{1}$$

Verification of solutions

$$y = x^{\frac{5}{2}}\left(-4 + c_1 \cosh\left(\frac{\ln(x)}{2}\right) + ic_2 \sinh\left(\frac{\ln(x)}{2}\right)\right)$$

Verified OK.

10.11.5 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= \frac{6}{x^2} - \frac{\left(-\frac{4}{x}\right)'}{2} - \frac{\left(-\frac{4}{x}\right)^2}{4} \\ &= \frac{6}{x^2} - \frac{\left(\frac{4}{x^2}\right)}{2} - \frac{\left(\frac{16}{x^2}\right)}{4} \\ &= \frac{6}{x^2} - \left(\frac{2}{x^2}\right) - \frac{4}{x^2} \\ &= 0 \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\ &= e^{-\int \frac{-\frac{4}{x}}{2}} \\ &= x^2 \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, x^2 \tag{4}$$

Applying this change of variable to the original ode results in

$$x^{\frac{3}{2}} v''(x) = 1$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$v''(x) = \frac{1}{x^{\frac{3}{2}}}$$

Integrating once gives

$$v'(x) = -\frac{2}{\sqrt{x}} + c_1$$

Integrating again gives

$$v(x) = -4\sqrt{x} + c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 x - 4\sqrt{x} + c_2\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x^2$$

Hence (7) becomes

$$y = \left(c_1 x - 4\sqrt{x} + c_2\right) x^2$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 x - 4\sqrt{x} + c_2\right) x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^5\right)^{\frac{2}{5}}$$

$$y_2 = \left(x^5\right)^{\frac{3}{5}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{d}{dx}\left((x^5)^{\frac{2}{5}}\right) & \frac{d}{dx}\left((x^5)^{\frac{3}{5}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^5)^{\frac{2}{5}} & (x^5)^{\frac{3}{5}} \\ \frac{2x^4}{(x^5)^{\frac{3}{5}}} & \frac{3x^4}{(x^5)^{\frac{2}{5}}} \end{vmatrix}$$

Therefore

$$W = \left((x^5)^{\frac{2}{5}}\right)\left(\frac{3x^4}{(x^5)^{\frac{2}{5}}}\right) - \left((x^5)^{\frac{3}{5}}\right)\left(\frac{2x^4}{(x^5)^{\frac{3}{5}}}\right)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}\, x^{\frac{5}{2}}}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^5)^{\frac{3}{5}}}{x^{\frac{7}{2}}} dx$$

Hence

$$u_1 = -\frac{2(x^5)^{\frac{3}{5}}}{x^{\frac{5}{2}}}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}} x^{\frac{5}{2}}}{x^6} dx$$

Which simplifies to

$$u_2 = \int \frac{(x^5)^{\frac{2}{5}}}{x^{\frac{7}{2}}} dx$$

Hence

$$u_2 = -\frac{2(x^5)^{\frac{2}{5}}}{x^{\frac{5}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -4x^{\frac{5}{2}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 x - 4\sqrt{x} + c_2\right) x^2\right) + \left(-4x^{\frac{5}{2}}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(c_1 x - 4\sqrt{x} + c_2\right) x^2 - 4x^{\frac{5}{2}} \tag{1}$$

Verification of solutions

$$y = \left(c_1 x - 4\sqrt{x} + c_2\right) x^2 - 4x^{\frac{5}{2}}$$

Verified OK.

10.11.6 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -4x, C = 6, f(x) = x^{\frac{5}{2}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 4y'x + 6y = 0$$

In normal form the ode

$$x^2y'' - 4y'x + 6y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{4}{x} \\ q(x) &= \frac{6}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{4n}{x^2} + \frac{6}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{2v'(x)}{x} &= 0 \\ v''(x) + \frac{2v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{2u}{x} \end{aligned}$$

Where $f(x) = -\frac{2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\, du &= -\frac{2}{x}\, dx \\ \int \frac{1}{u}\, du &= \int -\frac{2}{x}\, dx \\ \ln(u) &= -2\ln(x) + c_1 \\ u &= \mathrm{e}^{-2\ln(x)+c_1} \\ &= \frac{c_1}{x^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1}{x} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{x} + c_2\right) x^3 \\
&= (c_2 x - c_1)\, x^2
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' - 4y'x + 6y = x^{\frac{5}{2}}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^3
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x^2 & x^3 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^3) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x^2 & x^3 \\ 2x & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x^2)(3x^2) - (x^3)(2x)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{11}{2}}}{x^6}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{\sqrt{x}}dx$$

Hence

$$u_1 = -2\sqrt{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{9}{2}}}{x^6}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^{\frac{3}{2}}}dx$$

Hence

$$u_2 = -\frac{2}{\sqrt{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -4x^{\frac{5}{2}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{x} + c_2\right) x^3\right) + \left(-4x^{\frac{5}{2}}\right) \\ &= -4x^{\frac{5}{2}} + \left(-\frac{c_1}{x} + c_2\right) x^3 \end{aligned}$$

Which simplifies to

$$y = -4x^{\frac{5}{2}} + c_2 x^3 - c_1 x^2$$

Summary
The solution(s) found are the following

$$y = -4x^{\frac{5}{2}} + c_2 x^3 - c_1 x^2 \tag{1}$$

Verification of solutions

$$y = -4x^{\frac{5}{2}} + c_2 x^3 - c_1 x^2$$

Verified OK.

10.11.7 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 4y'x + 6y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 423: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx} \\ &= z_1 e^{2\ln(x)} \\ &= z_1 \left(x^2\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^2\right) + c_2 \left(x^2(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 4y'x + 6y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_2 x^3 + c_1 x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^3
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^3 \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^3 \\ 2x & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x^2)(3x^2) - (x^3)(2x)$$

Which simplifies to

$$W = x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{11}{2}}}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{1}{\sqrt{x}} dx$$

Hence

$$u_1 = -2\sqrt{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{\frac{9}{2}}}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^{\frac{3}{2}}} dx$$

Hence

$$u_2 = -\frac{2}{\sqrt{x}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -4x^{\frac{5}{2}}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_2 x^3 + c_1 x^2) + \left(-4x^{\frac{5}{2}}\right) \end{aligned}$$

Which simplifies to

$$y = x^2(c_2 x + c_1) - 4x^{\frac{5}{2}}$$

Summary

The solution(s) found are the following

$$y = x^2(c_2 x + c_1) - 4x^{\frac{5}{2}} \tag{1}$$

Verification of solutions

$$y = x^2(c_2 x + c_1) - 4x^{\frac{5}{2}}$$

Verified OK.

$$\boxed{x^2y'' - 3y'x + 3y = 2\sin(x)\, x^4}$$

10.12.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 3, f(x) = 2\sin(x)\, x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 3y'x + 3y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - 3xrx^{r-1} + 3x^r = 0$$

Simplifying gives

$$r(r-1)\, x^r - 3r\, x^r + 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - 3r + 3 = 0$$

Or

$$r^2 - 4r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = 1$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = c_2x^3 + c_1x$$

Next, we find the particular solution to the ODE

$$x^2y'' - 3y'x + 3y = 2\sin(x)\, x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^3 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^3 \\ 1 & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x)\left(3x^2\right) - \left(x^3\right)(1)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7 \sin(x)}{2x^5} dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\, x^2 dx$$

Hence

$$u_1 = x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5 \sin(x)}{2x^5} dx$$

Which simplifies to

$$u_2 = \int \sin(x)\, dx$$

Hence

$$u_2 = -\cos(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x\right) x - x^3 \cos(x)$$

Which simplifies to

$$y_p(x) = -2x(\sin(x)\, x + \cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_2 x^2 - 2\sin(x)\, x - 2\cos(x) + c_1\right) x \end{aligned}$$

Summary
The solution(s) found are the following

$$y = (c_2x^2 - 2\sin(x)\,x - 2\cos(x) + c_1)\,x \tag{1}$$

Verification of solutions

$$y = (c_2x^2 - 2\sin(x)\,x - 2\cos(x) + c_1)\,x$$

Verified OK.

10.12.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 3y'x + 3y = 0$$

In normal form the ode

$$x^2y'' - 3y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{3}{x^2}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int -\frac{3}{x} dx\right)} dx \\
&= \int e^{3\ln(x)}\, dx \\
&= \int x^3 dx \\
&= \frac{x^4}{4} \qquad (6)
\end{aligned}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{3}{x^2}}{x^6} \\
&= \frac{3}{x^8} \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{x^8} &= 0
\end{aligned}$$

But in terms of τ

$$\frac{3}{x^8} = \frac{3}{16\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{3y(\tau)}{16\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$16\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$16\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 3\tau^r = 0$$

Simplifying gives

$$16r(r-1)\,\tau^r + 0\,\tau^r + 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$16r(r-1) + 0 + 3 = 0$$

Or

$$16r^2 - 16r + 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{4}$$
$$r_2 = \frac{3}{4}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{\frac{1}{4}} + c_2\tau^{\frac{3}{4}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}}\left(c_2\sqrt{x^4} + 2c_1\right)}{4}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}}\left(c_2\sqrt{x^4} + 2c_1\right)}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^4\right)^{\frac{1}{4}}$$
$$y_2 = \left(x^4\right)^{\frac{3}{4}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \left(x^4\right)^{\frac{1}{4}} & \left(x^4\right)^{\frac{3}{4}} \\ \frac{d}{dx}\left(\left(x^4\right)^{\frac{1}{4}}\right) & \frac{d}{dx}\left(\left(x^4\right)^{\frac{3}{4}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \left(x^4\right)^{\frac{1}{4}} & \left(x^4\right)^{\frac{3}{4}} \\ \frac{x^3}{\left(x^4\right)^{\frac{3}{4}}} & \frac{3x^3}{\left(x^4\right)^{\frac{1}{4}}} \end{vmatrix}$$

Therefore

$$W = \left(\left(x^4\right)^{\frac{1}{4}}\right)\left(\frac{3x^3}{\left(x^4\right)^{\frac{1}{4}}}\right) - \left(\left(x^4\right)^{\frac{3}{4}}\right)\left(\frac{x^3}{\left(x^4\right)^{\frac{3}{4}}}\right)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x^4)^{\frac{3}{4}} \sin(x)\, x^4}{2x^5}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^4)^{\frac{3}{4}} \sin(x)}{x} dx$$

Hence

$$u_1 = \frac{(x^4)^{\frac{3}{4}} (x^2 - 2) \cos(x)}{x^3} - \frac{2(x^4)^{\frac{3}{4}} \sin(x)}{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2(x^4)^{\frac{1}{4}} \sin(x)\, x^4}{2x^5}\, dx$$

Which simplifies to

$$u_2 = \int \frac{(x^4)^{\frac{1}{4}} \sin(x)}{x} dx$$

Hence

$$u_2 = -\frac{(x^4)^{\frac{1}{4}} \cos(x)}{x}$$

Which simplifies to

$$u_1 = \frac{(x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x) (x^4)^{\frac{3}{4}}}{x^3}$$

$$u_2 = -\frac{(x^4)^{\frac{1}{4}} \cos(x)}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x)\, x - x^3 \cos(x)$$

Which simplifies to

$$y_p(x) = -2x(\sin(x)\,x + \cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{2}\,(x^4)^{\frac{1}{4}}\left(c_2\sqrt{x^4} + 2c_1\right)}{4}\right) + (-2x(\sin(x)\,x + \cos(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}}\left(c_2\sqrt{x^4} + 2c_1\right)}{4} - 2x(\sin(x)\,x + \cos(x)) \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,(x^4)^{\frac{1}{4}}\left(c_2\sqrt{x^4} + 2c_1\right)}{4} - 2x(\sin(x)\,x + \cos(x))$$

Verified OK.

10.12.3 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 3, f(x) = 2\sin(x)\,x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 3y'x + 3y = 0$$

In normal form the ode

$$x^2y'' - 3y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{3}{x} \\ q(x) &= \frac{3}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c} \\ \tau'' &= -\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\, x^3} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\sqrt{3}}{c\sqrt{\frac{1}{x^2}}\, x^3} - \frac{3}{x}\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}}{\left(\frac{\sqrt{3}\,\sqrt{\frac{1}{x^2}}}{c}\right)^2} \\ &= -\frac{4c\sqrt{3}}{3} \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2} y(\tau) - \frac{4c\sqrt{3}\left(\frac{d}{d\tau} y(\tau)\right)}{3} + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = \mathrm{e}^{\frac{2\sqrt{3}\,c\tau}{3}} \left(c_1 \cosh\left(\frac{\sqrt{3}\,c\tau}{3}\right) + i c_2 \sinh\left(\frac{\sqrt{3}\,c\tau}{3}\right) \right)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c} \sqrt{q}\, dx \\ &= \frac{\int \sqrt{3}\sqrt{\frac{1}{x^2}} dx}{c} \\ &= \frac{\sqrt{3}\sqrt{\frac{1}{x^2}}\, x \ln(x)}{c} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \frac{\left(\left(i c_2 + c_1\right) x^2 - i c_2 + c_1\right) x}{2}$$

Now the particular solution to this ODE is found

$$x^2 y'' - 3y'x + 3y = 2\sin(x)\, x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \left(x^4\right)^{\frac{1}{4}} \\ y_2 &= \left(x^4\right)^{\frac{3}{4}} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^4)^{\frac{1}{4}} & (x^4)^{\frac{3}{4}} \\ \frac{d}{dx}\left((x^4)^{\frac{1}{4}}\right) & \frac{d}{dx}\left((x^4)^{\frac{3}{4}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^4)^{\frac{1}{4}} & (x^4)^{\frac{3}{4}} \\ \frac{x^3}{(x^4)^{\frac{3}{4}}} & \frac{3x^3}{(x^4)^{\frac{1}{4}}} \end{vmatrix}$$

Therefore

$$W = \left((x^4)^{\frac{1}{4}}\right)\left(\frac{3x^3}{(x^4)^{\frac{1}{4}}}\right) - \left((x^4)^{\frac{3}{4}}\right)\left(\frac{x^3}{(x^4)^{\frac{3}{4}}}\right)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x^4)^{\frac{3}{4}} \sin(x)\, x^4}{2x^5}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{(x^4)^{\frac{3}{4}} \sin(x)}{x} dx$$

Hence

$$u_1 = \frac{(x^4)^{\frac{3}{4}} (x^2 - 2) \cos(x)}{x^3} - \frac{2(x^4)^{\frac{3}{4}} \sin(x)}{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2(x^4)^{\frac{1}{4}} \sin(x) x^4}{2x^5} dx$$

Which simplifies to

$$u_2 = \int \frac{(x^4)^{\frac{1}{4}} \sin(x)}{x} dx$$

Hence

$$u_2 = -\frac{(x^4)^{\frac{1}{4}} \cos(x)}{x}$$

Which simplifies to

$$u_1 = \frac{(x^2 \cos(x) - 2\cos(x) - 2\sin(x) x) (x^4)^{\frac{3}{4}}}{x^3}$$

$$u_2 = -\frac{(x^4)^{\frac{1}{4}} \cos(x)}{x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (x^2 \cos(x) - 2\cos(x) - 2\sin(x) x) x - x^3 \cos(x)$$

Which simplifies to

$$y_p(x) = -2x(\sin(x) x + \cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{((ic_2 + c_1) x^2 - ic_2 + c_1) x}{2}\right) + (-2x(\sin(x) x + \cos(x))) \\ &= -2x(\sin(x) x + \cos(x)) + \frac{((ic_2 + c_1) x^2 - ic_2 + c_1) x}{2} \end{aligned}$$

Which simplifies to

$$y = \frac{(-4\cos(x) - 4\sin(x)x + (ic_2 + c_1)x^2 - ic_2 + c_1)x}{2}$$

Summary

The solution(s) found are the following

$$y = \frac{(-4\cos(x) - 4\sin(x)x + (ic_2 + c_1)x^2 - ic_2 + c_1)x}{2} \tag{1}$$

Verification of solutions

$$y = \frac{(-4\cos(x) - 4\sin(x)x + (ic_2 + c_1)x^2 - ic_2 + c_1)x}{2}$$

Verified OK.

10.12.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -3x, C = 3, f(x) = 2\sin(x)x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - 3y'x + 3y = 0$$

In normal form the ode

$$x^2y'' - 3y'x + 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{3}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} - \frac{3n}{x^2} + \frac{3}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 3 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{3v'(x)}{x} &= 0 \\ v''(x) + \frac{3v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{3u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{3u}{x} \end{aligned}$$

Where $f(x) = -\frac{3}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{3}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{3}{x}\,dx \\
\ln(u) &= -3\ln(x) + c_1 \\
u &= \mathrm{e}^{-3\ln(x)+c_1} \\
&= \frac{c_1}{x^3}
\end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{c_1}{2x^2} + c_2
\end{aligned}$$

Hence

$$\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{c_1}{2x^2} + c_2\right)x^3 \\
&= c_2x^3 - \frac{1}{2}c_1x
\end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' - 3y'x + 3y = 2\sin(x)\,x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= x \\
y_2 &= x^3
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^3 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^3 \\ 1 & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x)\left(3x^2\right) - \left(x^3\right)(1)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7 \sin(x)}{2x^5} dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\, x^2 dx$$

Hence

$$u_1 = x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5 \sin(x)}{2x^5} dx$$

Which simplifies to

$$u_2 = \int \sin(x)\, dx$$

Hence

$$u_2 = -\cos(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x\right) x - x^3 \cos(x)$$

Which simplifies to

$$y_p(x) = -2x(\sin(x)\, x + \cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{2x^2} + c_2\right) x^3\right) + (-2x(\sin(x)\, x + \cos(x))) \\ &= -2x(\sin(x)\, x + \cos(x)) + \left(-\frac{c_1}{2x^2} + c_2\right) x^3 \end{aligned}$$

Which simplifies to

$$y = x\left(-2\sin(x)\, x - 2\cos(x) - \frac{c_1}{2} + c_2 x^2\right)$$

Summary

The solution(s) found are the following

$$y = x\left(-2\sin(x)\, x - 2\cos(x) - \frac{c_1}{2} + c_2 x^2\right) \tag{1}$$

Verification of solutions

$$y = x\left(-2\sin(x)\, x - 2\cos(x) - \frac{c_1}{2} + c_2 x^2\right)$$

Verified OK.

10.12.5 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right)u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x \\ C &= 3 \\ F &= 2\sin(x)\,x^4 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= \left(x^2\right)(0) + (-3x)(-3) + (3)(-3x) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-3x^3v'' + (3x^2)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$-3x^2(u'(x)\, x - u(x)) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= \frac{u}{x}
\end{aligned}$$

Where $f(x) = \frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= \frac{1}{x}\, dx \\
\int \frac{1}{u}\, du &= \int \frac{1}{x}\, dx \\
\ln(u) &= \ln(x) + c_1 \\
u &= e^{\ln(x)+c_1} \\
&= c_1 x
\end{aligned}$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1 x
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int c_1 x \,\mathrm{d}x \\
&= \frac{c_1 x^2}{2} + c_2
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= Bv \\
&= (-3x)\left(\frac{c_1 x^2}{2} + c_2\right) \\
&= -\frac{3x(c_1 x^2 + 2c_2)}{2}
\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & x^3 \\ \frac{d}{dx}(x) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & x^3 \\ 1 & 3x^2 \end{vmatrix}$$

Therefore

$$W = (x)\left(3x^2\right) - \left(x^3\right)(1)$$

Which simplifies to

$$W = 2x^3$$

Which simplifies to

$$W = 2x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2x^7 \sin(x)}{2x^5} dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\, x^2 dx$$

Hence

$$u_1 = x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5 \sin(x)}{2x^5} dx$$

Which simplifies to

$$u_2 = \int \sin(x)\, dx$$

Hence

$$u_2 = -\cos(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x\right) x - x^3 \cos(x)$$

Which simplifies to

$$y_p(x) = -2x(\sin(x)\, x + \cos(x))$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= \left(-\frac{3x(c_1 x^2 + 2c_2)}{2}\right) + (-2x(\sin(x)\, x + \cos(x))) \\ &= x\left(-\frac{3c_1 x^2}{2} - 3c_2 - 2\sin(x)\, x - 2\cos(x)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x\left(-\frac{3c_1x^2}{2} - 3c_2 - 2\sin(x)\,x - 2\cos(x)\right) \tag{1}$$

Verification of solutions

$$y = x\left(-\frac{3c_1x^2}{2} - 3c_2 - 2\sin(x)\,x - 2\cos(x)\right)$$

Verified OK.

10.12.6 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 3y'x + 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -3x \\ C &= 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 3 \\
t &= 4x^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{3}{4x^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) e^{-\int \frac{B}{2A} dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 424: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{4x^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{2x} + (-)(0) \\ &= -\frac{1}{2x} \\ &= -\frac{1}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x}\right)(0) + \left(\left(\frac{1}{2x^2}\right) + \left(-\frac{1}{2x}\right)^2 - \left(\frac{3}{4x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{2x} dx} \\ &= \frac{1}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-3x}{x^2} \, dx} \\ &= z_1 e^{\frac{3\ln(x)}{2}} \\ &= z_1 \left(x^{\frac{3}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{3\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{x^2}{2}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x) + c_2\left(x\left(\frac{x^2}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 3y'x + 3y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 x + \frac{1}{2} c_2 x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= \frac{x^3}{2}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{x^3}{2} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{x^3}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{x^3}{2} \\ 1 & \frac{3x^2}{2} \end{vmatrix}$$

Therefore

$$W = (x)\left(\frac{3x^2}{2}\right) - \left(\frac{x^3}{2}\right)(1)$$

Which simplifies to

$$W = x^3$$

Which simplifies to

$$W = x^3$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^7 \sin(x)}{x^5}\, dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\, x^2 dx$$

Hence

$$u_1 = x^2 \cos(x) - 2\cos(x) - 2\sin(x)\, x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x^5 \sin(x)}{x^5}\, dx$$

Which simplifies to

$$u_2 = \int 2\sin(x)\,dx$$

Hence

$$u_2 = -2\cos(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (x^2\cos(x) - 2\cos(x) - 2\sin(x)\,x)\,x - x^3\cos(x)$$

Which simplifies to

$$y_p(x) = -2x(\sin(x)\,x + \cos(x))$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1x + \frac{1}{2}c_2x^3\right) + (-2x(\sin(x)\,x + \cos(x))) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1x + \frac{c_2x^3}{2} - 2x(\sin(x)\,x + \cos(x)) \tag{1}$$

Verification of solutions

$$y = c_1x + \frac{c_2x^3}{2} - 2x(\sin(x)\,x + \cos(x))$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{(1+2x)\,y''-2y'-(2x+3)\,y=(1+2x)^2\,\mathrm{e}^{-x}}$$

10.13.1 Solving using Kovacic algorithm

Writing the ode as

$$(1+2x)\,y''-2y'+(-3-2x)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1+2x \\ B &= -2 \\ C &= -3-2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x^2 + 8x + 6}{(1 + 2x)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 4x^2 + 8x + 6$$
$$t = (1 + 2x)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x^2 + 8x + 6}{(1 + 2x)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 425: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (1+2x)^2$. There is a pole at $x = -\frac{1}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 1 + \frac{3}{4\left(x + \frac{1}{2}\right)^2} + \frac{1}{x + \frac{1}{2}}$$

For the pole at $x = -\frac{1}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{1}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 1 + \frac{1}{2x} - \frac{1}{4x^3} + \frac{11}{32x^4} - \frac{21}{64x^5} + \frac{15}{64x^6} - \frac{3}{32x^7} - \frac{117}{2048x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 1$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= 1 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 1$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4x^2 + 8x + 6}{4x^2 + 4x + 1} \\ &= Q + \frac{R}{4x^2 + 4x + 1} \\ &= (1) + \left(\frac{4x + 5}{4x^2 + 4x + 1}\right) \\ &= 1 + \frac{4x + 5}{4x^2 + 4x + 1} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 4. Dividing this by leading coefficient in t which is 4 gives 1. Now b can be found.

$$\begin{aligned} b &= (1) - (0) \\ &= 1 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 1 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{1}{1} - 0\right) &&= \frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{1}{1} - 0\right) &&= -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4x^2 + 8x + 6}{(1 + 2x)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-\frac{1}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	1	$\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2\left(x + \frac{1}{2}\right)} + (-)\,(1) \\
&= -\frac{1}{2\left(x + \frac{1}{2}\right)} - 1 \\
&= -\frac{2(x+1)}{1+2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right)(0) + \left(\left(\frac{1}{2\left(x + \frac{1}{2}\right)^2}\right) + \left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right)^2 - \left(\frac{4x^2 + 8x + 6}{(1+2x)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(x + \frac{1}{2}\right)} - 1\right) dx} \\
&= \frac{\mathrm{e}^{-x}}{\sqrt{1+2x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2}{1+2x}\, dx} \\
&= z_1 e^{\frac{\ln(1+2x)}{2}} \\
&= z_1\left(\sqrt{1+2x}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2}{1+2x}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{\ln(1+2x)}}{(y_1)^2}\, dx \\ &= y_1 \left(x\, \mathrm{e}^{2x}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{-x}\right) + c_2 \left(\mathrm{e}^{-x} \left(x\, \mathrm{e}^{2x}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$(1 + 2x)\, y'' - 2y' + (-3 - 2x)\, y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-x} + c_2 x\, \mathrm{e}^{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x}$$
$$y_2 = x\,\mathrm{e}^{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x} & x\,\mathrm{e}^{x} \\ \frac{d}{dx}\left(\mathrm{e}^{-x}\right) & \frac{d}{dx}\left(x\,\mathrm{e}^{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x} & x\,\mathrm{e}^{x} \\ -\mathrm{e}^{-x} & x\,\mathrm{e}^{x} + \mathrm{e}^{x} \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x}\right)\left(x\,\mathrm{e}^{x} + \mathrm{e}^{x}\right) - \left(x\,\mathrm{e}^{x}\right)\left(-\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = 2x\,\mathrm{e}^{x}\mathrm{e}^{-x} + \mathrm{e}^{-x}\mathrm{e}^{x}$$

Which simplifies to

$$W = 1 + 2x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x\,\mathrm{e}^{x}(1+2x)^2\,\mathrm{e}^{-x}}{(1+2x)^2}\,dx$$

Which simplifies to

$$u_1 = -\int x dx$$

Hence

$$u_1 = -\frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{-2x}(1+2x)^2}{(1+2x)^2}\,dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{-2x} dx$$

Hence

$$u_2 = -\frac{\mathrm{e}^{-2x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2\mathrm{e}^{-x}}{2} - \frac{\mathrm{e}^{-2x}x\,\mathrm{e}^{x}}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\mathrm{e}^{-x}x(x+1)}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x} + c_2x\,\mathrm{e}^{x}\right) + \left(-\frac{\mathrm{e}^{-x}x(x+1)}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-x} + c_2 x e^{x} - \frac{e^{-x} x(x+1)}{2} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x} + c_2 x e^{x} - \frac{e^{-x} x(x+1)}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{2xy'' + 2y' + 2y = \sin\left(\sqrt{x}\right)}$$

10.14.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + y'x + yx = \frac{x \sin\left(\sqrt{x}\right)}{2} \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned} \alpha &= 0 \\ \beta &= 2 \\ n &= 0 \\ \gamma &= \frac{1}{2} \end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = c_1 \operatorname{BesselJ}\left(0, 2\sqrt{x}\right) + c_2 \operatorname{BesselY}\left(0, 2\sqrt{x}\right)$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 \operatorname{BesselJ}\left(0, 2\sqrt{x}\right) + c_2 \operatorname{BesselY}\left(0, 2\sqrt{x}\right)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \operatorname{BesselJ}\left(0, 2\sqrt{x}\right) \\ y_2 &= \operatorname{BesselY}\left(0, 2\sqrt{x}\right) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \text{BesselJ}\left(0, 2\sqrt{x}\right) & \text{BesselY}\left(0, 2\sqrt{x}\right) \\ \frac{d}{dx}\left(\text{BesselJ}\left(0, 2\sqrt{x}\right)\right) & \frac{d}{dx}\left(\text{BesselY}\left(0, 2\sqrt{x}\right)\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \text{BesselJ}\left(0, 2\sqrt{x}\right) & \text{BesselY}\left(0, 2\sqrt{x}\right) \\ -\frac{\text{BesselJ}\left(1, 2\sqrt{x}\right)}{\sqrt{x}} & -\frac{\text{BesselY}\left(1, 2\sqrt{x}\right)}{\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\text{BesselJ}\left(0, 2\sqrt{x}\right)\right)\left(-\frac{\text{BesselY}\left(1, 2\sqrt{x}\right)}{\sqrt{x}}\right) - \left(\text{BesselY}\left(0, 2\sqrt{x}\right)\right)\left(-\frac{\text{BesselJ}\left(1, 2\sqrt{x}\right)}{\sqrt{x}}\right)$$

Which simplifies to

$$W = -\frac{\text{BesselJ}\left(0, 2\sqrt{x}\right)\text{BesselY}\left(1, 2\sqrt{x}\right) - \text{BesselY}\left(0, 2\sqrt{x}\right)\text{BesselJ}\left(1, 2\sqrt{x}\right)}{\sqrt{x}}$$

Which simplifies to

$$W = \frac{1}{x\pi}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\text{BesselY}\left(0, 2\sqrt{x}\right) x \sin\left(\sqrt{x}\right)}{2}}{\frac{x}{\pi}}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\text{BesselY}\left(0, 2\sqrt{x}\right)\sin\left(\sqrt{x}\right)\pi}{2} dx$$

Hence

$$u_1 = -\left(\int_0^x \frac{\text{BesselY}\left(0, 2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)\pi}{2} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\text{BesselJ}\left(0,2\sqrt{x}\right)x\sin\left(\sqrt{x}\right)}{2}}{\frac{x}{\pi}}dx$$

Which simplifies to

$$u_2 = \int \frac{\text{BesselJ}\left(0,2\sqrt{x}\right)\sin\left(\sqrt{x}\right)\pi}{2}dx$$

Hence

$$u_2 = \int_0^x \frac{\text{BesselJ}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)\pi}{2}d\alpha$$

Which simplifies to

$$u_1 = -\frac{\pi\left(\int_0^x \text{BesselY}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)}{2}$$
$$u_2 = \frac{\pi\left(\int_0^x \text{BesselJ}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\pi\left(\int_0^x \text{BesselY}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\text{BesselJ}\left(0,2\sqrt{x}\right)}{2} + \frac{\pi\left(\int_0^x \text{BesselJ}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\text{BesselY}\left(0,2\sqrt{x}\right)}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\pi\left(\left(\int_0^x \text{BesselY}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\text{BesselJ}\left(0,2\sqrt{x}\right) - \left(\int_0^x \text{BesselJ}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\text{BesselY}\right.}{2}$$

Therefore the general solution is

$$y = y_h + y_p$$
$$= \left(c_1\,\text{BesselJ}\left(0,2\sqrt{x}\right) + c_2\,\text{BesselY}\left(0,2\sqrt{x}\right)\right) + \left(-\frac{\pi\left(\left(\int_0^x \text{BesselY}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\text{BesselJ}\left(0,2\sqrt{x}\right) - \left(\int_0^x \text{BesselJ}\left(0,2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\text{Be}\right.}{2}\right.$$

Summary

The solution(s) found are the following

$$y = c_1 \,\mathrm{BesselJ}\left(0, 2\sqrt{x}\right) + c_2 \,\mathrm{BesselY}\left(0, 2\sqrt{x}\right) - \frac{\pi\left(\left(\int_0^x \mathrm{BesselY}\left(0, 2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\mathrm{BesselJ}\left(0, 2\sqrt{x}\right) - \left(\int_0^x \mathrm{BesselJ}\left(0, 2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\mathrm{BesselY}\right.}{2} \tag{1}$$

Verification of solutions

$$y = c_1 \,\mathrm{BesselJ}\left(0, 2\sqrt{x}\right) + c_2 \,\mathrm{BesselY}\left(0, 2\sqrt{x}\right) - \frac{\pi\left(\left(\int_0^x \mathrm{BesselY}\left(0, 2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\mathrm{BesselJ}\left(0, 2\sqrt{x}\right) - \left(\int_0^x \mathrm{BesselJ}\left(0, 2\sqrt{\alpha}\right)\sin\left(\sqrt{\alpha}\right)d\alpha\right)\mathrm{BesselY}\right.}{2}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{xy'' - (2+2x)\, y' + (2+x)\, y = 6\,\mathrm{e}^{x} x^{3}}$$

10.15.1 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + (-2x-2)\, y' + (2+x)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -2x-2 \\ C &= 2+x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2$$
$$t = x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 426: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2}{x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -1 - (-1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{1}{x} + (-)(0) \\ &= -\frac{1}{x} \\ &= -\frac{1}{x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int -\frac{1}{x} dx} \\ &= \frac{1}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-2x-2}{x} \, dx} \\ &= z_1 e^{x+\ln(x)} \\ &= z_1 (x \, e^x) \end{aligned}$$

Which simplifies to

$$y_1 = e^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x-2}{x} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{2x+2\ln(x)}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{x^3}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(\mathrm{e}^x) + c_2\left(\mathrm{e}^x\left(\frac{x^3}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
xy'' + (-2x - 2)\, y' + (2 + x)\, y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^x + \frac{c_2 \mathrm{e}^x x^3}{3}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^x \\
y_2 &= \frac{\mathrm{e}^x x^3}{3}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & \frac{e^x x^3}{3} \\ \frac{d}{dx}(e^x) & \frac{d}{dx}\left(\frac{e^x x^3}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & \frac{e^x x^3}{3} \\ e^x & \frac{e^x x^3}{3} + x^2 e^x \end{vmatrix}$$

Therefore

$$W = (e^x)\left(\frac{e^x x^3}{3} + x^2 e^x\right) - \left(\frac{e^x x^3}{3}\right)(e^x)$$

Which simplifies to

$$W = x^2 e^{2x}$$

Which simplifies to

$$W = x^2 e^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2 e^{2x} x^6}{e^{2x} x^3}\, dx$$

Which simplifies to

$$u_1 = -\int 2x^3 dx$$

Hence

$$u_1 = -\frac{x^4}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{6 e^{2x} x^3}{e^{2x} x^3}\, dx$$

Which simplifies to

$$u_2 = \int 6dx$$

Hence

$$u_2 = 6x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{3\,e^x x^4}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^x + \frac{c_2 e^x x^3}{3}\right) + \left(\frac{3\,e^x x^4}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^x\left(c_1 + \frac{c_2 x^3}{3}\right) + \frac{3\,e^x x^4}{2}$$

Summary

The solution(s) found are the following

$$y = e^x\left(c_1 + \frac{c_2 x^3}{3}\right) + \frac{3\,e^x x^4}{2} \tag{1}$$

Verification of solutions

$$y = e^x\left(c_1 + \frac{c_2 x^3}{3}\right) + \frac{3\,e^x x^4}{2}$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.7 Variation of Parameters. Page 262
Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - (2a-1)\,xy' + a^2y = x^{1+a}}$$

10.16.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = (-2a+1)\,x, C = a^2, f(x) = x^{1+a}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + (-2a+1)\,y'x + a^2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2}(-2a+1)\, xrx^{r-1} + a^2x^r = 0$$

Simplifying gives

$$r(r-1)\, x^r(-2a+1)\, r\, x^r + a^2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1)\,(-2a+1)\, r + a^2 = 0$$

Or

$$a^2 - 2ra + r^2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= a \\ r_2 &= a \end{aligned}$$

Since the roots are equal, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^r$ and $y_2 = x^r \ln(x)$. Hence

$$y = c_1x^a + c_2x^a \ln(x)$$

Next, we find the particular solution to the ODE

$$x^2y'' + (-2a+1)\, y'x + a^2y = x^{1+a}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^a \\ y_2 &= x^a \ln(x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^a & x^a \ln(x) \\ \frac{d}{dx}(x^a) & \frac{d}{dx}(x^a \ln(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^a & x^a \ln(x) \\ \frac{x^a a}{x} & \frac{x^a a \ln(x)}{x} + \frac{x^a}{x} \end{vmatrix}$$

Therefore

$$W = (x^a)\left(\frac{x^a a \ln(x)}{x} + \frac{x^a}{x}\right) - (x^a \ln(x))\left(\frac{x^a a}{x}\right)$$

Which simplifies to

$$W = \frac{x^{2a}}{x}$$

Which simplifies to

$$W = x^{2a-1}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^a \ln(x)\, x^{1+a}}{x^2 x^{2a-1}}\, dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\, dx$$

Hence

$$u_1 = -x \ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^a x^{1+a}}{x^2 x^{2a-1}}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-x \ln(x) + x)\, x^a + x\, x^a \ln(x)$$

Which simplifies to

$$y_p(x) = x^{1+a}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= x^a(x + c_1 + c_2 \ln(x)) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x^a(x + c_1 + c_2 \ln(x)) \tag{1}$$

Verification of solutions

$$y = x^a(x + c_1 + c_2 \ln(x))$$

Verified OK.

10.16.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + (-2ax + x)\,y' + a^2y = 0$$

In normal form the ode

$$x^2y'' + (-2ax + x)\,y' + a^2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-2a+1}{x} \\ q(x) &= \frac{a^2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int \frac{-2a+1}{x} dx\right)} dx \\
&= \int e^{(2a-1)\ln(x)} dx \\
&= \int x^{2a-1} dx \\
&= \frac{x^{2a}}{2a}
\end{aligned} \tag{6}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{a^2}{x^2}}{x^{4a-2}} \\
&= a^2 x^{-4a}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + a^2 x^{-4a} y(\tau) &= 0
\end{aligned}
$$

But in terms of τ

$$
a^2 x^{-4a} = \frac{1}{4\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2} y(\tau) + \frac{y(\tau)}{4\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
4\left(\frac{d^2}{d\tau^2} y(\tau)\right)\tau^2 + y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0
$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\left(c_1 + c_2\ln\left(\frac{x^{2a}}{a}\right) - c_2\ln(2)\right)}{2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\left(c_1 + c_2\ln\left(\frac{x^{2a}}{a}\right) - c_2\ln(2)\right)}{2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{\frac{x^{2a}}{a}}$$

$$y_2 = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln\left(\frac{x^{2a}}{a}\right)}{2} - \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln(2)}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{\frac{x^{2a}}{a}} & \frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\ln\left(\frac{x^{2a}}{a}\right)}{2} - \frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\ln(2)}{2} \\ \frac{d}{dx}\left(\sqrt{\frac{x^{2a}}{a}}\right) & \frac{d}{dx}\left(\frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\ln\left(\frac{x^{2a}}{a}\right)}{2} - \frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\ln(2)}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{\frac{x^{2a}}{a}} & \frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\ln\left(\frac{x^{2a}}{a}\right)}{2} - \frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\ln(2)}{2} \\ \frac{x^{2a}}{\sqrt{\frac{x^{2a}}{a}}\,x} & \frac{\sqrt{2}\ln\left(\frac{x^{2a}}{a}\right)x^{2a}}{2\sqrt{\frac{x^{2a}}{a}}\,x} + \frac{\sqrt{2}\sqrt{\frac{x^{2a}}{a}}\,a}{x} - \frac{\sqrt{2}\ln(2)x^{2a}}{2\sqrt{\frac{x^{2a}}{a}}\,x} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{\frac{x^{2a}}{a}}\right)\left(\frac{\sqrt{2}\,\ln\left(\frac{x^{2a}}{a}\right)x^{2a}}{2\sqrt{\frac{x^{2a}}{a}}\,x} + \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,a}{x} - \frac{\sqrt{2}\,\ln(2)\,x^{2a}}{2\sqrt{\frac{x^{2a}}{a}}\,x}\right) - \left(\frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln\left(\frac{x^{2a}}{a}\right)}{2} - \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln(2)}{2}\right)\left(\frac{x^{2a}}{\sqrt{\frac{x^{2a}}{a}}\,x}\right)$$

Which simplifies to

$$W = \frac{\sqrt{2}\, x^{2a}}{x}$$

Which simplifies to

$$W = x^{2a-1}\sqrt{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\left(\frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln\left(\frac{x^{2a}}{a}\right)}{2} - \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln(2)}{2}\right) x^{1+a}}{x^2 x^{2a-1}\sqrt{2}}\, dx$$

Which simplifies to

$$u_1 = -\int -\frac{x^{-a}\sqrt{\frac{x^{2a}}{a}}\left(-\ln\left(\frac{x^{2a}}{a}\right) + \ln(2)\right)}{2} dx$$

Hence

$$u_1 = -\left(\int_0^x -\frac{\alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right) + \ln(2)\right)}{2} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{\frac{x^{2a}}{a}}\, x^{1+a}}{x^2 x^{2a-1}\sqrt{2}}\, dx$$

Which simplifies to

$$u_2 = \int \frac{\sqrt{2}\, x^{-a}\sqrt{\frac{x^{2a}}{a}}}{2} dx$$

Hence

$$u_2 = \frac{\sqrt{2}\, x^{-a}\sqrt{\frac{x^{2a}}{a}}\, x}{2}$$

Which simplifies to

$$u_1 = \frac{\left(\int_0^x \alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right)+\ln(2)\right)d\alpha\right)}{2}$$

$$u_2 = \frac{x^{1-a}\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\int_0^x \alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right)+\ln(2)\right)d\alpha\right)\sqrt{\frac{x^{2a}}{a}}}{2} + \frac{x^{1-a}\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\left(\frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln\left(\frac{x^{2a}}{a}\right)}{2}-\frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\ln(2)}{2}\right)}{2}$$

Which simplifies to

$$y_p(x) = \frac{\left(\int_0^x \alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right)+\ln(2)\right)d\alpha\right)\sqrt{\frac{x^{2a}}{a}}\,a-\left(-\ln\left(\frac{x^{2a}}{a}\right)+\ln(2)\right)x^{1+a}}{2a}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\left(c_1+c_2\ln\left(\frac{x^{2a}}{a}\right)-c_2\ln(2)\right)}{2}\right) \\ &\quad + \left(\frac{\left(\int_0^x \alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right)+\ln(2)\right)d\alpha\right)\sqrt{\frac{x^{2a}}{a}}\,a-\left(-\ln\left(\frac{x^{2a}}{a}\right)+\ln(2)\right)x^{1+a}}{2a}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\left(c_1 + c_2 \ln\left(\frac{x^{2a}}{a}\right) - c_2 \ln(2)\right)}{2} + \frac{\left(\int_0^x \alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right) + \ln(2)\right) d\alpha\right)\sqrt{\frac{x^{2a}}{a}}\, a - \left(-\ln\left(\frac{x^{2a}}{a}\right) + \ln(2)\right) x^{1+a}}{2a} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\,\sqrt{\frac{x^{2a}}{a}}\,\left(c_1 + c_2 \ln\left(\frac{x^{2a}}{a}\right) - c_2 \ln(2)\right)}{2} + \frac{\left(\int_0^x \alpha^{-a}\sqrt{\frac{\alpha^{2a}}{a}}\left(-\ln\left(\frac{\alpha^{2a}}{a}\right) + \ln(2)\right) d\alpha\right)\sqrt{\frac{x^{2a}}{a}}\, a - \left(-\ln\left(\frac{x^{2a}}{a}\right) + \ln(2)\right) x^{1+a}}{2a}$$

Verified OK.

10.16.3 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -2ax + x, C = a^2, f(x) = x^{1+a}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + (-2ax + x)\,y' + a^2y = 0$$

In normal form the ode

$$x^2y'' + (-2ax + x)\,y' + a^2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{-2a+1}{x} \\
q(x) &= \frac{a^2}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} + \frac{n(-2a+1)}{x^2} + \frac{a^2}{x^2} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = a \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \left(\frac{2a}{x} + \frac{-2a+1}{x}\right) v'(x) &= 0 \\
v''(x) + \frac{v'(x)}{x} &= 0 \qquad (7)
\end{aligned}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \frac{u(x)}{x} = 0 \tag{8}
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{u}{x} \end{aligned}$$

Where $f(x) = -\frac{1}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{1}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{1}{x}\,dx \\ \ln(u) &= -\ln(x) + c_1 \\ u &= \mathrm{e}^{-\ln(x)+c_1} \\ &= \frac{c_1}{x} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= c_1 \ln(x) + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= (c_1 \ln(x) + c_2)\,x^a \\ &= (c_1 \ln(x) + c_2)\,x^a \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2 y'' + (-2ax + x)\,y' + a^2 y = x^{1+a}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^a$$
$$y_2 = x^a \ln(x)$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^a & x^a \ln(x) \\ \frac{d}{dx}(x^a) & \frac{d}{dx}(x^a \ln(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^a & x^a \ln(x) \\ \frac{x^a a}{x} & \frac{x^a a \ln(x)}{x} + \frac{x^a}{x} \end{vmatrix}$$

Therefore

$$W = (x^a)\left(\frac{x^a a \ln(x)}{x} + \frac{x^a}{x}\right) - (x^a \ln(x))\left(\frac{x^a a}{x}\right)$$

Which simplifies to

$$W = \frac{x^{2a}}{x}$$

Which simplifies to

$$W = x^{2a-1}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^a \ln(x)\, x^{1+a}}{x^2 x^{2a-1}}\, dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\,dx$$

Hence

$$u_1 = -x\ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^a x^{1+a}}{x^2 x^{2a-1}}\,dx$$

Which simplifies to

$$u_2 = \int 1dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-x\ln(x) + x)\,x^a + x\,x^a\ln(x)$$

Which simplifies to

$$y_p(x) = x^{1+a}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= ((c_1\ln(x) + c_2)\,x^a) + (x^{1+a}) \\ &= x^{1+a} + (c_1\ln(x) + c_2)\,x^a \end{aligned}$$

Which simplifies to

$$y = x^a(x + c_1\ln(x) + c_2)$$

Summary

The solution(s) found are the following

$$y = x^a(x + c_1\ln(x) + c_2) \tag{1}$$

Verification of solutions

$$y = x^a(x + c_1\ln(x) + c_2)$$

Verified OK.

10.16.4 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + (-2ax + x)\,y' + a^2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2ax + x \\ C &= a^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 427: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{1}{4x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = -\frac{1}{4x^2}
$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}$	$\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= \frac{1}{2} - \left(\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{1}{2x} + (-)(0) \\
&= \frac{1}{2x} \\
&= \frac{1}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{2x}\right)(0) + \left(\left(-\frac{1}{2x^2}\right) + \left(\frac{1}{2x}\right)^2 - \left(-\frac{1}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \frac{1}{2x} dx} \\
&= \sqrt{x}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2ax+x}{x^2}\,dx} \\
&= z_1 e^{\frac{(2a-1)\ln(x)}{2}} \\
&= z_1\left(x^{a-\frac{1}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^a
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2ax+x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{(2a-1)\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\ln(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x^a) + c_2(x^a(\ln(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + (-2ax + x)\,y' + a^2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x^a + c_2 x^a \ln(x)$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^a \\ y_2 &= x^a \ln(x) \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^a & x^a \ln(x) \\ \frac{d}{dx}(x^a) & \frac{d}{dx}(x^a \ln(x)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^a & x^a \ln(x) \\ \frac{x^a a}{x} & \frac{x^a a \ln(x)}{x} + \frac{x^a}{x} \end{vmatrix}$$

Therefore

$$W = (x^a) \left(\frac{x^a a \ln(x)}{x} + \frac{x^a}{x} \right) - (x^a \ln(x)) \left(\frac{x^a a}{x} \right)$$

Which simplifies to

$$W = \frac{x^{2a}}{x}$$

Which simplifies to

$$W = x^{2a-1}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^a \ln(x)\, x^{1+a}}{x^2 x^{2a-1}}\, dx$$

Which simplifies to

$$u_1 = -\int \ln(x)\, dx$$

Hence

$$u_1 = -x \ln(x) + x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^a x^{1+a}}{x^2 x^{2a-1}}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-x \ln(x) + x)\, x^a + x\, x^a \ln(x)$$

Which simplifies to

$$y_p(x) = x^{1+a}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= (c_1 x^a + c_2 x^a \ln(x)) + (x^{1+a})
\end{aligned}
$$

Which simplifies to

$$
y = (c_1 + c_2 \ln(x))\, x^a + x^{1+a}
$$

Summary

The solution(s) found are the following

$$
y = (c_1 + c_2 \ln(x))\, x^a + x^{1+a} \tag{1}
$$

Verification of solutions

$$
y = (c_1 + c_2 \ln(x))\, x^a + x^{1+a}
$$

Verified OK.

$$\boxed{x^2y'' - 2y'x + (x^2+2)\,y = x^3\cos(x)}$$

10.17.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 2y'x + (x^2+2)\,y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{x^2+2}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x^2+2}{x^2} - \frac{\left(-\frac{2}{x}\right)'}{2} - \frac{\left(-\frac{2}{x}\right)^2}{4} \\
&= \frac{x^2+2}{x^2} - \frac{\left(\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\
&= \frac{x^2+2}{x^2} - \left(\frac{1}{x^2}\right) - \frac{1}{x^2} \\
&= 1
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2}{x}}{2}} \\
&= x
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v(x) + v''(x) = \cos(x)
$$

Which is now solved for $v(x)$ This is second order non-homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = f(x)
$$

Where $A = 1, B = 0, C = 1, f(x) = \cos(x)$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$v(x) + v''(x) = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$v(x) = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$v(x) = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$v(x) = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\cos(x)$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{\cos(x), \sin(x)\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since $\cos(x)$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$[\{x \cos(x), \sin(x) x\}]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$v_p = A_1 x \cos(x) + A_2 \sin(x) x$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-2A_1 \sin(x) + 2A_2 \cos(x) = \cos(x)$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{2}\right]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = \frac{\sin(x)\, x}{2}$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{\sin(x)\, x}{2}\right) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2}\right)(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x$$

Hence (7) becomes

$$y = \left(c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2}\right) x$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2}\right) x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x \cos(x)$$
$$y_2 = \sin(x) x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x \cos(x) & \sin(x) x \\ \frac{d}{dx}(x \cos(x)) & \frac{d}{dx}(\sin(x) x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x \cos(x) & \sin(x) x \\ \cos(x) - \sin(x) x & x \cos(x) + \sin(x) \end{vmatrix}$$

Therefore

$$W = (x \cos(x)) (x \cos(x) + \sin(x)) - (\sin(x) x) (\cos(x) - \sin(x) x)$$

Which simplifies to

$$W = \cos(x)^2 x^2 + x^2 \sin(x)^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x) x^4 \cos(x)}{x^4} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x)}{2} dx$$

Hence

$$u_1 = \frac{\cos(2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4 \cos(x)^2}{x^4} dx$$

Which simplifies to

$$u_2 = \int \cos(x)^2 \, dx$$

Hence

$$u_2 = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2}$$

Which simplifies to

$$u_1 = \frac{\cos(2x)}{4}$$
$$u_2 = \frac{\sin(2x)}{4} + \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(2x)\, x \cos(x)}{4} + \left(\frac{\sin(2x)}{4} + \frac{x}{2}\right) \sin(x)\, x$$

Which simplifies to

$$y_p(x) = \frac{\sin(x)\, x^2}{2} + \frac{x \cos(x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2}\right) x\right) + \left(\frac{\sin(x)\, x^2}{2} + \frac{x \cos(x)}{4}\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \left(c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2}\right) x + \frac{\sin(x)\, x^2}{2} + \frac{x\cos(x)}{4} \tag{1}$$

Verification of solutions

$$y = \left(c_1 \cos(x) + c_2 \sin(x) + \frac{\sin(x)\, x}{2}\right) x + \frac{\sin(x)\, x^2}{2} + \frac{x\cos(x)}{4}$$

Verified OK.

10.17.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' - 2y'x + (x^2 + 2)\, y = x^3 \cos(x) \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2 y'' + y'x + (-n^2 + x^2)\, y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, xy' + (\beta^2\gamma^2 x^{2\gamma} - n^2\gamma^2 + \alpha^2)\, y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{3}{2}$$
$$\beta = 1$$
$$n = -\frac{1}{2}$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x \sqrt{2}\, \cos(x)}{\sqrt{\pi}} + \frac{c_2 x \sqrt{2}\, \sin(x)}{\sqrt{\pi}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 x \sqrt{2}\, \cos(x)}{\sqrt{\pi}} + \frac{c_2 x \sqrt{2}\, \sin(x)}{\sqrt{\pi}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x \cos(x)$$
$$y_2 = \sin(x)\, x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x \cos(x) & \sin(x)\, x \\ \frac{d}{dx}(x \cos(x)) & \frac{d}{dx}(\sin(x)\, x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\cos(x) & \sin(x)\, x \\ \cos(x) - \sin(x)\, x & x\cos(x) + \sin(x) \end{vmatrix}$$

Therefore

$$W = (x\cos(x))\,(x\cos(x) + \sin(x)) - (\sin(x)\, x)\,(\cos(x) - \sin(x)\, x)$$

Which simplifies to

$$W = \cos(x)^2\, x^2 + x^2 \sin(x)^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\, x^4 \cos(x)}{x^4}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x)}{2} dx$$

Hence

$$u_1 = \frac{\cos(2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4 \cos(x)^2}{x^4}\, dx$$

Which simplifies to

$$u_2 = \int \cos(x)^2\, dx$$

Hence

$$u_2 = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2}$$

Which simplifies to

$$u_1 = \frac{\cos(2x)}{4}$$
$$u_2 = \frac{\sin(2x)}{4} + \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(2x)\, x \cos(x)}{4} + \left(\frac{\sin(2x)}{4} + \frac{x}{2}\right)\sin(x)\, x$$

Which simplifies to

$$y_p(x) = \frac{\sin(x)\, x^2}{2} + \frac{x\cos(x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2 x\sqrt{2}\,\sin(x)}{\sqrt{\pi}}\right) + \left(\frac{\sin(x)\, x^2}{2} + \frac{x\cos(x)}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2 x\sqrt{2}\,\sin(x)}{\sqrt{\pi}} + \frac{\sin(x)\, x^2}{2} + \frac{x\cos(x)}{4} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2 x\sqrt{2}\,\sin(x)}{\sqrt{\pi}} + \frac{\sin(x)\, x^2}{2} + \frac{x\cos(x)}{4}$$

Verified OK.

10.17.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2y'x + (x^2 + 2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 428: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \cos(x)
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{\ln(x)} \\
&= z_1(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x \cos(x)) + c_2(x \cos(x)(\tan(x)))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 2y'x + (x^2 + 2)\, y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 x \cos(x) + c_2 \sin(x)\, x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x\cos(x)$$
$$y_2 = \sin(x)\,x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\cos(x) & \sin(x)\,x \\ \frac{d}{dx}(x\cos(x)) & \frac{d}{dx}(\sin(x)\,x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\cos(x) & \sin(x)\,x \\ \cos(x) - \sin(x)\,x & x\cos(x) + \sin(x) \end{vmatrix}$$

Therefore

$$W = (x\cos(x))\,(x\cos(x) + \sin(x)) - (\sin(x)\,x)\,(\cos(x) - \sin(x)\,x)$$

Which simplifies to

$$W = \cos(x)^2\,x^2 + x^2\sin(x)^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\, x^4 \cos(x)}{x^4} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(2x)}{2} dx$$

Hence

$$u_1 = \frac{\cos(2x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4 \cos(x)^2}{x^4} dx$$

Which simplifies to

$$u_2 = \int \cos(x)^2 \, dx$$

Hence

$$u_2 = \frac{\cos(x)\sin(x)}{2} + \frac{x}{2}$$

Which simplifies to

$$u_1 = \frac{\cos(2x)}{4}$$
$$u_2 = \frac{\sin(2x)}{4} + \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\cos(2x)\, x \cos(x)}{4} + \left(\frac{\sin(2x)}{4} + \frac{x}{2}\right) \sin(x)\, x$$

Which simplifies to

$$y_p(x) = \frac{\sin(x)\,x^2}{2} + \frac{x\cos(x)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 x\cos(x) + c_2\sin(x)\,x) + \left(\frac{\sin(x)\,x^2}{2} + \frac{x\cos(x)}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x\cos(x) + c_2\sin(x)\,x + \frac{\sin(x)\,x^2}{2} + \frac{x\cos(x)}{4} \tag{1}$$

Verification of solutions

$$y = c_1 x\cos(x) + c_2\sin(x)\,x + \frac{\sin(x)\,x^2}{2} + \frac{x\cos(x)}{4}$$

Verified OK.

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{xy'' - y' - 4yx^3 = 8x^5}$$

10.18.1 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$xy'' - y' - 4yx^3 = 0$$

In normal form the ode

$$xy'' - y' - 4yx^3 = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= -4x^2 \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\, \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\ &= \int \mathrm{e}^{-\left(\int -\frac{1}{x}dx\right)} dx \\ &= \int e^{\ln(x)}\, dx \\ &= \int x dx \\ &= \frac{x^2}{2} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned} q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{-4x^2}{x^2} \\ &= -4 \end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) - 4y(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -4$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau} - 4\,\mathrm{e}^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-4)}\\ &= \pm 2\end{aligned}$$

Hence

$$\lambda_1 = +2$$
$$\lambda_2 = -2$$

Which simplifies to

$$\lambda_1 = 2$$
$$\lambda_2 = -2$$

Since roots are real and distinct, then the solution is

$$y(\tau) = c_1 e^{\lambda_1\tau} + c_2 e^{\lambda_2\tau}$$
$$y(\tau) = c_1 e^{(2)\tau} + c_2 e^{(-2)\tau}$$

Or

$$y(\tau) = c_1 e^{2\tau} + c_2 e^{-2\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 e^{x^2} + c_2 e^{-x^2}$$

Therefore the homogeneous solution y_h is

$$y_h = c_1 e^{x^2} + c_2 e^{-x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-x^2}$$
$$y_2 = e^{x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x^2} & e^{x^2} \\ \frac{d}{dx}\left(e^{-x^2}\right) & \frac{d}{dx}\left(e^{x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x^2} & e^{x^2} \\ -2x\,e^{-x^2} & 2\,e^{x^2}x \end{vmatrix}$$

Therefore

$$W = \left(e^{-x^2}\right)\left(2\,e^{x^2}x\right) - \left(e^{x^2}\right)\left(-2x\,e^{-x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{8\,e^{x^2}x^5}{4x^2}\,dx$$

Which simplifies to

$$u_1 = -\int 2\,e^{x^2}x^3 dx$$

Hence

$$u_1 = -\left(x^2 - 1\right)e^{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,e^{-x^2}x^5}{4x^2}\,dx$$

Which simplifies to

$$u_2 = \int 2x^3 e^{-x^2} dx$$

Hence

$$u_2 = -\left(x^2 + 1\right)e^{-x^2}$$

Which simplifies to

$$u_1 = \left(-x^2+1\right) e^{x^2}$$
$$u_2 = -\left(x^2+1\right) e^{-x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^2+1-\left(x^2+1\right) e^{-x^2} e^{x^2}$$

Which simplifies to

$$y_p(x) = -2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{x^2} + c_2 e^{-x^2}\right) + \left(-2x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{x^2} + c_2 e^{-x^2} - 2x^2 \tag{1}$$

Verification of solutions

$$y = c_1 e^{x^2} + c_2 e^{-x^2} - 2x^2$$

Verified OK.

10.18.2 Solving as second order change of variable on x method 1 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x, B = -1, C = -4x^3, f(x) = 8x^5$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$xy'' - y' - 4yx^3 = 0$$

In normal form the ode

$$xy'' - y' - 4yx^3 = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= -4x^2 \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{2\sqrt{-x^2}}{c} \\ \tau'' &= -\frac{2x}{c\sqrt{-x^2}} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{2x}{c\sqrt{-x^2}} - \frac{1}{x}\frac{2\sqrt{-x^2}}{c}}{\left(\frac{2\sqrt{-x^2}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c} \sqrt{q}\, dx \\
&= \frac{\int 2\sqrt{-x^2} dx}{c} \\
&= \frac{x\sqrt{-x^2}}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 \cosh\left(x^2\right) + i c_2 \sinh\left(x^2\right)
$$

Now the particular solution to this ODE is found

$$
x y'' - y' - 4 y x^3 = 8x^5
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{-x^2} \\
y_2 &= \mathrm{e}^{x^2}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x^2} & e^{x^2} \\ \frac{d}{dx}\left(e^{-x^2}\right) & \frac{d}{dx}\left(e^{x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x^2} & e^{x^2} \\ -2x\,e^{-x^2} & 2\,e^{x^2} x \end{vmatrix}$$

Therefore

$$W = \left(e^{-x^2}\right)\left(2\,e^{x^2} x\right) - \left(e^{x^2}\right)\left(-2x\,e^{-x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{8\,e^{x^2} x^5}{4x^2}\,dx$$

Which simplifies to

$$u_1 = -\int 2\,e^{x^2} x^3 dx$$

Hence

$$u_1 = -\left(x^2 - 1\right) e^{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,\mathrm{e}^{-x^2} x^5}{4x^2}\, dx$$

Which simplifies to

$$u_2 = \int 2x^3 \mathrm{e}^{-x^2} dx$$

Hence

$$u_2 = -\left(x^2+1\right)\mathrm{e}^{-x^2}$$

Which simplifies to

$$u_1 = \left(-x^2+1\right)\mathrm{e}^{x^2}$$
$$u_2 = -\left(x^2+1\right)\mathrm{e}^{-x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^2 + 1 - \left(x^2+1\right)\mathrm{e}^{-x^2}\mathrm{e}^{x^2}$$

Which simplifies to

$$y_p(x) = -2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 \cosh\left(x^2\right) + i c_2 \sinh\left(x^2\right)\right) + \left(-2x^2\right) \\ &= -2x^2 + c_1 \cosh\left(x^2\right) + i c_2 \sinh\left(x^2\right) \end{aligned}$$

Which simplifies to

$$y = -2x^2 + c_1 \cosh\left(x^2\right) + i c_2 \sinh\left(x^2\right)$$

Summary

The solution(s) found are the following

$$y = -2x^2 + c_1 \cosh\left(x^2\right) + i c_2 \sinh\left(x^2\right) \tag{1}$$

Verification of solutions

$$y = -2x^2 + c_1 \cosh\left(x^2\right) + i c_2 \sinh\left(x^2\right)$$

Verified OK.

10.18.3 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - y'x - 4yx^4 = 8x^6 \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2)\, y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\, xy' + (\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2)\, y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned} \alpha &= 1 \\ \beta &= i \\ n &= \frac{1}{2} \\ \gamma &= 2 \end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{ic_1x\sqrt{2}\, \sinh(x^2)}{\sqrt{\pi}\, \sqrt{ix^2}} - \frac{c_2x\sqrt{2}\, \cosh(x^2)}{\sqrt{\pi}\, \sqrt{ix^2}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{ic_1x\sqrt{2}\, \sinh(x^2)}{\sqrt{\pi}\, \sqrt{ix^2}} - \frac{c_2x\sqrt{2}\, \cosh(x^2)}{\sqrt{\pi}\, \sqrt{ix^2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \mathrm{e}^{-x^2}$$
$$y_2 = \mathrm{e}^{x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \mathrm{e}^{-x^2} & \mathrm{e}^{x^2} \\ \frac{d}{dx}\left(\mathrm{e}^{-x^2}\right) & \frac{d}{dx}\left(\mathrm{e}^{x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \mathrm{e}^{-x^2} & \mathrm{e}^{x^2} \\ -2x\,\mathrm{e}^{-x^2} & 2\,\mathrm{e}^{x^2} x \end{vmatrix}$$

Therefore

$$W = \left(\mathrm{e}^{-x^2}\right)\left(2\,\mathrm{e}^{x^2} x\right) - \left(\mathrm{e}^{x^2}\right)\left(-2x\,\mathrm{e}^{-x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{8\,\mathrm{e}^{x^2} x^6}{4x^3}\,dx$$

Which simplifies to

$$u_1 = -\int 2\,\mathrm{e}^{x^2} x^3 dx$$

Hence

$$u_1 = -\left(x^2 - 1\right) \mathrm{e}^{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,\mathrm{e}^{-x^2} x^6}{4x^3}\,dx$$

Which simplifies to

$$u_2 = \int 2x^3 \mathrm{e}^{-x^2} dx$$

Hence

$$u_2 = -\left(x^2 + 1\right) \mathrm{e}^{-x^2}$$

Which simplifies to

$$u_1 = \left(-x^2 + 1\right) \mathrm{e}^{x^2}$$
$$u_2 = -\left(x^2 + 1\right) \mathrm{e}^{-x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -x^2 + 1 - \left(x^2 + 1\right) \mathrm{e}^{-x^2} \mathrm{e}^{x^2}$$

Which simplifies to

$$y_p(x) = -2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{i c_1 x \sqrt{2}\, \sinh\left(x^2\right)}{\sqrt{\pi}\, \sqrt{i x^2}} - \frac{c_2 x \sqrt{2}\, \cosh\left(x^2\right)}{\sqrt{\pi}\, \sqrt{i x^2}}\right) + \left(-2x^2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = \frac{i c_1 x \sqrt{2}\, \sinh(x^2)}{\sqrt{\pi}\, \sqrt{i x^2}} - \frac{c_2 x \sqrt{2}\, \cosh(x^2)}{\sqrt{\pi}\, \sqrt{i x^2}} - 2x^2 \tag{1}$$

Verification of solutions

$$y = \frac{i c_1 x \sqrt{2}\, \sinh(x^2)}{\sqrt{\pi}\, \sqrt{i x^2}} - \frac{c_2 x \sqrt{2}\, \cosh(x^2)}{\sqrt{\pi}\, \sqrt{i x^2}} - 2x^2$$

Verified OK.

10.18.4 Solving using Kovacic algorithm

Writing the ode as

$$xy'' - y' - 4yx^3 = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -1 \\ C &= -4x^3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{16x^4 + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 16x^4 + 3$$
$$t = 4x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{16x^4 + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 429: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = 4x^2 + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx 2x + \frac{3}{16x^3} - \frac{9}{1024x^7} + \frac{27}{32768x^{11}} - \frac{405}{4194304x^{15}} + \frac{1701}{134217728x^{19}} - \frac{15309}{8589934592x^{23}} + \frac{72171}{274877906944x^{27}} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = 2$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= 2x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = 4x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{16x^4 + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= (4x^2) + \left(\frac{3}{4x^2}\right) \\ &= 4x^2 + \frac{3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 2x \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{0}{2} - 1\right) = -\frac{1}{2} \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{0}{2} - 1\right) = -\frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{16x^4 + 3}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$2x$	$-\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{2x} + (-)(2x) \\
&= -\frac{1}{2x} - 2x \\
&= -\frac{1}{2x} - 2x
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2x} - 2x\right)(0) + \left(\left(\frac{1}{2x^2} - 2\right) + \left(-\frac{1}{2x} - 2x\right)^2 - \left(\frac{16x^4 + 3}{4x^2}\right)\right) = 0$$

$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{1}{2x} - 2x\right) dx} \\ &= \frac{e^{-x^2}}{\sqrt{x}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{-1}{x} \, dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1 \left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-1}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{e^{2x^2}}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{-x^2}\right) + c_2 \left(e^{-x^2} \left(\frac{e^{2x^2}}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
xy'' - y' - 4yx^3 = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 e^{-x^2} + \frac{c_2 e^{x^2}}{4}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = e^{-x^2}$$

$$y_2 = \frac{e^{x^2}}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{-x^2} & \frac{e^{x^2}}{4} \\ \frac{d}{dx}\left(e^{-x^2}\right) & \frac{d}{dx}\left(\frac{e^{x^2}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-x^2} & \frac{e^{x^2}}{4} \\ -2x\,e^{-x^2} & \frac{e^{x^2}x}{2} \end{vmatrix}$$

Therefore

$$W = \left(e^{-x^2}\right)\left(\frac{e^{x^2}x}{2}\right) - \left(\frac{e^{x^2}}{4}\right)\left(-2x\,e^{-x^2}\right)$$

Which simplifies to

$$W = e^{-x^2} e^{x^2} x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\,\mathrm{e}^{x^2} x^5}{x^2}\,dx$$

Which simplifies to

$$u_1 = -\int 2\,\mathrm{e}^{x^2} x^3 dx$$

Hence

$$u_1 = -\left(x^2-1\right)\mathrm{e}^{x^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,\mathrm{e}^{-x^2} x^5}{x^2}\,dx$$

Which simplifies to

$$u_2 = \int 8x^3 \mathrm{e}^{-x^2} dx$$

Hence

$$u_2 = -4\left(x^2+1\right)\mathrm{e}^{-x^2}$$

Which simplifies to

$$u_1 = \left(-x^2+1\right)\mathrm{e}^{x^2}$$
$$u_2 = -4\left(x^2+1\right)\mathrm{e}^{-x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-x^2+1\right)\mathrm{e}^{x^2}\mathrm{e}^{-x^2} - \left(x^2+1\right)\mathrm{e}^{-x^2}\mathrm{e}^{x^2}$$

Which simplifies to

$$y_p(x) = -2x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1\mathrm{e}^{-x^2} + \frac{c_2\mathrm{e}^{x^2}}{4}\right) + \left(-2x^2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-x^2} + \frac{c_2 e^{x^2}}{4} - 2x^2 \tag{1}$$

Verification of solutions

$$y = c_1 e^{-x^2} + \frac{c_2 e^{x^2}}{4} - 2x^2$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 5 linear second order equations. Section 5.7 Variation of Parameters. Page 262
Problem number: 20.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{4x^2y'' - 4y'x + (-16x^2 + 3)\, y = 8x^{\frac{5}{2}}}$$

10.20.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$4x^2y'' - 4y'x + (-16x^2 + 3)\, y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{-16x^2+3}{4x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{-16x^2+3}{4x^2} - \frac{\left(-\frac{1}{x}\right)'}{2} - \frac{\left(-\frac{1}{x}\right)^2}{4} \\
&= \frac{-16x^2+3}{4x^2} - \frac{\left(\frac{1}{x^2}\right)}{2} - \frac{\left(\frac{1}{x^2}\right)}{4} \\
&= \frac{-16x^2+3}{4x^2} - \left(\frac{1}{2x^2}\right) - \frac{1}{4x^2} \\
&= -4
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{1}{x}}{2}} \\
&= \sqrt{x}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\sqrt{x} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v''(x) - 4v(x) = 2
$$

Which is now solved for $v(x)$ This is second order non-homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = f(x)
$$

Where $A = 1, B = 0, C = -4, f(x) = 2$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$v''(x) - 4v(x) = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = -4$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - 4\,\mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(-4)}\\ &= \pm 2\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +2\\ \lambda_2 &= -2\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 2\\ \lambda_2 &= -2\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ v(x) &= c_1 e^{(2)x} + c_2 e^{(-2)x}\end{aligned}$$

Or

$$v(x) = c_1 e^{2x} + c_2 e^{-2x}$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 e^{2x} + c_2 e^{-2x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{-2x}, e^{2x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$v_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-4A_1 = 2$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = -\frac{1}{2}\right]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = -\frac{1}{2}$$

Therefore the general solution is

$$
\begin{aligned}
v &= v_h + v_p \\
&= \left(c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x}\right) + \left(-\frac{1}{2}\right)
\end{aligned}
$$

Now that $v(x)$ is known, then

$$
\begin{aligned}
y &= v(x)\, z(x) \\
&= \left(c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x} - \frac{1}{2}\right) (z(x))
\end{aligned}
\tag{7}
$$

But from (5)

$$
z(x) = \sqrt{x}
$$

Hence (7) becomes

$$
y = \left(c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x} - \frac{1}{2}\right) \sqrt{x}
$$

Therefore the homogeneous solution y_h is

$$
y_h = \left(c_1 \mathrm{e}^{2x} + c_2 \mathrm{e}^{-2x} - \frac{1}{2}\right) \sqrt{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^{2x} \sqrt{x} \\
y_2 &= \mathrm{e}^{-2x} \sqrt{x}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x}\sqrt{x} & e^{-2x}\sqrt{x} \\ \frac{d}{dx}\left(e^{2x}\sqrt{x}\right) & \frac{d}{dx}\left(e^{-2x}\sqrt{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x}\sqrt{x} & e^{-2x}\sqrt{x} \\ 2\,e^{2x}\sqrt{x} + \frac{e^{2x}}{2\sqrt{x}} & -2\,e^{-2x}\sqrt{x} + \frac{e^{-2x}}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\sqrt{x}\right)\left(-2\,e^{-2x}\sqrt{x} + \frac{e^{-2x}}{2\sqrt{x}}\right) - \left(e^{-2x}\sqrt{x}\right)\left(2\,e^{2x}\sqrt{x} + \frac{e^{2x}}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = -4\,e^{2x} x\,e^{-2x}$$

Which simplifies to

$$W = -4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{8\,e^{-2x} x^3}{-16x^3}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{e^{-2x}}{2}dx$$

Hence

$$u_1 = -\frac{e^{-2x}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,e^{2x} x^3}{-16x^3}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{e^{2x}}{2} dx$$

Hence

$$u_2 = -\frac{e^{2x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{e^{-2x} e^{2x} \sqrt{x}}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\sqrt{x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 e^{2x} + c_2 e^{-2x} - \frac{1}{2}\right)\sqrt{x}\right) + \left(-\frac{\sqrt{x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(c_1 e^{2x} + c_2 e^{-2x} - \frac{1}{2}\right)\sqrt{x} - \frac{\sqrt{x}}{2} \tag{1}$$

Verification of solutions

$$y = \left(c_1 e^{2x} + c_2 e^{-2x} - \frac{1}{2}\right)\sqrt{x} - \frac{\sqrt{x}}{2}$$

Verified OK.

10.20.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - y'x + \left(-4x^2 + \frac{3}{4}\right)y = 2x^{\frac{5}{2}} \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2)\,y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1\,\mathrm{BesselJ}\,(n, \beta\, x^{\gamma}) + c_2\,\mathrm{BesselY}\,(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= 1\\
\beta &= 2i\\
n &= -\frac{1}{2}\\
\gamma &= 1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1x\cosh(2x)}{\sqrt{\pi}\,\sqrt{ix}} + \frac{ic_2x\sinh(2x)}{\sqrt{\pi}\,\sqrt{ix}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1x\cosh(2x)}{\sqrt{\pi}\,\sqrt{ix}} + \frac{ic_2x\sinh(2x)}{\sqrt{\pi}\,\sqrt{ix}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= e^{2x}\sqrt{x} \\ y_2 &= e^{-2x}\sqrt{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x}\sqrt{x} & e^{-2x}\sqrt{x} \\ \frac{d}{dx}\left(e^{2x}\sqrt{x}\right) & \frac{d}{dx}\left(e^{-2x}\sqrt{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x}\sqrt{x} & e^{-2x}\sqrt{x} \\ 2\,e^{2x}\sqrt{x} + \frac{e^{2x}}{2\sqrt{x}} & -2\,e^{-2x}\sqrt{x} + \frac{e^{-2x}}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\sqrt{x}\right)\left(-2\,e^{-2x}\sqrt{x} + \frac{e^{-2x}}{2\sqrt{x}}\right) - \left(e^{-2x}\sqrt{x}\right)\left(2\,e^{2x}\sqrt{x} + \frac{e^{2x}}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = -4\,e^{2x} x\,e^{-2x}$$

Which simplifies to

$$W = -4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\,\mathrm{e}^{-2x} x^3}{-4x^3}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{\mathrm{e}^{-2x}}{2} dx$$

Hence

$$u_1 = -\frac{\mathrm{e}^{-2x}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\,\mathrm{e}^{2x} x^3}{-4x^3}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\mathrm{e}^{2x}}{2} dx$$

Hence

$$u_2 = -\frac{\mathrm{e}^{2x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\mathrm{e}^{-2x}\mathrm{e}^{2x}\sqrt{x}}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\sqrt{x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x \cosh(2x)}{\sqrt{\pi}\,\sqrt{ix}} + \frac{i c_2 x \sinh(2x)}{\sqrt{\pi}\,\sqrt{ix}}\right) + \left(-\frac{\sqrt{x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x \cosh(2x)}{\sqrt{\pi}\,\sqrt{ix}} + \frac{i c_2 x \sinh(2x)}{\sqrt{\pi}\,\sqrt{ix}} - \frac{\sqrt{x}}{2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x \cosh(2x)}{\sqrt{\pi}\,\sqrt{ix}} + \frac{i c_2 x \sinh(2x)}{\sqrt{\pi}\,\sqrt{ix}} - \frac{\sqrt{x}}{2}$$

Verified OK.

10.20.3 Solving using Kovacic algorithm

Writing the ode as

$$4x^2 y'' - 4y'x + (-16x^2 + 3)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x \\ C &= -16x^2 + 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 4z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 430: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 4$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-2x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\ &= z_1 e^{\frac{\ln(x)}{2}} \\ &= z_1\left(\sqrt{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-2x}\sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\ &= y_1\left(\frac{\mathrm{e}^{4x}}{4}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-2x}\sqrt{x}\right) + c_2\left(\mathrm{e}^{-2x}\sqrt{x}\left(\frac{\mathrm{e}^{4x}}{4}\right)\right) \end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$4x^2y''-4y'x+\left(-16x^2+3\right)y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 \mathrm{e}^{-2x}\sqrt{x}+\frac{c_2 \mathrm{e}^{2x}\sqrt{x}}{4}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \mathrm{e}^{-2x}\sqrt{x} \\ y_2 &= \frac{\mathrm{e}^{2x}\sqrt{x}}{4} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W=\begin{vmatrix} \mathrm{e}^{-2x}\sqrt{x} & \frac{\mathrm{e}^{2x}\sqrt{x}}{4} \\ \frac{d}{dx}\left(\mathrm{e}^{-2x}\sqrt{x}\right) & \frac{d}{dx}\left(\frac{\mathrm{e}^{2x}\sqrt{x}}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{-2x}\sqrt{x} & \frac{e^{2x}\sqrt{x}}{4} \\ -2\,e^{-2x}\sqrt{x}+\frac{e^{-2x}}{2\sqrt{x}} & \frac{e^{2x}\sqrt{x}}{2}+\frac{e^{2x}}{8\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(e^{-2x}\sqrt{x}\right)\left(\frac{e^{2x}\sqrt{x}}{2}+\frac{e^{2x}}{8\sqrt{x}}\right)-\left(\frac{e^{2x}\sqrt{x}}{4}\right)\left(-2\,e^{-2x}\sqrt{x}+\frac{e^{-2x}}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = e^{2x}x\,e^{-2x}$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\,e^{2x}x^3}{4x^3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{2x}}{2}dx$$

Hence

$$u_1 = -\frac{e^{2x}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{8\,e^{-2x}x^3}{4x^3}\,dx$$

Which simplifies to

$$u_2 = \int 2\,e^{-2x}dx$$

Hence

$$u_2 = -e^{-2x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{e^{-2x} e^{2x} \sqrt{x}}{2}$$

Which simplifies to

$$y_p(x) = -\frac{\sqrt{x}}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 e^{-2x} \sqrt{x} + \frac{c_2 e^{2x} \sqrt{x}}{4}\right) + \left(-\frac{\sqrt{x}}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-2x} \sqrt{x} + \frac{c_2 e^{2x} \sqrt{x}}{4} - \frac{\sqrt{x}}{2} \tag{1}$$

Verification of solutions

$$y = c_1 e^{-2x} \sqrt{x} + \frac{c_2 e^{2x} \sqrt{x}}{4} - \frac{\sqrt{x}}{2}$$

Verified OK.

$$\boxed{4x^2y'' - 4y'x + (4x^2 + 3)\, y = x^{\frac{7}{2}}}$$

10.21.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$4x^2y'' - 4y'x + (4x^2 + 3)\, y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= \frac{4x^2+3}{4x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{4x^2+3}{4x^2} - \frac{\left(-\frac{1}{x}\right)'}{2} - \frac{\left(-\frac{1}{x}\right)^2}{4} \\
&= \frac{4x^2+3}{4x^2} - \frac{\left(\frac{1}{x^2}\right)}{2} - \frac{\left(\frac{1}{x^2}\right)}{4} \\
&= \frac{4x^2+3}{4x^2} - \left(\frac{1}{2x^2}\right) - \frac{1}{4x^2} \\
&= 1
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2}dx\right)} \\
&= e^{-\int \frac{-\frac{1}{x}}{2}} \\
&= \sqrt{x}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\sqrt{x} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
4v''(x) + 4v(x) = x
$$

Which is now solved for $v(x)$ This is second order non-homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = f(x)
$$

Where $A = 4, B = 0, C = 4, f(x) = x$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$4v''(x) + 4v(x) = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 4, B = 0, C = 4$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 e^{\lambda x} + 4\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$4\lambda^2 + 4 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 0, C = 4$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{0^2 - (4)(4)(4)} \\ &= \pm i\end{aligned}$$

Hence

$$\lambda_1 = +i$$
$$\lambda_2 = -i$$

Which simplifies to

$$\lambda_1 = i$$
$$\lambda_2 = -i$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$v(x) = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$v(x) = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$v(x) = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$v_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$4A_2 x + 4A_1 = x$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = 0, A_2 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = \frac{x}{4}$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + \left(\frac{x}{4}\right) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 \cos(x) + c_2 \sin(x) + \frac{x}{4}\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \sqrt{x}$$

Hence (7) becomes

$$y = \left(c_1 \cos(x) + c_2 \sin(x) + \frac{x}{4}\right) \sqrt{x}$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 \cos(x) + c_2 \sin(x) + \frac{x}{4}\right) \sqrt{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \cos(x) \sqrt{x} \\ y_2 &= \sin(x) \sqrt{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\sqrt{x} & \sin(x)\sqrt{x} \\ \frac{d}{dx}\left(\cos(x)\sqrt{x}\right) & \frac{d}{dx}\left(\sin(x)\sqrt{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\sqrt{x} & \sin(x)\sqrt{x} \\ -\sin(x)\sqrt{x} + \frac{\cos(x)}{2\sqrt{x}} & \cos(x)\sqrt{x} + \frac{\sin(x)}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\cos(x)\sqrt{x}\right)\left(\cos(x)\sqrt{x} + \frac{\sin(x)}{2\sqrt{x}}\right) - \left(\sin(x)\sqrt{x}\right)\left(-\sin(x)\sqrt{x} + \frac{\cos(x)}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x\left(\cos(x)^2 + \sin(x)^2\right)$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\, x^4}{4x^3}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)\, x}{4} dx$$

Hence

$$u_1 = -\frac{\sin(x)}{4} + \frac{x\cos(x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4 \cos(x)}{4x^3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x\cos(x)}{4}dx$$

Hence

$$u_2 = \frac{\cos(x)}{4} + \frac{\sin(x)\,x}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\sin(x)}{4} + \frac{x\cos(x)}{4}\right)\cos(x)\sqrt{x} + \left(\frac{\cos(x)}{4} + \frac{\sin(x)\,x}{4}\right)\sin(x)\sqrt{x}$$

Which simplifies to

$$y_p(x) = \frac{x^{\frac{3}{2}}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1\cos(x) + c_2\sin(x) + \frac{x}{4}\right)\sqrt{x}\right) + \left(\frac{x^{\frac{3}{2}}}{4}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(c_1\cos(x) + c_2\sin(x) + \frac{x}{4}\right)\sqrt{x} + \frac{x^{\frac{3}{2}}}{4} \tag{1}$$

Verification of solutions

$$y = \left(c_1\cos(x) + c_2\sin(x) + \frac{x}{4}\right)\sqrt{x} + \frac{x^{\frac{3}{2}}}{4}$$

Verified OK.

10.21.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - y'x + \left(x^2 + \frac{3}{4}\right)y = \frac{x^{\frac{7}{2}}}{4} \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= 1\\ \beta &= 1\\ n &= -\frac{1}{2}\\ \gamma &= 1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sin(x)}{\sqrt{\pi}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1\sqrt{x}\,\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sin(x)}{\sqrt{\pi}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)\sqrt{x}$$
$$y_2 = \sin(x)\sqrt{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\sqrt{x} & \sin(x)\sqrt{x} \\ \frac{d}{dx}\left(\cos(x)\sqrt{x}\right) & \frac{d}{dx}\left(\sin(x)\sqrt{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\sqrt{x} & \sin(x)\sqrt{x} \\ -\sin(x)\sqrt{x} + \frac{\cos(x)}{2\sqrt{x}} & \cos(x)\sqrt{x} + \frac{\sin(x)}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\cos(x)\sqrt{x}\right)\left(\cos(x)\sqrt{x} + \frac{\sin(x)}{2\sqrt{x}}\right) - \left(\sin(x)\sqrt{x}\right)\left(-\sin(x)\sqrt{x} + \frac{\cos(x)}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x\left(\cos(x)^2 + \sin(x)^2\right)$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{\sin(x)x^4}{4}}{x^3} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)\, x}{4} dx$$

Hence

$$u_1 = -\frac{\sin(x)}{4} + \frac{x\cos(x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{x^4\cos(x)}{4}}{x^3} dx$$

Which simplifies to

$$u_2 = \int \frac{x\cos(x)}{4} dx$$

Hence

$$u_2 = \frac{\cos(x)}{4} + \frac{\sin(x)\, x}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\sin(x)}{4} + \frac{x\cos(x)}{4}\right)\cos(x)\sqrt{x} + \left(\frac{\cos(x)}{4} + \frac{\sin(x)\, x}{4}\right)\sin(x)\sqrt{x}$$

Which simplifies to

$$y_p(x) = \frac{x^{\frac{3}{2}}}{4}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1\sqrt{x}\,\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sin(x)}{\sqrt{\pi}}\right) + \left(\frac{x^{\frac{3}{2}}}{4}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sin(x)}{\sqrt{\pi}} + \frac{x^{\frac{3}{2}}}{4} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sin(x)}{\sqrt{\pi}} + \frac{x^{\frac{3}{2}}}{4}
$$

Verified OK.

10.21.3 Solving using Kovacic algorithm

Writing the ode as

$$
4x^2y'' - 4y'x + (4x^2+3)\,y = 0 \tag{1}
$$
$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 4x^2 \\
B &= -4x \\
C &= 4x^2 + 3
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x) = rz(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 431: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{4x^2}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \cos(x)\sqrt{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{4x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\cos(x)\sqrt{x}\right) + c_2\left(\cos(x)\sqrt{x}(\tan(x))\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$4x^2y'' - 4y'x + (4x^2 + 3)\, y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \sqrt{x}\, \cos(x)\, c_1 + \sqrt{x}\, \sin(x)\, c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \cos(x)\sqrt{x}$$
$$y_2 = \sin(x)\sqrt{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \cos(x)\sqrt{x} & \sin(x)\sqrt{x} \\ \frac{d}{dx}\left(\cos(x)\sqrt{x}\right) & \frac{d}{dx}\left(\sin(x)\sqrt{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \cos(x)\sqrt{x} & \sin(x)\sqrt{x} \\ -\sin(x)\sqrt{x} + \frac{\cos(x)}{2\sqrt{x}} & \cos(x)\sqrt{x} + \frac{\sin(x)}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\cos(x)\sqrt{x}\right)\left(\cos(x)\sqrt{x} + \frac{\sin(x)}{2\sqrt{x}}\right) - \left(\sin(x)\sqrt{x}\right)\left(-\sin(x)\sqrt{x} + \frac{\cos(x)}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x\left(\cos(x)^2 + \sin(x)^2\right)$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\,x^4}{4x^3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\sin(x)\,x}{4}dx$$

Hence

$$u_1 = -\frac{\sin(x)}{4} + \frac{x\cos(x)}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^4\cos(x)}{4x^3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{x\cos(x)}{4}dx$$

Hence

$$u_2 = \frac{\cos(x)}{4} + \frac{\sin(x)\,x}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(-\frac{\sin(x)}{4} + \frac{x\cos(x)}{4}\right)\cos(x)\sqrt{x} + \left(\frac{\cos(x)}{4} + \frac{\sin(x)\,x}{4}\right)\sin(x)\sqrt{x}$$

Which simplifies to

$$y_p(x) = \frac{x^{\frac{3}{2}}}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\sqrt{x}\,\cos(x)\,c_1 + \sqrt{x}\,\sin(x)\,c_2\right) + \left(\frac{x^{\frac{3}{2}}}{4}\right) \end{aligned}$$

Which simplifies to

$$y = \sqrt{x}\,(c_1\cos(x) + c_2\sin(x)) + \frac{x^{\frac{3}{2}}}{4}$$

Summary

The solution(s) found are the following

$$y = \sqrt{x}\,(c_1\cos(x) + c_2\sin(x)) + \frac{x^{\frac{3}{2}}}{4} \tag{1}$$

Verification of solutions

$$y = \sqrt{x}\,(c_1\cos(x) + c_2\sin(x)) + \frac{x^{\frac{3}{2}}}{4}$$

Verified OK.

$$\boxed{x^2y'' - 2y'x - (x^2 - 2)\, y = 3x^4}$$

10.22.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 2y'x + (-x^2 + 2)\, y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{2}{x} \\
q(x) &= \frac{-x^2+2}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{-x^2+2}{x^2} - \frac{\left(-\frac{2}{x}\right)'}{2} - \frac{\left(-\frac{2}{x}\right)^2}{4} \\
&= \frac{-x^2+2}{x^2} - \frac{\left(\frac{2}{x^2}\right)}{2} - \frac{\left(\frac{4}{x^2}\right)}{4} \\
&= \frac{-x^2+2}{x^2} - \left(\frac{1}{x^2}\right) - \frac{1}{x^2} \\
&= -1
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2}{x}}{2}} \\
&= x
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x \tag{4}
$$

Applying this change of variable to the original ode results in

$$
-v(x) + v''(x) = 3x
$$

Which is now solved for $v(x)$ This is second order non-homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = f(x)
$$

Where $A = 1, B = 0, C = -1, f(x) = 3x$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$-v(x) + v''(x) = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = -1$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(-1)} \\ &= \pm 1\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +1 \\ \lambda_2 &= -1\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= 1 \\ \lambda_2 &= -1\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ v(x) &= c_1 e^{(1)x} + c_2 e^{(-1)x}\end{aligned}$$

Or

$$v(x) = c_1 e^{x} + c_2 e^{-x}$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 e^{x} + c_2 e^{-x}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$x$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1, x\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{e^{x}, e^{-x}\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$v_p = A_2 x + A_1$$

The unknowns $\{A_1, A_2\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$-A_2 x - A_1 = 3x$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 0, A_2 = -3]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = -3x$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= \left(c_1 e^{x} + c_2 e^{-x}\right) + (-3x) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x)\\ &= \left(c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x} - 3x\right) (z(x)) \end{aligned}\tag{7}$$

But from (5)

$$z(x) = x$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x} - 3x\right) x$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 \mathrm{e}^{x} + c_2 \mathrm{e}^{-x} - 3x\right) x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}y_1 &= x\,\mathrm{e}^{x}\\ y_2 &= x\,\mathrm{e}^{-x}\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x\,\mathrm{e}^{-x} \\ \frac{d}{dx}\left(x\,\mathrm{e}^{x}\right) & \frac{d}{dx}\left(x\,\mathrm{e}^{-x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x\,\mathrm{e}^{-x} \\ x\,\mathrm{e}^{x} + \mathrm{e}^{x} & \mathrm{e}^{-x} - x\,\mathrm{e}^{-x} \end{vmatrix}$$

Therefore

$$W = (x\,\mathrm{e}^{x})\left(\mathrm{e}^{-x} - x\,\mathrm{e}^{-x}\right) - \left(x\,\mathrm{e}^{-x}\right)(x\,\mathrm{e}^{x} + \mathrm{e}^{x})$$

Which simplifies to

$$W = -2\,\mathrm{e}^{x}\mathrm{e}^{-x}x^{2}$$

Which simplifies to

$$W = -2x^{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{3x^{5}\mathrm{e}^{-x}}{-2x^{4}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{3x\,\mathrm{e}^{-x}}{2} dx$$

Hence

$$u_1 = -\frac{3(x+1)\,\mathrm{e}^{-x}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{3\,\mathrm{e}^{x}x^{5}}{-2x^{4}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{3x\,\mathrm{e}^{x}}{2} dx$$

Hence

$$u_2 = -\frac{3(x-1)\,\mathrm{e}^{x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{3(x+1)\,\mathrm{e}^{-x} x\,\mathrm{e}^{x}}{2} - \frac{3(x-1)\,\mathrm{e}^{x} x\,\mathrm{e}^{-x}}{2}$$

Which simplifies to

$$y_p(x) = -3x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1\mathrm{e}^{x} + c_2\mathrm{e}^{-x} - 3x\right)x\right) + \left(-3x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(c_1\mathrm{e}^{x} + c_2\mathrm{e}^{-x} - 3x\right)x - 3x^2 \tag{1}$$

Verification of solutions

$$y = \left(c_1\mathrm{e}^{x} + c_2\mathrm{e}^{-x} - 3x\right)x - 3x^2$$

Verified OK.

10.22.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - 2y'x + \left(-x^2 + 2\right)y = 3x^4 \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}\left(c_1 \operatorname{BesselJ}\left(n, \beta\, x^{\gamma}\right) + c_2 \operatorname{BesselY}\left(n, \beta\, x^{\gamma}\right)\right) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= \frac{3}{2} \\
\beta &= i \\
n &= -\frac{1}{2} \\
\gamma &= 1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x^{\frac{3}{2}} \sqrt{2}\, \cosh\left(x\right)}{\sqrt{\pi}\, \sqrt{i x}} + \frac{i c_2 x^{\frac{3}{2}} \sqrt{2}\, \sinh\left(x\right)}{\sqrt{\pi}\, \sqrt{i x}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 x^{\frac{3}{2}} \sqrt{2}\, \cosh\left(x\right)}{\sqrt{\pi}\, \sqrt{i x}} + \frac{i c_2 x^{\frac{3}{2}} \sqrt{2}\, \sinh\left(x\right)}{\sqrt{\pi}\, \sqrt{i x}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= x\,\mathrm{e}^{x} \\
y_2 &= x\,\mathrm{e}^{-x}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x\,\mathrm{e}^{-x} \\ \frac{d}{dx}(x\,\mathrm{e}^{x}) & \frac{d}{dx}(x\,\mathrm{e}^{-x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x\,\mathrm{e}^{-x} \\ x\,\mathrm{e}^{x} + \mathrm{e}^{x} & \mathrm{e}^{-x} - x\,\mathrm{e}^{-x} \end{vmatrix}$$

Therefore

$$W = (x\,\mathrm{e}^{x})\left(\mathrm{e}^{-x} - x\,\mathrm{e}^{-x}\right) - \left(x\,\mathrm{e}^{-x}\right)(x\,\mathrm{e}^{x} + \mathrm{e}^{x})$$

Which simplifies to

$$W = -2\,\mathrm{e}^{x}\mathrm{e}^{-x}x^{2}$$

Which simplifies to

$$W = -2x^{2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{3x^{5}\mathrm{e}^{-x}}{-2x^{4}}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{3x\,\mathrm{e}^{-x}}{2}dx$$

Hence

$$u_1 = -\frac{3(x+1)\,\mathrm{e}^{-x}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{3\,\mathrm{e}^{x}x^{5}}{-2x^{4}}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{3x\,\mathrm{e}^{x}}{2} dx$$

Hence

$$u_2 = -\frac{3(x-1)\,\mathrm{e}^{x}}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{3(x+1)\,\mathrm{e}^{-x} x\,\mathrm{e}^{x}}{2} - \frac{3(x-1)\,\mathrm{e}^{x} x\,\mathrm{e}^{-x}}{2}$$

Which simplifies to

$$y_p(x) = -3x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x^{\frac{3}{2}} \sqrt{2}\, \cosh(x)}{\sqrt{\pi}\, \sqrt{ix}} + \frac{i c_2 x^{\frac{3}{2}} \sqrt{2}\, \sinh(x)}{\sqrt{\pi}\, \sqrt{ix}}\right) + \left(-3x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^{\frac{3}{2}} \sqrt{2}\, \cosh(x)}{\sqrt{\pi}\, \sqrt{ix}} + \frac{i c_2 x^{\frac{3}{2}} \sqrt{2}\, \sinh(x)}{\sqrt{\pi}\, \sqrt{ix}} - 3x^2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^{\frac{3}{2}} \sqrt{2}\, \cosh(x)}{\sqrt{\pi}\, \sqrt{ix}} + \frac{i c_2 x^{\frac{3}{2}} \sqrt{2}\, \sinh(x)}{\sqrt{\pi}\, \sqrt{ix}} - 3x^2$$

Verified OK.

10.22.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' - 2y'x + (-x^2 + 2)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x \\ C &= -x^2 + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 432: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-x}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x}{x^2}\,dx}
\end{aligned}
$$

$$
\begin{aligned}
&= z_1 e^{\ln(x)} \\
&= z_1(x)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x \,\mathrm{e}^{-x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{2\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{2x}}{2}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x \,\mathrm{e}^{-x}\right) + c_2 \left(x \,\mathrm{e}^{-x} \left(\frac{\mathrm{e}^{2x}}{2}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - 2y'x + \left(-x^2 + 2\right) y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = x \,\mathrm{e}^{-x} c_1 + \frac{c_2 x \,\mathrm{e}^{x}}{2}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x\,\mathrm{e}^{-x}$$
$$y_2 = \frac{x\,\mathrm{e}^{x}}{2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,\mathrm{e}^{-x} & \frac{x\,\mathrm{e}^{x}}{2} \\ \frac{d}{dx}\left(x\,\mathrm{e}^{-x}\right) & \frac{d}{dx}\left(\frac{x\,\mathrm{e}^{x}}{2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,\mathrm{e}^{-x} & \frac{x\,\mathrm{e}^{x}}{2} \\ \mathrm{e}^{-x} - x\,\mathrm{e}^{-x} & \frac{x\,\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{x}}{2} \end{vmatrix}$$

Therefore

$$W = \left(x\,\mathrm{e}^{-x}\right)\left(\frac{x\,\mathrm{e}^{x}}{2} + \frac{\mathrm{e}^{x}}{2}\right) - \left(\frac{x\,\mathrm{e}^{x}}{2}\right)\left(\mathrm{e}^{-x} - x\,\mathrm{e}^{-x}\right)$$

Which simplifies to

$$W = \mathrm{e}^{x}\mathrm{e}^{-x}x^2$$

Which simplifies to

$$W = x^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{3\,e^{x} x^5}{2}}{x^4} dx$$

Which simplifies to

$$u_1 = -\int \frac{3x\,e^{x}}{2} dx$$

Hence

$$u_1 = -\frac{3(x-1)\,e^{x}}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{3x^5 e^{-x}}{x^4} dx$$

Which simplifies to

$$u_2 = \int 3x\,e^{-x} dx$$

Hence

$$u_2 = -3(x+1)\,e^{-x}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{3(x+1)\,e^{-x} x\,e^{x}}{2} - \frac{3(x-1)\,e^{x} x\,e^{-x}}{2}$$

Which simplifies to

$$y_p(x) = -3x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x\,e^{-x} c_1 + \frac{c_2 x\,e^{x}}{2}\right) + \left(-3x^2\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$y = x\,\mathrm{e}^{-x}c_1 + \frac{c_2 x\,\mathrm{e}^{x}}{2} - 3x^2 \tag{1}$$

Verification of solutions

$$y = x\,\mathrm{e}^{-x}c_1 + \frac{c_2 x\,\mathrm{e}^{x}}{2} - 3x^2$$

Verified OK.

10.23.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + \left(-2x^2-2x\right)y' + \left(x^2+2x+2\right)y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{-2x^2 - 2x}{x^2} \\
q(x) &= \frac{x^2 + 2x + 2}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x^2 + 2x + 2}{x^2} - \frac{\left(\frac{-2x^2-2x}{x^2}\right)'}{2} - \frac{\left(\frac{-2x^2-2x}{x^2}\right)^2}{4} \\
&= \frac{x^2 + 2x + 2}{x^2} - \frac{\left(\frac{-2-4x}{x^2} - \frac{2(-2x^2-2x)}{x^3}\right)}{2} - \frac{\left(\frac{(-2x^2-2x)^2}{x^4}\right)}{4} \\
&= \frac{x^2 + 2x + 2}{x^2} - \left(\frac{-2 - 4x}{2x^2} - \frac{-2x^2 - 2x}{x^3}\right) - \frac{(-2x^2 - 2x)^2}{4x^4} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{-2x^2-2x}{x^2}}{2}} \\
&= x\, \mathrm{e}^{x}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x\, \mathrm{e}^{x} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v''(x) = 1
$$

Which is now solved for $v(x)$ The ODE can be written as

$$
v''(x) = 1
$$

Integrating once gives

$$v'(x) = x + c_1$$

Integrating again gives

$$v(x) = \frac{x^2}{2} + c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(\frac{1}{2}x^2 + c_1 x + c_2\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x\,\mathrm{e}^{x}$$

Hence (7) becomes

$$y = \left(\frac{1}{2}x^2 + c_1 x + c_2\right) x\,\mathrm{e}^{x}$$

Therefore the homogeneous solution y_h is

$$y_h = \left(\frac{1}{2}x^2 + c_1 x + c_2\right) x\,\mathrm{e}^{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x\,\mathrm{e}^{x} \\ y_2 &= x^2 \mathrm{e}^{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x^2\mathrm{e}^{x} \\ \frac{d}{dx}(x\,\mathrm{e}^{x}) & \frac{d}{dx}(x^2\mathrm{e}^{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x^2\mathrm{e}^{x} \\ x\,\mathrm{e}^{x} + \mathrm{e}^{x} & 2x\,\mathrm{e}^{x} + x^2\mathrm{e}^{x} \end{vmatrix}$$

Therefore

$$W = (x\,\mathrm{e}^{x})\left(2x\,\mathrm{e}^{x} + x^2\mathrm{e}^{x}\right) - \left(x^2\mathrm{e}^{x}\right)(x\,\mathrm{e}^{x} + \mathrm{e}^{x})$$

Which simplifies to

$$W = x^2\mathrm{e}^{2x}$$

Which simplifies to

$$W = x^2\mathrm{e}^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5\mathrm{e}^{2x}}{\mathrm{e}^{2x}x^4}\,dx$$

Which simplifies to

$$u_1 = -\int x dx$$

Hence

$$u_1 = -\frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{2x}x^4}{\mathrm{e}^{2x}x^4}\,dx$$

Which simplifies to

$$u_2 = \int 1dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^x x^3}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(\frac{1}{2}x^2 + c_1 x + c_2\right) x\, e^x\right) + \left(\frac{e^x x^3}{2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(\frac{1}{2}x^2 + c_1 x + c_2\right) x\, e^x + \frac{e^x x^3}{2} \tag{1}$$

Verification of solutions

$$y = \left(\frac{1}{2}x^2 + c_1 x + c_2\right) x\, e^x + \frac{e^x x^3}{2}$$

Verified OK.

10.23.2 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + \left(-2x^2 - 2x\right) y' + \left(x^2 + 2x + 2\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2 - 2x \\ C &= x^2 + 2x + 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) \, e^{-\int \frac{B}{2A} \, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 433: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-2x}{x^2}\,dx} \\
&= z_1 e^{x+\ln(x)} \\
&= z_1 (x\,\mathrm{e}^{x})
\end{aligned}
$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2x+2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\,\mathrm{e}^{x}) + c_2(x\,\mathrm{e}^{x}(x))
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + \left(-2x^2 - 2x\right)y' + \left(x^2 + 2x + 2\right)y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 x\,\mathrm{e}^{x} + c_2 x^2 \mathrm{e}^{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x\,\mathrm{e}^{x}$$
$$y_2 = x^2 \mathrm{e}^{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x^2\mathrm{e}^{x} \\ \frac{d}{dx}(x\,\mathrm{e}^{x}) & \frac{d}{dx}(x^2\mathrm{e}^{x}) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x\,\mathrm{e}^{x} & x^2\mathrm{e}^{x} \\ x\,\mathrm{e}^{x} + \mathrm{e}^{x} & 2x\,\mathrm{e}^{x} + x^2\mathrm{e}^{x} \end{vmatrix}$$

Therefore

$$W = (x\,\mathrm{e}^{x})\left(2x\,\mathrm{e}^{x} + x^2\mathrm{e}^{x}\right) - \left(x^2\mathrm{e}^{x}\right)(x\,\mathrm{e}^{x} + \mathrm{e}^{x})$$

Which simplifies to

$$W = x^2\mathrm{e}^{2x}$$

Which simplifies to

$$W = x^2\mathrm{e}^{2x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^5 e^{2x}}{e^{2x} x^4} \, dx$$

Which simplifies to

$$u_1 = -\int x dx$$

Hence

$$u_1 = -\frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{2x} x^4}{e^{2x} x^4} \, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{e^x x^3}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x \, e^x + c_2 x^2 e^x\right) + \left(\frac{e^x x^3}{2}\right) \end{aligned}$$

Which simplifies to

$$y = e^x x (c_2 x + c_1) + \frac{e^x x^3}{2}$$

Summary
The solution(s) found are the following

$$y = e^x x(c_2 x + c_1) + \frac{e^x x^3}{2} \tag{1}$$

Verification of solutions

$$y = e^x x(c_2 x + c_1) + \frac{e^x x^3}{2}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - y'x - 3y = x^{\frac{3}{2}}}$$

10.24.1 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x, C = -3, f(x) = x^{\frac{3}{2}}$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' - y'x - 3y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} - xrx^{r-1} - 3x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r - r\,x^r - 3x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) - r - 3 = 0$$

Or

$$r^2 - 2r - 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 3$$

Since the roots are real and distinct, then the general solution is

$$y = c_1y_1 + c_2y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x} + c_2x^3$$

Next, we find the particular solution to the ODE

$$x^2y'' - y'x - 3y = x^{\frac{3}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ -\frac{1}{x^2} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(3x^2) - (x^3)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{9}{2}}}{4x^3} \, dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{\frac{3}{2}}}{4} dx$$

Hence

$$u_1 = -\frac{x^{\frac{5}{2}}}{10}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x}}{4x^3} \, dx$$

Which simplifies to

$$u_2 = \int \frac{1}{4x^{\frac{5}{2}}} dx$$

Hence

$$u_2 = -\frac{1}{6x^{\frac{3}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{4x^{\frac{3}{2}}}{15}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{4x^{\frac{3}{2}}}{15} + \frac{c_1}{x} + c_2 x^3 \end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{4x^{\frac{3}{2}}}{15} + \frac{c_1}{x} + c_2 x^3 \tag{1}$$

Verification of solutions

$$y = -\frac{4x^{\frac{3}{2}}}{15} + \frac{c_1}{x} + c_2 x^3$$

Verified OK.

10.24.2 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - y'x - 3y = 0$$

In normal form the ode

$$x^2y'' - y'x - 3y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{1}{x} \\ q(x) &= -\frac{3}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int -\frac{1}{x} dx\right)} dx \\
&= \int e^{\ln(x)}\, dx \\
&= \int x dx \\
&= \frac{x^2}{2}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{3}{x^2}}{x^2} \\
&= -\frac{3}{x^4}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) - \frac{3y(\tau)}{x^4} &= 0
\end{aligned}$$

But in terms of τ

$$-\frac{3}{x^4} = -\frac{3}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) - \frac{3y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 3y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 3\tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r - 3\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 - 3 = 0$$

Or

$$4r^2 - 4r - 3 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{1}{2}$$
$$r_2 = \frac{3}{2}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = \frac{c_1}{\sqrt{\tau}} + c_2\tau^{\frac{3}{2}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ -\frac{1}{x^2} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(3x^2) - (x^3)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{9}{2}}}{4x^3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{\frac{3}{2}}}{4}dx$$

Hence

$$u_1 = -\frac{x^{\frac{5}{2}}}{10}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x}}{4x^3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{4x^{\frac{5}{2}}}dx$$

Hence

$$u_2 = -\frac{1}{6x^{\frac{3}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{4x^{\frac{3}{2}}}{15}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x}\right) + \left(-\frac{4x^{\frac{3}{2}}}{15}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x} - \frac{4x^{\frac{3}{2}}}{15} \tag{1}
$$

Verification of solutions

$$
y = \frac{\sqrt{2}\,(c_2x^4 + 4c_1)}{4x} - \frac{4x^{\frac{3}{2}}}{15}
$$

Verified OK.

10.24.3 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$
Ay''(x) + By'(x) + Cy(x) = f(x)
$$

Where $A = x^2, B = -x, C = -3, f(x) = x^{\frac{3}{2}}$. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$
x^2y'' - y'x - 3y = 0
$$

In normal form the ode

$$
x^2y'' - y'x - 3y = 0 \tag{1}
$$

Becomes

$$
y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= -\frac{1}{x} \\
q(x) &= -\frac{3}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} - \frac{n}{x^2} - \frac{3}{x^2} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = 3 \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \frac{5v'(x)}{x} &= 0 \\
v''(x) + \frac{5v'(x)}{x} &= 0
\end{aligned} \tag{7}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) + \frac{5u(x)}{x} = 0 \tag{8}
$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{5u}{x} \end{aligned}$$

Where $f(x) = -\frac{5}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{5}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{5}{x}\,dx \\ \ln(u) &= -5\ln(x) + c_1 \\ u &= e^{-5\ln(x)+c_1} \\ &= \frac{c_1}{x^5} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= -\frac{c_1}{4x^4} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= \left(-\frac{c_1}{4x^4} + c_2\right)x^3 \\ &= \frac{4c_2x^4 - c_1}{4x} \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' - y'x - 3y = x^{\frac{3}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1y_1 + u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$

$$y_2 = x^3$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}(x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & x^3 \\ -\frac{1}{x^2} & 3x^2 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)(3x^2) - (x^3)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = 4x$$

Which simplifies to

$$W = 4x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{\frac{9}{2}}}{4x^3}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{\frac{3}{2}}}{4} dx$$

Hence

$$u_1 = -\frac{x^{\frac{5}{2}}}{10}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x}}{4x^3} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{4x^{\frac{5}{2}}} dx$$

Hence

$$u_2 = -\frac{1}{6x^{\frac{3}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{4x^{\frac{3}{2}}}{15}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(-\frac{c_1}{4x^4} + c_2\right) x^3\right) + \left(-\frac{4x^{\frac{3}{2}}}{15}\right) \\ &= -\frac{4x^{\frac{3}{2}}}{15} + \left(-\frac{c_1}{4x^4} + c_2\right) x^3 \end{aligned}$$

Which simplifies to

$$y = -\frac{-60c_2x^4 + 16x^{\frac{5}{2}} + 15c_1}{60x}$$

Summary
The solution(s) found are the following

$$y = -\frac{-60c_2x^4 + 16x^{\frac{5}{2}} + 15c_1}{60x} \tag{1}$$

Verification of solutions

$$y = -\frac{-60c_2x^4 + 16x^{\frac{5}{2}} + 15c_1}{60x}$$

Verified OK.

10.24.4 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x^2y'' - y'x - 3y\right) dx = \int x^{\frac{3}{2}} dx$$
$$y'x^2 - 3yx = \frac{2x^{\frac{5}{2}}}{5} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}$$

Hence the ode is

$$y' - \frac{3y}{x} = \frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{x}dx}$$
$$= \frac{1}{x^3}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^3}\right) = \left(\frac{1}{x^3}\right)\left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}\right)$$
$$d\left(\frac{y}{x^3}\right) = \left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^5}\right) dx$$

Integrating gives

$$\frac{y}{x^3} = \int \frac{2x^{\frac{5}{2}} + 5c_1}{5x^5} dx$$
$$\frac{y}{x^3} = -\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4}\right) + c_2 x^3$$

which simplifies to

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right)$$

Summary

The solution(s) found are the following

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right) \tag{1}$$

Verification of solutions

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right)$$

Verified OK.

10.24.5 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x^2y'' - y'x - 3y = x^{\frac{3}{2}}$$

Integrating both sides of the ODE w.r.t x gives

$$\int (x^2y'' - y'x - 3y)\,dx = \int x^{\frac{3}{2}}\,dx$$
$$y'x^2 - 3yx = \frac{2x^{\frac{5}{2}}}{5} + c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{3}{x}$$
$$q(x) = \frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}$$

Hence the ode is

$$y' - \frac{3y}{x} = \frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{3}{x}dx}$$
$$= \frac{1}{x^3}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}\right)$$
$$\frac{d}{dx}\left(\frac{y}{x^3}\right) = \left(\frac{1}{x^3}\right)\left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}\right)$$
$$d\left(\frac{y}{x^3}\right) = \left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^5}\right)dx$$

Integrating gives

$$\frac{y}{x^3} = \int \frac{2x^{\frac{5}{2}} + 5c_1}{5x^5} \mathrm{d}x$$
$$\frac{y}{x^3} = -\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4}\right) + c_2 x^3$$

which simplifies to

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right)$$

Summary
The solution(s) found are the following

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right) \tag{1}$$

Verification of solutions

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right)$$

Verified OK.

10.24.6 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - y'x - 3y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x \\ C &= -3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{15}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 15 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{15}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 434: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 0\\ &= 2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{15}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{15}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{15}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{15}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{5}{2}\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{3}{2}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{15}{4x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{5}{2}$	$-\frac{3}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{3}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\ &= -\frac{3}{2} - \left(-\frac{3}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{3}{2x} + (-)(0) \\ &= -\frac{3}{2x} \\ &= -\frac{3}{2x} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}(0) + 2\left(-\frac{3}{2x}\right)(0) + \left(\left(\frac{3}{2x^2}\right) + \left(-\frac{3}{2x}\right)^2 - \left(\frac{15}{4x^2}\right)\right) &= 0\\ 0 &= 0\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= p e^{\int \omega\, dx}\\ &= e^{\int -\frac{3}{2x} dx}\\ &= \frac{1}{x^{\frac{3}{2}}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{x^2}\, dx}\\ &= z_1 e^{\frac{\ln(x)}{2}}\\ &= z_1\left(\sqrt{x}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\ln(x)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{x^4}{4}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x}\right) + c_2 \left(\frac{1}{x}\left(\frac{x^4}{4}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' - y' x - 3y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1}{x} + \frac{c_2 x^3}{4}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x}$$
$$y_2 = \frac{x^3}{4}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$
$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^3}{4} \\ \frac{d}{dx}\left(\frac{1}{x}\right) & \frac{d}{dx}\left(\frac{x^3}{4}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x} & \frac{x^3}{4} \\ -\frac{1}{x^2} & \frac{3x^2}{4} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x}\right)\left(\frac{3x^2}{4}\right) - \left(\frac{x^3}{4}\right)\left(-\frac{1}{x^2}\right)$$

Which simplifies to

$$W = x$$

Which simplifies to

$$W = x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{x^{\frac{9}{2}}}{4}}{x^3} dx$$

Which simplifies to

$$u_1 = -\int \frac{x^{\frac{3}{2}}}{4} dx$$

Hence

$$u_1 = -\frac{x^{\frac{5}{2}}}{10}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\sqrt{x}}{x^3} dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x^{\frac{5}{2}}} dx$$

Hence

$$u_2 = -\frac{2}{3x^{\frac{3}{2}}}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{4x^{\frac{3}{2}}}{15}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x} + \frac{c_2 x^3}{4}\right) + \left(-\frac{4x^{\frac{3}{2}}}{15}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{x} + \frac{c_2 x^3}{4} - \frac{4x^{\frac{3}{2}}}{15} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{x} + \frac{c_2 x^3}{4} - \frac{4x^{\frac{3}{2}}}{15}$$

Verified OK.

10.24.7 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 \\ q(x) &= -x \\ r(x) &= -3 \\ s(x) &= x^{\frac{3}{2}} \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 2 \\ q'(x) &= -1 \end{aligned}$$

Therefore (1) becomes

$$2 - (-1) + (-3) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$y'x^2 - 3yx = \int x^{\frac{3}{2}}\,dx$$

We now have a first order ode to solve which is

$$y'x^2 - 3yx = \frac{2x^{\frac{5}{2}}}{5} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{3}{x} \\
q(x) &= \frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}
\end{aligned}$$

Hence the ode is

$$y' - \frac{3y}{x} = \frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= e^{\int -\frac{3}{x}dx} \\
&= \frac{1}{x^3}
\end{aligned}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}\right) \\
\frac{d}{dx}\left(\frac{y}{x^3}\right) &= \left(\frac{1}{x^3}\right)\left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^2}\right) \\
d\left(\frac{y}{x^3}\right) &= \left(\frac{2x^{\frac{5}{2}} + 5c_1}{5x^5}\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{y}{x^3} &= \int \frac{2x^{\frac{5}{2}} + 5c_1}{5x^5} dx \\
\frac{y}{x^3} &= -\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{1}{x^3}$ results in

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4}\right) + c_2x^3$$

which simplifies to

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right)$$

Summary

The solution(s) found are the following

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right) \tag{1}$$

Verification of solutions

$$y = x^3\left(-\frac{4}{15x^{\frac{3}{2}}} - \frac{c_1}{4x^4} + c_2\right)$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - x(x+4)\,y' + 2y(x+3) = \mathrm{e}^x x^4}$$

10.25.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + \left(-x^2 - 4x\right) y' + (2x+6)\,y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{-x^2-4x}{x^2} \\
q(x) &= \frac{2x+6}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{2x+6}{x^2} - \frac{\left(\frac{-x^2-4x}{x^2}\right)'}{2} - \frac{\left(\frac{-x^2-4x}{x^2}\right)^2}{4} \\
&= \frac{2x+6}{x^2} - \frac{\left(\frac{-2x-4}{x^2} - \frac{2(-x^2-4x)}{x^3}\right)}{2} - \frac{\left(\frac{(-x^2-4x)^2}{x^4}\right)}{4} \\
&= \frac{2x+6}{x^2} - \left(\frac{-2x-4}{2x^2} - \frac{-x^2-4x}{x^3}\right) - \frac{(-x^2-4x)^2}{4x^4} \\
&= -\frac{1}{4}
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{-x^2-4x}{x^2}}{2}} \\
&= x^2 \mathrm{e}^{\frac{x}{2}}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x^2 \mathrm{e}^{\frac{x}{2}} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
\mathrm{e}^{\frac{x}{2}} (4v''(x) - v(x)) = 4\, \mathrm{e}^{x}
$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$
v''(x) - \frac{v(x)}{4} = \mathrm{e}^{\frac{x}{2}}
$$

This is second order non-homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = f(x)$$

Where $A = 1, B = 0, C = -\frac{1}{4}, f(x) = \mathrm{e}^{\frac{x}{2}}$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$v''(x) - \frac{v(x)}{4} = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = -\frac{1}{4}$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} - \frac{\mathrm{e}^{\lambda x}}{4} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \frac{1}{4} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -\frac{1}{4}$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\left(-\frac{1}{4}\right)}\\ &= \pm\frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = +\frac{1}{2}$$

$$\lambda_2 = -\frac{1}{2}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2}$$

$$\lambda_2 = -\frac{1}{2}$$

Since roots are real and distinct, then the solution is

$$v(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$v(x) = c_1 e^{\left(\frac{1}{2}\right)x} + c_2 e^{\left(-\frac{1}{2}\right)x}$$

Or

$$v(x) = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\mathrm{e}^{\frac{x}{2}}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$\left[\left\{\mathrm{e}^{\frac{x}{2}}\right\}\right]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{x}{2}}, \mathrm{e}^{\frac{x}{2}}\right\}$$

Since $\mathrm{e}^{\frac{x}{2}}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$\left[\left\{\mathrm{e}^{\frac{x}{2}} x\right\}\right]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$v_p = A_1 \mathrm{e}^{\frac{x}{2}} x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{\frac{x}{2}} = e^{\frac{x}{2}}$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = e^{\frac{x}{2}} x$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}}\right) + \left(e^{\frac{x}{2}} x\right) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} + e^{\frac{x}{2}} x\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x^2 e^{\frac{x}{2}}$$

Hence (7) becomes

$$y = \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} + e^{\frac{x}{2}} x\right) x^2 e^{\frac{x}{2}}$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} + e^{\frac{x}{2}} x\right) x^2 e^{\frac{x}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2 e^x$$
$$y_2 = e^{-\frac{x}{2}} x^2 e^{\frac{x}{2}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 e^x & e^{-\frac{x}{2}} x^2 e^{\frac{x}{2}} \\ \frac{d}{dx}(x^2 e^x) & \frac{d}{dx}\left(e^{-\frac{x}{2}} x^2 e^{\frac{x}{2}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 e^x & e^{-\frac{x}{2}} x^2 e^{\frac{x}{2}} \\ 2x\, e^x + x^2 e^x & 2\, e^{-\frac{x}{2}} x\, e^{\frac{x}{2}} \end{vmatrix}$$

Therefore

$$W = \left(x^2 e^x\right)\left(2\, e^{-\frac{x}{2}} x\, e^{\frac{x}{2}}\right) - \left(e^{-\frac{x}{2}} x^2 e^{\frac{x}{2}}\right)\left(2x\, e^x + x^2 e^x\right)$$

Which simplifies to

$$W = -e^{\frac{3x}{2}} e^{-\frac{x}{2}} x^4$$

Which simplifies to

$$W = -e^x x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{-\frac{x}{2}} x^6 e^{\frac{x}{2}} e^x}{-x^6 e^x} \, dx$$

Which simplifies to

$$u_1 = -\int (-1)\,dx$$

Hence

$$u_1 = x$$

And Eq. (3) becomes

$$u_2 = \int \frac{(\mathrm{e}^x)^2\, x^6}{-x^6 \mathrm{e}^x}\,dx$$

Which simplifies to

$$u_2 = \int -\mathrm{e}^x dx$$

Hence

$$u_2 = -\mathrm{e}^x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \mathrm{e}^x x^3 - \mathrm{e}^x \mathrm{e}^{-\frac{x}{2}} x^2 \mathrm{e}^{\frac{x}{2}}$$

Which simplifies to

$$y_p(x) = \mathrm{e}^x x^2(x-1)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}} + \mathrm{e}^{\frac{x}{2}} x\right) x^2 \mathrm{e}^{\frac{x}{2}}\right) + \left(\mathrm{e}^x x^2 (x-1)\right) \end{aligned}$$

Which simplifies to

$$y = ((x + c_1)\,\mathrm{e}^x + c_2)\,x^2 + \mathrm{e}^x x^2 (x-1)$$

Summary

The solution(s) found are the following

$$y = ((x + c_1)\,\mathrm{e}^x + c_2)\,x^2 + \mathrm{e}^x x^2 (x-1) \tag{1}$$

Verification of solutions

$$y = ((x + c_1)\,\mathrm{e}^x + c_2)\,x^2 + \mathrm{e}^x x^2 (x-1)$$

Verified OK.

10.25.2 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = -x^2 - 4x, C = 2x + 6, f(x) = e^x x^4$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + (-x^2 - 4x) y' + (2x + 6) y = 0$$

In normal form the ode

$$x^2y'' + (-x^2 - 4x) y' + (2x + 6) y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-x - 4}{x} \\ q(x) &= \frac{2x + 6}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x) x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(-x-4)}{x^2} + \frac{2x+6}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4}{x} + \frac{-x-4}{x}\right) v'(x) &= 0 \\ v''(x) - v'(x) &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) - u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. Integrating both sides gives

$$\begin{aligned} \int \frac{1}{u} du &= x + c_1 \\ \ln(u) &= x + c_1 \\ u &= e^{x+c_1} \\ u &= c_1 e^x \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= c_1 e^x + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= (c_1 e^x + c_2)\, x^2 \\ &= (c_1 e^x + c_2)\, x^2 \end{aligned}$$

Now the particular solution to this ODE is found

$$x^2y'' + (-x^2 - 4x)\, y' + (2x + 6)\, y = e^x x^4$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2$$
$$y_2 = x^2 e^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^2 e^x \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^2 e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^2 e^x \\ 2x & 2x\, e^x + x^2 e^x \end{vmatrix}$$

Therefore

$$W = (x^2)\left(2x\, e^x + x^2 e^x\right) - \left(x^2 e^x\right)(2x)$$

Which simplifies to

$$W = \mathrm{e}^{x} x^{4}$$

Which simplifies to

$$W = \mathrm{e}^{x} x^{4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\mathrm{e}^{2x} x^{6}}{x^{6} \mathrm{e}^{x}}\, dx$$

Which simplifies to

$$u_1 = -\int \mathrm{e}^{x} dx$$

Hence

$$u_1 = -\mathrm{e}^{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{6} \mathrm{e}^{x}}{x^{6} \mathrm{e}^{x}}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \mathrm{e}^{x} x^{3} - x^{2} \mathrm{e}^{x}$$

Which simplifies to

$$y_p(x) = \mathrm{e}^{x} x^{2} (x - 1)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 e^x + c_2\right) x^2\right) + \left(e^x x^2 (x-1)\right) \\ &= e^x x^2 (x-1) + \left(c_1 e^x + c_2\right) x^2 \end{aligned}$$

Which simplifies to

$$y = \left((x + c_1 - 1) e^x + c_2\right) x^2$$

Summary

The solution(s) found are the following

$$y = \left((x + c_1 - 1) e^x + c_2\right) x^2 \tag{1}$$

Verification of solutions

$$y = \left((x + c_1 - 1) e^x + c_2\right) x^2$$

Verified OK.

10.25.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' + \left(-x^2 - 4x\right) y' + (2x + 6) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -x^2 - 4x \\ C &= 2x + 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = 1$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 435: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{-\frac{x}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x^2-4x}{x^2}\,dx} \\ &= z_1 e^{\frac{x}{2}+2\ln(x)} \\ &= z_1\left(x^2 \mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{x+4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(\mathrm{e}^x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(x^2\right) + c_2\left(x^2(\mathrm{e}^x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + \left(-x^2 - 4x\right)y' + (2x+6)\,y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1x^2 + c_2x^2\mathrm{e}^x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2 \\
y_2 &= x^2\mathrm{e}^x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 & x^2 e^x \\ \frac{d}{dx}(x^2) & \frac{d}{dx}(x^2 e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 & x^2 e^x \\ 2x & 2x\, e^x + x^2 e^x \end{vmatrix}$$

Therefore

$$W = (x^2)\left(2x\, e^x + x^2 e^x\right) - \left(x^2 e^x\right)(2x)$$

Which simplifies to

$$W = e^x x^4$$

Which simplifies to

$$W = e^x x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{2x} x^6}{x^6 e^x}\, dx$$

Which simplifies to

$$u_1 = -\int e^x dx$$

Hence

$$u_1 = -e^x$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^6 e^x}{x^6 e^x}\, dx$$

Which simplifies to

$$u_2 = \int 1 dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = e^x x^3 - x^2 e^x$$

Which simplifies to

$$y_p(x) = e^x x^2 (x - 1)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1 x^2 + c_2 x^2 e^x) + (e^x x^2 (x - 1)) \end{aligned}$$

Which simplifies to

$$y = x^2 (c_1 + c_2 e^x) + e^x x^2 (x - 1)$$

Summary

The solution(s) found are the following

$$y = x^2 (c_1 + c_2 e^x) + e^x x^2 (x - 1) \tag{1}$$

Verification of solutions

$$y = x^2 (c_1 + c_2 e^x) + e^x x^2 (x - 1)$$

Verified OK.

Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{x^2y'' - 2x(2+x)\,y' + \left(x^2+4x+6\right)y = 2x\,\mathrm{e}^x}$$

10.26.1 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + \left(-2x^2-4x\right)y' + \left(x^2+4x+6\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2x^2-4x \\ C &= x^2+4x+6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 436: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2x^2-4x}{x^2}\,dx} \\ &= z_1 e^{x+2\ln(x)} \\ &= z_1\left(x^2 \mathrm{e}^x\right) \end{aligned}$$

Which simplifies to

$$y_1 = x^2 \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2x^2-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2x+4\ln(x)}}{(y_1)^2}\,dx \\ &= y_1(x) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(x^2\mathrm{e}^x\right) + c_2\left(x^2\mathrm{e}^x(x)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2y'' + \left(-2x^2 - 4x\right)y' + \left(x^2 + 4x + 6\right)y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = x^2\mathrm{e}^x c_1 + c_2\mathrm{e}^x x^3
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^2\mathrm{e}^x \\
y_2 &= \mathrm{e}^x x^3
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 e^x & e^x x^3 \\ \frac{d}{dx}(x^2 e^x) & \frac{d}{dx}(e^x x^3) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 e^x & e^x x^3 \\ 2x\, e^x + x^2 e^x & e^x x^3 + 3x^2 e^x \end{vmatrix}$$

Therefore

$$W = (x^2 e^x)(e^x x^3 + 3x^2 e^x) - (e^x x^3)(2x\, e^x + x^2 e^x)$$

Which simplifies to

$$W = e^{2x} x^4$$

Which simplifies to

$$W = e^{2x} x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2\, e^{2x} x^4}{e^{2x} x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{2}{x^2} dx$$

Hence

$$u_1 = \frac{2}{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2\, e^{2x} x^3}{e^{2x} x^6}\, dx$$

Which simplifies to

$$u_2 = \int \frac{2}{x^3} dx$$

Hence

$$u_2 = -\frac{1}{x^2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = x\,\mathrm{e}^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(x^2\mathrm{e}^x c_1 + c_2\mathrm{e}^x x^3\right) + \left(x\,\mathrm{e}^x\right) \end{aligned}$$

Which simplifies to

$$y = \mathrm{e}^x x^2(c_2 x + c_1) + x\,\mathrm{e}^x$$

Summary
The solution(s) found are the following

$$y = \mathrm{e}^x x^2(c_2 x + c_1) + x\,\mathrm{e}^x \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^x x^2(c_2 x + c_1) + x\,\mathrm{e}^x$$

Verified OK.

10.26.2 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$x^2y'' + \left(-2x^2 - 4x\right)y' + \left(x^2 + 4x + 6\right)y = 2x\,\mathrm{e}^x \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = r(x) \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-2x - 4}{x} \\ q(x) &= \frac{x^2 + 4x + 6}{x^2} \\ r(x) &= \frac{2\,\mathrm{e}^x}{x} \end{aligned}$$

The Lagrange adjoint ode is given by

$$
\begin{aligned}
\xi'' - (\xi\, p)' + \xi q &= 0 \\
\xi'' - \left(\frac{(-2x-4)\,\xi(x)}{x}\right)' + \left(\frac{(x^2+4x+6)\,\xi(x)}{x^2}\right) &= 0 \\
\xi''(x) - \frac{(-2x-4)\,\xi'(x)}{x} + \left(\frac{2}{x} + \frac{-2x-4}{x^2} + \frac{x^2+4x+6}{x^2}\right)\xi(x) &= 0
\end{aligned}
$$

Which is solved for $\xi(x)$. In normal form the given ode is written as

$$
\xi''(x) + p(x)\,\xi'(x) + q(x)\,\xi(x) = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{2x^2+4x}{x^2} \\
q(x) &= \frac{x^2+4x+2}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x^2+4x+2}{x^2} - \frac{\left(\frac{2x^2+4x}{x^2}\right)'}{2} - \frac{\left(\frac{2x^2+4x}{x^2}\right)^2}{4} \\
&= \frac{x^2+4x+2}{x^2} - \frac{\left(\frac{4x+4}{x^2} - \frac{2(2x^2+4x)}{x^3}\right)}{2} - \frac{\left(\frac{(2x^2+4x)^2}{x^4}\right)}{4} \\
&= \frac{x^2+4x+2}{x^2} - \left(\frac{4x+4}{2x^2} - \frac{2x^2+4x}{x^3}\right) - \frac{(2x^2+4x)^2}{4x^4} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
\xi(x) = v(x)\,z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{2x^2+4x}{x^2}}{2}} \\
&= \frac{\mathrm{e}^{-x}}{x^2}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$\xi(x) = \frac{v(x)\,\mathrm{e}^{-x}}{x^2} \tag{4}$$

Applying this change of variable to the original ode results in

$$v''(x)\,\mathrm{e}^{-x} = 0$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$v(x) = c_1 x + c_2$$

Now that $v(x)$ is known, then

$$\begin{aligned}\xi(x) &= v(x)\,z(x)\\ &= (c_1 x + c_2)\,(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \frac{\mathrm{e}^{-x}}{x^2}$$

Hence (7) becomes

$$\xi(x) = \frac{(c_1 x + c_2)\,\mathrm{e}^{-x}}{x^2}$$

The original ode (2) now reduces to first order ode

$$\begin{aligned}\xi(x)\,y' - y\xi'(x) + \xi(x)\,p(x)\,y &= \int \xi(x)\,r(x)\,dx\\ y' + y\left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)\,r(x)\,dx}{\xi\,(x)}\\ y' + y\left(\frac{-2x-4}{x} - \frac{\left(\frac{c_3\mathrm{e}^{-x}}{x^2} - \frac{2(c_3x+c_2)\mathrm{e}^{-x}}{x^3} - \frac{(c_3x+c_2)\mathrm{e}^{-x}}{x^2}\right)x^2\mathrm{e}^{x}}{c_3x+c_2}\right) &= -\frac{\mathrm{e}^{x}(2c_3x+c_2)}{c_3x+c_2}\end{aligned}$$

Which is now a first order ode. This is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{c_3x^2 + (c_2 + 3c_3)\,x + 2c_2}{x\,(c_3x + c_2)}\\ q(x) &= \frac{(-2c_3x - c_2)\,\mathrm{e}^{x}}{c_3x + c_2}\end{aligned}$$

Hence the ode is

$$y' - \frac{(c_3x^2 + (c_2+3c_3)\,x + 2c_2)\,y}{x\,(c_3x+c_2)} = \frac{(-2c_3x - c_2)\,\mathrm{e}^x}{c_3x+c_2}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{c_3x^2+(c_2+3c_3)x+2c_2}{x(c_3x+c_2)}dx}\\ &= \mathrm{e}^{-x-2\ln(x)-\ln(c_3x+c_2)}\end{aligned}$$

Which simplifies to

$$\mu = \frac{\mathrm{e}^{-x}}{x^2\,(c_3x+c_2)}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{(-2c_3x-c_2)\,\mathrm{e}^x}{c_3x+c_2}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{-x}y}{x^2\,(c_3x+c_2)}\right) &= \left(\frac{\mathrm{e}^{-x}}{x^2\,(c_3x+c_2)}\right)\left(\frac{(-2c_3x-c_2)\,\mathrm{e}^x}{c_3x+c_2}\right)\\ \mathrm{d}\left(\frac{\mathrm{e}^{-x}y}{x^2\,(c_3x+c_2)}\right) &= \left(\frac{-2c_3x-c_2}{x^2\,(c_3x+c_2)^2}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{\mathrm{e}^{-x}y}{x^2\,(c_3x+c_2)} &= \int \frac{-2c_3x-c_2}{x^2\,(c_3x+c_2)^2}\,\mathrm{d}x\\ \frac{\mathrm{e}^{-x}y}{x^2\,(c_3x+c_2)} &= -\frac{c_3}{c_2\,(c_3x+c_2)} + \frac{1}{c_2x} + c_3\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{-x}}{x^2(c_3x+c_2)}$ results in

$$y = x^2(c_3x+c_2)\,\mathrm{e}^x\left(-\frac{c_3}{c_2\,(c_3x+c_2)} + \frac{1}{c_2x}\right) + c_3x^2(c_3x+c_2)\,\mathrm{e}^x$$

which simplifies to

$$y = \mathrm{e}^x x\left(c_3^2x^2 + c_2c_3x + 1\right)$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = \mathrm{e}^x c_2c_3x^2 + x\,\mathrm{e}^x\left(c_3^2x^2 + 1\right)$$

Summary
The solution(s) found are the following

$$y = e^{x} c_2 c_3 x^2 + x e^{x} (c_3^2 x^2 + 1) \tag{1}$$

Verification of solutions

$$y = e^{x} c_2 c_3 x^2 + x e^{x} (c_3^2 x^2 + 1)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{x^2y'' - 4y'x + (x^2 + 6)\, y = x^4}$$

10.27.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' - 4y'x + (x^2 + 6)\, y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= -\frac{4}{x} \\
q(x) &= \frac{x^2+6}{x^2}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{x^2+6}{x^2} - \frac{\left(-\frac{4}{x}\right)'}{2} - \frac{\left(-\frac{4}{x}\right)^2}{4} \\
&= \frac{x^2+6}{x^2} - \frac{\left(\frac{4}{x^2}\right)}{2} - \frac{\left(\frac{16}{x^2}\right)}{4} \\
&= \frac{x^2+6}{x^2} - \left(\frac{2}{x^2}\right) - \frac{4}{x^2} \\
&= 1
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{4}{x}}{2}} \\
&= x^2
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, x^2 \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v''(x) + v(x) = 1
$$

Which is now solved for $v(x)$ This is second order non-homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = f(x)
$$

Where $A = 1, B = 0, C = 1, f(x) = 1$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$v''(x) + v(x) = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = 1$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + 1 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = 1$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(1)} \\ &= \pm i\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +i \\ \lambda_2 &= -i\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= i \\ \lambda_2 &= -i\end{aligned}$$

Since roots are complex conjugate of each others, then let the roots be

$$\lambda_{1,2} = \alpha \pm i\beta$$

Where $\alpha = 0$ and $\beta = 1$. Therefore the final solution, when using Euler relation, can be written as

$$v(x) = e^{\alpha x}(c_1 \cos(\beta x) + c_2 \sin(\beta x))$$

Which becomes

$$v(x) = e^0(c_1 \cos(x) + c_2 \sin(x))$$

Or

$$v(x) = c_1 \cos(x) + c_2 \sin(x)$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 \cos(x) + c_2 \sin(x)$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$1$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$[\{1\}]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\{\cos(x), \sin(x)\}$$

Since there is no duplication between the basis function in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis in the UC_set.

$$v_p = A_1$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 = 1$$

Solving for the unknowns by comparing coefficients results in

$$[A_1 = 1]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = 1$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= (c_1 \cos(x) + c_2 \sin(x)) + (1) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= (c_1 \cos(x) + c_2 \sin(x) + 1)\, (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = x^2$$

Hence (7) becomes

$$y = (c_1 \cos(x) + c_2 \sin(x) + 1)\, x^2$$

Therefore the homogeneous solution y_h is

$$y_h = (c_1 \cos(x) + c_2 \sin(x) + 1)\, x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= x^2 \cos(x) \\ y_2 &= \sin(x)\, x^2 \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 \cos(x) & \sin(x) x^2 \\ \frac{d}{dx}(x^2 \cos(x)) & \frac{d}{dx}(\sin(x) x^2) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 \cos(x) & \sin(x) x^2 \\ 2x \cos(x) - \sin(x) x^2 & x^2 \cos(x) + 2\sin(x) x \end{vmatrix}$$

Therefore

$$W = \left(x^2 \cos(x)\right)\left(x^2 \cos(x) + 2\sin(x) x\right) - \left(\sin(x) x^2\right)\left(2x \cos(x) - \sin(x) x^2\right)$$

Which simplifies to

$$W = \cos(x)^2 x^4 + \sin(x)^2 x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x) x^6}{x^6}\, dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\, dx$$

Hence

$$u_1 = \cos(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^6 \cos(x)}{x^6}\, dx$$

Which simplifies to

$$u_2 = \int \cos(x)\, dx$$

Hence

$$u_2 = \sin(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \cos(x)^2 x^2 + x^2 \sin(x)^2$$

Which simplifies to

$$y_p(x) = x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left((c_1 \cos(x) + c_2 \sin(x) + 1)\, x^2\right) + \left(x^2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = (c_1 \cos(x) + c_2 \sin(x) + 1)\, x^2 + x^2 \tag{1}$$

Verification of solutions

$$y = (c_1 \cos(x) + c_2 \sin(x) + 1)\, x^2 + x^2$$

Verified OK.

10.27.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - 4y'x + (x^2 + 6)\,y = x^4 \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2)\,y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + (\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2)\,y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1\,\text{BesselJ}\,(n, \beta\,x^{\gamma}) + c_2\,\text{BesselY}\,(n, \beta\,x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= \frac{5}{2} \\
\beta &= 1 \\
n &= -\frac{1}{2} \\
\gamma &= 1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1x^2\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2x^2\sqrt{2}\,\sin(x)}{\sqrt{\pi}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1x^2\sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2x^2\sqrt{2}\,\sin(x)}{\sqrt{\pi}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of

parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2 \cos(x)$$
$$y_2 = \sin(x)\, x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 \cos(x) & \sin(x)\, x^2 \\ \frac{d}{dx}\left(x^2 \cos(x)\right) & \frac{d}{dx}\left(\sin(x)\, x^2\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 \cos(x) & \sin(x)\, x^2 \\ 2x \cos(x) - \sin(x)\, x^2 & x^2 \cos(x) + 2\sin(x)\, x \end{vmatrix}$$

Therefore

$$W = \left(x^2 \cos(x)\right)\left(x^2 \cos(x) + 2\sin(x)\, x\right) - \left(\sin(x)\, x^2\right)\left(2x \cos(x) - \sin(x)\, x^2\right)$$

Which simplifies to

$$W = \cos(x)^2\, x^4 + \sin(x)^2\, x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x)\,x^6}{x^6}\,dx$$

Which simplifies to

$$u_1 = -\int \sin(x)\,dx$$

Hence

$$u_1 = \cos(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^6 \cos(x)}{x^6}\,dx$$

Which simplifies to

$$u_2 = \int \cos(x)\,dx$$

Hence

$$u_2 = \sin(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \cos(x)^2 x^2 + x^2 \sin(x)^2$$

Which simplifies to

$$y_p(x) = x^2$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 x^2 \sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2 x^2 \sqrt{2}\,\sin(x)}{\sqrt{\pi}}\right) + (x^2) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^2 \sqrt{2}\,\cos(x)}{\sqrt{\pi}} + \frac{c_2 x^2 \sqrt{2}\,\sin(x)}{\sqrt{\pi}} + x^2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^2 \sqrt{2}\, \cos(x)}{\sqrt{\pi}} + \frac{c_2 x^2 \sqrt{2}\, \sin(x)}{\sqrt{\pi}} + x^2$$

Verified OK.

10.27.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 4y'x + (x^2 + 6)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -4x \\ C &= x^2 + 6 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-1}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -1 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = -z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 437: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -1$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \cos(x)$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-4x}{x^2}\,dx} \\
&= z_1 e^{2\ln(x)} \\
&= z_1 \left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^2 \cos(x)
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)}}{(y_1)^2}\,dx \\
&= y_1(\tan(x))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^2\cos(x)\right) + c_2\left(x^2\cos(x)\,(\tan(x))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$
x^2y'' - 4y'x + \left(x^2+6\right)y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \cos(x)\, x^2 c_1 + \sin(x)\, x^2 c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x^2 \cos(x)$$
$$y_2 = \sin(x)\, x^2$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x^2 \cos(x) & \sin(x)\, x^2 \\ \frac{d}{dx}\left(x^2 \cos(x)\right) & \frac{d}{dx}\left(\sin(x)\, x^2\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x^2 \cos(x) & \sin(x)\, x^2 \\ 2x \cos(x) - \sin(x)\, x^2 & x^2 \cos(x) + 2\sin(x)\, x \end{vmatrix}$$

Therefore

$$W = \left(x^2 \cos(x)\right)\left(x^2 \cos(x) + 2\sin(x)\, x\right) - \left(\sin(x)\, x^2\right)\left(2x \cos(x) - \sin(x)\, x^2\right)$$

Which simplifies to

$$W = \cos(x)^2 x^4 + \sin(x)^2 x^4$$

Which simplifies to

$$W = x^4$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\sin(x) x^6}{x^6} dx$$

Which simplifies to

$$u_1 = -\int \sin(x) dx$$

Hence

$$u_1 = \cos(x)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^6 \cos(x)}{x^6} dx$$

Which simplifies to

$$u_2 = \int \cos(x) dx$$

Hence

$$u_2 = \sin(x)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \cos(x)^2 x^2 + x^2 \sin(x)^2$$

Which simplifies to

$$y_p(x) = x^2$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\cos(x)\, x^2 c_1 + \sin(x)\, x^2 c_2\right) + \left(x^2\right)
\end{aligned}
$$

Which simplifies to

$$
y = x^2(c_1 \cos(x) + c_2 \sin(x)) + x^2
$$

Summary

The solution(s) found are the following

$$
y = x^2(c_1 \cos(x) + c_2 \sin(x)) + x^2 \tag{1}
$$

Verification of solutions

$$
y = x^2(c_1 \cos(x) + c_2 \sin(x)) + x^2
$$

Verified OK.

10.28.1 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x)+By'(x)+Cy(x)=f(x)$$

Where $A=x-1, B=-x, C=1, f(x)=2(x-1)^2\,\mathrm{e}^{x}$. Let the solution be

$$y=y_h+y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. Solving for y_h from

$$(x-1)\,y''-y'x+y=0$$

In normal form the ode

$$(x-1)\,y''-y'x+y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x)&=-\frac{x}{x-1}\\ q(x)&=\frac{1}{x-1} \end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}-\frac{n}{x-1}+\frac{1}{x-1}=0 \tag{5}$$

Solving (5) for n gives

$$n=1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x)+\left(\frac{2}{x}-\frac{x}{x-1}\right)v'(x)&=0\\ v''(x)+\left(\frac{2}{x}-\frac{x}{x-1}\right)v'(x)&=0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} - \frac{x}{x-1}\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u(x^2-2x+2)}{x\,(x-1)} \end{aligned}$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= \frac{x^2-2x+2}{x\,(x-1)}\,dx \\ \int \frac{1}{u}\,du &= \int \frac{x^2-2x+2}{x\,(x-1)}\,dx \\ \ln(u) &= x - 2\ln(x) + \ln(x-1) + c_1 \\ u &= \mathrm{e}^{x-2\ln(x)+\ln(x-1)+c_1} \\ &= c_1 \mathrm{e}^{x-2\ln(x)+\ln(x-1)} \end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2}\right)$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= \frac{c_1 \mathrm{e}^x}{x} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= \left(\frac{c_1 \mathrm{e}^x}{x} + c_2\right) x \\ &= c_1 \mathrm{e}^x + c_2 x \end{aligned}$$

Now the particular solution to this ODE is found

$$(x-1)\,y''-y'x+y=2(x-1)^2\,\mathrm{e}^x$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=x$$
$$y_2=\mathrm{e}^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$
$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix}y_1 & y_2\\ y_1' & y_2'\end{vmatrix}$. Hence

$$W=\begin{vmatrix}x & \mathrm{e}^x\\ \frac{d}{dx}(x) & \frac{d}{dx}(\mathrm{e}^x)\end{vmatrix}$$

Which gives

$$W=\begin{vmatrix}x & \mathrm{e}^x\\ 1 & \mathrm{e}^x\end{vmatrix}$$

Therefore

$$W=(x)\,(\mathrm{e}^x)-(\mathrm{e}^x)\,(1)$$

Which simplifies to

$$W = x\,e^{x} - e^{x}$$

Which simplifies to

$$W = (x-1)\,e^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x-1)^2\,e^{2x}}{(x-1)^2\,e^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int 2\,e^{x} dx$$

Hence

$$u_1 = -2\,e^{x}$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x(x-1)^2\,e^{x}}{(x-1)^2\,e^{x}}\,dx$$

Which simplifies to

$$u_2 = \int 2x dx$$

Hence

$$u_2 = x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x\,e^{x} + x^2 e^{x}$$

Which simplifies to

$$y_p(x) = x(-2+x)\,e^{x}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(\frac{c_1 e^x}{x} + c_2\right) x\right) + (x(-2+x)\, e^x) \\
&= x(-2+x)\, e^x + \left(\frac{c_1 e^x}{x} + c_2\right) x
\end{aligned}
$$

Which simplifies to

$$
y = \left(x^2 + c_1 - 2x\right) e^x + c_2 x
$$

Summary

The solution(s) found are the following

$$
y = \left(x^2 + c_1 - 2x\right) e^x + c_2 x \tag{1}
$$

Verification of solutions

$$
y = \left(x^2 + c_1 - 2x\right) e^x + c_2 x
$$

Verified OK.

10.28.2 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$
Ay'' + By' + Cy = F(x)
$$

This method reduces the order ode the ODE by one by applying the transformation

$$
y = Bv
$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0
\end{aligned} \tag{1}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned}
A &= x - 1 \\
B &= -x \\
C &= 1 \\
F &= 2(x - 1)^2 \, \mathrm{e}^x
\end{aligned}$$

The above shows that for this ode

$$\begin{aligned}
AB'' + BB' + CB &= (x - 1)\,(0) + (-x)\,(-1) + (1)\,(-x) \\
&= 0
\end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-x(x - 1)\,v'' + \left(x^2 - 2x + 2\right) v' = 0$$

Now by applying $v' = u$ the above becomes

$$\left(-x^2 + x\right) u'(x) + \left(x^2 - 2x + 2\right) u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= \frac{u(x^2 - 2x + 2)}{x\,(x - 1)}
\end{aligned}$$

Where $f(x) = \frac{x^2-2x+2}{x(x-1)}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= \frac{x^2-2x+2}{x\,(x-1)}\,dx \\
\int \frac{1}{u}\,du &= \int \frac{x^2-2x+2}{x\,(x-1)}\,dx \\
\ln(u) &= x - 2\ln(x) + \ln(x-1) + c_1 \\
u &= \mathrm{e}^{x-2\ln(x)+\ln(x-1)+c_1} \\
&= c_1 \mathrm{e}^{x-2\ln(x)+\ln(x-1)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2}\right)$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1\left(\frac{\mathrm{e}^x}{x} - \frac{\mathrm{e}^x}{x^2}\right)
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{(x-1)\,c_1\mathrm{e}^x}{x^2}\,\mathrm{d}x \\
&= \frac{c_1\mathrm{e}^x}{x} + c_2
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= Bv \\
&= (-x)\left(\frac{c_1\mathrm{e}^x}{x} + c_2\right) \\
&= -c_1\mathrm{e}^x - c_2 x
\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = e^x$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & e^x \\ \frac{d}{dx}(x) & \frac{d}{dx}(e^x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & e^x \\ 1 & e^x \end{vmatrix}$$

Therefore

$$W = (x)(e^x) - (e^x)(1)$$

Which simplifies to

$$W = x e^x - e^x$$

Which simplifies to

$$W = (x-1)e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{2(x-1)^2 e^{2x}}{(x-1)^2 e^x} dx$$

Which simplifies to

$$u_1 = -\int 2\,\mathrm{e}^x dx$$

Hence

$$u_1 = -2\,\mathrm{e}^x$$

And Eq. (3) becomes

$$u_2 = \int \frac{2x(x-1)^2\,\mathrm{e}^x}{(x-1)^2\,\mathrm{e}^x}\,dx$$

Which simplifies to

$$u_2 = \int 2x dx$$

Hence

$$u_2 = x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x\,\mathrm{e}^x + x^2\mathrm{e}^x$$

Which simplifies to

$$y_p(x) = x(-2+x)\,\mathrm{e}^x$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= (-c_1\mathrm{e}^x - c_2 x) + (x(-2+x)\,\mathrm{e}^x) \\ &= \left(x^2 - c_1 - 2x\right)\mathrm{e}^x - c_2 x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(x^2 - c_1 - 2x\right)\mathrm{e}^x - c_2 x \tag{1}$$

Verification of solutions

$$y = \left(x^2 - c_1 - 2x\right)\mathrm{e}^x - c_2 x$$

Verified OK.

10.28.3 Solving using Kovacic algorithm

Writing the ode as

$$(x-1)\,y''-y'x+y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=x-1\\B&=-x\\C&=1\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{x^2-4x+6}{4\,(x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=x^2-4x+6\\t&=4(x-1)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{x^2-4x+6}{4\,(x-1)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y=z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 438: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x-1)^2$. There is a pole at $x = 1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{1}{4} - \frac{1}{2(x-1)} + \frac{3}{4(x-1)^2}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{1}{2} - \frac{1}{2x} + \frac{1}{x^3} + \frac{11}{4x^4} + \frac{21}{4x^5} + \frac{15}{2x^6} + \frac{6}{x^7} - \frac{117}{16x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{1}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{1}{2}
\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v=0$ or not. Since $v=0$ then starting from $r=\frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{x^2-4x+6}{4x^2-8x+4} \\ &= Q + \frac{R}{4x^2-8x+4} \\ &= \left(\frac{1}{4}\right) + \left(\frac{-2x+5}{4x^2-8x+4}\right) \\ &= \frac{1}{4} + \frac{-2x+5}{4x^2-8x+4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -2. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(-\frac{1}{2}\right) - (0) \\ &= -\frac{1}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{1}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= -\frac{1}{2} \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{1}{2}}{\frac{1}{2}} - 0\right) &= \frac{1}{2} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^2-4x+6}{4(x-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	$\frac{1}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = -\frac{1}{2}$ then

$$\begin{aligned} d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\ &= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (+)[\sqrt{r}]_\infty \\ &= -\frac{1}{2\,(x-1)} + \left(\frac{1}{2}\right) \\ &= -\frac{1}{2\,(x-1)} + \frac{1}{2} \\ &= \frac{-2+x}{2x-2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)(0) + \left(\left(\frac{1}{2(x-1)^2}\right) + \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right)^2 - \left(\frac{x^2-4x+6}{4(x-1)^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \left(-\frac{1}{2(x-1)} + \frac{1}{2}\right) dx} \\ &= \frac{\mathrm{e}^{\frac{x}{2}}}{\sqrt{x-1}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{x-1}\, dx} \\ &= z_1 e^{\frac{x}{2} + \frac{\ln(x-1)}{2}} \\ &= z_1\left(\sqrt{x-1}\,\mathrm{e}^{\frac{x}{2}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^x$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{x-1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{x+\ln(x-1)}}{(y_1)^2}\, dx \\ &= y_1\left(-x\,\mathrm{e}^{-x}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 (\mathrm{e}^x) + c_2 \left(\mathrm{e}^x \left(-x\,\mathrm{e}^{-x}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
(x-1)\,y'' - y'x + y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1 \mathrm{e}^x - c_2 x
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \mathrm{e}^x \\
y_2 &= -x
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^x & -x \\ \frac{d}{dx}(e^x) & \frac{d}{dx}(-x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^x & -x \\ e^x & -1 \end{vmatrix}$$

Therefore

$$W = (e^x)(-1) - (-x)(e^x)$$

Which simplifies to

$$W = x e^x - e^x$$

Which simplifies to

$$W = (x-1)e^x$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2x(x-1)^2 e^x}{(x-1)^2 e^x}\,dx$$

Which simplifies to

$$u_1 = -\int -2x dx$$

Hence

$$u_1 = x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{2(x-1)^2 e^{2x}}{(x-1)^2 e^x}\,dx$$

Which simplifies to

$$u_2 = \int 2\,\mathrm{e}^x dx$$

Hence

$$u_2 = 2\,\mathrm{e}^x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -2x\,\mathrm{e}^x + x^2\mathrm{e}^x$$

Which simplifies to

$$y_p(x) = x(-2+x)\,\mathrm{e}^x$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1\mathrm{e}^x - c_2x) + (x(-2+x)\,\mathrm{e}^x) \end{aligned}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1\mathrm{e}^x - c_2x + x(-2+x)\,\mathrm{e}^x \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1\mathrm{e}^x - c_2x + x(-2+x)\,\mathrm{e}^x$$

Verified OK.

10.29.1 Solving as second order change of variable on y method 1 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$4x^2y'' + \left(-4x^2 - 4x\right)y' + (2x+3)\,y = 0$$

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{-4x^2 - 4x}{4x^2}$$
$$q(x) = \frac{2x + 3}{4x^2}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{2x+3}{4x^2} - \frac{\left(\frac{-4x^2-4x}{4x^2}\right)'}{2} - \frac{\left(\frac{-4x^2-4x}{4x^2}\right)^2}{4} \\
&= \frac{2x+3}{4x^2} - \frac{\left(\frac{-8x-4}{4x^2} - \frac{-4x^2-4x}{2x^3}\right)}{2} - \frac{\left(\frac{(-4x^2-4x)^2}{16x^4}\right)}{4} \\
&= \frac{2x+3}{4x^2} - \left(\frac{-8x-4}{8x^2} - \frac{-4x^2-4x}{4x^3}\right) - \frac{(-4x^2-4x)^2}{64x^4} \\
&= -\frac{1}{4}
\end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned}
z(x) &= e^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{\frac{-4x^2-4x}{4x^2}}{2}} \\
&= \sqrt{x}\, e^{\frac{x}{2}}
\end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\sqrt{x}\, e^{\frac{x}{2}} \tag{4}$$

Applying this change of variable to the original ode results in

$$e^{\frac{x}{2}} (4v''(x) - v(x)) = e^x$$

Which is now solved for $v(x)$ Simplyfing the ode gives

$$v''(x) - \frac{v(x)}{4} = \frac{e^{\frac{x}{2}}}{4}$$

This is second order non-homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = f(x)$$

Where $A = 1, B = 0, C = -\frac{1}{4}, f(x) = \frac{e^{\frac{x}{2}}}{4}$. Let the solution be

$$v(x) = v_h + v_p$$

Where v_h is the solution to the homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = 0$, and v_p is a particular solution to the non-homogeneous ODE $Av''(x)+Bv'(x)+Cv(x) = f(x)$. v_h is the solution to

$$v''(x) - \frac{v(x)}{4} = 0$$

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = -\frac{1}{4}$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} - \frac{e^{\lambda x}}{4} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 - \frac{1}{4} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -\frac{1}{4}$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)\left(-\frac{1}{4}\right)} \\ &= \pm\frac{1}{2}\end{aligned}$$

Hence

$$\lambda_1 = +\frac{1}{2}$$

$$\lambda_2 = -\frac{1}{2}$$

Which simplifies to

$$\lambda_1 = \frac{1}{2}$$
$$\lambda_2 = -\frac{1}{2}$$

Since roots are real and distinct, then the solution is

$$v(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$v(x) = c_1 e^{\left(\frac{1}{2}\right)x} + c_2 e^{\left(-\frac{1}{2}\right)x}$$

Or

$$v(x) = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

Therefore the homogeneous solution v_h is

$$v_h = c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}}$$

The particular solution is now found using the method of undetermined coefficients. Looking at the RHS of the ode, which is

$$\frac{\mathrm{e}^{\frac{x}{2}}}{4}$$

Shows that the corresponding undetermined set of the basis functions (UC_set) for the trial solution is

$$\left[\left\{\mathrm{e}^{\frac{x}{2}}\right\}\right]$$

While the set of the basis functions for the homogeneous solution found earlier is

$$\left\{\mathrm{e}^{-\frac{x}{2}}, \mathrm{e}^{\frac{x}{2}}\right\}$$

Since $\mathrm{e}^{\frac{x}{2}}$ is duplicated in the UC_set, then this basis is multiplied by extra x. The UC_set becomes

$$\left[\left\{\mathrm{e}^{\frac{x}{2}} x\right\}\right]$$

Since there was duplication between the basis functions in the UC_set and the basis functions of the homogeneous solution, the trial solution is a linear combination of all the basis function in the above updated UC_set.

$$v_p = A_1 \mathrm{e}^{\frac{x}{2}} x$$

The unknowns $\{A_1\}$ are found by substituting the above trial solution v_p into the ODE and comparing coefficients. Substituting the trial solution into the ODE and simplifying gives

$$A_1 e^{\frac{x}{2}} = \frac{e^{\frac{x}{2}}}{4}$$

Solving for the unknowns by comparing coefficients results in

$$\left[A_1 = \frac{1}{4}\right]$$

Substituting the above back in the above trial solution v_p, gives the particular solution

$$v_p = \frac{e^{\frac{x}{2}} x}{4}$$

Therefore the general solution is

$$\begin{aligned} v &= v_h + v_p \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}}\right) + \left(\frac{e^{\frac{x}{2}} x}{4}\right) \end{aligned}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} + \frac{e^{\frac{x}{2}} x}{4}\right) (z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \sqrt{x}\, e^{\frac{x}{2}}$$

Hence (7) becomes

$$y = \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} + \frac{e^{\frac{x}{2}} x}{4}\right) \sqrt{x}\, e^{\frac{x}{2}}$$

Therefore the homogeneous solution y_h is

$$y_h = \left(c_1 e^{\frac{x}{2}} + c_2 e^{-\frac{x}{2}} + \frac{e^{\frac{x}{2}} x}{4}\right) \sqrt{x}\, e^{\frac{x}{2}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{x}\, e^{x}$$
$$y_2 = e^{-\frac{x}{2}} \sqrt{x}\, e^{\frac{x}{2}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x}\, e^{x} & e^{-\frac{x}{2}} \sqrt{x}\, e^{\frac{x}{2}} \\ \frac{d}{dx}\left(\sqrt{x}\, e^{x}\right) & \frac{d}{dx}\left(e^{-\frac{x}{2}} \sqrt{x}\, e^{\frac{x}{2}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x}\, e^{x} & e^{-\frac{x}{2}} \sqrt{x}\, e^{\frac{x}{2}} \\ \sqrt{x}\, e^{x} + \frac{e^{x}}{2\sqrt{x}} & \frac{e^{-\frac{x}{2}} e^{\frac{x}{2}}}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x}\, e^{x}\right) \left(\frac{e^{-\frac{x}{2}} e^{\frac{x}{2}}}{2\sqrt{x}}\right) - \left(e^{-\frac{x}{2}} \sqrt{x}\, e^{\frac{x}{2}}\right) \left(\sqrt{x}\, e^{x} + \frac{e^{x}}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = -e^{\frac{3x}{2}} e^{-\frac{x}{2}} x$$

Which simplifies to

$$W = -x\,\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\mathrm{e}^{-\frac{x}{2}} x^3 \mathrm{e}^{\frac{x}{2}} \mathrm{e}^{x}}{-4\,\mathrm{e}^{x} x^3}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{1}{4} dx$$

Hence

$$u_1 = \frac{x}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(\mathrm{e}^{x})^2\, x^3}{-4\,\mathrm{e}^{x} x^3}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{\mathrm{e}^{x}}{4} dx$$

Hence

$$u_2 = -\frac{\mathrm{e}^{x}}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^{\frac{3}{2}} \mathrm{e}^{x}}{4} - \frac{\mathrm{e}^{x} \mathrm{e}^{-\frac{x}{2}} \sqrt{x}\,\mathrm{e}^{\frac{x}{2}}}{4}$$

Which simplifies to

$$y_p(x) = \frac{\mathrm{e}^{x} \sqrt{x}\,(x-1)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\left(c_1 \mathrm{e}^{\frac{x}{2}} + c_2 \mathrm{e}^{-\frac{x}{2}} + \frac{\mathrm{e}^{\frac{x}{2}} x}{4}\right) \sqrt{x}\,\mathrm{e}^{\frac{x}{2}}\right) + \left(\frac{\mathrm{e}^{x} \sqrt{x}\,(x-1)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{((x + 4c_1)\,e^x + 4c_2)\,\sqrt{x}}{4} + \frac{e^x \sqrt{x}\,(x - 1)}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{((x + 4c_1)\,e^x + 4c_2)\,\sqrt{x}}{4} + \frac{e^x \sqrt{x}\,(x - 1)}{4} \tag{1}$$

Verification of solutions

$$y = \frac{((x + 4c_1)\,e^x + 4c_2)\,\sqrt{x}}{4} + \frac{e^x \sqrt{x}\,(x - 1)}{4}$$

Verified OK.

10.29.2 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = 4x^2, B = -4x^2 - 4x, C = 2x + 3, f(x) = x^{\frac{5}{2}} e^x$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$4x^2y'' + (-4x^2 - 4x)\,y' + (2x + 3)\,y = 0$$

In normal form the ode

$$4x^2y'' + (-4x^2 - 4x)\,y' + (2x + 3)\,y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$
\begin{aligned}
p(x) &= \frac{-x-1}{x} \\
q(x) &= \frac{2x+3}{4x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} + \frac{n(-x-1)}{x^2} + \frac{2x+3}{4x^2} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = \frac{1}{2} \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \left(\frac{1}{x} + \frac{-x-1}{x}\right) v'(x) &= 0 \\
v''(x) - v'(x) &= 0 \qquad (7)
\end{aligned}
$$

Using the substitution

$$
u(x) = v'(x)
$$

Then (7) becomes

$$
u'(x) - u(x) = 0 \tag{8}
$$

The above is now solved for $u(x)$. Integrating both sides gives

$$
\begin{aligned}
\int \frac{1}{u} du &= x + c_1 \\
\ln(u) &= x + c_1 \\
u &= e^{x+c_1} \\
u &= c_1 e^x
\end{aligned}
$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= c_1 \mathrm{e}^{x} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^{n} \\ &= (c_1 \mathrm{e}^{x} + c_2)\,\sqrt{x} \\ &= (c_1 \mathrm{e}^{x} + c_2)\,\sqrt{x} \end{aligned}$$

Now the particular solution to this ODE is found

$$4x^{2}y'' + \left(-4x^{2} - 4x\right) y' + (2x+3)\,y = x^{\frac{5}{2}} \mathrm{e}^{x}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \sqrt{x} \\ y_2 &= \sqrt{x}\,\mathrm{e}^{x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x} & \sqrt{x}\,e^{x} \\ \frac{d}{dx}\left(\sqrt{x}\right) & \frac{d}{dx}\left(\sqrt{x}\,e^{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x} & \sqrt{x}\,e^{x} \\ \frac{1}{2\sqrt{x}} & \sqrt{x}\,e^{x} + \frac{e^{x}}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x}\right)\left(\sqrt{x}\,e^{x} + \frac{e^{x}}{2\sqrt{x}}\right) - \left(\sqrt{x}\,e^{x}\right)\left(\frac{1}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x\,e^{x}$$

Which simplifies to

$$W = x\,e^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{e^{2x} x^3}{4\,e^{x} x^3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{e^{x}}{4} dx$$

Hence

$$u_1 = -\frac{e^{x}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{e^{x} x^3}{4\,e^{x} x^3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{4} dx$$

Hence

$$u_2 = \frac{x}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^{\frac{3}{2}} \mathrm{e}^x}{4} - \frac{\sqrt{x}\, \mathrm{e}^x}{4}$$

Which simplifies to

$$y_p(x) = \frac{\mathrm{e}^x \sqrt{x}\, (x - 1)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left((c_1 \mathrm{e}^x + c_2) \sqrt{x}\right) + \left(\frac{\mathrm{e}^x \sqrt{x}\, (x - 1)}{4}\right) \\ &= \frac{\mathrm{e}^x \sqrt{x}\, (x - 1)}{4} + (c_1 \mathrm{e}^x + c_2) \sqrt{x} \end{aligned}$$

Which simplifies to

$$y = \frac{\sqrt{x}\, ((x + 4c_1 - 1)\, \mathrm{e}^x + 4c_2)}{4}$$

Summary

The solution(s) found are the following

$$y = \frac{\sqrt{x}\, ((x + 4c_1 - 1)\, \mathrm{e}^x + 4c_2)}{4} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{x}\, ((x + 4c_1 - 1)\, \mathrm{e}^x + 4c_2)}{4}$$

Verified OK.

10.29.3 Solving using Kovacic algorithm

Writing the ode as

$$4x^2y'' + (-4x^2 - 4x)\,y' + (2x+3)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 4x^2 \\ B &= -4x^2 - 4x \\ C &= 2x + 3 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{1}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 1 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \frac{z(x)}{4} \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 439: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{1}{4}$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = \mathrm{e}^{-\frac{x}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2} \frac{-4x^2-4x}{4x^2}\, dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\, \mathrm{e}^{\frac{x}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \sqrt{x}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-4x^2-4x}{4x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{x+\ln(x)}}{(y_1)^2}\, dx \\
&= y_1(\mathrm{e}^{x})
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x}\right) + c_2\left(\sqrt{x}(\mathrm{e}^{x})\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
4x^2y'' + \left(-4x^2 - 4x\right) y' + (2x + 3)\, y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \sqrt{x}\, c_1 + c_2\sqrt{x}\, \mathrm{e}^{x}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \sqrt{x}$$
$$y_2 = \sqrt{x}\,\mathrm{e}^{x}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \sqrt{x} & \sqrt{x}\,\mathrm{e}^{x} \\ \frac{d}{dx}\left(\sqrt{x}\right) & \frac{d}{dx}\left(\sqrt{x}\,\mathrm{e}^{x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \sqrt{x} & \sqrt{x}\,\mathrm{e}^{x} \\ \frac{1}{2\sqrt{x}} & \sqrt{x}\,\mathrm{e}^{x} + \frac{\mathrm{e}^{x}}{2\sqrt{x}} \end{vmatrix}$$

Therefore

$$W = \left(\sqrt{x}\right)\left(\sqrt{x}\,\mathrm{e}^{x} + \frac{\mathrm{e}^{x}}{2\sqrt{x}}\right) - \left(\sqrt{x}\,\mathrm{e}^{x}\right)\left(\frac{1}{2\sqrt{x}}\right)$$

Which simplifies to

$$W = x\,\mathrm{e}^{x}$$

Which simplifies to

$$W = x\,\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\mathrm{e}^{2x} x^{3}}{4\,\mathrm{e}^{x} x^{3}}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\mathrm{e}^{x}}{4}dx$$

Hence

$$u_1 = -\frac{\mathrm{e}^{x}}{4}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{x} x^{3}}{4\,\mathrm{e}^{x} x^{3}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{4}dx$$

Hence

$$u_2 = \frac{x}{4}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^{\frac{3}{2}}\mathrm{e}^{x}}{4} - \frac{\sqrt{x}\,\mathrm{e}^{x}}{4}$$

Which simplifies to

$$y_p(x) = \frac{\mathrm{e}^{x}\sqrt{x}\,(x-1)}{4}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\sqrt{x}\,c_1 + c_2\sqrt{x}\,\mathrm{e}^{x}\right) + \left(\frac{\mathrm{e}^{x}\sqrt{x}\,(x-1)}{4}\right) \end{aligned}$$

Which simplifies to

$$y = (c_1 + c_2 e^x)\sqrt{x} + \frac{e^x\sqrt{x}\,(x-1)}{4}$$

Summary

The solution(s) found are the following

$$y = (c_1 + c_2 e^x)\sqrt{x} + \frac{e^x\sqrt{x}\,(x-1)}{4} \tag{1}$$

Verification of solutions

$$y = (c_1 + c_2 e^x)\sqrt{x} + \frac{e^x\sqrt{x}\,(x-1)}{4}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _linear, _nonhomogeneous]]
```

$$\boxed{(3x-1)\,y''-(3x+2)\,y'-(6x-8)\,y=(3x-1)^2\,\mathrm{e}^{2x}}$$

With initial conditions

$$[y(0)=1, y'(0)=2]$$

10.30.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$\begin{aligned}p(x)&=\frac{-3x-2}{3x-1}\\q(x)&=\frac{-6x+8}{3x-1}\\F&=(3x-1)\,\mathrm{e}^{2x}\end{aligned}$$

Hence the ode is

$$y'' + \frac{(-3x-2)\,y'}{3x-1} + \frac{(-6x+8)\,y}{3x-1} = (3x-1)\,\mathrm{e}^{2x}$$

The domain of $p(x) = \frac{-3x-2}{3x-1}$ is

$$\left\{x < \frac{1}{3} \lor \frac{1}{3} < x\right\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{-6x+8}{3x-1}$ is

$$\left\{x < \frac{1}{3} \lor \frac{1}{3} < x\right\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = (3x-1)\,\mathrm{e}^{2x}$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.30.2 Solving using Kovacic algorithm

Writing the ode as

$$(3x-1)\,y'' + (-3x-2)\,y' + (-6x+8)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 3x-1 \\ B &= -3x-2 \\ C &= -6x+8 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{81x^2 - 108x + 54}{4(3x-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 81x^2 - 108x + 54 \\ t &= 4(3x-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{81x^2 - 108x + 54}{4(3x-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 440: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(3x-1)^2$. There is a pole at $x = \frac{1}{3}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{9}{4} + \frac{3}{4\left(x - \frac{1}{3}\right)^2} - \frac{3}{2\left(x - \frac{1}{3}\right)}$$

For the pole at $x = \frac{1}{3}$ let b be the coefficient of $\frac{1}{\left(x-\frac{1}{3}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{3}{2} - \frac{1}{2x} + \frac{1}{9x^3} + \frac{11}{108x^4} + \frac{7}{108x^5} + \frac{5}{162x^6} + \frac{2}{243x^7} - \frac{13}{3888x^8} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{3}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{3}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{9}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{81x^2 - 108x + 54}{36x^2 - 24x + 4} \\ &= Q + \frac{R}{36x^2 - 24x + 4} \\ &= \left(\frac{9}{4}\right) + \left(\frac{-54x + 45}{36x^2 - 24x + 4}\right) \\ &= \frac{9}{4} + \frac{-54x + 45}{36x^2 - 24x + 4} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is -54. Dividing this by leading coefficient in t which is 36 gives $-\frac{3}{2}$. Now b can be found.

$$
\begin{aligned}
b &= \left(-\frac{3}{2}\right) - (0) \\
&= -\frac{3}{2}
\end{aligned}
$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{3}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-\frac{3}{2}}{\frac{3}{2}} - 0\right) &= -\frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-\frac{3}{2}}{\frac{3}{2}} - 0\right) &= \frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{81x^2 - 108x + 54}{4(3x-1)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{1}{3}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{3}{2}$	$-\frac{1}{2}$	$\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - (\alpha_{c_1}^-) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (+)[\sqrt{r}]_\infty \\
&= -\frac{1}{2\left(x - \frac{1}{3}\right)} + \left(\frac{3}{2}\right) \\
&= -\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2} \\
&= \frac{9x - 6}{6x - 2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2}\right)(0) + \left(\left(\frac{1}{2\left(x - \frac{1}{3}\right)^2}\right) + \left(-\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2}\right)^2 - \left(\frac{81x^2 - 108x + 54}{4\left(3x - 1\right)^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2\left(x - \frac{1}{3}\right)} + \frac{3}{2}\right) dx} \\
&= \frac{\mathrm{e}^{\frac{3x}{2}}}{\sqrt{3x - 1}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x-2}{3x-1}\,dx} \\
&= z_1 e^{\frac{x}{2}+\frac{\ln(3x-1)}{2}} \\
&= z_1\left(\mathrm{e}^{\frac{x}{2}}\sqrt{3x-1}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-3x-2}{3x-1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{x+\ln(3x-1)}}{(y_1)^2}\,dx \\
&= y_1\left(-x\,\mathrm{e}^{-3x}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{2x}\right) + c_2\left(\mathrm{e}^{2x}\left(-x\,\mathrm{e}^{-3x}\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$(3x-1)\,y'' + (-3x-2)\,y' + (-6x+8)\,y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = c_1 e^{2x} - x\,e^{-x} c_2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= e^{2x} \\ y_2 &= -x\,e^{-x} \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} e^{2x} & -x\,e^{-x} \\ \frac{d}{dx}\left(e^{2x}\right) & \frac{d}{dx}\left(-x\,e^{-x}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} e^{2x} & -x\,e^{-x} \\ 2\,e^{2x} & -e^{-x} + x\,e^{-x} \end{vmatrix}$$

Therefore

$$W = \left(e^{2x}\right)\left(-e^{-x} + x\,e^{-x}\right) - \left(-x\,e^{-x}\right)\left(2\,e^{2x}\right)$$

Which simplifies to

$$W = 3x\,\mathrm{e}^{-x}\mathrm{e}^{2x} - \mathrm{e}^{2x}\mathrm{e}^{-x}$$

Which simplifies to

$$W = (3x-1)\,\mathrm{e}^{x}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-x\,\mathrm{e}^{-x}(3x-1)^2\,\mathrm{e}^{2x}}{(3x-1)^2\,\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_1 = -\int -x dx$$

Hence

$$u_1 = \frac{x^2}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\mathrm{e}^{4x}(3x-1)^2}{(3x-1)^2\,\mathrm{e}^{x}}\,dx$$

Which simplifies to

$$u_2 = \int \mathrm{e}^{3x} dx$$

Hence

$$u_2 = \frac{\mathrm{e}^{3x}}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{x^2\mathrm{e}^{2x}}{2} - \frac{\mathrm{e}^{3x}x\,\mathrm{e}^{-x}}{3}$$

Which simplifies to

$$y_p(x) = \frac{\mathrm{e}^{2x}x(3x-2)}{6}$$

Therefore the general solution is

$$
\begin{aligned}
y &= y_h + y_p \\
&= \left(c_1 \mathrm{e}^{2x} - x\,\mathrm{e}^{-x} c_2\right) + \left(\frac{\mathrm{e}^{2x} x(3x-2)}{6}\right)
\end{aligned}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = c_1 \mathrm{e}^{2x} - x\,\mathrm{e}^{-x} c_2 + \frac{\mathrm{e}^{2x} x(3x-2)}{6} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 0$ in the above gives

$$
1 = c_1 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = 2c_1 \mathrm{e}^{2x} - c_2 \mathrm{e}^{-x} + x\,\mathrm{e}^{-x} c_2 + \frac{\mathrm{e}^{2x} x(3x-2)}{3} + \frac{\mathrm{e}^{2x}(3x-2)}{6} + \frac{x\,\mathrm{e}^{2x}}{2}
$$

substituting $y' = 2$ and $x = 0$ in the above gives

$$
2 = 2c_1 - c_2 - \frac{1}{3} \tag{2A}
$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= 1 \\
c_2 &= -\frac{1}{3}
\end{aligned}
$$

Substituting these values back in above solution results in

$$
y = \mathrm{e}^{2x} + \frac{x\,\mathrm{e}^{-x}}{3} + \frac{x^2 \mathrm{e}^{2x}}{2} - \frac{x\,\mathrm{e}^{2x}}{3}
$$

Which simplifies to

$$
y = \frac{(3x^2 - 2x + 6)\,\mathrm{e}^{2x}}{6} + \frac{x\,\mathrm{e}^{-x}}{3}
$$

Summary

The solution(s) found are the following

$$
y = \frac{(3x^2 - 2x + 6)\,\mathrm{e}^{2x}}{6} + \frac{x\,\mathrm{e}^{-x}}{3} \tag{1}
$$

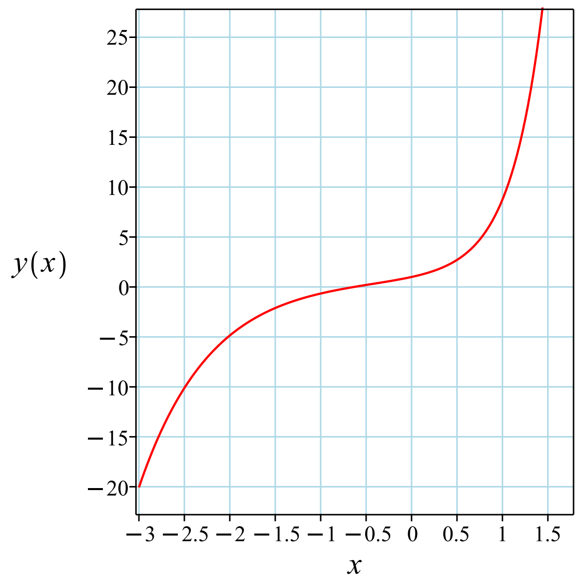

Figure 521: Solution plot

Verification of solutions

$$y = \frac{(3x^2 - 2x + 6)\,e^{2x}}{6} + \frac{x\,e^{-x}}{3}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x-1)^2 y''-2(x-1)\,y'+2y=(x-1)^2}$$

With initial conditions

$$[y(0)=3, y'(0)=-6]$$

10.31.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned} p(x) &= \frac{-2x+2}{(x-1)^2} \\ q(x) &= \frac{2}{(x-1)^2} \\ F &= 1 \end{aligned}$$

Hence the ode is

$$y'' + \frac{(-2x+2)\,y'}{(x-1)^2} + \frac{2y}{(x-1)^2} = 1$$

The domain of $p(x) = \frac{-2x+2}{(x-1)^2}$ is

$$\{x < 1 \lor 1 < x\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{2}{(x-1)^2}$ is

$$\{x < 1 \lor 1 < x\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.31.2 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{(p(x)^2 + p'(x))\,y}{2} = f(x)$$

Where $p(x) = -\frac{2}{x-1}$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int -\frac{2}{x-1}\,dx} \\ &= \frac{1}{x-1} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$\begin{aligned} (M(x)y)'' &= \frac{1}{x-1} \\ \left(\frac{y}{x-1}\right)'' &= \frac{1}{x-1} \end{aligned}$$

Integrating once gives

$$\left(\frac{y}{x-1}\right)' = \ln(x-1) + c_1$$

Integrating again gives

$$\left(\frac{y}{x-1}\right) = \ln(x-1)(x-1) + 1 + (c_1 - 1)x + c_2$$

Hence the solution is

$$y = \frac{\ln(x-1)(x-1) + 1 + (c_1 - 1)x + c_2}{\frac{1}{x-1}}$$

Or

$$y = x^2 \ln(x-1) - x^2 - 2x \ln(x-1) + (x^2 - x) c_1 + (x-1) c_2 + 2x + \ln(x-1) - 1$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = x^2 \ln(x-1) - x^2 - 2x \ln(x-1) + (x^2 - x) c_1 + (x-1) c_2 + 2x + \ln(x-1) - 1 \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = i\pi - c_2 - 1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2x\ln(x-1) + \frac{x^2}{x-1} - 2x - 2\ln(x-1) - \frac{2x}{x-1} + (2x-1)c_1 + c_2 + 2 + \frac{1}{x-1}$$

substituting $y' = -6$ and $x = 0$ in the above gives

$$-6 = -2i\pi - c_1 + c_2 + 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -i\pi + 3 \\ c_2 &= i\pi - 4 \end{aligned}$$

Substituting these values back in above solution results in

$$y = x^2\ln(x-1) + 2x^2 - 2x\ln(x-1) - 5x - ix^2\pi + 2ix\pi - i\pi + 3 + \ln(x-1)$$

Summary
The solution(s) found are the following

$$y = -((1-x)\ln(x-1) + ix\pi - i\pi - 2x + 3)(x-1) \tag{1}$$

Verification of solutions

$$y = -((1-x)\ln(x-1) + ix\pi - i\pi - 2x + 3)(x-1)$$

Verified OK.

10.31.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$(x-1)^2 y'' + (-2x+2)y' + 2y = 0$$

In normal form the ode

$$(x-1)^2 y'' + (-2x+2) y' + 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2}{1-x} \\ q(x) &= \frac{2}{(x-1)^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau) \right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x) \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x) \tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned} \tau &= \int e^{-(\int p(x) dx)} dx \\ &= \int e^{-\left(\int \frac{2}{1-x} dx\right)} dx \\ &= \int e^{2\ln(1-x)} dx \\ &= \int (x-1)^2 dx \\ &= \frac{(x-1)^3}{3} \end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{2}{(x-1)^2}}{(x-1)^4} \\
&= \frac{2}{(x-1)^6}
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{(x-1)^6} &= 0
\end{aligned}
$$

But in terms of τ

$$
\frac{2}{(x-1)^6} = \frac{2}{9\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) + \frac{2y(\tau)}{9\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
9\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + 2y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
9\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + 2\tau^r = 0
$$

Simplifying gives

$$
9r(r-1)\,\tau^r + 0\,\tau^r + 2\tau^r = 0
$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$
9r(r-1) + 0 + 2 = 0
$$

Or

$$
9r^2 - 9r + 2 = 0 \tag{1}
$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{3}$$
$$r_2 = \frac{2}{3}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{\frac{1}{3}} + c_2 \tau^{\frac{2}{3}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{c_1 3^{\frac{2}{3}} \left((x-1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x-1)^3\right)^{\frac{2}{3}}}{3}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 3^{\frac{2}{3}} \left((x-1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x-1)^3\right)^{\frac{2}{3}}}{3}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \left(x^3 - 3x^2 + 3x - 1\right)^{\frac{1}{3}}$$
$$y_2 = \left(x^3 - 3x^2 + 3x - 1\right)^{\frac{2}{3}}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} (x^3-3x^2+3x-1)^{\frac{1}{3}} & (x^3-3x^2+3x-1)^{\frac{2}{3}} \\ \frac{d}{dx}\left((x^3-3x^2+3x-1)^{\frac{1}{3}}\right) & \frac{d}{dx}\left((x^3-3x^2+3x-1)^{\frac{2}{3}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} (x^3-3x^2+3x-1)^{\frac{1}{3}} & (x^3-3x^2+3x-1)^{\frac{2}{3}} \\ \frac{3x^2-6x+3}{3(x^3-3x^2+3x-1)^{\frac{2}{3}}} & \frac{2x^2-4x+2}{(x^3-3x^2+3x-1)^{\frac{1}{3}}} \end{vmatrix}$$

Therefore

$$W = \left((x^3-3x^2+3x-1)^{\frac{1}{3}}\right)\left(\frac{2x^2-4x+2}{(x^3-3x^2+3x-1)^{\frac{1}{3}}}\right) - \left((x^3-3x^2+3x-1)^{\frac{2}{3}}\right)\left(\frac{3x^2-6x+3}{3(x^3-3x^2+3x-1)^{\frac{2}{3}}}\right)$$

Which simplifies to

$$W = x^2 - 2x + 1$$

Which simplifies to

$$W = (x-1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(x^3-3x^2+3x-1)^{\frac{2}{3}}(x-1)^2}{(x-1)^4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{\left((x-1)^3\right)^{\frac{2}{3}}}{(x-1)^2}dx$$

Hence

$$u_1 = -\frac{\left((x-1)^3\right)^{\frac{2}{3}} x}{(x-1)^2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x^3 - 3x^2 + 3x - 1)^{\frac{1}{3}} (x - 1)^2}{(x - 1)^4} dx$$

Which simplifies to

$$u_2 = \int \frac{\left((x - 1)^3\right)^{\frac{1}{3}}}{(x - 1)^2} dx$$

Hence

$$u_2 = \frac{\left((x - 1)^3\right)^{\frac{1}{3}} \ln (x - 1)}{x - 1}$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) \\ &= -\frac{\left((x - 1)^3\right)^{\frac{2}{3}} x(x^3 - 3x^2 + 3x - 1)^{\frac{1}{3}}}{(x - 1)^2} + \frac{\left((x - 1)^3\right)^{\frac{1}{3}} \ln (x - 1) (x^3 - 3x^2 + 3x - 1)^{\frac{2}{3}}}{x - 1} \end{aligned}$$

Which simplifies to

$$y_p(x) = (x - 1) (\ln (x - 1) (x - 1) - x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 3^{\frac{2}{3}} \left((x - 1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x - 1)^3\right)^{\frac{2}{3}}}{3}\right) + ((x - 1) (\ln (x - 1) (x - 1) - x)) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1 3^{\frac{2}{3}} \left((x - 1)^3\right)^{\frac{1}{3}}}{3} + \frac{c_2 3^{\frac{1}{3}} \left((x - 1)^3\right)^{\frac{2}{3}}}{3} + (x - 1) (\ln (x - 1) (x - 1) - x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = \frac{3^{\frac{2}{3}} c_1}{6} + \frac{i 3^{\frac{1}{6}} c_1}{2} - \frac{3^{\frac{1}{3}} c_2}{6} + \frac{i 3^{\frac{5}{6}} c_2}{6} + i\pi \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{c_1 3^{\frac{2}{3}} (x-1)^2}{3 \left((x-1)^3\right)^{\frac{2}{3}}} + \frac{2 c_2 3^{\frac{1}{3}} (x-1)^2}{3 \left((x-1)^3\right)^{\frac{1}{3}}} + 2 \ln(x-1)(x-1) - x$$

substituting $y' = -6$ and $x = 0$ in the above gives

$$-6 = -\frac{3^{\frac{2}{3}} c_1}{6} - \frac{i 3^{\frac{1}{6}} c_1}{2} + \frac{3^{\frac{1}{3}} c_2}{3} - \frac{i 3^{\frac{5}{6}} c_2}{3} - 2i\pi \tag{2A}$$

Equations $\{1A, 2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = -\frac{6(3i + \pi)}{3^{\frac{5}{6}} + i 3^{\frac{1}{3}}}$$

Substituting these values back in above solution results in

$$y = \frac{3^{\frac{5}{6}} \ln(x-1) x^2 - 2\, 3^{\frac{5}{6}} \ln(x-1) x - 3^{\frac{5}{6}} x^2 + 3^{\frac{5}{6}} \ln(x-1) + 3^{\frac{5}{6}} x + i 3^{\frac{1}{3}} \ln(x-1) x^2 - 2 i 3^{\frac{1}{3}} \ln(x-1)}{3^{\frac{5}{6}} + i 3^{\frac{1}{3}}}$$

Summary

The solution(s) found are the following

$$y = \frac{-6\left(i + \frac{\pi}{3}\right) 3^{\frac{1}{3}} \left((x-1)^3\right)^{\frac{2}{3}} + (\ln(x-1)(x-1) - x)\left(3^{\frac{5}{6}} + i 3^{\frac{1}{3}}\right)(x-1)}{3^{\frac{5}{6}} + i 3^{\frac{1}{3}}} \tag{1}$$

Verification of solutions

$$y = \frac{-6\left(i + \frac{\pi}{3}\right) 3^{\frac{1}{3}} \left((x-1)^3\right)^{\frac{2}{3}} + (\ln(x-1)(x-1) - x)\left(3^{\frac{5}{6}} + i 3^{\frac{1}{3}}\right)(x-1)}{3^{\frac{5}{6}} + i 3^{\frac{1}{3}}}$$

Verified OK.

10.31.4 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right)v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right)u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= (x-1)^2 \\ B &= -2x + 2 \\ C &= 2 \\ F &= (x-1)^2 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= \left((x-1)^2\right)(0) + (-2x+2)(-2) + (2)(-2x+2) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$-2(x-1)^3\, v'' + (0)\, v' = 0$$

Now by applying $v' = u$ the above becomes

$$-2(x-1)^3\, u'(x) = 0$$

Which is now solved for u. Integrating both sides gives

$$\begin{aligned} u(x) &= \int 0 \,\mathrm{d}x \\ &= c_1 \end{aligned}$$

The ode for v now becomes

$$\begin{aligned} v' &= u \\ &= c_1 \end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned} v(x) &= \int c_1 \,\mathrm{d}x \\ &= c_1 x + c_2 \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= Bv \\ &= (-2x+2)\,(c_1 x + c_2) \\ &= -2(x-1)\,(c_1 x + c_2) \end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= -2x + 2 \\ y_2 &= -2x^2 + 2x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} -2x+2 & -2x^2+2x \\ \frac{d}{dx}(-2x+2) & \frac{d}{dx}(-2x^2+2x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} -2x+2 & -2x^2+2x \\ -2 & -4x+2 \end{vmatrix}$$

Therefore

$$W = (-2x+2)(-4x+2) - (-2x^2+2x)(-2)$$

Which simplifies to

$$W = 4x^2 - 8x + 4$$

Which simplifies to

$$W = 4(x-1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{(-2x^2+2x)(x-1)^2}{4(x-1)^4}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{x}{2x-2}\,dx$$

Hence

$$u_1 = \frac{x}{2} + \frac{\ln(x-1)}{2}$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x-1)^2(-2x+2)}{4(x-1)^4}\, dx$$

Which simplifies to

$$u_2 = \int -\frac{1}{2x-2} dx$$

Hence

$$u_2 = -\frac{\ln(x-1)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \left(\frac{x}{2} + \frac{\ln(x-1)}{2}\right)(-2x+2) - \frac{\ln(x-1)(-2x^2+2x)}{2}$$

Which simplifies to

$$y_p(x) = (x-1)(\ln(x-1)(x-1) - x)$$

Hence the complete solution is

$$\begin{aligned}y(x) &= y_h + y_p \\ &= (-2(x-1)(c_1x + c_2)) + ((x-1)(\ln(x-1)(x-1) - x)) \\ &= (x-1)^2 \ln(x-1) - (x-1)(2c_1x + 2c_2 + x)\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (x-1)^2 \ln(x-1) - (x-1)(2c_1x + 2c_2 + x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = i\pi + 2c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = 2\ln(x-1)(x-1) - 1 - 2c_1x - 2c_2 - (x-1)(2c_1+1)$$

substituting $y' = -6$ and $x = 0$ in the above gives

$$-6 = -2i\pi + 2c_1 - 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -\frac{3}{2} + \frac{i\pi}{2} \\ c_2 &= \frac{3}{2} - \frac{i\pi}{2} \end{aligned}$$

Substituting these values back in above solution results in

$$y = x^2 \ln(x-1) + 2x^2 - 2x\ln(x-1) - 5x - ix^2\pi + 2ix\pi - i\pi + 3 + \ln(x-1)$$

Summary

The solution(s) found are the following

$$y = -((1-x)\ln(x-1) + ix\pi - i\pi - 2x + 3)(x-1) \tag{1}$$

Verification of solutions

$$y = -((1-x)\ln(x-1) + ix\pi - i\pi - 2x + 3)(x-1)$$

Verified OK.

10.31.5 Solving using Kovacic algorithm

Writing the ode as

$$(x-1)^2 y'' + (-2x+2)y' + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (x-1)^2 \\ B &= -2x+2 \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 441: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = 1
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2x+2}{(x-1)^2}\,dx} \\
&= z_1 e^{\ln(x-1)} \\
&= z_1(x-1)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x - 1
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2x+2}{(x-1)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2\ln(x-1)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x-1) + c_2(x - 1(x))
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$
(x-1)^2 y'' + (-2x+2)\, y' + 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = c_1(x-1) + c_2 x(x-1)
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x - 1 \\
y_2 &= x(x-1)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x-1 & x(x-1) \\ \frac{d}{dx}(x-1) & \frac{d}{dx}(x(x-1)) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x-1 & x(x-1) \\ 1 & 2x-1 \end{vmatrix}$$

Therefore

$$W = (x-1)(2x-1) - (x(x-1))(1)$$

Which simplifies to

$$W = x^2 - 2x + 1$$

Which simplifies to

$$W = (x-1)^2$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x(x-1)^3}{(x-1)^4}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{x}{x-1}dx$$

Hence

$$u_1 = -x - \ln(x-1)$$

And Eq. (3) becomes

$$u_2 = \int \frac{(x-1)^3}{(x-1)^4}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{x-1}dx$$

Hence

$$u_2 = \ln(x-1)$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = (-x - \ln(x-1))(x-1) + \ln(x-1)\,x(x-1)$$

Which simplifies to

$$y_p(x) = (x-1)(\ln(x-1)(x-1) - x)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= (c_1(x-1) + c_2 x(x-1)) + ((x-1)(\ln(x-1)(x-1) - x)) \end{aligned}$$

Which simplifies to

$$y = (x-1)(c_2 x + c_1) + (x-1)(\ln(x-1)(x-1) - x)$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = (x-1)(c_2 x + c_1) + (x-1)(\ln(x-1)(x-1) - x) \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 3$ and $x = 0$ in the above gives

$$3 = i\pi - c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = c_2 x + c_1 + (x-1)c_2 + 2\ln(x-1)(x-1) - x$$

substituting $y' = -6$ and $x = 0$ in the above gives

$$-6 = -2i\pi + c_1 - c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = i\pi - 3$$
$$c_2 = -i\pi + 3$$

Substituting these values back in above solution results in

$$y = x^2 \ln(x-1) + 2x^2 - 2x \ln(x-1) - 5x - ix^2\pi + 2ix\pi - i\pi + 3 + \ln(x-1)$$

Summary

The solution(s) found are the following

$$y = -((1-x)\ln(x-1) + ix\pi - i\pi - 2x + 3)(x-1) \tag{1}$$

Verification of solutions

$$y = -((1-x)\ln(x-1) + ix\pi - i\pi - 2x + 3)(x-1)$$

Verified OK.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

Unable to solve or complete the solution.

$$\boxed{(x-1)^2 y''-\left(x^2-1\right) y'+(x-1)^3 y=(x-1)^3 \mathrm{e}^x}$$

With initial conditions

$$[y(0)=4, y'(0)=-6]$$

10.32.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$\begin{aligned} p(x) &= \frac{-x^2+1}{(x-1)^2} \\ q(x) &= x-1 \\ F &= (x-1)\,\mathrm{e}^x \end{aligned}$$

Hence the ode is

$$y'' + \frac{(-x^2+1)\, y'}{(x-1)^2} + y(x-1) = (x-1)\, e^x$$

The domain of $p(x) = \frac{-x^2+1}{(x-1)^2}$ is

$$\{x < 1 \lor 1 < x\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = x - 1$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = (x-1)\, e^x$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{(x-1)^2 y'' + 4y'x + 2y = 2x}$$

With initial conditions

$$[y(0) = 0, y'(0) = -2]$$

10.33.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}p(x) &= \frac{4x}{(x-1)^2}\\ q(x) &= \frac{2}{(x-1)^2}\\ F &= \frac{2x}{(x-1)^2}\end{aligned}$$

Hence the ode is

$$y'' + \frac{4xy'}{(x-1)^2} + \frac{2y}{(x-1)^2} = \frac{2x}{(x-1)^2}$$

The domain of $p(x) = \frac{4x}{(x-1)^2}$ is

$$\{x < 1 \lor 1 < x\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{2}{(x-1)^2}$ is

$$\{x < 1 \lor 1 < x\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = \frac{2x}{(x-1)^2}$ is

$$\{x < 1 \lor 1 < x\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.33.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}\int \left((x-1)^2 y'' + 4y'x + 2y\right) dx &= \int 2x dx\\ (2+2x)\, y + \left(x^2 - 2x + 1\right) y' &= x^2 + c_1\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-2x-2}{(x-1)^2}$$
$$q(x) = \frac{x^2+c_1}{(x-1)^2}$$

Hence the ode is

$$y' - \frac{(-2x-2)\,y}{(x-1)^2} = \frac{x^2+c_1}{(x-1)^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-2x-2}{(x-1)^2}dx}$$
$$= e^{2\ln(x-1)-\frac{4}{x-1}}$$

Which simplifies to

$$\mu = (x-1)^2\,e^{-\frac{4}{x-1}}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^2+c_1}{(x-1)^2}\right)$$
$$\frac{d}{dx}\left((x-1)^2\,e^{-\frac{4}{x-1}}y\right) = \left((x-1)^2\,e^{-\frac{4}{x-1}}\right)\left(\frac{x^2+c_1}{(x-1)^2}\right)$$
$$d\left((x-1)^2\,e^{-\frac{4}{x-1}}y\right) = \left((x^2+c_1)\,e^{-\frac{4}{x-1}}\right)\,dx$$

Integrating gives

$$(x-1)^2\,e^{-\frac{4}{x-1}}y = \int (x^2+c_1)\,e^{-\frac{4}{x-1}}\,dx$$
$$(x-1)^2\,e^{-\frac{4}{x-1}}y = -\frac{e^{-\frac{4}{x-1}}(x-1)}{3} + \frac{4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + 4c_1\left(\frac{e^{-\frac{4}{x-1}}(x-1)}{4} - \text{expIntegral}_1\left(\frac{4}{x-1}\right)\right.$$

Dividing both sides by the integrating factor $\mu = (x-1)^2\,e^{-\frac{4}{x-1}}$ results in

$$y = \frac{e^{\frac{4}{x-1}}\left(-\frac{e^{-\frac{4}{x-1}}(x-1)}{3} + \frac{4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + 4c_1\left(\frac{e^{-\frac{4}{x-1}}(x-1)}{4} - \text{expIntegral}_1\left(\frac{4}{x-1}\right)\right) + \frac{(x-1)^2 e^{-\frac{4}{x-1}}}{3} + \frac{(x-1)^3}{\ldots}}{(x-1)^2}$$

which simplifies to

$$y = \frac{(-12c_1+4)\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)+3c_2\mathrm{e}^{\frac{4}{x-1}}+(x-1)\,(x^2+3c_1-x-1)}{3\,(x-1)^2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{(-12c_1+4)\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)+3c_2\mathrm{e}^{\frac{4}{x-1}}+(x-1)\,(x^2+3c_1-x-1)}{3\,(x-1)^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=0$ and $x=0$ in the above gives

$$0 = \frac{1}{3}+\frac{4(-3c_1+1)\,\mathrm{e}^{-4}\,\mathrm{expIntegral}_1\,(-4)}{3}+c_2\mathrm{e}^{-4}-c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{-\frac{4(-12c_1+4)\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{(x-1)^2}+\frac{(-12c_1+4)\mathrm{e}^{\frac{4}{x-1}}\mathrm{e}^{-\frac{4}{x-1}}}{x-1}-\frac{12c_2\mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2}+x^2+3c_1-x-1+(x-1)\,(2x-1)}{3\,(x-1)^2}$$

substituting $y'=-2$ and $x=0$ in the above gives

$$-2 = -\frac{2}{3}+\frac{8(3c_1-1)\,\mathrm{e}^{-4}\,\mathrm{expIntegral}_1\,(-4)}{3}-2c_2\mathrm{e}^{-4}+3c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -2 \\ c_2 &= -\frac{28\,\mathrm{expIntegral}_1\,(-4)}{3}-\frac{7\,\mathrm{e}^4}{3} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{x^3+28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}}-28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\,(-4)-7\,\mathrm{e}^{\frac{4x}{x-1}}-2x^2-6x+7}{3x^2-6x+3}$$

Which simplifies to

$$y = \frac{x^3+28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}}-28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\,(-4)-7\,\mathrm{e}^{\frac{4x}{x-1}}-2x^2-6x+7}{3\,(x-1)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} - 28\, e^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1(-4) - 7\, e^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3(x-1)^2} \tag{1}$$

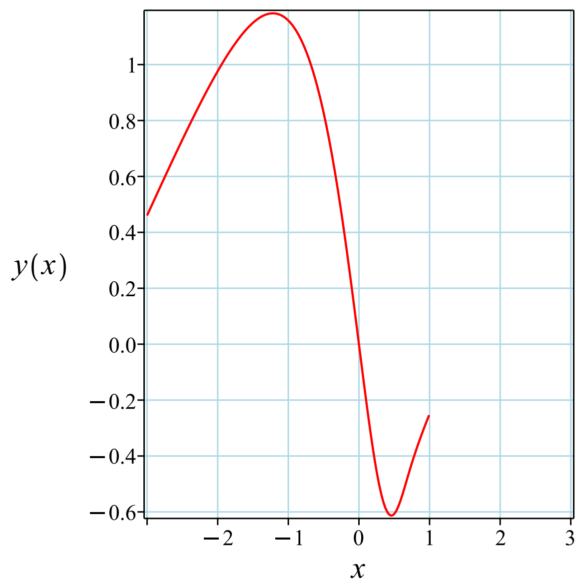

Figure 522: Solution plot

Verification of solutions

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} - 28\, e^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1(-4) - 7\, e^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3(x-1)^2}$$

Verified OK.

10.33.3 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x-1)^2 y'' + 4y'x + 2y = 2x$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(\left(x-1\right)^{2} y''+4y'x+2y\right)dx = \int 2x dx$$
$$\left(2+2x\right) y+\left(x^{2}-2x+1\right) y' = x^{2}+c_{1}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-2x-2}{\left(x-1\right)^{2}}$$
$$q(x) = \frac{x^{2}+c_{1}}{\left(x-1\right)^{2}}$$

Hence the ode is

$$y'-\frac{\left(-2x-2\right) y}{\left(x-1\right)^{2}} = \frac{x^{2}+c_{1}}{\left(x-1\right)^{2}}$$

The integrating factor μ is

$$\mu = {\mathrm e}^{\int -\frac{-2x-2}{\left(x-1\right)^{2}}d x}$$
$$= {\mathrm e}^{2\ln\left(x-1\right)-\frac{4}{x-1}}$$

Which simplifies to

$$\mu = \left(x-1\right)^{2} {\mathrm e}^{-\frac{4}{x-1}}$$

The ode becomes

$$\frac{\mathop{d}}{dx}(\mu y) = (\mu)\left(\frac{x^{2}+c_{1}}{\left(x-1\right)^{2}}\right)$$
$$\frac{\mathop{d}}{dx}\left(\left(x-1\right)^{2} {\mathrm e}^{-\frac{4}{x-1}} y\right) = \left(\left(x-1\right)^{2} {\mathrm e}^{-\frac{4}{x-1}}\right)\left(\frac{x^{2}+c_{1}}{\left(x-1\right)^{2}}\right)$$
$$\mathrm{d}\left(\left(x-1\right)^{2} {\mathrm e}^{-\frac{4}{x-1}} y\right) = \left(\left(x^{2}+c_{1}\right) {\mathrm e}^{-\frac{4}{x-1}}\right)\mathrm{d}x$$

Integrating gives

$$\left(x-1\right)^{2} {\mathrm e}^{-\frac{4}{x-1}} y = \int \left(x^{2}+c_{1}\right) {\mathrm e}^{-\frac{4}{x-1}}\,\mathrm{d}x$$
$$\left(x-1\right)^{2} {\mathrm e}^{-\frac{4}{x-1}} y = -\frac{{\mathrm e}^{-\frac{4}{x-1}} \left(x-1\right)}{3}+\frac{4\,\mathrm{expIntegral}_{1}\left(\frac{4}{x-1}\right)}{3}+4c_{1} \left(\frac{{\mathrm e}^{-\frac{4}{x-1}} \left(x-1\right)}{4}-\mathrm{expIntegral}_{1}\left(\frac{4}{x-1}\right)\right)$$

Dividing both sides by the integrating factor $\mu = (x-1)^2 \mathrm{e}^{-\frac{4}{x-1}}$ results in

$$y = \frac{\mathrm{e}^{\frac{4}{x-1}} \left(-\frac{\mathrm{e}^{-\frac{4}{x-1}}(x-1)}{3} + \frac{4 \,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + 4c_1 \left(\frac{\mathrm{e}^{-\frac{4}{x-1}}(x-1)}{4} - \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\right) + \frac{(x-1)^2 \mathrm{e}^{-\frac{4}{x-1}}}{3} + \frac{(x-1)^3}{\ldots}}{(x-1)^2}$$

which simplifies to

$$y = \frac{(-12c_1 + 4)\,\mathrm{e}^{\frac{4}{x-1}} \,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) + 3c_2 \mathrm{e}^{\frac{4}{x-1}} + (x-1)\left(x^2 + 3c_1 - x - 1\right)}{3(x-1)^2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{(-12c_1 + 4)\,\mathrm{e}^{\frac{4}{x-1}} \,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) + 3c_2 \mathrm{e}^{\frac{4}{x-1}} + (x-1)\left(x^2 + 3c_1 - x - 1\right)}{3(x-1)^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{1}{3} + \frac{4(-3c_1 + 1)\,\mathrm{e}^{-4} \,\mathrm{expIntegral}_1(-4)}{3} + c_2 \mathrm{e}^{-4} - c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{-\frac{4(-12c_1+4)\mathrm{e}^{\frac{4}{x-1}} \,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{(x-1)^2} + \frac{(-12c_1+4)\mathrm{e}^{\frac{4}{x-1}} \mathrm{e}^{-\frac{4}{x-1}}}{x-1} - \frac{12c_2 \mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2} + x^2 + 3c_1 - x - 1 + (x-1)(2x-1)}{3(x-1)^2}$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -\frac{2}{3} + \frac{8(3c_1 - 1)\,\mathrm{e}^{-4} \,\mathrm{expIntegral}_1(-4)}{3} - 2c_2 \mathrm{e}^{-4} + 3c_1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -2$$
$$c_2 = -\frac{28 \,\mathrm{expIntegral}_1(-4)}{3} - \frac{7\,\mathrm{e}^4}{3}$$

Substituting these values back in above solution results in

$$y = \frac{x^3 + 28 \,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}} \,\mathrm{expIntegral}_1(-4) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3x^2 - 6x + 3}$$

Which simplifies to

$$y = \frac{x^3 + 28 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} - 28 e^{\frac{4}{x-1}} \operatorname{expIntegral}_1(-4) - 7 e^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3(x-1)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 + 28 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} - 28 e^{\frac{4}{x-1}} \operatorname{expIntegral}_1(-4) - 7 e^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3(x-1)^2} \tag{1}$$

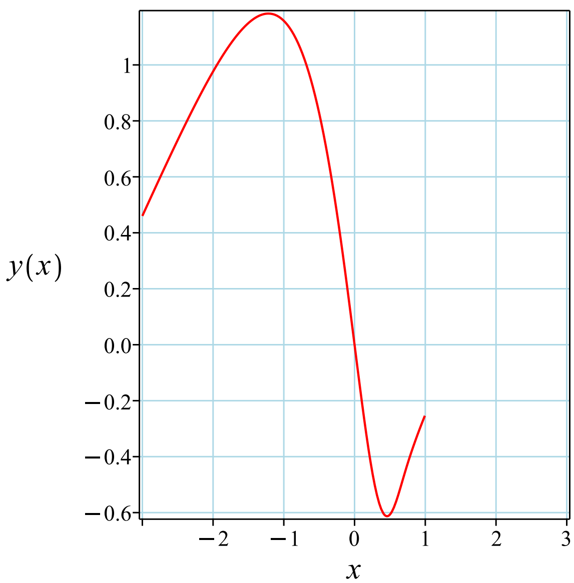

Figure 523: Solution plot

Verification of solutions

$$y = \frac{x^3 + 28 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} - 28 e^{\frac{4}{x-1}} \operatorname{expIntegral}_1(-4) - 7 e^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3(x-1)^2}$$

Verified OK.

10.33.4 Solving using Kovacic algorithm

Writing the ode as

$$(x-1)^2 y'' + 4y'x + 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (x-1)^2 \\ B &= 4x \\ C &= 2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4x}{(x-1)^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4x \\ t &= (x-1)^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4x}{(x-1)^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 442: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 1 \\ &= 3 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x-1)^4$. There is a pole at $x = 1$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 3 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\alpha_c^+ = \frac{1}{2}\left(\frac{b}{a} + v\right)$$
$$\alpha_c^- = \frac{1}{2}\left(-\frac{b}{a} + v\right)$$

The partial fraction decomposition of r is

$$r = \frac{4}{(x-1)^3} + \frac{4}{(x-1)^4}$$

There is pole in r at $x = 1$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 1$ gives

$$[\sqrt{r}]_c \approx \frac{2}{(x-1)^2} + \frac{1}{x-1} - \frac{3}{8} + \frac{x}{8} - \frac{5(x-1)^2}{64} + \frac{7(x-1)^3}{128} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{2}{(x-1)^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-1)^2}$ is

$$a = 2$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 1$. This term becomes $\frac{1}{(x-1)^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be 4. Therefore

$$\begin{aligned} b &= (4) - (0) \\ &= 4 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{2}{(x-1)^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) = \frac{1}{2}\left(\frac{4}{2} + 2\right) = 2 \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) = \frac{1}{2}\left(-\frac{4}{2} + 2\right) = 0 \end{aligned}$$

Since the order of r at ∞ is $3 > 2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{4x}{(x-1)^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
1	4	$\frac{2}{(x-1)^2}$	2	0

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
3	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = 0$ then

$$\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\
&= 0 - (0) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= -\frac{2}{(x-1)^2} + (0) \\
&= -\frac{2}{(x-1)^2} \\
&= -\frac{2}{(x-1)^2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{2}{(x-1)^2}\right)(0) + \left(\left(\frac{4}{(x-1)^3}\right) + \left(-\frac{2}{(x-1)^2}\right)^2 - \left(\frac{4x}{(x-1)^4}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int -\frac{2}{(x-1)^2} dx} \\
&= \mathrm{e}^{\frac{2}{x-1}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{4x}{(x-1)^2} \, dx} \\
&= z_1 e^{-2\ln(x-1) + \frac{2}{x-1}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{2}{x-1}}}{(x-1)^2}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \frac{e^{\frac{4}{x-1}}}{(x-1)^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{4x}{(x-1)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-4\ln(x-1)+\frac{4}{x-1}}}{(y_1)^2}\,dx \\
&= y_1 \left(e^{-\frac{4}{x-1}} (x-1) - 4 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right)\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{\frac{4}{x-1}}}{(x-1)^2}\right) + c_2 \left(\frac{e^{\frac{4}{x-1}}}{(x-1)^2} \left(e^{-\frac{4}{x-1}} (x-1) - 4 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right)\right)\right)
\end{aligned}$$

This is second order nonhomogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$(x-1)^2 y'' + 4y'x + 2y = 0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h = \frac{c_1 e^{\frac{4}{x-1}}}{(x-1)^2} + \frac{c_2 \left(-4 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} + x - 1\right)}{(x-1)^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{e^{\frac{4}{x-1}}}{(x-1)^2}$$

$$y_2 = \frac{-4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} + x - 1}{(x-1)^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{e^{\frac{4}{x-1}}}{(x-1)^2} & \frac{-4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} + x - 1}{(x-1)^2} \\ \frac{d}{dx}\left(\frac{e^{\frac{4}{x-1}}}{(x-1)^2}\right) & \frac{d}{dx}\left(\frac{-4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} + x - 1}{(x-1)^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{e^{\frac{4}{x-1}}}{(x-1)^2} & \frac{-4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} + x - 1}{(x-1)^2} \\ -\frac{2 e^{\frac{4}{x-1}}}{(x-1)^3} - \frac{4 e^{\frac{4}{x-1}}}{(x-1)^4} & \frac{-\frac{4 e^{-\frac{4}{x-1}} e^{\frac{4}{x-1}}}{x-1} + \frac{16\,\text{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}}}{(x-1)^2} + 1}{(x-1)^2} - \frac{2\left(-4\,\text{expIntegral}_1\left(\frac{4}{x-1}\right) e^{\frac{4}{x-1}} + x - 1\right)}{(x-1)^3} \end{vmatrix}$$

Therefore

$$W = \left(\frac{e^{\frac{4}{x-1}}}{(x-1)^2}\right)\left(\frac{-\frac{4\,e^{-\frac{4}{x-1}}\,e^{\frac{4}{x-1}}}{x-1}+\frac{16\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)e^{\frac{4}{x-1}}}{(x-1)^2}+1}{(x-1)^2} - \frac{2\left(-4\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)e^{\frac{4}{x-1}}+x-1\right)}{(x-1)^3}\right) - \left(\frac{-4\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)e^{\frac{4}{x-1}}+x-1}{(x-1)^2}\right)\left(-\frac{2\,e^{\frac{4}{x-1}}}{(x-1)^3}-\frac{4\,e^{\frac{4}{x-1}}}{(x-1)^4}\right)$$

Which simplifies to

$$W = -\frac{e^{\frac{4}{x-1}}\left(4\,e^{-\frac{4}{x-1}}\,e^{\frac{4}{x-1}}-x-3\right)}{(x-1)^5}$$

Which simplifies to

$$W = \frac{e^{\frac{4}{x-1}}}{(x-1)^4}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{2\left(-4\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)e^{\frac{4}{x-1}}+x-1\right)x}{(x-1)^2}}{\frac{e^{\frac{4}{x-1}}}{(x-1)^2}}\,dx$$

Which simplifies to

$$u_1 = -\int 2\left(e^{-\frac{4}{x-1}}(x-1)-4\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\right)x\,dx$$

Hence

$$u_1 = -\frac{2\,e^{-\frac{4}{x-1}}x^3}{3}+\frac{e^{-\frac{4}{x-1}}x^2}{3}+4\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)x^2+\frac{e^{-\frac{4}{x-1}}}{3}+\frac{4\ \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{2\,\mathrm{e}^{\frac{4}{x-1}} x}{(x-1)^2}}{\frac{\mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2}}\,dx$$

Which simplifies to

$$u_2 = \int 2x dx$$

Hence

$$u_2 = x^2$$

Which simplifies to

$$u_1 = \frac{4(3x^2+1)\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + \frac{(-2x^3+x^2+1)\,\mathrm{e}^{-\frac{4}{x-1}}}{3}$$
$$u_2 = x^2$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{\left(\frac{4(3x^2+1)\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + \frac{(-2x^3+x^2+1)\,\mathrm{e}^{-\frac{4}{x-1}}}{3}\right)\mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2} + \frac{x^2\left(-4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}} + x - 1\right)}{(x-1)^2}$$

Which simplifies to

$$y_p(x) = \frac{x^3 - 2x^2 + 4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}} + 1}{3\,(x-1)^2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1 \mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2} + \frac{c_2\left(-4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}} + x - 1\right)}{(x-1)^2}\right) \\ &\quad + \left(\frac{x^3 - 2x^2 + 4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}} + 1}{3\,(x-1)^2}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{-4\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) c_2 + \mathrm{e}^{\frac{4}{x-1}} c_1 + (x-1)\,c_2}{(x-1)^2} + \frac{x^3 - 2x^2 + 4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} + 1}{3\,(x-1)^2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{-4\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) c_2 + \mathrm{e}^{\frac{4}{x-1}} c_1 + (x-1)\,c_2}{(x-1)^2} + \frac{x^3 - 2x^2 + 4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} + 1}{3\,(x-1)^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{1}{3} + \frac{4(-3c_2+1)\,\mathrm{e}^{-4}\,\mathrm{expIntegral}_1(-4)}{3} + \mathrm{e}^{-4} c_1 - c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{\frac{16\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) c_2}{(x-1)^2} - \frac{4\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{e}^{-\frac{4}{x-1}} c_2}{x-1} - \frac{4c_1\,\mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2} + c_2}{(x-1)^2} - \frac{2\left(-4\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) c_2 + \mathrm{e}^{\frac{4}{x-1}} c_1 + \right.}{(x-1)^3}$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -\frac{2}{3} + \frac{8(3c_2-1)\,\mathrm{e}^{-4}\,\mathrm{expIntegral}_1(-4)}{3} - 2\,\mathrm{e}^{-4} c_1 + 3c_2 \tag{2A}$$

Equations $\{1\mathrm{A}, 2\mathrm{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{28\,\mathrm{expIntegral}_1(-4)}{3} - \frac{7\,\mathrm{e}^4}{3}$$
$$c_2 = -2$$

Substituting these values back in above solution results in

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1(-4) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3x^2 - 6x + 3}$$

Which simplifies to

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1(-4) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3\,(x-1)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1(-4) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3\,(x-1)^2} \tag{1}$$

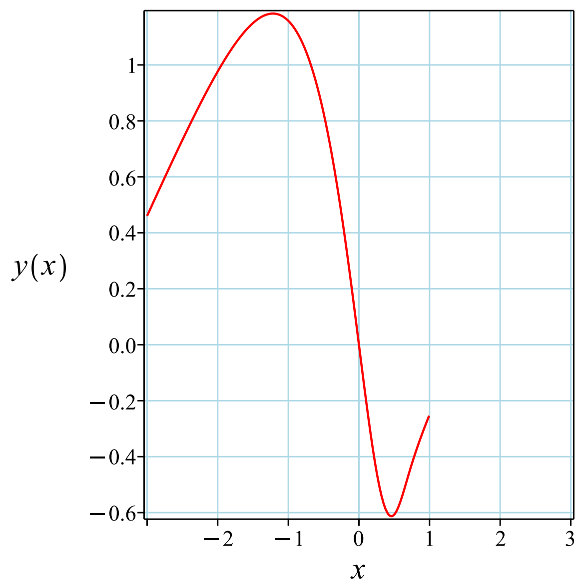

Figure 524: Solution plot

Verification of solutions

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1(-4) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3\,(x-1)^2}$$

Verified OK.

10.33.5 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= (x-1)^2 \\
q(x) &= 4x \\
r(x) &= 2 \\
s(x) &= 2x
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 2 \\
q'(x) &= 4
\end{aligned}$$

Therefore (1) becomes

$$2 - (4) + (2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$(x-1)^2\,y' + (2+2x)\,y = \int 2x\,dx$$

We now have a first order ode to solve which is

$$(x-1)^2\,y' + (2+2x)\,y = x^2 + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-2x-2}{(x-1)^2}$$
$$q(x) = \frac{x^2+c_1}{(x-1)^2}$$

Hence the ode is

$$y' - \frac{(-2x-2)\,y}{(x-1)^2} = \frac{x^2+c_1}{(x-1)^2}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-2x-2}{(x-1)^2}dx}$$
$$= e^{2\ln(x-1)-\frac{4}{x-1}}$$

Which simplifies to

$$\mu = (x-1)^2 e^{-\frac{4}{x-1}}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{x^2+c_1}{(x-1)^2}\right)$$
$$\frac{d}{dx}\left((x-1)^2 e^{-\frac{4}{x-1}}y\right) = \left((x-1)^2 e^{-\frac{4}{x-1}}\right)\left(\frac{x^2+c_1}{(x-1)^2}\right)$$
$$d\left((x-1)^2 e^{-\frac{4}{x-1}}y\right) = \left((x^2+c_1)\,e^{-\frac{4}{x-1}}\right)dx$$

Integrating gives

$$(x-1)^2 e^{-\frac{4}{x-1}}y = \int (x^2+c_1)\,e^{-\frac{4}{x-1}}\,dx$$
$$(x-1)^2 e^{-\frac{4}{x-1}}y = -\frac{e^{-\frac{4}{x-1}}(x-1)}{3} + \frac{4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + 4c_1\left(\frac{e^{-\frac{4}{x-1}}(x-1)}{4} - \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\right.$$

Dividing both sides by the integrating factor $\mu = (x-1)^2 e^{-\frac{4}{x-1}}$ results in

$$y = \frac{e^{\frac{4}{x-1}}\left(-\frac{e^{-\frac{4}{x-1}}(x-1)}{3} + \frac{4\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)}{3} + 4c_1\left(\frac{e^{-\frac{4}{x-1}}(x-1)}{4} - \mathrm{expIntegral}_1\left(\frac{4}{x-1}\right)\right) + \frac{(x-1)^2 e^{-\frac{4}{x-1}}}{3} + \frac{(x-1)^3}{\cdots}\right.}{(x-1)^2}$$

which simplifies to

$$y = \frac{(-12c_1+4)\,\mathrm{e}^{\frac{4}{x-1}} \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right) + 3c_2\mathrm{e}^{\frac{4}{x-1}} + (x-1)\left(x^2+3c_1-x-1\right)}{3\left(x-1\right)^2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{(-12c_1+4)\,\mathrm{e}^{\frac{4}{x-1}} \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right) + 3c_2\mathrm{e}^{\frac{4}{x-1}} + (x-1)\left(x^2+3c_1-x-1\right)}{3\left(x-1\right)^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = \frac{1}{3} + \frac{4(-3c_1+1)\,\mathrm{e}^{-4} \operatorname{expIntegral}_1\left(-4\right)}{3} + c_2\mathrm{e}^{-4} - c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{-\frac{4(-12c_1+4)\mathrm{e}^{\frac{4}{x-1}} \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right)}{(x-1)^2} + \frac{(-12c_1+4)\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{e}^{-\frac{4}{x-1}}}{x-1} - \frac{12c_2\mathrm{e}^{\frac{4}{x-1}}}{(x-1)^2} + x^2+3c_1-x-1+(x-1)(2x-1)}{3\left(x-1\right)^2}$$

substituting $y' = -2$ and $x = 0$ in the above gives

$$-2 = -\frac{2}{3} + \frac{8(3c_1-1)\,\mathrm{e}^{-4} \operatorname{expIntegral}_1\left(-4\right)}{3} - 2c_2\mathrm{e}^{-4} + 3c_1 \tag{2A}$$

Equations $\{1\text{A},2\text{A}\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= -2 \\ c_2 &= -\frac{28 \operatorname{expIntegral}_1\left(-4\right)}{3} - \frac{7\,\mathrm{e}^4}{3} \end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{x^3 + 28 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}} \operatorname{expIntegral}_1\left(-4\right) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3x^2-6x+3}$$

Which simplifies to

$$y = \frac{x^3 + 28 \operatorname{expIntegral}_1\left(\frac{4}{x-1}\right)\mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}} \operatorname{expIntegral}_1\left(-4\right) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3\left(x-1\right)^2}$$

Summary

The solution(s) found are the following

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(-4\right) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3\left(x-1\right)^2} \tag{1}$$

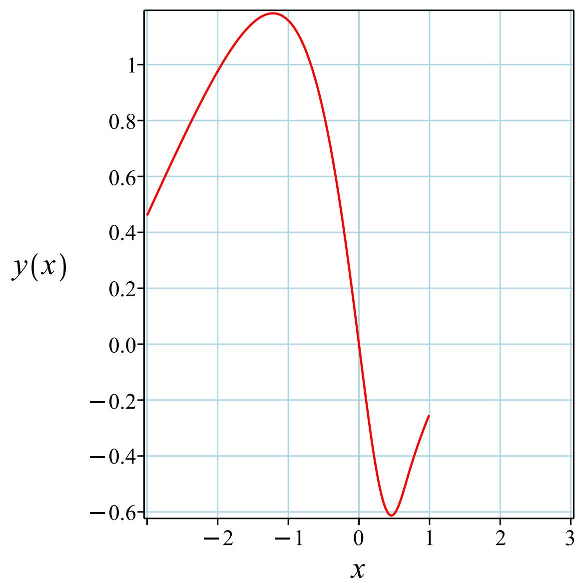

Figure 525: Solution plot

Verification of solutions

$$y = \frac{x^3 + 28\,\mathrm{expIntegral}_1\left(\frac{4}{x-1}\right) \mathrm{e}^{\frac{4}{x-1}} - 28\,\mathrm{e}^{\frac{4}{x-1}}\,\mathrm{expIntegral}_1\left(-4\right) - 7\,\mathrm{e}^{\frac{4x}{x-1}} - 2x^2 - 6x + 7}{3\left(x-1\right)^2}$$

Verified OK.

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + 2y'x - 2y = -2x^2}$$

With initial conditions

$$[y(1) = 1, y'(1) = -1]$$

10.34.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}p(x) &= \frac{2}{x}\\ q(x) &= -\frac{2}{x^2}\\ F &= -2\end{aligned}$$

Hence the ode is

$$y'' + \frac{2y'}{x} - \frac{2y}{x^2} = -2$$

The domain of $p(x) = \frac{2}{x}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = -\frac{2}{x^2}$ is

$$\{x < 0 \lor 0 < x\}$$

And the point $x_0 = 1$ is also inside this domain. The domain of $F = -2$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

10.34.2 Solving as second order euler ode ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 2x, C = -2, f(x) = -2x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 2y'x - 2y = 0$$

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 2xrx^{r-1} - 2x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 2r\,x^r - 2x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 2r - 2 = 0$$

Or

$$r^2 + r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned} r_1 &= -2 \\ r_2 &= 1 \end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y = c_1 y_1 + c_2 y_2$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$y = \frac{c_1}{x^2} + c_2 x$$

Next, we find the particular solution to the ODE

$$x^2 y'' + 2y'x - 2y = -2x^2$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned} y_1 &= \frac{1}{x^2} \\ y_2 &= x \end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & x \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}(x) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & x \\ -\frac{2}{x^3} & 1 \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)(1) - (x)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{3}{x^2}$$

Which simplifies to

$$W = \frac{3}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2x^3}{3} \, dx$$

Which simplifies to

$$u_1 = -\int -\frac{2x^3}{3} dx$$

Hence

$$u_1 = \frac{x^4}{6}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2}{3}\,dx$$

Which simplifies to

$$u_2 = \int -\frac{2}{3}dx$$

Hence

$$u_2 = -\frac{2x}{3}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= -\frac{x^2}{2} + \frac{c_1}{x^2} + c_2 x \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{x^2}{2} + \frac{c_1}{x^2} + c_2 x \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 + c_2 - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -x - \frac{2c_1}{x^3} + c_2$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = -2c_1 + c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = \frac{1}{2}$$
$$c_2 = 1$$

Substituting these values back in above solution results in

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2} \tag{1}$$

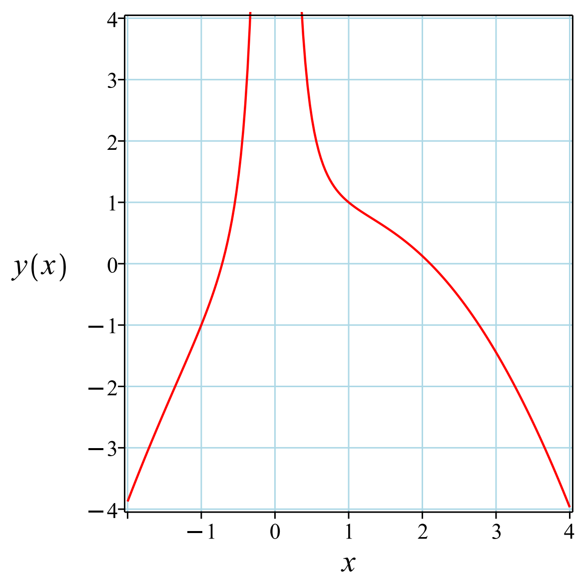

Figure 526: Solution plot

Verification of solutions

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Verified OK.

10.34.3 Solving as second order change of variable on x method 2 ode

This is second order non-homogeneous ODE. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. y_h is the solution to

$$x^2y'' + 2y'x - 2y = 0$$

In normal form the ode

$$x^2y'' + 2y'x - 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2}{x} \\ q(x) &= -\frac{2}{x^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$
\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int \frac{2}{x}dx\right)}dx \\
&= \int e^{-2\ln(x)}\, dx \\
&= \int \frac{1}{x^2}dx \\
&= -\frac{1}{x}
\end{aligned} \tag{6}
$$

Using (6) to evaluate q_1 from (5) gives

$$
\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{2}{x^2}}{\frac{1}{x^4}} \\
&= -2x^2
\end{aligned} \tag{7}
$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$
\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) - 2x^2 y(\tau) &= 0
\end{aligned}
$$

But in terms of τ

$$
-2x^2 = -\frac{2}{\tau^2}
$$

Hence the above ode becomes

$$
\frac{d^2}{d\tau^2}y(\tau) - \frac{2y(\tau)}{\tau^2} = 0
$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$
\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 - 2y(\tau) = 0
$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$
\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} - 2\tau^r = 0
$$

Simplifying gives

$$r(r-1)\,\tau^r + 0\,\tau^r - 2\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$r(r-1) + 0 - 2 = 0$$

Or

$$r^2 - r - 2 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -1$$
$$r_2 = 2$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = \frac{c_1}{\tau} + c_2\tau^2$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{-c_1 x^3 + c_2}{x^2}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{-c_1 x^3 + c_2}{x^2}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$
$$y_2 = \frac{1}{x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x^2} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x^2} \\ 1 & -\frac{2}{x^3} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{2}{x^3}\right) - \left(\frac{1}{x^2}\right)(1)$$

Which simplifies to

$$W = -\frac{3}{x^2}$$

Which simplifies to

$$W = -\frac{3}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2}{-3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{2}{3}dx$$

Hence

$$u_1 = -\frac{2x}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2x^3}{-3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{2x^3}{3}dx$$

Hence

$$u_2 = \frac{x^4}{6}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{-c_1x^3 + c_2}{x^2}\right) + \left(-\frac{x^2}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{-c_1x^3 + c_2}{x^2} - \frac{x^2}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -c_1 + c_2 - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -3c_1 - \frac{2(-c_1x^3 + c_2)}{x^3} - x$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = -c_1 - 2c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -1$$
$$c_2 = \frac{1}{2}$$

Substituting these values back in above solution results in

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2} \tag{1}$$

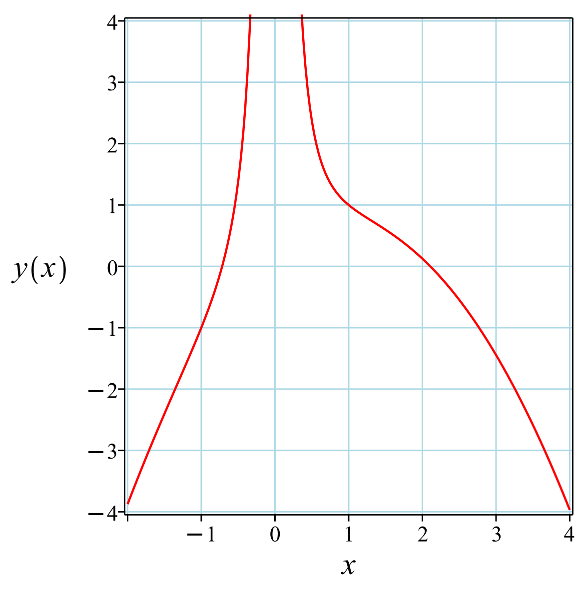

Figure 527: Solution plot

Verification of solutions

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Verified OK.

10.34.4 Solving as second order change of variable on y method 2 ode

This is second order non-homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = f(x)$$

Where $A = x^2, B = 2x, C = -2, f(x) = -2x^2$. Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the non-homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = f(x)$. Solving for y_h from

$$x^2y'' + 2y'x - 2y = 0$$

In normal form the ode

$$x^2y'' + 2y'x - 2y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2}{x} \\ q(x) &= -\frac{2}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{2n}{x^2} - \frac{2}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \frac{4v'(x)}{x} &= 0 \\ v''(x) + \frac{4v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{4u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{4u}{x} \end{aligned}$$

Where $f(x) = -\frac{4}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{4}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{4}{x}\,dx \\ \ln(u) &= -4\ln(x) + c_1 \\ u &= e^{-4\ln(x)+c_1} \\ &= \frac{c_1}{x^4} \end{aligned}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= -\frac{c_1}{3x^3} + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
y &= v(x)\, x^n \\
&= \left(-\frac{c_1}{3x^3} + c_2\right) x \\
&= \left(-\frac{c_1}{3x^3} + c_2\right) x
\end{aligned}
$$

Now the particular solution to this ODE is found

$$
x^2 y'' + 2y'x - 2y = -2x^2
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x \\
y_2 &= \frac{1}{x^2}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{a W(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{a W(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x & \frac{1}{x^2} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x^2}\right) \end{vmatrix}
$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x^2} \\ 1 & -\frac{2}{x^3} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{2}{x^3}\right) - \left(\frac{1}{x^2}\right)(1)$$

Which simplifies to

$$W = -\frac{3}{x^2}$$

Which simplifies to

$$W = -\frac{3}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2}{-3}\,dx$$

Which simplifies to

$$u_1 = -\int \frac{2}{3}dx$$

Hence

$$u_1 = -\frac{2x}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2x^3}{-3}\,dx$$

Which simplifies to

$$u_2 = \int \frac{2x^3}{3}dx$$

Hence

$$u_2 = \frac{x^4}{6}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2}{2}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\left(-\frac{c_1}{3x^3} + c_2\right) x\right) + \left(-\frac{x^2}{2}\right) \\
&= -\frac{x^2}{2} + \left(-\frac{c_1}{3x^3} + c_2\right) x
\end{aligned}$$

Which simplifies to

$$y = -\frac{-6c_2x^3 + 3x^4 + 2c_1}{6x^2}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = -\frac{-6c_2x^3 + 3x^4 + 2c_1}{6x^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -\frac{c_1}{3} + c_2 - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{-6c_2x^3 + 3x^4 + 2c_1}{3x^3} - \frac{-18c_2x^2 + 12x^3}{6x^2}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{2c_1}{3} + c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}
c_1 &= -\frac{3}{2} \\
c_2 &= 1
\end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2} \tag{1}$$

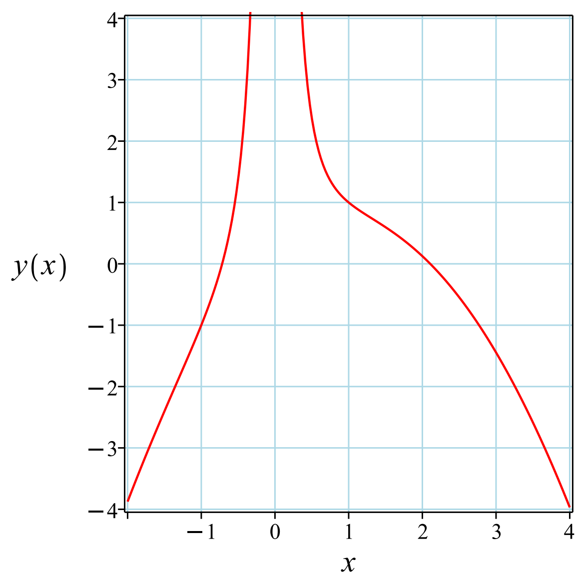

Figure 528: Solution plot

Verification of solutions

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Verified OK.

10.34.5 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right)v' + \left(AB'' + BB' + CB\right)v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right)v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right)u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= x^2 \\
B &= 2x \\
C &= -2 \\
F &= -2x^2
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(x^2\right)(0) + (2x)(2) + (-2)(2x) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
2x^3v'' + \left(8x^2\right)v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
2x^2(u'(x)\,x + 4u(x)) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{4u}{x}
\end{aligned}
$$

Where $f(x) = -\frac{4}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\, du &= -\frac{4}{x}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{4}{x}\, dx \\
\ln(u) &= -4\ln(x) + c_1 \\
u &= \mathrm{e}^{-4\ln(x)+c_1} \\
&= \frac{c_1}{x^4}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= \frac{c_1}{x^4}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int \frac{c_1}{x^4}\, \mathrm{d}x \\
&= -\frac{c_1}{3x^3} + c_2
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= Bv \\
&= (2x)\left(-\frac{c_1}{3x^3} + c_2\right) \\
&= \frac{6c_2x^3 - 2c_1}{3x^2}
\end{aligned}
$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1y_1 + u_2y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = x$$

$$y_2 = \frac{1}{x^2}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} x & \frac{1}{x^2} \\ \frac{d}{dx}(x) & \frac{d}{dx}\left(\frac{1}{x^2}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} x & \frac{1}{x^2} \\ 1 & -\frac{2}{x^3} \end{vmatrix}$$

Therefore

$$W = (x)\left(-\frac{2}{x^3}\right) - \left(\frac{1}{x^2}\right)(1)$$

Which simplifies to

$$W = -\frac{3}{x^2}$$

Which simplifies to

$$W = -\frac{3}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-2}{-3}\, dx$$

Which simplifies to

$$u_1 = -\int \frac{2}{3} dx$$

Hence

$$u_1 = -\frac{2x}{3}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2x^3}{-3} dx$$

Which simplifies to

$$u_2 = \int \frac{2x^3}{3} dx$$

Hence

$$u_2 = \frac{x^4}{6}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2}{2}$$

Hence the complete solution is

$$\begin{aligned} y(x) &= y_h + y_p \\ &= \left(\frac{6c_2x^3 - 2c_1}{3x^2}\right) + \left(-\frac{x^2}{2}\right) \\ &= \frac{12c_2x^3 - 3x^4 - 4c_1}{6x^2} \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{12c_2x^3 - 3x^4 - 4c_1}{6x^2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = -\frac{2c_1}{3} + 2c_2 - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{36c_2x^2 - 12x^3}{6x^2} - \frac{12c_2x^3 - 3x^4 - 4c_1}{3x^3}$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = \frac{4c_1}{3} + 2c_2 - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{3}{4}$$
$$c_2 = \frac{1}{2}$$

Substituting these values back in above solution results in

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2} \tag{1}$$

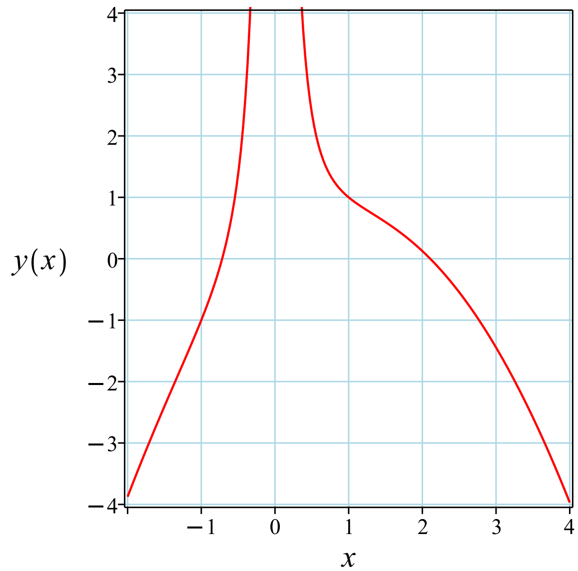

Figure 529: Solution plot

<u>Verification of solutions</u>

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Verified OK.

10.34.6 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 2y'x - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 2x \\ C &= -2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = 2$$
$$t = x^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 443: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2}{x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2}{x^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -1 - (-1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + (-)(0) \\
&= -\frac{1}{x} \\
&= -\frac{1}{x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{x}\right)(0) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x}\right)^2 - \left(\frac{2}{x^2}\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int -\frac{1}{x} dx} \\ &= \frac{1}{x} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2} \, dx} \\ &= z_1 e^{-\ln(x)} \\ &= z_1\left(\frac{1}{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{1}{x^2}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2} \, dx \\ &= y_1\left(\frac{x^3}{3}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{1}{x^2}\right) + c_2 \left(\frac{1}{x^2} \left(\frac{x^3}{3}\right)\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
x^2 y'' + 2y'x - 2y = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
y_h = \frac{c_1}{x^2} + \frac{c_2 x}{3}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= \frac{1}{x^2} \\
y_2 &= \frac{x}{3}
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE.

The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{x}{3} \\ \frac{d}{dx}\left(\frac{1}{x^2}\right) & \frac{d}{dx}\left(\frac{x}{3}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x^2} & \frac{x}{3} \\ -\frac{2}{x^3} & \frac{1}{3} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x^2}\right)\left(\frac{1}{3}\right) - \left(\frac{x}{3}\right)\left(-\frac{2}{x^3}\right)$$

Which simplifies to

$$W = \frac{1}{x^2}$$

Which simplifies to

$$W = \frac{1}{x^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{2x^3}{3}}{1}\,dx$$

Which simplifies to

$$u_1 = -\int -\frac{2x^3}{3}dx$$

Hence

$$u_1 = \frac{x^4}{6}$$

And Eq. (3) becomes

$$u_2 = \int \frac{-2}{1}\,dx$$

Which simplifies to

$$u_2 = \int (-2)\, dx$$

Hence

$$u_2 = -2x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{x^2}{2}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x^2} + \frac{c_2 x}{3}\right) + \left(-\frac{x^2}{2}\right) \end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_1}{x^2} + \frac{c_2 x}{3} - \frac{x^2}{2} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 1$ and $x = 1$ in the above gives

$$1 = c_1 + \frac{c_2}{3} - \frac{1}{2} \tag{1A}$$

Taking derivative of the solution gives

$$y' = -\frac{2c_1}{x^3} + \frac{c_2}{3} - x$$

substituting $y' = -1$ and $x = 1$ in the above gives

$$-1 = -2c_1 + \frac{c_2}{3} - 1 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned} c_1 &= \frac{1}{2} \\ c_2 &= 3 \end{aligned}$$

Substituting these values back in above solution results in

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2}$$

Summary

The solution(s) found are the following

$$y = -\frac{x^4 - 2x^3 - 1}{2x^2} \tag{1}$$

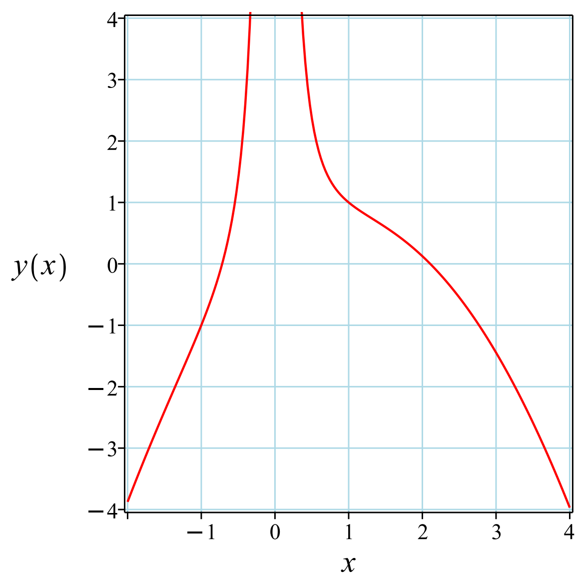

Figure 530: Solution plot

```
[[_2nd_order, _exact, _linear, _nonhomogeneous]]
```

$$\boxed{(x+1)(2x+3)y''+2(2+x)y'-2y=(2x+3)^2}$$

With initial conditions

$$[y(0)=0, y'(0)=0]$$

10.35.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y'' + p(x)y' + q(x)y = F$$

Where here

$$\begin{aligned}
p(x) &= \frac{2x + 4}{2x^2 + 5x + 3} \\
q(x) &= -\frac{2}{2x^2 + 5x + 3} \\
F &= \frac{4\left(x + \frac{3}{2}\right)^2}{2x^2 + 5x + 3}
\end{aligned}$$

Hence the ode is

$$y'' + \frac{(2x + 4)\, y'}{2x^2 + 5x + 3} - \frac{2y}{2x^2 + 5x + 3} = \frac{4\left(x + \frac{3}{2}\right)^2}{2x^2 + 5x + 3}$$

The domain of $p(x) = \frac{2x+4}{2x^2+5x+3}$ is

$$\left\{-\infty \le x < -1, -1 < x < -\frac{3}{2}, -\frac{3}{2} < x \le \infty\right\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = -\frac{2}{2x^2+5x+3}$ is

$$\left\{-\infty \le x < -1, -1 < x < -\frac{3}{2}, -\frac{3}{2} < x \le \infty\right\}$$

And the point $x_0 = 0$ is also inside this domain. The domain of $F = \frac{4\left(x+\frac{3}{2}\right)^2}{2x^2+5x+3}$ is

$$\left\{-\infty \le x < -1, -1 < x < -\frac{3}{2}, -\frac{3}{2} < x \le \infty\right\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

10.35.2 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y''(2x^2+5x+3)+(2x+4)\,y'-2y)\,dx = \int 4\left(x+\frac{3}{2}\right)^2 dx$$

$$(-1-2x)\,y+(2x^2+5x+3)\,y' = \frac{4(x+\frac{3}{2})^3}{3}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{1+2x}{2x^2+5x+3} \\ q(x) &= \frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18} \end{aligned}$$

Hence the ode is

$$y'-\frac{(1+2x)\,y}{2x^2+5x+3} = \frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{1+2x}{2x^2+5x+3}dx} \\ &= \mathrm{e}^{-2\ln(2x+3)+\ln(x+1)} \end{aligned}$$

Which simplifies to

$$\mu = \frac{x+1}{(2x+3)^2}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{(x+1)\,y}{(2x+3)^2}\right) &= \left(\frac{x+1}{(2x+3)^2}\right)\left(\frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}\right) \\ \mathrm{d}\left(\frac{(x+1)\,y}{(2x+3)^2}\right) &= \left(\frac{8x^3+36x^2+6c_1+54x+27}{6\,(2x+3)^3}\right)\mathrm{d}x \end{aligned}$$

Integrating gives

$$\frac{(x+1)\,y}{(2x+3)^2} = \int \frac{8x^3+36x^2+6c_1+54x+27}{6\,(2x+3)^3}\,\mathrm{d}x$$
$$\frac{(x+1)\,y}{(2x+3)^2} = \frac{x}{6}-\frac{c_1}{4\,(2x+3)^2}+c_2$$

Dividing both sides by the integrating factor $\mu = \frac{x+1}{(2x+3)^2}$ results in

$$y = \frac{(2x+3)^2\left(\frac{x}{6}-\frac{c_1}{4(2x+3)^2}\right)}{x+1}+\frac{c_2(2x+3)^2}{x+1}$$

which simplifies to

$$y = \frac{8x^3+(48c_2+24)\,x^2+(144c_2+18)\,x-3c_1+108c_2}{12x+12}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{8x^3+(48c_2+24)\,x^2+(144c_2+18)\,x-3c_1+108c_2}{12x+12} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -\frac{c_1}{4}+9c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{24x^2+2(48c_2+24)\,x+144c_2+18}{12x+12}-\frac{12(8x^3+(48c_2+24)\,x^2+(144c_2+18)\,x-3c_1+108c_2)}{(12x+12)^2}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{c_1}{4}+3c_2+\frac{3}{2} \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{9}{2}$$
$$c_2 = -\frac{1}{8}$$

Substituting these values back in above solution results in

$$y = \frac{x^2(4x+9)}{6x+6}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2(4x+9)}{6x+6} \tag{1}$$

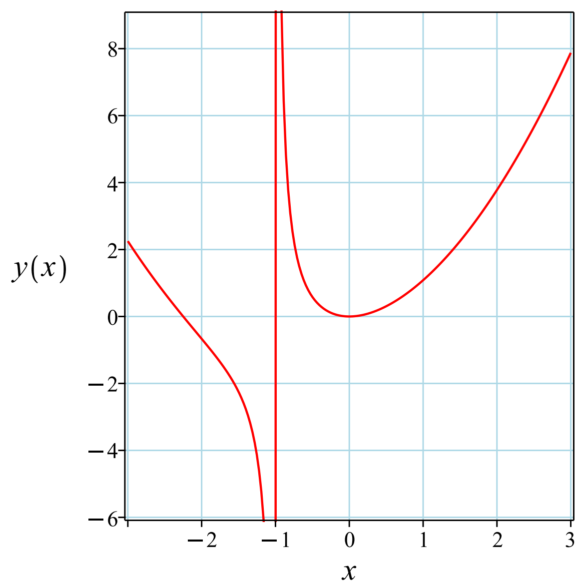

Figure 531: Solution plot

Verification of solutions

$$y = \frac{x^2(4x+9)}{6x+6}$$

Verified OK.

10.35.3 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$
\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}
$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0
\end{aligned} \tag{1}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= 2x^2 + 5x + 3 \\
B &= 2x + 4 \\
C &= -2 \\
F &= 4\left(x + \frac{3}{2}\right)^2
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(2x^2 + 5x + 3\right)(0) + (2x + 4)(2) + (-2)(2x + 4) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
4x^3 + 18x^2 + 26x + 12v'' + \left(12x^2 + 36x + 28\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
\left(4x^3 + 18x^2 + 26x + 12\right) u'(x) + 12\left(x^2 + 3x + \frac{7}{3}\right) u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned}
u' &= F(x,u) \\
&= f(x)g(u) \\
&= -\frac{2u(3x^2+9x+7)}{2x^3+9x^2+13x+6}
\end{aligned}$$

Where $f(x) = -\frac{2(3x^2+9x+7)}{2x^3+9x^2+13x+6}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{2(3x^2+9x+7)}{2x^3+9x^2+13x+6}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{2(3x^2+9x+7)}{2x^3+9x^2+13x+6}\,dx \\
\ln(u) &= \ln(2x+3) - 2\ln(x+1) - 2\ln(2+x) + c_1 \\
u &= e^{\ln(2x+3)-2\ln(x+1)-2\ln(2+x)+c_1} \\
&= c_1 e^{\ln(2x+3)-2\ln(x+1)-2\ln(2+x)}
\end{aligned}$$

Which simplifies to

$$u(x) = c_1\left(\frac{2x}{(x+1)^2(2+x)^2} + \frac{3}{(x+1)^2(2+x)^2}\right)$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1\left(\frac{2x}{(x+1)^2(2+x)^2} + \frac{3}{(x+1)^2(2+x)^2}\right)
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{c_1(2x+3)}{(x+1)^2(2+x)^2}\,\mathrm{d}x \\
&= c_1\left(\frac{1}{2+x} - \frac{1}{x+1}\right) + c_2
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= Bv \\
&= (2x+4)\left(c_1\left(\frac{1}{2+x} - \frac{1}{x+1}\right) + c_2\right) \\
&= \frac{(2x^2+6x+4)c_2 - 2c_1}{x+1}
\end{aligned}$$

And now the particular solution $y_p(x)$ will be found. The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1 = \frac{1}{x+1}$$

$$y_2 = \frac{2x^2}{x+1} + \frac{6x}{x+1} + \frac{4}{x+1}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{2x^2}{x+1} + \frac{6x}{x+1} + \frac{4}{x+1} \\ \frac{d}{dx}\left(\frac{1}{x+1}\right) & \frac{d}{dx}\left(\frac{2x^2}{x+1} + \frac{6x}{x+1} + \frac{4}{x+1}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{2x^2}{x+1} + \frac{6x}{x+1} + \frac{4}{x+1} \\ -\frac{1}{(x+1)^2} & \frac{4x}{x+1} - \frac{2x^2}{(x+1)^2} - \frac{6x}{(x+1)^2} + \frac{6}{x+1} - \frac{4}{(x+1)^2} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x+1}\right)\left(\frac{4x}{x+1} - \frac{2x^2}{(x+1)^2} - \frac{6x}{(x+1)^2} + \frac{6}{x+1} - \frac{4}{(x+1)^2}\right) - \left(\frac{2x^2}{x+1} + \frac{6x}{x+1} + \frac{4}{x+1}\right)\left(-\frac{1}{(x+1)^2}\right)$$

Which simplifies to

$$W = \frac{4x+6}{(x+1)^2}$$

Which simplifies to

$$W = \frac{4x+6}{(x+1)^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{4\left(\frac{2x^2}{x+1} + \frac{6x}{x+1} + \frac{4}{x+1}\right)\left(x+\frac{3}{2}\right)^2}{\frac{(2x^2+5x+3)(4x+6)}{(x+1)^2}}\,dx$$

Which simplifies to

$$u_1 = -\int (2+x)(x+1)\,dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - \frac{3}{2}x^2 - 2x$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\left(x+\frac{3}{2}\right)^2}{x+1}}{\frac{(2x^2+5x+3)(4x+6)}{(x+1)^2}}\,dx$$

Which simplifies to

$$u_2 = \int \frac{1}{2}dx$$

Hence

$$u_2 = \frac{x}{2}$$

Which simplifies to

$$u_1 = -\frac{\left(x^2+\frac{9}{2}x+6\right)x}{3}$$
$$u_2 = \frac{x}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{\left(x^2+\frac{9}{2}x+6\right)x}{3\left(x+1\right)} + \frac{x\left(\frac{2x^2}{x+1}+\frac{6x}{x+1}+\frac{4}{x+1}\right)}{2}$$

Which simplifies to

$$y_p(x) = \frac{x^2(4x+9)}{6x+6}$$

Hence the complete solution is

$$\begin{aligned}
y(x) &= y_h + y_p \\
&= \left(\frac{\left(2x^2+6x+4\right)c_2 - 2c_1}{x+1}\right) + \left(\frac{x^2(4x+9)}{6x+6}\right) \\
&= \frac{4x^3+\left(12c_2+9\right)x^2+36c_2x-12c_1+24c_2}{6x+6}
\end{aligned}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{4x^3+\left(12c_2+9\right)x^2+36c_2x-12c_1+24c_2}{6x+6} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -2c_1 + 4c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{12x^2+2(12c_2+9)\,x+36c_2}{6x+6} - \frac{6(4x^3+\left(12c_2+9\right)x^2+36c_2x-12c_1+24c_2)}{\left(6x+6\right)^2}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = 2c_1 + 2c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$\begin{aligned}
c_1 &= 0 \\
c_2 &= 0
\end{aligned}$$

Substituting these values back in above solution results in

$$y = \frac{x^2(4x+9)}{6x+6}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2(4x+9)}{6x+6} \tag{1}$$

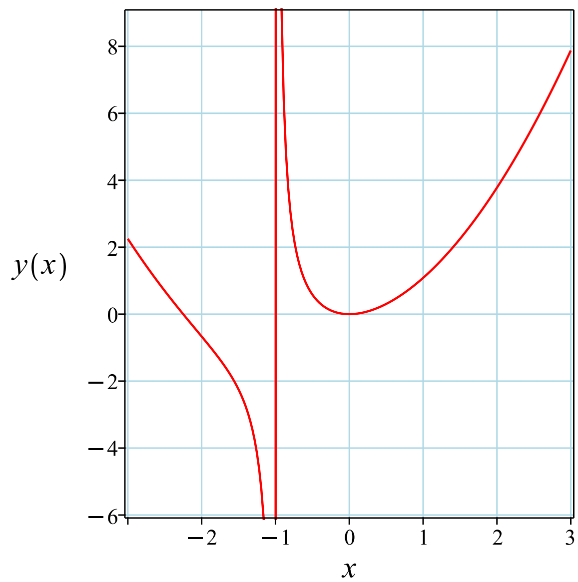

Figure 532: Solution plot

Verification of solutions

$$y = \frac{x^2(4x+9)}{6x+6}$$

Verified OK.

10.35.4 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y''(2x^2+5x+3)+(2x+4)\,y'-2y = 4\left(x+\frac{3}{2}\right)^2$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y''\left(2x^2+5x+3\right)+\left(2x+4\right)y'-2y\right)dx = \int 4\left(x+\frac{3}{2}\right)^2 dx$$
$$\left(-1-2x\right)y+\left(2x^2+5x+3\right)y' = \frac{4\left(x+\frac{3}{2}\right)^3}{3}+c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = -\frac{1+2x}{2x^2+5x+3}$$
$$q(x) = \frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}$$

Hence the ode is

$$y'-\frac{\left(1+2x\right)y}{2x^2+5x+3} = \frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{1+2x}{2x^2+5x+3}dx}$$
$$= e^{-2\ln(2x+3)+\ln(x+1)}$$

Which simplifies to

$$\mu = \frac{x+1}{\left(2x+3\right)^2}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}\right)$$
$$\frac{d}{dx}\left(\frac{\left(x+1\right)y}{\left(2x+3\right)^2}\right) = \left(\frac{x+1}{\left(2x+3\right)^2}\right)\left(\frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}\right)$$
$$d\left(\frac{\left(x+1\right)y}{\left(2x+3\right)^2}\right) = \left(\frac{8x^3+36x^2+6c_1+54x+27}{6\left(2x+3\right)^3}\right)dx$$

Integrating gives

$$
\begin{aligned}
\frac{(x+1)\,y}{(2x+3)^2} &= \int \frac{8x^3+36x^2+6c_1+54x+27}{6\,(2x+3)^3}\, \mathrm{d}x \\
\frac{(x+1)\,y}{(2x+3)^2} &= \frac{x}{6}-\frac{c_1}{4\,(2x+3)^2}+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{x+1}{(2x+3)^2}$ results in

$$
y = \frac{(2x+3)^2\left(\frac{x}{6}-\frac{c_1}{4(2x+3)^2}\right)}{x+1}+\frac{c_2(2x+3)^2}{x+1}
$$

which simplifies to

$$
y = \frac{8x^3+(48c_2+24)\,x^2+(144c_2+18)\,x-3c_1+108c_2}{12x+12}
$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$
y = \frac{8x^3+(48c_2+24)\,x^2+(144c_2+18)\,x-3c_1+108c_2}{12x+12} \tag{1}
$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y=0$ and $x=0$ in the above gives

$$
0 = -\frac{c_1}{4}+9c_2 \tag{1A}
$$

Taking derivative of the solution gives

$$
y' = \frac{24x^2+2(48c_2+24)\,x+144c_2+18}{12x+12}-\frac{12(8x^3+(48c_2+24)\,x^2+(144c_2+18)\,x-3c_1+108c_2)}{(12x+12)^2}
$$

substituting $y'=0$ and $x=0$ in the above gives

$$
0 = \frac{c_1}{4}+3c_2+\frac{3}{2} \tag{2A}
$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$
\begin{aligned}
c_1 &= -\frac{9}{2} \\
c_2 &= -\frac{1}{8}
\end{aligned}
$$

Substituting these values back in above solution results in

$$y = \frac{x^2(4x+9)}{6x+6}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2(4x+9)}{6x+6} \tag{1}$$

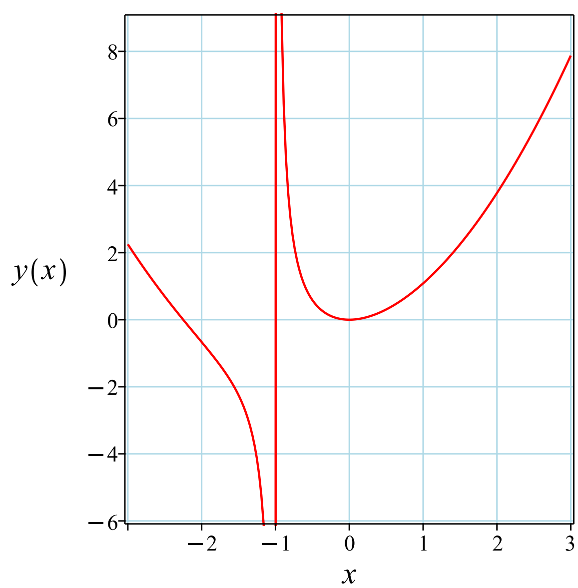

Figure 533: Solution plot

Verification of solutions

$$y = \frac{x^2(4x+9)}{6x+6}$$

Verified OK.

10.35.5 Solving using Kovacic algorithm

Writing the ode as

$$y''(2x^2+5x+3) + (2x+4)\,y' - 2y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= 2x^2 + 5x + 3 \\
B &= 2x + 4 \\
C &= -2
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{3}{(2x + 3)^2} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= 3 \\
t &= (2x + 3)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{3}{(2x + 3)^2} \right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 444: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (2x + 3)^2$. There is a pole at $x = -\frac{3}{2}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{3}{4\left(x + \frac{3}{2}\right)^2}$$

For the pole at $x = -\frac{3}{2}$ let b be the coefficient of $\frac{1}{\left(x+\frac{3}{2}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3}{(2x+3)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2} \\
\alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{(2x+3)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{3}{2}$	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω.

Trying $\alpha_{\infty}^{-} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_{\infty}^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2\left(x + \frac{3}{2}\right)} + (-)(0) \\
&= -\frac{1}{2\left(x + \frac{3}{2}\right)} \\
&= -\frac{1}{2x + 3}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{2\left(x + \frac{3}{2}\right)}\right)(0) + \left(\left(\frac{1}{2\left(x + \frac{3}{2}\right)^2} \right) + \left(-\frac{1}{2\left(x + \frac{3}{2}\right)} \right)^2 - \left(\frac{3}{(2x + 3)^2} \right) \right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int -\frac{1}{2\left(x + \frac{3}{2}\right)} dx} \\
&= \frac{1}{\sqrt{2x + 3}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x+4}{2x^2+5x+3}\,dx} \\
&= z_1 e^{\frac{\ln(2x+3)}{2}-\ln(x+1)} \\
&= z_1 \left(\frac{\sqrt{2x+3}}{x+1}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{1}{x+1}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x+4}{2x^2+5x+3}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\ln(2x+3)-2\ln(x+1)}}{(y_1)^2}\,dx \\
&= y_1(x(x+3))
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{1}{x+1}\right) + c_2\left(\frac{1}{x+1}(x(x+3))\right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x)=0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x)+By'(x)+Cy(x)=f(x)$. y_h is the solution to

$$y''\left(2x^2+5x+3\right)+(2x+4)\,y'-2y=0$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$y_h=\frac{c_1}{x+1}+\frac{c_2x(x+3)}{x+1}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x)=u_1y_1+u_2y_2 \tag{1}$$

Where u_1,u_2 to be determined, and y_1,y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$y_1=\frac{1}{x+1}$$

$$y_2=\frac{x(x+3)}{x+1}$$

In the Variation of parameters u_1,u_2 are found using

$$u_1=-\int\frac{y_2f(x)}{aW(x)} \tag{2}$$

$$u_2=\int\frac{y_1f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W=\begin{vmatrix}y_1 & y_2\\ y_1' & y_2'\end{vmatrix}$. Hence

$$W=\begin{vmatrix}\frac{1}{x+1} & \frac{x(x+3)}{x+1}\\ \frac{d}{dx}\left(\frac{1}{x+1}\right) & \frac{d}{dx}\left(\frac{x(x+3)}{x+1}\right)\end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{1}{x+1} & \frac{x(x+3)}{x+1} \\ -\frac{1}{(x+1)^2} & -\frac{x(x+3)}{(x+1)^2} + \frac{x+3}{x+1} + \frac{x}{x+1} \end{vmatrix}$$

Therefore

$$W = \left(\frac{1}{x+1}\right)\left(-\frac{x(x+3)}{(x+1)^2} + \frac{x+3}{x+1} + \frac{x}{x+1}\right) - \left(\frac{x(x+3)}{x+1}\right)\left(-\frac{1}{(x+1)^2}\right)$$

Which simplifies to

$$W = \frac{2x+3}{(x+1)^2}$$

Which simplifies to

$$W = \frac{2x+3}{(x+1)^2}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{\frac{4x(x+3)\left(x+\frac{3}{2}\right)^2}{x+1}}{\frac{(2x^2+5x+3)(2x+3)}{(x+1)^2}}\,dx$$

Which simplifies to

$$u_1 = -\int x(x+3)\,dx$$

Hence

$$u_1 = -\frac{1}{3}x^3 - \frac{3}{2}x^2$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{4\left(x+\frac{3}{2}\right)^2}{x+1}}{\frac{(2x^2+5x+3)(2x+3)}{(x+1)^2}}\,dx$$

Which simplifies to

$$u_2 = \int 1dx$$

Hence

$$u_2 = x$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = \frac{-\frac{1}{3}x^3 - \frac{3}{2}x^2}{x+1} + \frac{x^2(x+3)}{x+1}$$

Which simplifies to

$$y_p(x) = \frac{x^2(4x+9)}{6x+6}$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(\frac{c_1}{x+1} + \frac{c_2 x(x+3)}{x+1}\right) + \left(\frac{x^2(4x+9)}{6x+6}\right) \end{aligned}$$

Which simplifies to

$$y = \frac{c_2 x^2 + 3c_2 x + c_1}{x+1} + \frac{x^2(4x+9)}{6x+6}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{c_2 x^2 + 3c_2 x + c_1}{x+1} + \frac{x^2(4x+9)}{6x+6} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = c_1 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{2c_2 x + 3c_2}{x+1} - \frac{c_2 x^2 + 3c_2 x + c_1}{(x+1)^2} + \frac{2x(4x+9)}{6x+6} + \frac{4x^2}{6x+6} - \frac{6x^2(4x+9)}{(6x+6)^2}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = -c_1 + 3c_2 \tag{2A}$$

Equations {1A,2A} are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = 0$$
$$c_2 = 0$$

Substituting these values back in above solution results in

$$y = \frac{x^2(4x+9)}{6x+6}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2(4x+9)}{6x+6} \tag{1}$$

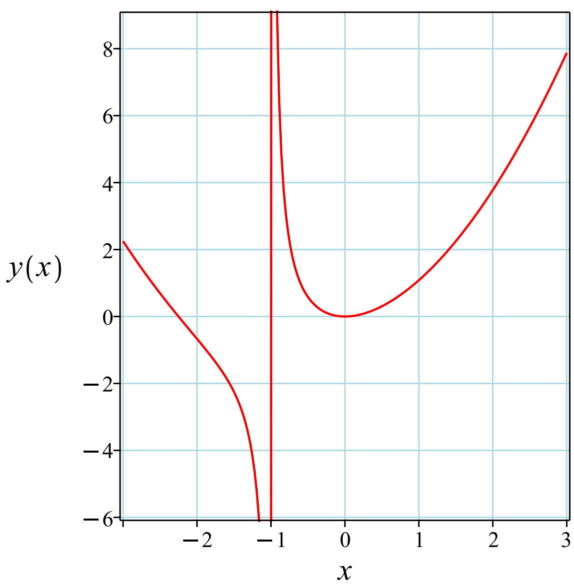

Figure 534: Solution plot

Verification of solutions

$$y = \frac{x^2(4x+9)}{6x+6}$$

Verified OK.

10.35.6 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 2x^2 + 5x + 3 \\ q(x) &= 2x + 4 \\ r(x) &= -2 \\ s(x) &= 4\left(x + \frac{3}{2}\right)^2 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 4 \\ q'(x) &= 2 \end{aligned}$$

Therefore (1) becomes

$$4 - (2) + (-2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$(-1 - 2x)\,y + \left(2x^2 + 5x + 3\right)y' = \int 4\left(x + \frac{3}{2}\right)^2 dx$$

We now have a first order ode to solve which is

$$(-1 - 2x)\,y + \left(2x^2 + 5x + 3\right)y' = \frac{4\left(x + \frac{3}{2}\right)^3}{3} + c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= -\frac{1+2x}{2x^2+5x+3} \\
q(x) &= \frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}
\end{aligned}$$

Hence the ode is

$$y' - \frac{(1+2x)\, y}{2x^2+5x+3} = \frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}$$

The integrating factor μ is

$$\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{1+2x}{2x^2+5x+3}dx} \\
&= \mathrm{e}^{-2\ln(2x+3)+\ln(x+1)}
\end{aligned}$$

Which simplifies to

$$\mu = \frac{x+1}{(2x+3)^2}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{(x+1)\, y}{(2x+3)^2}\right) &= \left(\frac{x+1}{(2x+3)^2}\right)\left(\frac{8x^3+36x^2+6c_1+54x+27}{12x^2+30x+18}\right) \\
\mathrm{d}\left(\frac{(x+1)\, y}{(2x+3)^2}\right) &= \left(\frac{8x^3+36x^2+6c_1+54x+27}{6\,(2x+3)^3}\right)\, \mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\frac{(x+1)\, y}{(2x+3)^2} &= \int \frac{8x^3+36x^2+6c_1+54x+27}{6\,(2x+3)^3}\, \mathrm{d}x \\
\frac{(x+1)\, y}{(2x+3)^2} &= \frac{x}{6} - \frac{c_1}{4\,(2x+3)^2} + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{x+1}{(2x+3)^2}$ results in

$$y = \frac{(2x+3)^2\left(\frac{x}{6} - \frac{c_1}{4(2x+3)^2}\right)}{x+1} + \frac{c_2(2x+3)^2}{x+1}$$

which simplifies to

$$y = \frac{8x^3 + (48c_2 + 24)\,x^2 + (144c_2 + 18)\,x - 3c_1 + 108c_2}{12x + 12}$$

Initial conditions are used to solve for the constants of integration.

Looking at the above solution

$$y = \frac{8x^3 + (48c_2 + 24)\,x^2 + (144c_2 + 18)\,x - 3c_1 + 108c_2}{12x + 12} \tag{1}$$

Initial conditions are now substituted in the above solution. This will generate the required equations to solve for the integration constants. substituting $y = 0$ and $x = 0$ in the above gives

$$0 = -\frac{c_1}{4} + 9c_2 \tag{1A}$$

Taking derivative of the solution gives

$$y' = \frac{24x^2 + 2(48c_2 + 24)\,x + 144c_2 + 18}{12x + 12} - \frac{12(8x^3 + (48c_2 + 24)\,x^2 + (144c_2 + 18)\,x - 3c_1 + 108c_2)}{(12x + 12)^2}$$

substituting $y' = 0$ and $x = 0$ in the above gives

$$0 = \frac{c_1}{4} + 3c_2 + \frac{3}{2} \tag{2A}$$

Equations $\{1A,2A\}$ are now solved for $\{c_1, c_2\}$. Solving for the constants gives

$$c_1 = -\frac{9}{2}$$
$$c_2 = -\frac{1}{8}$$

Substituting these values back in above solution results in

$$y = \frac{x^2(4x + 9)}{6x + 6}$$

Summary

The solution(s) found are the following

$$y = \frac{x^2(4x + 9)}{6x + 6} \tag{1}$$

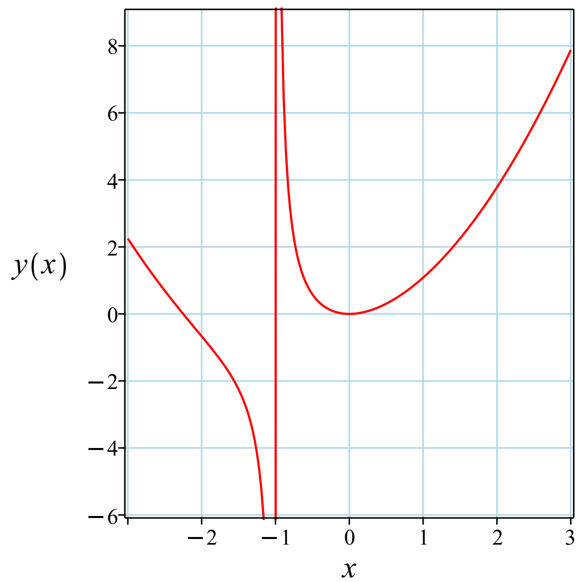

Figure 535: Solution plot

Verification of solutions

$$y = \frac{x^2(4x+9)}{6x+6}$$

Verified OK.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(2+x)\, y''+y'x+3y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0)+(x-x_0)\, y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\ &= y_0+xy'_0+\frac{x^2}{2}\, f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}\, f'|_{x_0,y_0,y'_0}+\cdots \\ &= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\, \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0} \end{aligned}$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (785)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (786)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} F_n|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{3y + y'x}{2 + x} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(x^2 - 3x - 8)\, y' + 3(x + 1)\, y}{(2 + x)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-x^2 + 8x + 8)\, y' - 3y(x - 4)}{(2 + x)^2} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(x^2 - 13x + 12)\, y' + 3y(x - 9)}{(2 + x)^2} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-x^3 + 16x^2 - 16x - 104)\, y' - 3y(x^2 - 12x - 8)}{(2 + x)^3}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -\frac{3y(0)}{2} \\
F_1 &= \frac{3y(0)}{4} - 2y'(0) \\
F_2 &= 3y(0) + 2y'(0) \\
F_3 &= -\frac{27y(0)}{4} + 3y'(0) \\
F_4 &= 3y(0) - 13y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = \left(1-\frac{3}{4}x^2+\frac{1}{8}x^3+\frac{1}{8}x^4-\frac{9}{160}x^5+\frac{1}{240}x^6\right)y(0) \\ +\left(x-\frac{1}{3}x^3+\frac{1}{12}x^4+\frac{1}{40}x^5-\frac{13}{720}x^6\right)y'(0)+O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(2+x)\,y''+y'x+3y=0$$

Let the solution be represented as power series of the form

$$y=\sum_{n=0}^{\infty} a_n x^n$$

Then

$$y'=\sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y''=\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(2+x)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)x+3\left(\sum_{n=0}^{\infty} a_n x^n\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\,x^{n-1}a_n(n-1)\right)+\left(\sum_{n=2}^{\infty} 2n(n-1)\,a_n x^{n-2}\right)+\left(\sum_{n=1}^{\infty} n a_n x^n\right)+\left(\sum_{n=0}^{\infty} 3a_n x^n\right)=0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\,x^{n-1}a_n(n-1)=\sum_{n=1}^{\infty}(n+1)\,a_{n+1}n\,x^n$$
$$\sum_{n=2}^{\infty} 2n(n-1)\,a_n x^{n-2}=\sum_{n=0}^{\infty} 2(n+2)\,a_{n+2}(n+1)\,x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (n+1)\, a_{n+1} n\, x^{n}\right) + \left(\sum_{n=0}^{\infty} 2(n+2)\, a_{n+2}(n+1)\, x^{n}\right) + \left(\sum_{n=1}^{\infty} n a_{n} x^{n}\right) + \left(\sum_{n=0}^{\infty} 3 a_{n} x^{n}\right) = 0 \tag{3}$$

$n = 0$ gives

$$4a_2 + 3a_0 = 0$$

$$a_2 = -\frac{3a_0}{4}$$

For $1 \leq n$, the recurrence equation is

$$(n+1)\, a_{n+1} n + 2(n+2)\, a_{n+2}(n+1) + n a_n + 3a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_{n+1} + n a_n + n a_{n+1} + 3a_n}{2\,(n+2)\,(n+1)} \\ &= -\frac{(n+3)\, a_n}{2\,(n+2)\,(n+1)} - \frac{(n^2+n)\, a_{n+1}}{2\,(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$2a_2 + 12a_3 + 4a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{a_0}{8} - \frac{a_1}{3}$$

For $n = 2$ the recurrence equation gives

$$6a_3 + 24a_4 + 5a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{8} + \frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$12a_4 + 40a_5 + 6a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{9a_0}{160} + \frac{a_1}{40}$$

For $n = 4$ the recurrence equation gives

$$20a_5 + 60a_6 + 7a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{240} - \frac{13a_1}{720}$$

For $n = 5$ the recurrence equation gives

$$30a_6 + 84a_7 + 8a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{13a_0}{3360} + \frac{41a_1}{10080}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x - \frac{3a_0x^2}{4} + \left(\frac{a_0}{8} - \frac{a_1}{3}\right)x^3 + \left(\frac{a_0}{8} + \frac{a_1}{12}\right)x^4 + \left(-\frac{9a_0}{160} + \frac{a_1}{40}\right)x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{3}{4}x^2 + \frac{1}{8}x^3 + \frac{1}{8}x^4 - \frac{9}{160}x^5\right)a_0 + \left(x - \frac{1}{3}x^3 + \frac{1}{12}x^4 + \frac{1}{40}x^5\right)a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{3}{4}x^2 + \frac{1}{8}x^3 + \frac{1}{8}x^4 - \frac{9}{160}x^5\right)c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{12}x^4 + \frac{1}{40}x^5\right)c_2 + O(x^6)$$

Summary
The solution(s) found are the following

$$\begin{aligned} y = &\left(1 - \frac{3}{4}x^2 + \frac{1}{8}x^3 + \frac{1}{8}x^4 - \frac{9}{160}x^5 + \frac{1}{240}x^6\right)y(0) \\ &+ \left(x - \frac{1}{3}x^3 + \frac{1}{12}x^4 + \frac{1}{40}x^5 - \frac{13}{720}x^6\right)y'(0) + O(x^6) \end{aligned} \quad (1)$$

$$y = \left(1 - \frac{3}{4}x^2 + \frac{1}{8}x^3 + \frac{1}{8}x^4 - \frac{9}{160}x^5\right)c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{12}x^4 + \frac{1}{40}x^5\right)c_2 + O(x^6) \quad (2)$$

Verification of solutions

$$\begin{aligned} y = &\left(1 - \frac{3}{4}x^2 + \frac{1}{8}x^3 + \frac{1}{8}x^4 - \frac{9}{160}x^5 + \frac{1}{240}x^6\right)y(0) \\ &+ \left(x - \frac{1}{3}x^3 + \frac{1}{12}x^4 + \frac{1}{40}x^5 - \frac{13}{720}x^6\right)y'(0) + O(x^6) \end{aligned}$$

Verified OK.

$$y = \left(1 - \frac{3}{4}x^2 + \frac{1}{8}x^3 + \frac{1}{8}x^4 - \frac{9}{160}x^5\right)c_1 + \left(x - \frac{1}{3}x^3 + \frac{1}{12}x^4 + \frac{1}{40}x^5\right)c_2 + O(x^6)$$

Verified OK.

11.1.1 Maple step by step solution

Let's solve

$(2 + x)\,y'' + y'x + 3y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = -\frac{3y}{2+x} - \frac{xy'}{2+x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + \frac{xy'}{2+x} + \frac{3y}{2+x} = 0$

□ Check to see if $x_0 = -2$ is a regular singular point

- Define functions

$\left[P_2(x) = \frac{x}{2+x}, P_3(x) = \frac{3}{2+x}\right]$

- $(2+x) \cdot P_2(x)$ is analytic at $x = -2$

$((2+x) \cdot P_2(x))\Big|_{x=-2} = -2$

- $(2+x)^2 \cdot P_3(x)$ is analytic at $x = -2$

$((2+x)^2 \cdot P_3(x))\Big|_{x=-2} = 0$

- $x = -2$is a regular singular point

Check to see if $x_0 = -2$ is a regular singular point

$x_0 = -2$

- Multiply by denominators

$(2+x)\, y'' + y'x + 3y = 0$

- Change variables using $x = u - 2$ so that the regular singular point is at $u = 0$

$u\left(\frac{d^2}{du^2}y(u)\right) + (u-2)\left(\frac{d}{du}y(u)\right) + 3y(u) = 0$

- Assume series solution for $y(u)$

$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-1}$$

- Shift index using $k- > k+1$

$$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-3+r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)(k-2+r) + a_k(k+r+3)\right) u^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-3+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, 3\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k-2+r) + a_k(k+r+3) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k(k+r+3)}{(k+1+r)(k-2+r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-2)}$$

- Series not valid for $r = 0$, division by 0 in the recursion relation at $k = 2$

$$a_{k+1} = -\frac{a_k(k+3)}{(k+1)(k-2)}$$

- Recursion relation for $r = 3$

$$a_{k+1} = -\frac{a_k(k+6)}{(k+4)(k+1)}$$

- Solution for $r = 3$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+3}, a_{k+1} = -\frac{a_k(k+6)}{(k+4)(k+1)}\right]$$

- Revert the change of variables $u = 2+x$

$$\left[y = \sum_{k=0}^{\infty} a_k(2+x)^{k+3}, a_{k+1} = -\frac{a_k(k+6)}{(k+4)(k+1)}\right]$$

Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 12.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(3x^2+1)\,y''+3y'x^2-2y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y_0'$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy_0'+\frac{x^2}{2}f|_{x_0,y_0,y_0'}+\frac{x^3}{3!}f'|_{x_0,y_0,y_0'}+\cdots \\
&= y_0+xy_0'+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}\left.\frac{d^nf}{dx^n}\right|_{x_0,y_0,y_0'}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{788}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{789}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{3y'x^2 - 2y}{3x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(9x^4 + 6x^2 - 6x + 2)\, y' - 6x(2+x)\, y}{(3x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-27x^6 - 36x^4 - 18x^3 + 42x^2 - 24x - 6)\, y' + 18\left(x^4 + 2x^3 + \frac{20}{3}x^2 - \frac{4}{3}x - \frac{4}{9}\right) y}{(3x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(81x^8 + 162x^6 + 216x^5 + 414x^4 - 612x^3 + 420x^2 + 168x - 32)\, y' - 54\left(x^6 + 2x^5 + \frac{22}{3}x^4 + 26x^3 - \frac{92}{9}\right.}{(3x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-243x^{10} - 648x^8 - 1296x^7 - 4428x^6 - 6480x^5 + 10260x^4 - 6804x^3 - 4824x^2 + 1944x + 132)\, y' +}{(3x^2+1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 2y(0) \\
F_1 &= 2y'(0) \\
F_2 &= -8y(0) - 6y'(0) \\
F_3 &= -36y(0) - 32y'(0) \\
F_4 &= 272y(0) + 132y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 + x^2 - \frac{1}{3}x^4 - \frac{3}{10}x^5 + \frac{17}{45}x^6\right) y(0) + \left(x + \frac{1}{3}x^3 - \frac{1}{4}x^4 - \frac{4}{15}x^5 + \frac{11}{60}x^6\right) y'(0) + O(x^6)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(3x^2 + 1\right) y'' + 3y' x^2 - 2y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\left(3x^2 + 1\right) \left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + 3\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x^2 - 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \quad (1)$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} 3x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 3n\, x^{1+n} a_n\right) + \sum_{n=0}^{\infty} \left(-2 a_n x^n\right) = 0 \quad (2)$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n$$
$$\sum_{n=1}^{\infty} 3n\, x^{1+n} a_n = \sum_{n=2}^{\infty} 3(n-1) a_{n-1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} 3x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(1+n) x^n\right) + \left(\sum_{n=2}^{\infty} 3(n-1) a_{n-1} x^n\right) + \sum_{n=0}^{\infty} (-2a_n x^n) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - 2a_0 = 0$$

$$a_2 = a_0$$

$n = 1$ gives

$$6a_3 - 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_1}{3}$$

For $2 \leq n$, the recurrence equation is

$$3na_n(n-1) + (n+2) a_{n+2}(1+n) + 3(n-1) a_{n-1} - 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{3n^2 a_n - 3na_n + 3na_{n-1} - 2a_n - 3a_{n-1}}{(n+2)(1+n)} \\ &= -\frac{(3n^2 - 3n - 2) a_n}{(n+2)(1+n)} - \frac{(3n-3) a_{n-1}}{(n+2)(1+n)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$4a_2 + 12a_4 + 3a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{3} - \frac{a_1}{4}$$

For $n = 3$ the recurrence equation gives

$$16a_3 + 20a_5 + 6a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{4a_1}{15} - \frac{3a_0}{10}$$

For $n = 4$ the recurrence equation gives

$$34a_4 + 30a_6 + 9a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{17a_0}{45} + \frac{11a_1}{60}$$

For $n = 5$ the recurrence equation gives

$$58a_5 + 42a_7 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{277a_1}{630} + \frac{107a_0}{210}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x + a_0x^2 + \frac{a_1x^3}{3} + \left(-\frac{a_0}{3} - \frac{a_1}{4}\right)x^4 + \left(-\frac{4a_1}{15} - \frac{3a_0}{10}\right)x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1+x^{2}-\frac{1}{3}x^{4}-\frac{3}{10}x^{5}\right) a_{0}+\left(x+\frac{1}{3}x^{3}-\frac{1}{4}x^{4}-\frac{4}{15}x^{5}\right) a_{1}+O\left(x^{6}\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1+x^{2}-\frac{1}{3}x^{4}-\frac{3}{10}x^{5}\right) c_{1}+\left(x+\frac{1}{3}x^{3}-\frac{1}{4}x^{4}-\frac{4}{15}x^{5}\right) c_{2}+O\left(x^{6}\right)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &\left(1+x^{2}-\frac{1}{3}x^{4}-\frac{3}{10}x^{5}+\frac{17}{45}x^{6}\right) y(0) \\ &+\left(x+\frac{1}{3}x^{3}-\frac{1}{4}x^{4}-\frac{4}{15}x^{5}+\frac{11}{60}x^{6}\right) y'(0)+O\left(x^{6}\right) \end{aligned} \tag{1}$$

$$y = \left(1+x^{2}-\frac{1}{3}x^{4}-\frac{3}{10}x^{5}\right) c_{1}+\left(x+\frac{1}{3}x^{3}-\frac{1}{4}x^{4}-\frac{4}{15}x^{5}\right) c_{2}+O\left(x^{6}\right) \tag{2}$$

Verification of solutions

$$y = \left(1+x^{2}-\frac{1}{3}x^{4}-\frac{3}{10}x^{5}+\frac{17}{45}x^{6}\right) y(0)+\left(x+\frac{1}{3}x^{3}-\frac{1}{4}x^{4}-\frac{4}{15}x^{5}+\frac{11}{60}x^{6}\right) y'(0)+O\left(x^{6}\right)$$

Verified OK.

$$y = \left(1+x^{2}-\frac{1}{3}x^{4}-\frac{3}{10}x^{5}\right) c_{1}+\left(x+\frac{1}{3}x^{3}-\frac{1}{4}x^{4}-\frac{4}{15}x^{5}\right) c_{2}+O\left(x^{6}\right)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 13.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(2x^2+1)\,y''+(-3x+2)\,y'+4y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y_0'$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\ &= y_0+xy_0'+\frac{x^2}{2}f|_{x_0,y_0,y_0'}+\frac{x^3}{3!}f'|_{x_0,y_0,y_0'}+\cdots \\ &= y_0+xy_0'+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}\left.\frac{d^nf}{dx^n}\right|_{x_0,y_0,y_0'} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{791}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{792}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \tag{7}$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= \frac{3y'x-2y'-4y}{2x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x}+\frac{\partial F_0}{\partial y}y'+\frac{\partial F_0}{\partial y'}F_0 \\
&= \frac{(-5x^2-4x+3)\,y'+4(2+x)\,y}{(2x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x}+\frac{\partial F_1}{\partial y}y'+\frac{\partial F_1}{\partial y'}F_1 \\
&= \frac{(13x^3+38x^2-13x-2)\,y'-4y(x^2+12x+2)}{(2x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x}+\frac{\partial F_2}{\partial y}y'+\frac{\partial F_2}{\partial y'}F_2 \\
&= \frac{(-47x^4-312x^3+34x^2+72x-17)\,y'-20\left(x^3-\frac{82}{5}x^2-7x+2\right)y}{(2x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x}+\frac{\partial F_3}{\partial y}y'+\frac{\partial F_3}{\partial y'}F_3 \\
&= \frac{(195x^5+2934x^4+390x^3-1548x^2+285x+66)\,y'+388y\left(x^4-\frac{672}{97}x^3-\frac{539}{97}x^2+\frac{252}{97}x+\frac{52}{97}\right)}{(2x^2+1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and $y'(0)=y'(0)$ gives

$$
\begin{aligned}
F_0 &= -4y(0)-2y'(0) \\
F_1 &= 8y(0)+3y'(0) \\
F_2 &= -8y(0)-2y'(0) \\
F_3 &= -40y(0)-17y'(0) \\
F_4 &= 208y(0)+66y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1-2x^{2}+\frac{4}{3}x^{3}-\frac{1}{3}x^{4}-\frac{1}{3}x^{5}+\frac{13}{45}x^{6}\right) y(0) \\
&+\left(x-x^{2}+\frac{1}{2}x^{3}-\frac{1}{12}x^{4}-\frac{17}{120}x^{5}+\frac{11}{120}x^{6}\right) y'(0)+O(x^{6})
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
\left(2x^{2}+1\right) y''+\left(-3x+2\right) y'+4y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_{n} x^{n}
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_{n} x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\left(2x^{2}+1\right)\left(\sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}\right)+\left(-3x+2\right)\left(\sum_{n=1}^{\infty} n a_{n} x^{n-1}\right)+4\left(\sum_{n=0}^{\infty} a_{n} x^{n}\right) = 0 \tag{1}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty} 2x^{n} a_{n} n(n-1)\right)+\left(\sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}\right) \\
&+\sum_{n=1}^{\infty}\left(-3n a_{n} x^{n}\right)+\left(\sum_{n=1}^{\infty} 2n a_{n} x^{n-1}\right)+\left(\sum_{n=0}^{\infty} 4a_{n} x^{n}\right) = 0
\end{aligned} \tag{2}
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^{n} and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1) a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n$$

$$\sum_{n=1}^{\infty} 2n a_n x^{n-1} = \sum_{n=0}^{\infty} 2(n+1) a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} 2x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2) a_{n+2}(n+1) x^n\right) + \sum_{n=1}^{\infty} (-3n a_n x^n) + \left(\sum_{n=0}^{\infty} 2(n+1) a_{n+1} x^n\right) + \left(\sum_{n=0}^{\infty} 4a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + 2a_1 + 4a_0 = 0$$

$$a_2 = -2a_0 - a_1$$

$n = 1$ gives

$$6a_3 + a_1 + 4a_2 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{4a_0}{3} + \frac{a_1}{2}$$

For $2 \leq n$, the recurrence equation is

$$2na_n(n-1) + (n+2) a_{n+2}(n+1) - 3na_n + 2(n+1) a_{n+1} + 4a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{2n^2 a_n - 5na_n + 2na_{n+1} + 4a_n + 2a_{n+1}}{(n+2)(n+1)} \\ &= -\frac{(2n^2 - 5n + 4) a_n}{(n+2)(n+1)} - \frac{(2n+2) a_{n+1}}{(n+2)(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$2a_2 + 12a_4 + 6a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{3} - \frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$7a_3 + 20a_5 + 8a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_0}{3} - \frac{17a_1}{120}$$

For $n = 4$ the recurrence equation gives

$$16a_4 + 30a_6 + 10a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{13a_0}{45} + \frac{11a_1}{120}$$

For $n = 5$ the recurrence equation gives

$$29a_5 + 42a_7 + 12a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{31a_0}{210} + \frac{361a_1}{5040}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + (-2a_0 - a_1) x^2 + \left(\frac{4a_0}{3} + \frac{a_1}{2}\right) x^3 + \left(-\frac{a_0}{3} - \frac{a_1}{12}\right) x^4 + \left(-\frac{a_0}{3} - \frac{17a_1}{120}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - 2x^2 + \frac{4}{3}x^3 - \frac{1}{3}x^4 - \frac{1}{3}x^5\right) a_0 + \left(x - x^2 + \frac{1}{2}x^3 - \frac{1}{12}x^4 - \frac{17}{120}x^5\right) a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - 2x^2 + \frac{4}{3}x^3 - \frac{1}{3}x^4 - \frac{1}{3}x^5\right) c_1 + \left(x - x^2 + \frac{1}{2}x^3 - \frac{1}{12}x^4 - \frac{17}{120}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = &\left(1 - 2x^2 + \frac{4}{3}x^3 - \frac{1}{3}x^4 - \frac{1}{3}x^5 + \frac{13}{45}x^6\right) y(0) \\ &+ \left(x - x^2 + \frac{1}{2}x^3 - \frac{1}{12}x^4 - \frac{17}{120}x^5 + \frac{11}{120}x^6\right) y'(0) + O(x^6) \end{aligned} \quad (1)$$

$$y = \left(1 - 2x^2 + \frac{4}{3}x^3 - \frac{1}{3}x^4 - \frac{1}{3}x^5\right) c_1 + \left(x - x^2 + \frac{1}{2}x^3 - \frac{1}{12}x^4 - \frac{17}{120}x^5\right) c_2 + O(x^6) \quad (2)$$

Verification of solutions

$$\begin{aligned} y = &\left(1 - 2x^2 + \frac{4}{3}x^3 - \frac{1}{3}x^4 - \frac{1}{3}x^5 + \frac{13}{45}x^6\right) y(0) \\ &+ \left(x - x^2 + \frac{1}{2}x^3 - \frac{1}{12}x^4 - \frac{17}{120}x^5 + \frac{11}{120}x^6\right) y'(0) + O(x^6) \end{aligned}$$

Verified OK.

$$y = \left(1 - 2x^2 + \frac{4}{3}x^3 - \frac{1}{3}x^4 - \frac{1}{3}x^5\right) c_1 + \left(x - x^2 + \frac{1}{2}x^3 - \frac{1}{12}x^4 - \frac{17}{120}x^5\right) c_2 + O(x^6)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\, y''+(2-x)\, y'+3y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\, y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy'_0+\frac{x^2}{2}\, f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}\, f'|_{x_0,y_0,y'_0}+\cdots \\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\, \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{794}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{795}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= \frac{y'x-2y'-3y}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x}+\frac{\partial F_0}{\partial y}y'+\frac{\partial F_0}{\partial y'}F_0 \\
&= \frac{-3y'x^2+3yx+2y'+6y}{(x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x}+\frac{\partial F_1}{\partial y}y'+\frac{\partial F_1}{\partial y'}F_1 \\
&= \frac{(6x^3+12x^2-9x+2)\,y'+(-24x-3)\,y}{(x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x}+\frac{\partial F_2}{\partial y}y'+\frac{\partial F_2}{\partial y'}F_2 \\
&= \frac{(-12x^4-72x^3+27x^2+8x-16)\,y'-18\left(x^3-\frac{14}{3}x^2-\frac{5}{2}x+\frac{5}{3}\right)y}{(x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x}+\frac{\partial F_3}{\partial y}y'+\frac{\partial F_3}{\partial y'}F_3 \\
&= \frac{(18x^5+396x^4-12x^3-264x^2+195x+10)\,y'+126\left(x^4-\frac{16}{7}x^3-\frac{25}{7}x^2+\frac{64}{21}x+\frac{31}{42}\right)y}{(x^2+1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=y(0)$ and $y'(0)=y'(0)$ gives

$$
\begin{aligned}
F_0 &= -3y(0)-2y'(0) \\
F_1 &= 6y(0)+2y'(0) \\
F_2 &= -3y(0)+2y'(0) \\
F_3 &= -30y(0)-16y'(0) \\
F_4 &= 93y(0)+10y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y = &\left(1-\frac{3}{2}x^{2}+x^{3}-\frac{1}{8}x^{4}-\frac{1}{4}x^{5}+\frac{31}{240}x^{6}\right) y(0) \\
&+\left(x-x^{2}+\frac{1}{3}x^{3}+\frac{1}{12}x^{4}-\frac{2}{15}x^{5}+\frac{1}{72}x^{6}\right) y'(0)+O(x^{6})
\end{aligned}
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
(x^{2}+1)\, y''+(2-x)\, y'+3y = 0
$$

Let the solution be represented as power series of the form

$$
y = \sum_{n=0}^{\infty} a_{n} x^{n}
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=1}^{\infty} n a_{n} x^{n-1} \\
y'' &= \sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
(x^{2}+1)\left(\sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}\right)+(2-x)\left(\sum_{n=1}^{\infty} n a_{n} x^{n-1}\right)+3\left(\sum_{n=0}^{\infty} a_{n} x^{n}\right) = 0 \quad (1)
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty} x^{n} a_{n} n(n-1)\right)+\left(\sum_{n=2}^{\infty} n(n-1)\, a_{n} x^{n-2}\right) \\
&+\left(\sum_{n=1}^{\infty} 2n a_{n} x^{n-1}\right)+\sum_{n=1}^{\infty} (-n a_{n} x^{n})+\left(\sum_{n=0}^{\infty} 3a_{n} x^{n}\right) = 0
\end{aligned} \quad (2)
$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^{n} and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

$$\sum_{n=1}^{\infty} 2n a_n x^{n-1} = \sum_{n=0}^{\infty} 2(n+1)\, a_{n+1} x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \left(\sum_{n=0}^{\infty} 2(n+1)\, a_{n+1} x^n\right) + \sum_{n=1}^{\infty} (-n a_n x^n) + \left(\sum_{n=0}^{\infty} 3a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + 2a_1 + 3a_0 = 0$$

$$a_2 = -\frac{3a_0}{2} - a_1$$

$n = 1$ gives

$$6a_3 + 4a_2 + 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = a_0 + \frac{a_1}{3}$$

For $2 \leq n$, the recurrence equation is

$$n a_n(n-1) + (n+2)\, a_{n+2}(n+1) + 2(n+1)\, a_{n+1} - n a_n + 3a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_n - 2n a_n + 2n a_{n+1} + 3a_n + 2a_{n+1}}{(n+2)\,(n+1)} \\ &= -\frac{(n^2 - 2n + 3)\, a_n}{(n+2)\,(n+1)} - \frac{(2n+2)\, a_{n+1}}{(n+2)\,(n+1)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$3a_2 + 12a_4 + 6a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{8} + \frac{a_1}{12}$$

For $n = 3$ the recurrence equation gives

$$6a_3 + 20a_5 + 8a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{a_0}{4} - \frac{2a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$11a_4 + 30a_6 + 10a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{31a_0}{240} + \frac{a_1}{72}$$

For $n = 5$ the recurrence equation gives

$$18a_5 + 42a_7 + 12a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{59a_0}{840} + \frac{67a_1}{1260}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + \left(-\frac{3a_0}{2} - a_1\right) x^2 + \left(a_0 + \frac{a_1}{3}\right) x^3 + \left(-\frac{a_0}{8} + \frac{a_1}{12}\right) x^4 + \left(-\frac{a_0}{4} - \frac{2a_1}{15}\right) x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{3}{2}x^2 + x^3 - \frac{1}{8}x^4 - \frac{1}{4}x^5\right) a_0 + \left(x - x^2 + \frac{1}{3}x^3 + \frac{1}{12}x^4 - \frac{2}{15}x^5\right) a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{3}{2}x^2 + x^3 - \frac{1}{8}x^4 - \frac{1}{4}x^5\right) c_1 + \left(x - x^2 + \frac{1}{3}x^3 + \frac{1}{12}x^4 - \frac{2}{15}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= \left(1 - \frac{3}{2}x^2 + x^3 - \frac{1}{8}x^4 - \frac{1}{4}x^5 + \frac{31}{240}x^6\right) y(0) \\ &+ \left(x - x^2 + \frac{1}{3}x^3 + \frac{1}{12}x^4 - \frac{2}{15}x^5 + \frac{1}{72}x^6\right) y'(0) + O(x^6) \end{aligned} \quad (1)$$

$$y = \left(1 - \frac{3}{2}x^2 + x^3 - \frac{1}{8}x^4 - \frac{1}{4}x^5\right) c_1 + \left(x - x^2 + \frac{1}{3}x^3 + \frac{1}{12}x^4 - \frac{2}{15}x^5\right) c_2 + O(x^6) \quad (2)$$

Verification of solutions

$$\begin{aligned} y &= \left(1 - \frac{3}{2}x^2 + x^3 - \frac{1}{8}x^4 - \frac{1}{4}x^5 + \frac{31}{240}x^6\right) y(0) \\ &+ \left(x - x^2 + \frac{1}{3}x^3 + \frac{1}{12}x^4 - \frac{2}{15}x^5 + \frac{1}{72}x^6\right) y'(0) + O(x^6) \end{aligned}$$

Verified OK.

$$y = \left(1 - \frac{3}{2}x^2 + x^3 - \frac{1}{8}x^4 - \frac{1}{4}x^5\right) c_1 + \left(x - x^2 + \frac{1}{3}x^3 + \frac{1}{12}x^4 - \frac{2}{15}x^5\right) c_2 + O(x^6)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(3x^2+1)\,y''-2y'x+4y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy'_0+\frac{x^2}{2}f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}f'|_{x_0,y_0,y'_0}+\cdots \\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\,\frac{d^nf}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{797}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{798}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n|_{x_0,y_0,y_0'} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= \frac{2y'x - 4y}{3x^2 + 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{-14y'x^2 + 16yx - 2y'}{\left(3x^2 + 1\right)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{104x^3y' - 88x^2y + 8y'x + 24y}{\left(3x^2 + 1\right)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{32(-31x^4 + 6x^2 + 1)\, y' + 640(x^3 - x)\, y}{\left(3x^2 + 1\right)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{\left(11840x^5 - 8320x^3 - 960x\right) y' + \left(-5632x^4 + 14592x^2 - 768\right) y}{\left(3x^2 + 1\right)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -4y(0) \\
F_1 &= -2y'(0) \\
F_2 &= 24y(0) \\
F_3 &= 32y'(0) \\
F_4 &= -768y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - 2x^2 + x^4 - \frac{16}{15}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{4}{15}x^5\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(3x^2 + 1)\, y'' - 2y'x + 4y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(3x^2 + 1) \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) - 2\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 4\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} 3x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-2n a_n x^n) + \left(\sum_{n=0}^{\infty} 4a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} 3x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=1}^{\infty} (-2n a_n x^n) + \left(\sum_{n=0}^{\infty} 4a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 + 4a_0 = 0$$

$$a_2 = -2a_0$$

$n = 1$ gives

$$6a_3 + 2a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{a_1}{3}$$

For $2 \leq n$, the recurrence equation is

$$3na_n(n-1) + (n+2)\, a_{n+2}(n+1) - 2na_n + 4a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n(3n^2 - 5n + 4)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$6a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = a_0$$

For $n = 3$ the recurrence equation gives

$$16a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{4a_1}{15}$$

For $n = 4$ the recurrence equation gives

$$32a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -\frac{16a_0}{15}$$

For $n = 5$ the recurrence equation gives

$$54a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{12a_1}{35}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x - 2a_0x^2 - \frac{1}{3}a_1x^3 + a_0x^4 + \frac{4}{15}a_1x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(x^4 - 2x^2 + 1\right) a_0 + \left(x - \frac{1}{3}x^3 + \frac{4}{15}x^5\right) a_1 + O\left(x^6\right) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(x^4 - 2x^2 + 1\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{4}{15}x^5\right) c_2 + O\left(x^6\right)$$

<u>Summary</u>

The solution(s) found are the following

$$y = \left(1 - 2x^2 + x^4 - \frac{16}{15}x^6\right) y(0) + \left(x - \frac{1}{3}x^3 + \frac{4}{15}x^5\right) y'(0) + O\left(x^6\right) \tag{1}$$

$$y = \left(x^4 - 2x^2 + 1\right) c_1 + \left(x - \frac{1}{3}x^3 + \frac{4}{15}x^5\right) c_2 + O\left(x^6\right) \tag{2}$$

Verification of solutions

$$y = \left(1-2x^2+x^4-\frac{16}{15}x^6\right) y(0)+\left(x-\frac{1}{3}x^3+\frac{4}{15}x^5\right) y'(0)+O(x^6)$$

Verified OK.

$$y = (x^4-2x^2+1)\, c_1+\left(x-\frac{1}{3}x^3+\frac{4}{15}x^5\right) c_2+O(x^6)$$

Verified OK.

Internal file name [`OUTPUT/1196_Sunday_June_05_2022_02_04_49_AM_56123841/index.tex`]

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 16.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy'' + (2x+4)\,y' + (2+x)\,y = 0}$$

With the expansion point for the power series method at $x = -1$.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x + 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\left(\frac{d^2}{dt^2}y(t)\right)(-1+t) + (2t+2)\left(\frac{d}{dt}y(t)\right) + (t+1)\,y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n} \bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x} \frac{dx}{dx} + \frac{\partial f}{\partial y} \frac{dy}{dx} + \frac{\partial f}{\partial y'} \frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' \tag{800}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f \tag{801}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx} \left(\frac{df}{dx} \right)$$

$$= \frac{\partial}{\partial x} \left(\frac{df}{dx} \right) + \frac{\partial}{\partial y} \left(\frac{df}{dx} \right) y' + \frac{\partial}{\partial y'} \left(\frac{df}{dx} \right) f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx} \left(\frac{d^2 f}{dx^2} \right)$$

$$= \frac{\partial}{\partial x} \left(\frac{d^2 f}{dx^2} \right) + \left(\frac{\partial}{\partial y} \frac{d^2 f}{dx^2} \right) y' + \frac{\partial}{\partial y'} \left(\frac{d^2 f}{dx^2} \right) f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{y(t)\,t + 2t\left(\frac{d}{dt}y(t)\right) + y(t) + 2\frac{d}{dt}y(t)}{-1+t} \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y\left(t\right)}F_0 \\
&= \frac{\left(3t^2+8t+9\right)\left(\frac{d}{dt}y(t)\right) + 2y(t)\left(t^2+2t+2\right)}{\left(-1+t\right)^2} \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y\left(t\right)}F_1 \\
&= \frac{\left(-4t^3-20t^2-48t-48\right)\left(\frac{d}{dt}y(t)\right) - 3\left(t^3+\frac{11}{3}t^2+\frac{25}{3}t+7\right)y(t)}{\left(-1+t\right)^3} \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y\left(t\right)}F_2 \\
&= \frac{\left(5t^4+40t^3+154t^2+332t+309\right)\left(\frac{d}{dt}y(t)\right) + 4y(t)\left(t^4+6t^3+22t^2+42t+34\right)}{\left(-1+t\right)^4} \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y\left(t\right)}F_3 \\
&= \frac{\left(-6t^5-70t^4-384t^3-1320t^2-2618t-2322\right)\left(\frac{d}{dt}y(t)\right) - 5y(t)\left(t^5+9t^4+\frac{234}{5}t^3+\frac{734}{5}t^2+\frac{1321}{5}t+\right.}{\left(-1+t\right)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= y(0) + 2y'(0) \\
F_1 &= 4y(0) + 9y'(0) \\
F_2 &= 21y(0) + 48y'(0) \\
F_3 &= 136y(0) + 309y'(0) \\
F_4 &= 1021y(0) + 2322y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y(t) = \left(1+\frac{1}{2}t^2+\frac{2}{3}t^3+\frac{7}{8}t^4+\frac{17}{15}t^5+\frac{1021}{720}t^6\right)y(0) + \left(t+t^2+\frac{3}{2}t^3+2t^4+\frac{103}{40}t^5+\frac{129}{40}t^6\right)y'(0)+O(t^6)$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)(-1+t)+(2t+2)\left(\frac{d}{dt}y(t)\right)+(t+1)\,y(t)=0$$

Let the solution be represented as power series of the form

$$y(t)=\sum_{n=0}^{\infty}a_n t^n$$

Then

$$\frac{d}{dt}y(t)=\sum_{n=1}^{\infty}n a_n t^{n-1}$$
$$\frac{d^2}{dt^2}y(t)=\sum_{n=2}^{\infty}n(n-1)\,a_n t^{n-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=2}^{\infty}n(n-1)\,a_n t^{n-2}\right)(-1+t)+(2t+2)\left(\sum_{n=1}^{\infty}n a_n t^{n-1}\right)+(t+1)\left(\sum_{n=0}^{\infty}a_n t^n\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty}n\,t^{n-1}a_n(n-1)\right)+\sum_{n=2}^{\infty}\left(-n(n-1)\,a_n t^{n-2}\right)+\left(\sum_{n=1}^{\infty}2n a_n t^n\right) + \left(\sum_{n=1}^{\infty}2n a_n t^{n-1}\right)+\left(\sum_{n=0}^{\infty}t^{1+n}a_n\right)+\left(\sum_{n=0}^{\infty}a_n t^n\right)=0 \tag{2}$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, t^n$$

$$\sum_{n=2}^{\infty} \left(-n(n-1)\, a_n t^{n-2}\right) = \sum_{n=0}^{\infty} \left(-(n+2)\, a_{n+2} (1+n)\, t^n\right)$$

$$\sum_{n=1}^{\infty} 2n a_n t^{n-1} = \sum_{n=0}^{\infty} 2(1+n)\, a_{1+n} t^n$$

$$\sum_{n=0}^{\infty} t^{1+n} a_n = \sum_{n=1}^{\infty} a_{n-1} t^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, t^n\right) + \sum_{n=0}^{\infty} \left(-(n+2)\, a_{n+2} (1+n)\, t^n\right) + \left(\sum_{n=1}^{\infty} 2n a_n t^n\right) + \left(\sum_{n=0}^{\infty} 2(1+n)\, a_{1+n} t^n\right) + \left(\sum_{n=1}^{\infty} a_{n-1} t^n\right) + \left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$-2a_2 + 2a_1 + a_0 = 0$$

$$a_2 = \frac{a_0}{2} + a_1$$

For $1 \leq n$, the recurrence equation is

$$(1+n)\, a_{1+n} n - (n+2)\, a_{n+2} (1+n) + 2n a_n + 2(1+n)\, a_{1+n} + a_{n-1} + a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{n^2 a_{1+n} + 2n a_n + 3n a_{1+n} + a_n + 2a_{1+n} + a_{n-1}}{(n+2)\,(1+n)} \\ &= \frac{(2n+1)\, a_n}{(n+2)\,(1+n)} + \frac{(n^2+3n+2)\, a_{1+n}}{(n+2)\,(1+n)} + \frac{a_{n-1}}{(n+2)\,(1+n)} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$6a_2 - 6a_3 + 3a_1 + a_0 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = \frac{2a_0}{3} + \frac{3a_1}{2}$$

For $n = 2$ the recurrence equation gives

$$12a_3 - 12a_4 + 5a_2 + a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{7a_0}{8} + 2a_1$$

For $n = 3$ the recurrence equation gives

$$20a_4 - 20a_5 + 7a_3 + a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{17a_0}{15} + \frac{103a_1}{40}$$

For $n = 4$ the recurrence equation gives

$$30a_5 - 30a_6 + 9a_4 + a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{1021a_0}{720} + \frac{129a_1}{40}$$

For $n = 5$ the recurrence equation gives

$$42a_6 - 42a_7 + 11a_5 + a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{243a_0}{140} + \frac{6631a_1}{1680}$$

And so on. Therefore the solution is

$$\begin{aligned} y(t) &= \sum_{n=0}^{\infty} a_n t^n \\ &= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y(t) = a_0 + a_1 t &+ \left(\frac{a_0}{2} + a_1\right) t^2 + \left(\frac{2a_0}{3} + \frac{3a_1}{2}\right) t^3 + \left(\frac{7a_0}{8} + 2a_1\right) t^4 + \left(\frac{17a_0}{15} + \frac{103a_1}{40}\right) t^5 \\ &+ \dots \end{aligned}$$

Collecting terms, the solution becomes

$$y(t) = \left(1 + \frac{1}{2}t^2 + \frac{2}{3}t^3 + \frac{7}{8}t^4 + \frac{17}{15}t^5\right) a_0 + \left(t + t^2 + \frac{3}{2}t^3 + 2t^4 + \frac{103}{40}t^5\right) a_1 + O(t^6) \quad (3)$$

At $t = 0$ the solution above becomes

$$y(t) = \left(1 + \frac{1}{2}t^2 + \frac{2}{3}t^3 + \frac{7}{8}t^4 + \frac{17}{15}t^5\right) c_1 + \left(t + t^2 + \frac{3}{2}t^3 + 2t^4 + \frac{103}{40}t^5\right) c_2 + O(t^6)$$

Replacing t in the above with the original independent variable $x$using $t = x+1$ results in

$$\begin{aligned} y = &\left(1 + \frac{(x+1)^2}{2} + \frac{2(x+1)^3}{3} + \frac{7(x+1)^4}{8} + \frac{17(x+1)^5}{15} + \frac{1021(x+1)^6}{720}\right) y(-1) \\ &+ \left(x + 1 + (x+1)^2 + \frac{3(x+1)^3}{2} + 2(x+1)^4 + \frac{103(x+1)^5}{40} + \frac{129(x+1)^6}{40}\right) y'(-1) \\ &+ O\left((x+1)^6\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(1+\frac{(x+1)^{2}}{2}+\frac{2(x+1)^{3}}{3}+\frac{7(x+1)^{4}}{8}+\frac{17(x+1)^{5}}{15}+\frac{1021(x+1)^{6}}{720}\right)y(-1) + \left(x+1+(x+1)^{2}+\frac{3(x+1)^{3}}{2}+2(x+1)^{4}+\frac{103(x+1)^{5}}{40}+\frac{129(x+1)^{6}}{40}\right)y'(-1) + O\left((x+1)^{6}\right) \tag{1}$$

Verification of solutions

$$y = \left(1+\frac{(x+1)^{2}}{2}+\frac{2(x+1)^{3}}{3}+\frac{7(x+1)^{4}}{8}+\frac{17(x+1)^{5}}{15}+\frac{1021(x+1)^{6}}{720}\right)y(-1) + \left(x+1+(x+1)^{2}+\frac{3(x+1)^{3}}{2}+2(x+1)^{4}+\frac{103(x+1)^{5}}{40}+\frac{129(x+1)^{6}}{40}\right)y'(-1) + O\left((x+1)^{6}\right)$$

Verified OK.

11.6.1 Maple step by step solution

Let's solve

$y''x+(2x+4)\,y'+(2+x)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(2+x)y}{x}-\frac{2(2+x)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2(2+x)y'}{x}+\frac{(2+x)y}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{2(2+x)}{x}, P_3(x)=\frac{2+x}{x}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $\left.(x\cdot P_2(x))\right|_{x=0}=4$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (2x+4)\, y' + (2+x)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- > k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k- > k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$

- Shift index using $k- > k+1$

  $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(3+r)\, x^{-1+r} + \left(a_1(1+r)\,(4+r) + 2a_0(1+r)\right) x^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)\,(k+4+r) + 2a_k\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(3+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{-3, 0\}$
- Each term must be 0

  $a_1(1+r)(4+r) + 2a_0(1+r) = 0$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k+4+r) + 2a_k k + 2a_k r + 2a_k + a_{k-1} = 0$
- Shift index using $k- >k+1$

  $a_{k+2}(k+2+r)(k+5+r) + 2a_{k+1}(k+1) + 2ra_{k+1} + 2a_{k+1} + a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{2ka_{k+1}+2ra_{k+1}+a_k+4a_{k+1}}{(k+2+r)(k+5+r)}$
- Recursion relation for $r = -3$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k-2a_{k+1}}{(k-1)(k+2)}$
- Series not valid for $r = -3$, division by 0 in the recursion relation at $k = 1$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k-2a_{k+1}}{(k-1)(k+2)}$
- Recursion relation for $r = 0$

  $a_{k+2} = -\frac{2ka_{k+1}+a_k+4a_{k+1}}{(k+2)(k+5)}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{2ka_{k+1}+a_k+4a_{k+1}}{(k+2)(k+5)}, 4a_1 + 2a_0 = 0\right]$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 17.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + 2y'x - 3yx = 0}$$

With the expansion point for the power series method at $x = 2$.

The ODE is

$$x^2y'' + 2y'x - 3yx = 0$$

Or

$$x(xy'' - 3y + 2y') = 0$$

For $x \neq 0$ the above simplifies to

$$xy'' - 3y + 2y' = 0$$

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = -2 + x$$

The ode is converted to be in terms of the new independent variable t. This results in

$$(2+t)^2 \left(\frac{d^2}{dt^2}y(t)\right) + 2(2+t)\left(\frac{d}{dt}y(t)\right) - 3(2+t)\,y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\,y'(x_0) + \frac{(x - x_0)^2}{2}y''(x_0) + \frac{(x - x_0)^3}{3!}y'''(x_0) + \cdots \\
&= y_0 + xy'_0 + \frac{x^2}{2}\,f|_{x_0,y_0,y'_0} + \frac{x^3}{3!}\,f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!}\,\frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (803) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (804) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{2\frac{d}{dt}y(t) - 3y(t)}{2+t} \\
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0 \\
&= \frac{(3t+12)\left(\frac{d}{dt}y(t)\right) - 9y(t)}{(2+t)^2} \\
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1 \\
&= \frac{(-18t-60)\left(\frac{d}{dt}y(t)\right) + 9y(t)(t+6)}{(2+t)^3} \\
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2 \\
&= \frac{(9t^2+144t+372)\left(\frac{d}{dt}y(t)\right) + (-72t-324)\,y(t)}{(2+t)^4} \\
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y(t)}F_3 \\
&= \frac{(-108t^2-1152t-2592)\left(\frac{d}{dt}y(t)\right) + 27y(t)(t^2+24t+84)}{(2+t)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $t = 0$ and $y(0) = y(0)$ and

$y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -y'(0) + \frac{3y(0)}{2} \\
F_1 &= -\frac{9y(0)}{4} + 3y'(0) \\
F_2 &= \frac{27y(0)}{4} - \frac{15y'(0)}{2} \\
F_3 &= -\frac{81y(0)}{4} + \frac{93y'(0)}{4} \\
F_4 &= \frac{567y(0)}{8} - 81y'(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
\begin{aligned}
y(t) = {} & \left(1 + \frac{3}{4}t^2 - \frac{3}{8}t^3 + \frac{9}{32}t^4 - \frac{27}{160}t^5 + \frac{63}{640}t^6\right) y(0) \\
& + \left(t - \frac{1}{2}t^2 + \frac{1}{2}t^3 - \frac{5}{16}t^4 + \frac{31}{160}t^5 - \frac{9}{80}t^6\right) y'(0) + O(t^6)
\end{aligned}
$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$
\left(t^2 + 4t + 4\right) \left(\frac{d^2}{dt^2}y(t)\right) + (2t + 4) \left(\frac{d}{dt}y(t)\right) + (-3t - 6)\, y(t) = 0
$$

Let the solution be represented as power series of the form

$$
y(t) = \sum_{n=0}^{\infty} a_n t^n
$$

Then

$$
\begin{aligned}
\frac{d}{dt}y(t) &= \sum_{n=1}^{\infty} n a_n t^{n-1} \\
\frac{d^2}{dt^2}y(t) &= \sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$
\left(t^2 + 4t + 4\right) \left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right) + (2t + 4) \left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right) + (-3t - 6) \left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \tag{1}
$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} t^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} 4n\, t^{n-1} a_n (n-1)\right) + \left(\sum_{n=2}^{\infty} 4n(n-1)\, a_n t^{n-2}\right) \\ + \left(\sum_{n=1}^{\infty} 2n a_n t^n\right) + \left(\sum_{n=1}^{\infty} 4n a_n t^{n-1}\right) + \sum_{n=0}^{\infty} \left(-3t^{1+n} a_n\right) + \sum_{n=0}^{\infty} \left(-6a_n t^n\right) = 0 \tag{2}$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} 4n\, t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} 4(1+n)\, a_{1+n} n\, t^n$$

$$\sum_{n=2}^{\infty} 4n(n-1)\, a_n t^{n-2} = \sum_{n=0}^{\infty} 4(n+2)\, a_{n+2} (1+n)\, t^n$$

$$\sum_{n=1}^{\infty} 4n a_n t^{n-1} = \sum_{n=0}^{\infty} 4(1+n)\, a_{1+n} t^n$$

$$\sum_{n=0}^{\infty} \left(-3t^{1+n} a_n\right) = \sum_{n=1}^{\infty} \left(-3a_{n-1} t^n\right)$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=2}^{\infty} t^n a_n n(n-1)\right) + \left(\sum_{n=1}^{\infty} 4(1+n)\, a_{1+n} n\, t^n\right) + \left(\sum_{n=0}^{\infty} 4(n+2)\, a_{n+2} (1+n)\, t^n\right) \\ + \left(\sum_{n=1}^{\infty} 2n a_n t^n\right) + \left(\sum_{n=0}^{\infty} 4(1+n)\, a_{1+n} t^n\right) + \sum_{n=1}^{\infty} \left(-3a_{n-1} t^n\right) + \sum_{n=0}^{\infty} \left(-6a_n t^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$8a_2 + 4a_1 - 6a_0 = 0$$

$$a_2 = \frac{3a_0}{4} - \frac{a_1}{2}$$

$n = 1$ gives

$$16a_2 + 24a_3 - 4a_1 - 3a_0 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{3a_0}{8} + \frac{a_1}{2}$$

For $2 \leq n$, the recurrence equation is

$$\begin{aligned} &na_n(n-1) + 4(1+n)\, a_{1+n} n + 4(n+2)\, a_{n+2}(1+n) \\ &+ 2na_n + 4(1+n)\, a_{1+n} - 3a_{n-1} - 6a_n = 0 \end{aligned} \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= -\frac{n^2 a_n + 4n^2 a_{1+n} + na_n + 8na_{1+n} - 6a_n + 4a_{1+n} - 3a_{n-1}}{4\,(n+2)\,(1+n)} \\ &= -\frac{(n^2+n-6)\, a_n}{4\,(n+2)\,(1+n)} - \frac{(4n^2+8n+4)\, a_{1+n}}{4\,(n+2)\,(1+n)} + \frac{3a_{n-1}}{4\,(n+2)\,(1+n)} \end{aligned} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$36a_3 + 48a_4 - 3a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{9a_0}{32} - \frac{5a_1}{16}$$

For $n = 3$ the recurrence equation gives

$$6a_3 + 64a_4 + 80a_5 - 3a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = -\frac{27a_0}{160} + \frac{31a_1}{160}$$

For $n = 4$ the recurrence equation gives

$$14a_4 + 100a_5 + 120a_6 - 3a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{63a_0}{640} - \frac{9a_1}{80}$$

For $n = 5$ the recurrence equation gives

$$24a_5 + 144a_6 + 168a_7 - 3a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -\frac{99a_0}{1792} + \frac{283a_1}{4480}$$

And so on. Therefore the solution is

$$\begin{aligned} y(t) &= \sum_{n=0}^{\infty} a_n t^n \\ &= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$\begin{aligned} y(t) = a_0 + a_1 t + \left(\frac{3a_0}{4} - \frac{a_1}{2}\right) t^2 + \left(-\frac{3a_0}{8} + \frac{a_1}{2}\right) t^3 \\ + \left(\frac{9a_0}{32} - \frac{5a_1}{16}\right) t^4 + \left(-\frac{27a_0}{160} + \frac{31a_1}{160}\right) t^5 + \dots \end{aligned}$$

Collecting terms, the solution becomes

$$y(t) = \left(1 + \frac{3}{4}t^2 - \frac{3}{8}t^3 + \frac{9}{32}t^4 - \frac{27}{160}t^5\right) a_0 + \left(t - \frac{1}{2}t^2 + \frac{1}{2}t^3 - \frac{5}{16}t^4 + \frac{31}{160}t^5\right) a_1 + O(t^6) \tag{3}$$

At $t = 0$ the solution above becomes

$$y(t) = \left(1 + \frac{3}{4}t^2 - \frac{3}{8}t^3 + \frac{9}{32}t^4 - \frac{27}{160}t^5\right) c_1 + \left(t - \frac{1}{2}t^2 + \frac{1}{2}t^3 - \frac{5}{16}t^4 + \frac{31}{160}t^5\right) c_2 + O(t^6)$$

Replacing t in the above with the original independent variable $x$using $t = -2 + x$ results in

$$y = \left(1 + \frac{3(-2+x)^2}{4} - \frac{3(-2+x)^3}{8} + \frac{9(-2+x)^4}{32} - \frac{27(-2+x)^5}{160} + \frac{63(-2+x)^6}{640}\right) y(2) + \left(-2 + x - \frac{(-2+x)^2}{2} + \frac{(-2+x)^3}{2} - \frac{5(-2+x)^4}{16} + \frac{31(-2+x)^5}{160} - \frac{9(-2+x)^6}{80}\right) y'(2) + O\left((-2+x)^6\right)$$

Summary

The solution(s) found are the following

$$y = \left(1 + \frac{3(-2+x)^2}{4} - \frac{3(-2+x)^3}{8} + \frac{9(-2+x)^4}{32} - \frac{27(-2+x)^5}{160} + \frac{63(-2+x)^6}{640}\right) y(2) + \left(-2 + x - \frac{(-2+x)^2}{2} + \frac{(-2+x)^3}{2} - \frac{5(-2+x)^4}{16} + \frac{31(-2+x)^5}{160} - \frac{9(-2+x)^6}{80}\right) y'(2) + O\left((-2+x)^6\right) \tag{1}$$

Verification of solutions

$$y = \left(1 + \frac{3(-2+x)^2}{4} - \frac{3(-2+x)^3}{8} + \frac{9(-2+x)^4}{32} - \frac{27(-2+x)^5}{160} + \frac{63(-2+x)^6}{640}\right) y(2) + \left(-2 + x - \frac{(-2+x)^2}{2} + \frac{(-2+x)^3}{2} - \frac{5(-2+x)^4}{16} + \frac{31(-2+x)^5}{160} - \frac{9(-2+x)^6}{80}\right) y'(2) + O\left((-2+x)^6\right)$$

Verified OK.

11.7.1 Maple step by step solution

Let's solve

$x^2y'' + 2y'x - 3yx = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{3y}{x} - \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{x} - \frac{3y}{x} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{2}{x}, P_3(x) = -\frac{3}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 2$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x - 3y + 2y' = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

  $y' = \sum_{k=0}^{\infty} a_k(k + r)\, x^{k+r-1}$

  ◦ Shift index using $k- >k + 1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k- >k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(1+r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+2+r) - 3a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(k+2+r) - 3a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = \frac{3a_k}{(k+1+r)(k+2+r)}$$

- Recursion relation for $r = -1$

$$a_{k+1} = \frac{3a_k}{k(k+1)}$$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+1} = \frac{3a_k}{k(k+1)}\right]$$

- Recursion relation for $r = 0$

$$a_{k+1} = \frac{3a_k}{(k+1)(k+2)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = \frac{3a_k}{(k+1)(k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} b_k x^k\right), a_{1+k} = \frac{3a_k}{k(1+k)}, b_{1+k} = \frac{3b_k}{(1+k)(k+2)}\right]$$

Problem number: 18.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{(2-x)\,y''+2y=0}$$

With initial conditions

$$[y(0)=a_0, y'(0)=a_1]$$

With the expansion point for the power series method at $x=0$.

11.8.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$\begin{aligned} p(x) &= 0 \\ q(x) &= \frac{2}{2-x} \\ F &= 0 \end{aligned}$$

Hence the ode is

$$y'' + \frac{2y}{2-x} = 0$$

The domain of $p(x) = 0$ is

$$\{-\infty < x < \infty\}$$

And the point $x_0 = 0$ is inside this domain. The domain of $q(x) = \frac{2}{2-x}$ is

$$\{x < 2 \lor 2 < x\}$$

And the point $x_0 = 0$ is also inside this domain. Hence solution exists and is unique.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned} y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\ &= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0, y_0, y'_0} + \frac{x^3}{3!} f'|_{x_0, y_0, y'_0} + \cdots \\ &= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y'_0} \end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{806}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{807}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx} f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_1 + \left(\frac{\partial F_1}{\partial y}\right) y' + \left(\frac{\partial F_1}{\partial y'}\right) F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) y''\\
&= \frac{\partial}{\partial x} F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right) y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right) F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n \big|_{x_0, y_0, y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$
\begin{aligned}
F_0 &= \frac{2y}{-2+x} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{(-4+2x)\, y' - 2y}{(-2+x)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{(-4x+8)\, y' + 4y(x-1)}{(-2+x)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(4x^2-4x-8)\, y' + (-16x+20)\, y}{(-2+x)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-24x^2+48x)\, y' + 8y(x^2+5x-8)}{(-2+x)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x=0$ and $y(0)=a_0$ and $y'(0)=a_1$ gives

$$
\begin{aligned}
F_0 &= -a_0 \\
F_1 &= -\frac{a_0}{2} - a_1 \\
F_2 &= \frac{a_0}{2} - a_1 \\
F_3 &= \frac{5a_0}{4} - \frac{a_1}{2} \\
F_4 &= 2a_0
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = xa_1 + a_0 - \frac{a_0x^2}{2} - \frac{x^3a_0}{12} - \frac{x^3a_1}{6} + \frac{x^4a_0}{48} - \frac{x^4a_1}{24} + \frac{x^5a_0}{96} - \frac{x^5a_1}{240} + \frac{a_0x^6}{360} + O(x^6)$$

$$y = xa_1 + a_0 - \frac{a_0x^2}{2} - \frac{x^3a_0}{12} - \frac{x^3a_1}{6} + \frac{x^4a_0}{48} - \frac{x^4a_1}{24} + \frac{x^5a_0}{96} - \frac{x^5a_1}{240} + \frac{a_0x^6}{360} + O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(2-x)\,y'' + 2y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(2-x)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) + 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=2}^{\infty} \left(-n\,x^{n-1} a_n(n-1)\right) + \left(\sum_{n=2}^{\infty} 2n(n-1)\,a_n x^{n-2}\right) + \left(\sum_{n=0}^{\infty} 2a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} \left(-n\,x^{n-1} a_n(n-1)\right) = \sum_{n=1}^{\infty} \left(-(n+1)\,a_{n+1} n\,x^n\right)$$
$$\sum_{n=2}^{\infty} 2n(n-1)\,a_n x^{n-2} = \sum_{n=0}^{\infty} 2(n+2)\,a_{n+2}(n+1)\,x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\sum_{n=1}^{\infty} \left(-(n+1) a_{n+1} n x^{n}\right) + \left(\sum_{n=0}^{\infty} 2(n+2) a_{n+2}(n+1) x^{n}\right) + \left(\sum_{n=0}^{\infty} 2a_{n} x^{n}\right) = 0 \quad (3)$$

$n = 0$ gives

$$4a_2 + 2a_0 = 0$$

$$a_2 = -\frac{a_0}{2}$$

For $1 \leq n$, the recurrence equation is

$$-(n+1) a_{n+1} n + 2(n+2) a_{n+2}(n+1) + 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$\begin{aligned} a_{n+2} &= \frac{n^2 a_{n+1} + n a_{n+1} - 2a_n}{2(n+2)(n+1)} \\ &= -\frac{a_n}{(n+2)(n+1)} + \frac{(n^2+n) a_{n+1}}{2(n+2)(n+1)} \end{aligned} \tag{5}$$

For $n = 1$ the recurrence equation gives

$$-2a_2 + 12a_3 + 2a_1 = 0$$

Which after substituting the earlier terms found becomes

$$a_3 = -\frac{a_0}{12} - \frac{a_1}{6}$$

For $n = 2$ the recurrence equation gives

$$-6a_3 + 24a_4 + 2a_2 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{a_0}{48} - \frac{a_1}{24}$$

For $n = 3$ the recurrence equation gives

$$-12a_4 + 40a_5 + 2a_3 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_0}{96} - \frac{a_1}{240}$$

For $n = 4$ the recurrence equation gives

$$-20a_5 + 60a_6 + 2a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{360}$$

For $n = 5$ the recurrence equation gives

$$-30a_6 + 84a_7 + 2a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = \frac{a_0}{1344} + \frac{a_1}{10080}$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3x^3 + a_2x^2 + a_1x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1x - \frac{a_0x^2}{2} + \left(-\frac{a_0}{12} - \frac{a_1}{6}\right)x^3 + \left(\frac{a_0}{48} - \frac{a_1}{24}\right)x^4 + \left(\frac{a_0}{96} - \frac{a_1}{240}\right)x^5 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{12}x^3 + \frac{1}{48}x^4 + \frac{1}{96}x^5\right)a_0 + \left(x - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{240}x^5\right)a_1 + O(x^6) \quad (3)$$

At $x = 0$ the solution above becomes

$$y = \left(1 - \frac{1}{2}x^2 - \frac{1}{12}x^3 + \frac{1}{48}x^4 + \frac{1}{96}x^5\right)c_1 + \left(x - \frac{1}{6}x^3 - \frac{1}{24}x^4 - \frac{1}{240}x^5\right)c_2 + O(x^6)$$

$$y = a_0 - \frac{a_0 x^2}{2} - \frac{x^3 a_0}{12} + \frac{x^4 a_0}{48} + \frac{x^5 a_0}{96} + x a_1 - \frac{x^3 a_1}{6} - \frac{x^4 a_1}{24} - \frac{x^5 a_1}{240} + O(x^6)$$

Summary

The solution(s) found are the following

$$y = x a_1 + a_0 - \frac{a_0 x^2}{2} - \frac{x^3 a_0}{12} - \frac{x^3 a_1}{6} + \frac{x^4 a_0}{48} - \frac{x^4 a_1}{24} + \frac{x^5 a_0}{96} - \frac{x^5 a_1}{240} + \frac{a_0 x^6}{360} + O(x^6) \tag{1}$$

$$y = a_0 - \frac{a_0 x^2}{2} - \frac{x^3 a_0}{12} + \frac{x^4 a_0}{48} + \frac{x^5 a_0}{96} + x a_1 - \frac{x^3 a_1}{6} - \frac{x^4 a_1}{24} - \frac{x^5 a_1}{240} + O(x^6) \tag{2}$$

Verification of solutions

$$y = x a_1 + a_0 - \frac{a_0 x^2}{2} - \frac{x^3 a_0}{12} - \frac{x^3 a_1}{6} + \frac{x^4 a_0}{48} - \frac{x^4 a_1}{24} + \frac{x^5 a_0}{96} - \frac{x^5 a_1}{240} + \frac{a_0 x^6}{360} + O(x^6)$$

Verified OK.

$$y = a_0 - \frac{a_0 x^2}{2} - \frac{x^3 a_0}{12} + \frac{x^4 a_0}{48} + \frac{x^5 a_0}{96} + x a_1 - \frac{x^3 a_1}{6} - \frac{x^4 a_1}{24} - \frac{x^5 a_1}{240} + O(x^6)$$

Verified OK.

Problem number: 19.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x+1)\,y''+2(x-1)^2\,y'+3y=0}$$

With initial conditions

$$[y(1)=a_0, y'(1)=a_1]$$

With the expansion point for the power series method at $x=1$.

11.9.1 Existence and uniqueness analysis

This is a linear ODE. In canonical form it is written as

$$y''+p(x)y'+q(x)y=F$$

Where here

$$\begin{aligned}p(x)&=\frac{2(x-1)^2}{x+1}\\q(x)&=\frac{3}{x+1}\\F&=0\end{aligned}$$

Hence the ode is

$$y'' + \frac{2(x-1)^2 y'}{x+1} + \frac{3y}{x+1} = 0$$

The domain of $p(x) = \frac{2(x-1)^2}{x+1}$ is

$$\{x < -1 \lor -1 < x\}$$

And the point $x_0 = 1$ is inside this domain. The domain of $q(x) = \frac{3}{x+1}$ is

$$\{x < -1 \lor -1 < x\}$$

And the point $x_0 = 1$ is also inside this domain. Hence solution exists and is unique.

The ode does not have its expansion point at $x = 0$, therefore to simplify the computation of power series expansion, change of variable is made on the independent variable to shift the initial conditions and the expasion point back to zero. The new ode is then solved more easily since the expansion point is now at zero. The solution converted back to the original independent variable. Let

$$t = x - 1$$

The ode is converted to be in terms of the new independent variable t. This results in

$$\left(\frac{d^2}{dt^2}y(t)\right)(2+t) + 2\left(\frac{d}{dt}y(t)\right)t^2 + 3y(t) = 0$$

With its expansion point and initial conditions now at $t = 0$. With initial conditions now becoming

$$y(0) = a_0$$
$$y'(0) = a_1$$

The transformed ODE is now solved. Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the

case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x-x_0)^2}{2} y''(x_0) + \frac{(x-x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + x y'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (809) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (810) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \tag{7}
$$

To find $y(x)$ series solution around $x=0$. Hence

$$F_0 = -\frac{2\left(\frac{d}{dt}y(t)\right)t^2 + 3y(t)}{2+t}$$

$$\begin{aligned}
F_1 &= \frac{dF_0}{dt} \\
&= \frac{\partial F_0}{\partial t} + \frac{\partial F_0}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_0}{\partial \frac{d}{dt}y(t)}F_0 \\
&= \frac{(4t^4 - 2t^2 - 11t - 6)\left(\frac{d}{dt}y(t)\right) + (6t^2+3)\,y(t)}{(2+t)^2}
\end{aligned}$$

$$\begin{aligned}
F_2 &= \frac{dF_1}{dt} \\
&= \frac{\partial F_1}{\partial t} + \frac{\partial F_1}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_1}{\partial \frac{d}{dt}y(t)}F_1 \\
&= \frac{(-8t^6 + 12t^4 + 60t^3 + 24t^2 + 6t - 4)\left(\frac{d}{dt}y(t)\right) - 12\left(t^4 - \frac{1}{2}t^2 - \frac{19}{4}t - 1\right)y(t)}{(2+t)^3}
\end{aligned}$$

$$\begin{aligned}
F_3 &= \frac{dF_2}{dt} \\
&= \frac{\partial F_2}{\partial t} + \frac{\partial F_2}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_2}{\partial \frac{d}{dt}y(t)}F_2 \\
&= \frac{(16t^8 - 48t^6 - 228t^5 - 60t^4 + 90t^3 + 413t^2 + 210t + 48)\left(\frac{d}{dt}y(t)\right) + 24\left(t^6 - 2t^4 - \frac{23}{2}t^3 - \frac{13}{4}t^2 - \frac{9}{2}t +}{(2+t)^4}
\end{aligned}$$

$$\begin{aligned}
F_4 &= \frac{dF_3}{dt} \\
&= \frac{\partial F_3}{\partial t} + \frac{\partial F_3}{\partial y}\frac{d}{dt}y(t) + \frac{\partial F_3}{\partial \frac{d}{dt}y(t)}F_3 \\
&= \frac{(-32t^{10} + 160t^8 + 736t^7 + 72t^6 - 1032t^5 - 3478t^4 - 1620t^3 - 646t^2 + 896t + 408)\left(\frac{d}{dt}y(t)\right) - 48\left(t^8}{(2+t)^5}
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $t=0$ and $y(0)=a_0$ and $y'(0)=a_1$ gives

$$\begin{aligned}
F_0 &= -\frac{3a_0}{2} \\
F_1 &= \frac{3a_0}{4} - \frac{3a_1}{2} \\
F_2 &= \frac{3a_0}{2} - \frac{a_1}{2} \\
F_3 &= \frac{45a_0}{8} + 3a_1 \\
F_4 &= -\frac{45a_0}{2} + \frac{51a_1}{4}
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y(t) = ta_1 + a_0 - \frac{3a_0t^2}{4} + \frac{t^3a_0}{8} - \frac{t^3a_1}{4} + \frac{t^4a_0}{16} - \frac{t^4a_1}{48} + \frac{3t^5a_0}{64} + \frac{t^5a_1}{40} - \frac{t^6a_0}{32} + \frac{17t^6a_1}{960} + O(t^6)$$

$$y(t) = ta_1 + a_0 - \frac{3a_0t^2}{4} + \frac{t^3a_0}{8} - \frac{t^3a_1}{4} + \frac{t^4a_0}{16} - \frac{t^4a_1}{48} + \frac{3t^5a_0}{64} + \frac{t^5a_1}{40} - \frac{t^6a_0}{32} + \frac{17t^6a_1}{960} + O(t^6)$$

Since the expansion point $t = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(\frac{d^2}{dt^2}y(t)\right)(2+t) + 2\left(\frac{d}{dt}y(t)\right)t^2 + 3y(t) = 0$$

Let the solution be represented as power series of the form

$$y(t) = \sum_{n=0}^{\infty} a_n t^n$$

Then

$$\frac{d}{dt}y(t) = \sum_{n=1}^{\infty} n a_n t^{n-1}$$
$$\frac{d^2}{dt^2}y(t) = \sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}$$

Substituting the above back into the ode gives

$$\left(\sum_{n=2}^{\infty} n(n-1)\, a_n t^{n-2}\right)(2+t) + 2\left(\sum_{n=1}^{\infty} n a_n t^{n-1}\right)t^2 + 3\left(\sum_{n=0}^{\infty} a_n t^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1)\right) + \left(\sum_{n=2}^{\infty} 2n(n-1)\, a_n t^{n-2}\right) + \left(\sum_{n=1}^{\infty} 2n\, t^{1+n} a_n\right) + \left(\sum_{n=0}^{\infty} 3a_n t^n\right) = 0 \tag{2}$$

The next step is to make all powers of t be n in each summation term. Going over each summation term above with power of t in it which is not already t^n and adjusting the

power and the corresponding index gives

$$\sum_{n=2}^{\infty} n\, t^{n-1} a_n (n-1) = \sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, t^n$$

$$\sum_{n=2}^{\infty} 2n(n-1)\, a_n t^{n-2} = \sum_{n=0}^{\infty} 2(n+2)\, a_{n+2}(1+n)\, t^n$$

$$\sum_{n=1}^{\infty} 2n\, t^{1+n} a_n = \sum_{n=2}^{\infty} 2(n-1)\, a_{n-1} t^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of t are the same and equal to n.

$$\left(\sum_{n=1}^{\infty} (1+n)\, a_{1+n} n\, t^n\right) + \left(\sum_{n=0}^{\infty} 2(n+2)\, a_{n+2}(1+n)\, t^n\right) + \left(\sum_{n=2}^{\infty} 2(n-1)\, a_{n-1} t^n\right) + \left(\sum_{n=0}^{\infty} 3a_n t^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$4a_2 + 3a_0 = 0$$

$$a_2 = -\frac{3a_0}{4}$$

$n = 1$ gives

$$2a_2 + 12a_3 + 3a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{a_0}{8} - \frac{a_1}{4}$$

For $2 \leq n$, the recurrence equation is

$$(1+n)\, a_{1+n} n + 2(n+2)\, a_{n+2}(1+n) + 2(n-1)\, a_{n-1} + 3a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$
\begin{aligned}
a_{n+2} &= -\frac{n^2 a_{1+n} + n a_{1+n} + 2n a_{n-1} + 3a_n - 2a_{n-1}}{2(n+2)(1+n)} \\
&= -\frac{3a_n}{2(n+2)(1+n)} - \frac{(n^2+n)\, a_{1+n}}{2(n+2)(1+n)} - \frac{(2n-2)\, a_{n-1}}{2(n+2)(1+n)}
\end{aligned} \tag{5}
$$

For $n = 2$ the recurrence equation gives

$$
6a_3 + 24a_4 + 2a_1 + 3a_2 = 0
$$

Which after substituting the earlier terms found becomes

$$
a_4 = \frac{a_0}{16} - \frac{a_1}{48}
$$

For $n = 3$ the recurrence equation gives

$$
12a_4 + 40a_5 + 4a_2 + 3a_3 = 0
$$

Which after substituting the earlier terms found becomes

$$
a_5 = \frac{3a_0}{64} + \frac{a_1}{40}
$$

For $n = 4$ the recurrence equation gives

$$
20a_5 + 60a_6 + 6a_3 + 3a_4 = 0
$$

Which after substituting the earlier terms found becomes

$$
a_6 = -\frac{a_0}{32} + \frac{17a_1}{960}
$$

For $n = 5$ the recurrence equation gives

$$
30a_6 + 84a_7 + 8a_4 + 3a_5 = 0
$$

Which after substituting the earlier terms found becomes

$$
a_7 = \frac{19a_0}{5376} - \frac{211a_1}{40320}
$$

And so on. Therefore the solution is

$$
\begin{aligned}
y(t) &= \sum_{n=0}^{\infty} a_n t^n \\
&= a_3 t^3 + a_2 t^2 + a_1 t + a_0 + \dots
\end{aligned}
$$

Substituting the values for a_n found above, the solution becomes

$$
y(t) = a_0 + a_1 t - \frac{3a_0 t^2}{4} + \left(\frac{a_0}{8} - \frac{a_1}{4}\right) t^3 + \left(\frac{a_0}{16} - \frac{a_1}{48}\right) t^4 + \left(\frac{3a_0}{64} + \frac{a_1}{40}\right) t^5 + \dots
$$

Collecting terms, the solution becomes

$$
y(t) = \left(1 - \frac{3}{4}t^2 + \frac{1}{8}t^3 + \frac{1}{16}t^4 + \frac{3}{64}t^5\right) a_0 + \left(t - \frac{1}{4}t^3 - \frac{1}{48}t^4 + \frac{1}{40}t^5\right) a_1 + O(t^6) \quad (3)
$$

At $t = 0$ the solution above becomes

$$
y(t) = \left(1 - \frac{3}{4}t^2 + \frac{1}{8}t^3 + \frac{1}{16}t^4 + \frac{3}{64}t^5\right) c_1 + \left(t - \frac{1}{4}t^3 - \frac{1}{48}t^4 + \frac{1}{40}t^5\right) c_2 + O(t^6)
$$

$$
y(t) = a_0 - \frac{3a_0 t^2}{4} + \frac{t^3 a_0}{8} + \frac{t^4 a_0}{16} + \frac{3t^5 a_0}{64} + t a_1 - \frac{t^3 a_1}{4} - \frac{t^4 a_1}{48} + \frac{t^5 a_1}{40} + O(t^6)
$$

Replacing t in the above with the original independent variable $x$susing $t = x-1$ results in

$$
\begin{aligned}
y = (x-1)\, a_1 + a_0 - \frac{3a_0(x-1)^2}{4} + \frac{(x-1)^3 a_0}{8} - \frac{(x-1)^3 a_1}{4} + \frac{(x-1)^4 a_0}{16} - \frac{(x-1)^4 a_1}{48} \\
+ \frac{3(x-1)^5 a_0}{64} + \frac{(x-1)^5 a_1}{40} - \frac{(x-1)^6 a_0}{32} + \frac{17(x-1)^6 a_1}{960} + O\left((x-1)^6\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
\begin{aligned}
y = (x-1)\, a_1 + a_0 - \frac{3a_0(x-1)^2}{4} + \frac{(x-1)^3 a_0}{8} - \frac{(x-1)^3 a_1}{4} \\
+ \frac{(x-1)^4 a_0}{16} - \frac{(x-1)^4 a_1}{48} + \frac{3(x-1)^5 a_0}{64} + \frac{(x-1)^5 a_1}{40} \\
- \frac{(x-1)^6 a_0}{32} + \frac{17(x-1)^6 a_1}{960} + O\left((x-1)^6\right)
\end{aligned} \quad (1)
$$

Verification of solutions

$$y = (x-1)\,a_1 + a_0 - \frac{3a_0(x-1)^2}{4} + \frac{(x-1)^3\,a_0}{8} - \frac{(x-1)^3\,a_1}{4} + \frac{(x-1)^4\,a_0}{16} - \frac{(x-1)^4\,a_1}{48} + \frac{3(x-1)^5\,a_0}{64} + \frac{(x-1)^5\,a_1}{40} - \frac{(x-1)^6\,a_0}{32} + \frac{17(x-1)^6\,a_1}{960} + O\big((x-1)^6\big)$$

Verified OK.

11.9.2 Maple step by step solution

Let's solve

$\left[(x+1)\,y''+2(x-1)^2\,y'+3y=0, y(1)=a_0, y'\Big|_{\{x=1\}}=a_1\right]$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{3y}{x+1}-\frac{2(x-1)^2 y'}{x+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2(x-1)^2 y'}{x+1}+\frac{3y}{x+1}=0$

□ Check to see if $x_0=-1$ is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{2(x-1)^2}{x+1}, P_3(x)=\frac{3}{x+1}\right]$

  - $(x+1)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((x+1)\cdot P_2(x)\right)\Big|_{x=-1}=8$

  - $(x+1)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((x+1)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

  - $x=-1$is a regular singular point

  Check to see if $x_0=-1$ is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $(x+1)\,y''+2(x-1)^2\,y'+3y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $u\left(\frac{d^{2}}{d u^{2}} y(u)\right)+\left(2 u^{2}-8 u+8\right)\left(\frac{d}{d u} y(u)\right)+3 y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_{k} u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^{m} \cdot\left(\frac{d}{d u} y(u)\right)$ to series expansion for $m=0..2$

    $u^{m} \cdot\left(\frac{d}{d u} y(u)\right)=\sum_{k=0}^{\infty} a_{k}(k+r) u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $u^{m} \cdot\left(\frac{d}{d u} y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r) u^{k+r}$

  - Convert $u \cdot\left(\frac{d^{2}}{d u^{2}} y(u)\right)$ to series expansion

    $u \cdot\left(\frac{d^{2}}{d u^{2}} y(u)\right)=\sum_{k=0}^{\infty} a_{k}(k+r)(k+r-1) u^{k+r-1}$

  - Shift index using $k->k+1$

    $u \cdot\left(\frac{d^{2}}{d u^{2}} y(u)\right)=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) u^{k+r}$

  Rewrite ODE with series expansions

  $a_{0} r(7+r) u^{-1+r}+\left(a_{1}(1+r)(8+r)-a_{0}(-3+8 r)\right) u^{r}+\left(\sum_{k=1}^{\infty}\left(a_{k+1}(k+1+r)(k+8+r)-a_{\right.\right.$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $r(7+r)=0$

- Values of r that satisfy the indicial equation

  $r \in\{-7,0\}$

- Each term must be 0

  $a_{1}(1+r)(8+r)-a_{0}(-3+8 r)=0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k+8+r)+\left(-8 a_{k}+2 a_{k-1}\right) k+\left(-8 a_{k}+2 a_{k-1}\right) r+3 a_{k}-2 a_{k-1}=0$

- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)(k+9+r)+\left(-8 a_{k+1}+2 a_{k}\right)(k+1)+\left(-8 a_{k+1}+2 a_{k}\right) r+3 a_{k+1}-2 a_{k}=0$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2a_k k - 8k a_{k+1} + 2a_k r - 8r a_{k+1} - 5a_{k+1}}{(k+2+r)(k+9+r)}$$

- Recursion relation for $r = -7$

$$a_{k+2} = -\frac{2a_k k - 8k a_{k+1} - 14a_k + 51a_{k+1}}{(k-5)(k+2)}$$

- Series not valid for $r = -7$, division by 0 in the recursion relation at $k = 5$

$$a_{k+2} = -\frac{2a_k k - 8k a_{k+1} - 14a_k + 51a_{k+1}}{(k-5)(k+2)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{2a_k k - 8k a_{k+1} - 5a_{k+1}}{(k+2)(k+9)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{2a_k k - 8k a_{k+1} - 5a_{k+1}}{(k+2)(k+9)}, 8a_1 + 3a_0 = 0\right]$$

- Revert the change of variables $u = x + 1$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+1)^k , a_{k+2} = -\frac{2a_k k - 8k a_{k+1} - 5a_{k+1}}{(k+2)(k+9)}, 8a_1 + 3a_0 = 0\right]$$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 21.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(1-x)\,y''+x(x+4)\,y'+(2-x)\,y=0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(-x^3+x^2\right)y''+\left(x^2+4x\right)y'+(2-x)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x) = -\frac{x+4}{x\,(x-1)}$$
$$q(x) = \frac{-2+x}{x^2\,(x-1)}$$

Table 449: Table $p(x), q(x)$ singularites.

$p(x) = -\frac{x+4}{x(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

$q(x) = \frac{-2+x}{x^2(x-1)}$	
singularity	type
$x = 0$	"regular"
$x = 1$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, 1, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$-y''x^2(x-1) + (x^2+4x)\, y' + (2-x)\, y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$-\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) x^2(x-1) + (x^2+4x)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + (2-x)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=0}^{\infty}\left(-x^{1+n+r} a_n(n+r)(n+r-1)\right)+\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) \\ +\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n(n+r)\right)+\left(\sum_{n=0}^{\infty} 4 x^{n+r} a_n(n+r)\right) \\ +\left(\sum_{n=0}^{\infty} 2 a_n x^{n+r}\right)+\sum_{n=0}^{\infty}\left(-x^{1+n+r} a_n\right)=0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-x^{1+n+r} a_n(n+r)(n+r-1)\right)=\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1)(n+r-2) x^{n+r}\right)$$

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n(n+r)=\sum_{n=1}^{\infty} a_{n-1}(n+r-1) x^{n+r}$$

$$\sum_{n=0}^{\infty}\left(-x^{1+n+r} a_n\right)=\sum_{n=1}^{\infty}\left(-a_{n-1} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\sum_{n=1}^{\infty}\left(-a_{n-1}(n+r-1)(n+r-2) x^{n+r}\right)+\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) \\ +\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1) x^{n+r}\right)+\left(\sum_{n=0}^{\infty} 4 x^{n+r} a_n(n+r)\right) \\ +\left(\sum_{n=0}^{\infty} 2 a_n x^{n+r}\right)+\sum_{n=1}^{\infty}\left(-a_{n-1} x^{n+r}\right)=0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1)+4 x^{n+r} a_n(n+r)+2 a_n x^{n+r}=0$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) + 4x^r a_0 r + 2a_0 x^r = 0$$

Or

$$(x^r r(-1+r) + 4x^r r + 2x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(r^2 + 3r + 2)\, x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 + 3r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -1$$
$$r_2 = -2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(r^2 + 3r + 2)\, x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \frac{\sum_{n=0}^{\infty} a_n x^n}{x}$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n-1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2} \right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$-a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) \\ + a_{n-1}(n+r-1) + 4a_n(n+r) + 2a_n - a_{n-1} = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = \frac{a_{n-1}(n^2 + 2nr + r^2 - 4n - 4r + 4)}{n^2 + 2nr + r^2 + 3n + 3r + 2} \tag{4}$$

Which for the root $r = -1$ becomes

$$a_n = \frac{a_{n-1}(n-3)^2}{n(1+n)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{(-1+r)^2}{r^2 + 5r + 6}$$

Which for the root $r = -1$ becomes

$$a_1 = 2$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(-1+r)^2}{r^2+5r+6}$	2

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^2(-1+r)^2}{(r+3)^2(r+2)(r+4)}$$

Which for the root $r = -1$ becomes

$$a_2 = \frac{1}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(-1+r)^2}{r^2+5r+6}$	2
a_2	$\frac{r^2(-1+r)^2}{(r+3)^2(r+2)(r+4)}$	$\frac{1}{3}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{(-1+r)^2 r^2 (r+1)^2}{(r+3)^2 (r+2) (r+4)^2 (r+5)}$$

Which for the root $r = -1$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(-1+r)^2}{r^2+5r+6}$	2
a_2	$\frac{r^2(-1+r)^2}{(r+3)^2(r+2)(r+4)}$	$\frac{1}{3}$
a_3	$\frac{(-1+r)^2 r^2(r+1)^2}{(r+3)^2(r+2)(r+4)^2(r+5)}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{(r+2)(-1+r)^2 r^2 (r+1)^2}{(r+6)(r+5)^2 (r+4)^2 (r+3)^2}$$

Which for the root $r = -1$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(-1+r)^2}{r^2+5r+6}$	2
a_2	$\frac{r^2(-1+r)^2}{(r+3)^2(r+2)(r+4)}$	$\frac{1}{3}$
a_3	$\frac{(-1+r)^2 r^2(r+1)^2}{(r+3)^2(r+2)(r+4)^2(r+5)}$	0
a_4	$\frac{(r+2)(-1+r)^2 r^2(r+1)^2}{(r+6)(r+5)^2(r+4)^2(r+3)^2}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{(r+2)(-1+r)^2 r^2(r+1)^2}{(r+7)(r+6)^2(r+4)^2(r+5)^2}$$

Which for the root $r = -1$ becomes

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{(-1+r)^2}{r^2+5r+6}$	2
a_2	$\frac{r^2(-1+r)^2}{(r+3)^2(r+2)(r+4)}$	$\frac{1}{3}$
a_3	$\frac{(-1+r)^2 r^2(r+1)^2}{(r+3)^2(r+2)(r+4)^2(r+5)}$	0
a_4	$\frac{(r+2)(-1+r)^2 r^2(r+1)^2}{(r+6)(r+5)^2(r+4)^2(r+3)^2}$	0
a_5	$\frac{(r+2)(-1+r)^2 r^2(r+1)^2}{(r+7)(r+6)^2(r+4)^2(r+5)^2}$	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \frac{1}{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= \frac{1 + 2x + \frac{x^2}{3} + O(x^6)}{x} \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_1 \\ &= \frac{(-1+r)^2}{r^2+5r+6} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} \frac{(-1+r)^2}{r^2+5r+6} &= \lim_{r\to -2} \frac{(-1+r)^2}{r^2+5r+6} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\begin{aligned} \frac{d}{dx} y_2(x) &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2}(n+r_2)}{x}\right) \\ &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) \\ \frac{d^2}{dx^2} y_2(x) &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \\ &\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right) \\ &= C y_1''(x) \ln(x) + \frac{2C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)(-1+n+r_2)\right) \end{aligned}$$

Substituting these back into the given ode $-y'' x^2(x-1) + (x^2+4x) y' + (2-x) y = 0$

gives

$$
\begin{aligned}
&-\left(Cy_1''(x)\ln(x)+\frac{2Cy_1'(x)}{x}-\frac{Cy_1(x)}{x^2}\right.\\
&\left.+\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2(x-1)\\
&+\left(x^2+4x\right)\left(Cy_1'(x)\ln(x)+\frac{Cy_1(x)}{x}+\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right)\\
&+(2-x)\left(Cy_1(x)\ln(x)+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)\right)=0
\end{aligned}
$$

Which can be written as

$$
\begin{aligned}
&\left(\left(-y_1''(x)\,x^2(x-1)+\left(x^2+4x\right)y_1'(x)+(2-x)\,y_1(x)\right)\ln(x)\right.\\
&\left.-\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x^2(x-1)+\frac{\left(x^2+4x\right)y_1(x)}{x}\right)C\\
&-\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2(x-1)\\
&+\left(x^2+4x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+(2-x)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0
\end{aligned} \tag{7}
$$

But since $y_1(x)$ is a solution to the ode, then

$$
-y_1''(x)\,x^2(x-1)+\left(x^2+4x\right)y_1'(x)+(2-x)\,y_1(x)=0
$$

Eq (7) simplifes to

$$
\begin{aligned}
&\left(-\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)x^2(x-1)+\frac{\left(x^2+4x\right)y_1(x)}{x}\right)C\\
&-\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)x^2(x-1)\\
&+\left(x^2+4x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+(2-x)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0
\end{aligned} \tag{8}
$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$\left(-2x(x-1)\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n (n+r_1)\right) + (2x+3)\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right)\right) C \\ + \left(-x^3+x^2\right)\left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2)\left(-1+n+r_2\right)\right) \\ + \left(x^2+4x\right)\left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2)\right) - (-2+x)\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{9}$$

Since $r_1 = -1$ and $r_2 = -2$ then the above becomes

$$\left(-2x(x-1)\left(\sum_{n=0}^{\infty} x^{n-2} a_n (n-1)\right) + (2x+3)\left(\sum_{n=0}^{\infty} a_n x^{n-1}\right)\right) C \\ + \left(-x^3+x^2\right)\left(\sum_{n=0}^{\infty} x^{-4+n} b_n (n-2)(n-3)\right) \\ + \left(x^2+4x\right)\left(\sum_{n=0}^{\infty} x^{n-3} b_n (n-2)\right) - (-2+x)\left(\sum_{n=0}^{\infty} b_n x^{n-2}\right) = 0 \tag{10}$$

Which simplifies to

$$\sum_{n=0}^{\infty}\left(-2C\, x^n a_n (n-1)\right) + \left(\sum_{n=0}^{\infty} 2C\, x^{n-1} a_n (n-1)\right) + \left(\sum_{n=0}^{\infty} 2C a_n x^n\right) \\ + \left(\sum_{n=0}^{\infty} 3C\, x^{n-1} a_n\right) + \sum_{n=0}^{\infty}\left(-b_n x^{n-1}(n-2)(n-3)\right) \\ + \left(\sum_{n=0}^{\infty} x^{n-2} b_n \left(n^2-5n+6\right)\right) + \left(\sum_{n=0}^{\infty} x^{n-1} b_n (n-2)\right) \\ + \left(\sum_{n=0}^{\infty} 4x^{n-2} b_n (n-2)\right) + \left(\sum_{n=0}^{\infty} 2b_n x^{n-2}\right) + \sum_{n=0}^{\infty}\left(-x^{n-1} b_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n-2$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-2} and

adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}\left(-2C\,x^{n}a_{n}(n-1)\right)=\sum_{n=2}^{\infty}\left(-2Ca_{n-2}(n-3)\,x^{n-2}\right)$$

$$\sum_{n=0}^{\infty}2C\,x^{n-1}a_{n}(n-1)=\sum_{n=1}^{\infty}2Ca_{n-1}(n-2)\,x^{n-2}$$

$$\sum_{n=0}^{\infty}2Ca_{n}x^{n}=\sum_{n=2}^{\infty}2Ca_{n-2}x^{n-2}$$

$$\sum_{n=0}^{\infty}3C\,x^{n-1}a_{n}=\sum_{n=1}^{\infty}3Ca_{n-1}x^{n-2}$$

$$\sum_{n=0}^{\infty}\left(-b_{n}x^{n-1}(n-2)\,(n-3)\right)=\sum_{n=1}^{\infty}\left(-b_{n-1}(-4+n)\,(n-3)\,x^{n-2}\right)$$

$$\sum_{n=0}^{\infty}x^{n-1}b_{n}(n-2)=\sum_{n=1}^{\infty}b_{n-1}(n-3)\,x^{n-2}$$

$$\sum_{n=0}^{\infty}\left(-x^{n-1}b_{n}\right)=\sum_{n=1}^{\infty}\left(-b_{n-1}x^{n-2}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-2$.

$$\begin{aligned}
&\sum_{n=2}^{\infty}\left(-2Ca_{n-2}(n-3)\,x^{n-2}\right)+\left(\sum_{n=1}^{\infty}2Ca_{n-1}(n-2)\,x^{n-2}\right)\\
&+\left(\sum_{n=2}^{\infty}2Ca_{n-2}x^{n-2}\right)+\left(\sum_{n=1}^{\infty}3Ca_{n-1}x^{n-2}\right)\\
&+\sum_{n=1}^{\infty}\left(-b_{n-1}(-4+n)\,(n-3)\,x^{n-2}\right)+\left(\sum_{n=0}^{\infty}x^{n-2}b_{n}\left(n^{2}-5n+6\right)\right)\\
&+\left(\sum_{n=1}^{\infty}b_{n-1}(n-3)\,x^{n-2}\right)+\left(\sum_{n=0}^{\infty}4x^{n-2}b_{n}(n-2)\right)\\
&+\left(\sum_{n=0}^{\infty}2b_{n}x^{n-2}\right)+\sum_{n=1}^{\infty}\left(-b_{n-1}x^{n-2}\right)=0
\end{aligned}\tag{2B}$$

For $n = 0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n = N$, where $N = 1$ which is the difference between the two roots, we are free to choose $b_1 = 0$. Hence for $n = 1$, Eq (2B) gives

$$C - 9 = 0$$

Which is solved for C. Solving for C gives

$$C = 9$$

For $n = 2$, Eq (2B) gives

$$(4a_0 + 3a_1) C - 4b_1 + 2b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$90 + 2b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = -45$$

For $n = 3$, Eq (2B) gives

$$(2a_1 + 5a_2) C - b_2 + 6b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$96 + 6b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = -16$$

For $n = 4$, Eq (2B) gives

$$7Ca_3 + 12b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$12b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = 0$$

For $n = 5$, Eq (2B) gives

$$(-2a_3 + 9a_4) C - b_4 + 20b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$20b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = 9$ and all b_n, then the second solution becomes

$$y_2(x) = 9\left(\frac{1 + 2x + \frac{x^2}{3} + O(x^6)}{x}\right)\ln(x) + \frac{1 - 45x^2 - 16x^3 + O(x^6)}{x^2}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{c_1\left(1 + 2x + \frac{x^2}{3} + O(x^6)\right)}{x} \\ &\quad + c_2\left(9\left(\frac{1 + 2x + \frac{x^2}{3} + O(x^6)}{x}\right)\ln(x) + \frac{1 - 45x^2 - 16x^3 + O(x^6)}{x^2}\right) \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= \frac{c_1\left(1 + 2x + \frac{x^2}{3} + O(x^6)\right)}{x} \\ &\quad + c_2\left(\frac{9\left(1 + 2x + \frac{x^2}{3} + O(x^6)\right)\ln(x)}{x} + \frac{1 - 45x^2 - 16x^3 + O(x^6)}{x^2}\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y &= \frac{c_1\left(1 + 2x + \frac{x^2}{3} + O(x^6)\right)}{x} \\ &\quad + c_2\left(\frac{9\left(1 + 2x + \frac{x^2}{3} + O(x^6)\right)\ln(x)}{x} + \frac{1 - 45x^2 - 16x^3 + O(x^6)}{x^2}\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\left(1+2x+\frac{x^2}{3}+O(x^6)\right)}{x} + c_2\left(\frac{9\left(1+2x+\frac{x^2}{3}+O(x^6)\right)\ln(x)}{x} + \frac{1-45x^2-16x^3+O(x^6)}{x^2}\right)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 22.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2(x+1)\,y''+x(1+2x)\,y'-(6x+4)\,y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+x^2\right)y''+\left(2x^2+x\right)y'+(-6x-4)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$\begin{aligned}p(x)&=\frac{1+2x}{x\,(x+1)}\\ q(x)&=-\frac{2(3x+2)}{x^2\,(x+1)}\end{aligned}$$

Table 450: Table $p(x), q(x)$ singularites.

$p(x) = \frac{1+2x}{x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = -\frac{2(3x+2)}{x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0, \infty]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x+1)\,y'' + \left(2x^2+x\right) y' + (-6x-4)\,y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$
$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x+1)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \left(2x^2+x\right)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + (-6x-4)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \\
&+ \left(\sum_{n=0}^{\infty} 2x^{1+n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\
&+ \sum_{n=0}^{\infty} \left(-6x^{1+n+r} a_n\right) + \sum_{n=0}^{\infty} \left(-4a_n x^{n+r}\right) = 0
\end{aligned} \tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) &= \sum_{n=1}^{\infty} a_{n-1} (n+r-1)(n+r-2)\, x^{n+r} \\
\sum_{n=0}^{\infty} 2x^{1+n+r} a_n (n+r) &= \sum_{n=1}^{\infty} 2a_{n-1} (n+r-1)\, x^{n+r} \\
\sum_{n=0}^{\infty} \left(-6x^{1+n+r} a_n\right) &= \sum_{n=1}^{\infty} \left(-6a_{n-1} x^{n+r}\right)
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=1}^{\infty} a_{n-1} (n+r-1)(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) \\
&+ \left(\sum_{n=1}^{\infty} 2a_{n-1} (n+r-1)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)\right) \\
&+ \sum_{n=1}^{\infty} \left(-6a_{n-1} x^{n+r}\right) + \sum_{n=0}^{\infty} \left(-4a_n x^{n+r}\right) = 0
\end{aligned} \tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r} a_n (n+r)(n+r-1) + x^{n+r} a_n (n+r) - 4a_n x^{n+r} = 0
$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) + x^r a_0 r - 4a_0 x^r = 0$$

Or

$$(x^r r(-1+r) + x^r r - 4x^r)\, a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 - 4\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 - 4 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 2$$
$$r_2 = -2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 - 4\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 4$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = x^2\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+2}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. For $1 \leq n$ the recursive equation is

$$\begin{aligned} a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) \\ + 2a_{n-1}(n+r-1) + a_n(n+r) - 6a_{n-1} - 4a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{(n+r-3)\,a_{n-1}}{n+r-2} \tag{4}$$

Which for the root $r = 2$ becomes

$$a_n = -\frac{(n-1)\,a_{n-1}}{n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 2$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1

For $n = 1$, using the above recursive equation gives

$$a_1 = \frac{-r+2}{-1+r}$$

Which for the root $r = 2$ becomes

$$a_1 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r+2}{-1+r}$	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r-2}{r}$$

Which for the root $r = 2$ becomes

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r+2}{-1+r}$	0
a_2	$\frac{r-2}{r}$	0

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r+2}{1+r}$$

Which for the root $r = 2$ becomes

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r+2}{-1+r}$	0
a_2	$\frac{r-2}{r}$	0
a_3	$\frac{-r+2}{1+r}$	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r-2}{2+r}$$

Which for the root $r = 2$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r+2}{-1+r}$	0
a_2	$\frac{r-2}{r}$	0
a_3	$\frac{-r+2}{1+r}$	0
a_4	$\frac{r-2}{2+r}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-r+2}{3+r}$$

Which for the root $r = 2$ becomes

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r+2}{-1+r}$	0
a_2	$\frac{r-2}{r}$	0
a_3	$\frac{-r+2}{1+r}$	0
a_4	$\frac{r-2}{2+r}$	0
a_5	$\frac{-r+2}{3+r}$	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= x^2\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= x^2\left(1 + O(x^6)\right) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 4$. Now we need to determine if

C is zero or not. This is done by finding $\lim_{r \to r_2} a_4(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_4 \\ &= \frac{r-2}{2+r} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{r-2}{2+r} &= \lim_{r \to -2} \frac{r-2}{2+r} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2} \right)$$

Therefore

$$\begin{aligned} \frac{d}{dx} y_2(x) &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} \frac{b_n x^{n+r_2} (n+r_2)}{x} \right) \\ &= C y_1'(x) \ln(x) + \frac{C y_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n (n+r_2) \right) \\ \frac{d^2}{dx^2} y_2(x) &= C y_1''(x) \ln(x) + \frac{2 C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} \\ &\quad + \sum_{n=0}^{\infty} \left(\frac{b_n x^{n+r_2} (n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2} (n+r_2)}{x^2} \right) \\ &= C y_1''(x) \ln(x) + \frac{2 C y_1'(x)}{x} - \frac{C y_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n (n+r_2) (-1+n+r_2) \right) \end{aligned}$$

Substituting these back into the given ode $x^2(x+1) y'' + (2x^2 + x) y' + (-6x - 4) y = 0$

gives

$$
\begin{aligned}
&x^2(x+1)\left(Cy_1''(x)\ln(x)+\frac{2Cy_1'(x)}{x}-\frac{Cy_1(x)}{x^2}\right.\\
&\left.+\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\
&+\left(2x^2+x\right)\left(Cy_1'(x)\ln(x)+\frac{Cy_1(x)}{x}+\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right)\\
&+(-6x-4)\left(Cy_1(x)\ln(x)+\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)\right)=0
\end{aligned}
$$

Which can be written as

$$
\begin{aligned}
&\left(\left(x^2(x+1)\,y_1''(x)+\left(2x^2+x\right)y_1'(x)+(-6x-4)\,y_1(x)\right)\ln(x)\right.\\
&\left.+x^2(x+1)\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{\left(2x^2+x\right)y_1(x)}{x}\right)C\\
&+x^2(x+1)\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\
&+\left(2x^2+x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+(-6x-4)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0
\end{aligned}
\tag{7}
$$

But since $y_1(x)$ is a solution to the ode, then

$$
x^2(x+1)\,y_1''(x)+\left(2x^2+x\right)y_1'(x)+(-6x-4)\,y_1(x)=0
$$

Eq (7) simplifes to

$$
\begin{aligned}
&\left(x^2(x+1)\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{\left(2x^2+x\right)y_1(x)}{x}\right)C\\
&+x^2(x+1)\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\
&+\left(2x^2+x\right)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+(-6x-4)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0
\end{aligned}
\tag{8}
$$

Substituting $y_1 = \sum_{n=0}^{\infty} a_n x^{n+r_1}$ into the above gives

$$
\begin{aligned}
&\left(2x(x+1)\left(\sum_{n=0}^{\infty} x^{-1+n+r_1} a_n(n+r_1)\right)+\left(\sum_{n=0}^{\infty} a_n x^{n+r_1}\right) x\right) C \\
&+x^2(x+1)\left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right) \\
&+\left(2x^2+x\right)\left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right)+(-6x-4)\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)=0
\end{aligned}
\tag{9}
$$

Since $r_1 = 2$ and $r_2 = -2$ then the above becomes

$$
\begin{aligned}
&\left(2x(x+1)\left(\sum_{n=0}^{\infty} x^{1+n} a_n(n+2)\right)+\left(\sum_{n=0}^{\infty} a_n x^{n+2}\right) x\right) C \\
&+x^2(x+1)\left(\sum_{n=0}^{\infty} x^{-4+n} b_n(n-2)(-3+n)\right) \\
&+\left(2x^2+x\right)\left(\sum_{n=0}^{\infty} x^{-3+n} b_n(n-2)\right)+(-6x-4)\left(\sum_{n=0}^{\infty} b_n x^{n-2}\right)=0
\end{aligned}
\tag{10}
$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\, x^{n+3} a_n(n+2)\right)+\left(\sum_{n=0}^{\infty} 2C\, x^{n+2} a_n(n+2)\right) \\
&+\left(\sum_{n=0}^{\infty} C\, x^{n+3} a_n\right)+\left(\sum_{n=0}^{\infty} x^{n-1} b_n\left(n^2-5n+6\right)\right) \\
&+\left(\sum_{n=0}^{\infty} x^{n-2} b_n\left(n^2-5n+6\right)\right)+\left(\sum_{n=0}^{\infty} 2x^{n-1} b_n(n-2)\right) \\
&+\left(\sum_{n=0}^{\infty} x^{n-2} b_n(n-2)\right)+\sum_{n=0}^{\infty}\left(-6x^{n-1} b_n\right)+\sum_{n=0}^{\infty}\left(-4b_n x^{n-2}\right)=0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n-2$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-2} and

adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{n+3} a_n(n+2) = \sum_{n=5}^{\infty} 2C a_{n-5}(-3+n)\, x^{n-2}$$

$$\sum_{n=0}^{\infty} 2C\, x^{n+2} a_n(n+2) = \sum_{n=4}^{\infty} 2C a_{-4+n}(n-2)\, x^{n-2}$$

$$\sum_{n=0}^{\infty} C\, x^{n+3} a_n = \sum_{n=5}^{\infty} C a_{n-5} x^{n-2}$$

$$\sum_{n=0}^{\infty} x^{n-1} b_n \left(n^2-5n+6\right) = \sum_{n=1}^{\infty} b_{n-1}\left((n-1)^2-5n+11\right) x^{n-2}$$

$$\sum_{n=0}^{\infty} 2x^{n-1} b_n(n-2) = \sum_{n=1}^{\infty} 2b_{n-1}(-3+n)\, x^{n-2}$$

$$\sum_{n=0}^{\infty} \left(-6x^{n-1} b_n\right) = \sum_{n=1}^{\infty} \left(-6b_{n-1} x^{n-2}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-2$.

$$\begin{aligned} &\left(\sum_{n=5}^{\infty} 2C a_{n-5}(-3+n)\, x^{n-2}\right) + \left(\sum_{n=4}^{\infty} 2C a_{-4+n}(n-2)\, x^{n-2}\right) \\ &+ \left(\sum_{n=5}^{\infty} C a_{n-5} x^{n-2}\right) + \left(\sum_{n=1}^{\infty} b_{n-1}\left((n-1)^2-5n+11\right) x^{n-2}\right) \\ &+ \left(\sum_{n=0}^{\infty} x^{n-2} b_n \left(n^2-5n+6\right)\right) + \left(\sum_{n=1}^{\infty} 2b_{n-1}(-3+n)\, x^{n-2}\right) \\ &+ \left(\sum_{n=0}^{\infty} x^{n-2} b_n(n-2)\right) + \sum_{n=1}^{\infty} \left(-6b_{n-1} x^{n-2}\right) + \sum_{n=0}^{\infty} \left(-4b_n x^{n-2}\right) = 0 \end{aligned} \tag{2B}$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-4b_0 - 3b_1 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-4 - 3b_1 = 0$$

Solving the above for b_1 gives

$$b_1 = -\frac{4}{3}$$

For $n = 2$, Eq (2B) gives

$$-6b_1 - 4b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$8 - 4b_2 = 0$$

Solving the above for b_2 gives

$$b_2 = 2$$

For $n = 3$, Eq (2B) gives

$$-3b_3 - 6b_2 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-3b_3 - 12 = 0$$

Solving the above for b_3 gives

$$b_3 = -4$$

For $n = N$, where $N = 4$ which is the difference between the two roots, we are free to choose $b_4 = 0$. Hence for $n = 4$, Eq (2B) gives

$$4C + 16 = 0$$

Which is solved for C. Solving for C gives

$$C = -4$$

For $n = 5$, Eq (2B) gives

$$(5a_0 + 6a_1) C + 5b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-20 + 5b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 4$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -4$ and all b_n, then the second solution becomes

$$y_2(x) = (-4)\left(x^2\left(1 + O\left(x^6\right)\right)\right)\ln(x) + \frac{1 - \frac{4x}{3} + 2x^2 - 4x^3 + 4x^5 + O(x^6)}{x^2}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 x^2\left(1 + O\left(x^6\right)\right) \\
&\quad + c_2\left((-4)\left(x^2\left(1 + O\left(x^6\right)\right)\right)\ln(x) + \frac{1 - \frac{4x}{3} + 2x^2 - 4x^3 + 4x^5 + O(x^6)}{x^2}\right)
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1 x^2\left(1+O\left(x^6\right)\right) + c_2\left(-4x^2\left(1+O\left(x^6\right)\right)\ln(x) + \frac{1 - \frac{4x}{3} + 2x^2 - 4x^3 + 4x^5 + O(x^6)}{x^2}\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned}
y &= c_1 x^2\left(1 + O\left(x^6\right)\right) \\
&\quad + c_2\left(-4x^2\left(1 + O\left(x^6\right)\right)\ln(x) + \frac{1 - \frac{4x}{3} + 2x^2 - 4x^3 + 4x^5 + O(x^6)}{x^2}\right)
\end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 x^2\left(1+O\left(x^6\right)\right) + c_2\left(-4x^2\left(1+O\left(x^6\right)\right)\ln(x) + \frac{1 - \frac{4x}{3} + 2x^2 - 4x^3 + 4x^5 + O(x^6)}{x^2}\right)$$

Verified OK.

11.11.1 Maple step by step solution

Let's solve

$x^2(x+1)\,y'' + (2x^2 + x)\,y' + (-6x - 4)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

$y'' = \frac{2(3x+2)y}{x^2(x+1)} - \frac{(1+2x)y'}{x(x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(1+2x)y'}{x(x+1)} - \frac{2(3x+2)y}{x^2(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x) = \frac{1+2x}{x(x+1)}, P_3(x) = -\frac{2(3x+2)}{x^2(x+1)}\right]$

- ○ $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

  $\left((x+1) \cdot P_2(x)\right)\bigg|_{x=-1} = 1$

- ○ $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $\left((x+1)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

- ○ $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $x^2(x+1)\,y'' + x(1+2x)\,y' + (-6x-4)\,y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u = 0$

  $(u^3 - 2u^2 + u)\left(\frac{d^2}{du^2}y(u)\right) + (2u^2 - 3u + 1)\left(\frac{d}{du}y(u)\right) + (-6u+2)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- ○ Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- ○ Shift index using $k- >k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- ○ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r^2 u^{-1+r} + \left(a_1(1+r)^2 - a_0(2r^2+r-2)\right) u^r + \left(\sum_{k=1}^{\infty} \left(a_{k+1}(k+1+r)^2 - a_k(2k^2+4kr+2r^2+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r^2 = 0$$

- Values of r that satisfy the indicial equation

$$r = 0$$

- Each term must be 0

$$a_1(1+r)^2 - a_0(2r^2+r-2) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2-k-6)\, a_{k-1} + (-2k^2-k+2)\, a_k + a_{k+1}(k+1)^2 = 0$$

- Shift index using $k- >k+1$

$$\left((k+1)^2-k-7\right) a_k + \left(-2(k+1)^2-k+1\right) a_{k+1} + a_{k+2}(k+2)^2 = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}, a_1 + 2a_0 = 0\right]$$

- Revert the change of variables $u = x + 1$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+1)^k, a_{k+2} = -\frac{k^2 a_k - 2k^2 a_{k+1} + k a_k - 5k a_{k+1} - 6a_k - a_{k+1}}{(k+2)^2}, a_1 + 2a_0 = 0\right]$$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 23.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Repeated root"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2(x+1)\,y''-x\left(-x^2-6x+1\right)y'+\left(x^2+6x+1\right)y=0}$$

With the expansion point for the power series method at $x=0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(x^3+x^2\right)y''+\left(x^3+6x^2-x\right)y'+\left(x^2+6x+1\right)y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{x^2+6x-1}{x\,(x+1)}$$
$$q(x)=\frac{x^2+6x+1}{x^2\,(x+1)}$$

Table 452: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2+6x-1}{x(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

$q(x) = \frac{x^2+6x+1}{x^2(x+1)}$	
singularity	type
$x = -1$	"regular"
$x = 0$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[-1, 0]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x+1)\, y'' + \left(x^3 + 6x^2 - x\right) y' + \left(x^2 + 6x + 1\right) y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x+1)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}\right) + \left(x^3 + 6x^2 - x\right)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + \left(x^2 + 6x + 1\right)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 6 x^{1+n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-x^{n+r} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} 6 x^{1+n+r} a_n\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{1+n+r} a_n (n+r)(n+r-1) = \sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r) = \sum_{n=2}^{\infty} a_{n-2}(n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} 6 x^{1+n+r} a_n (n+r) = \sum_{n=1}^{\infty} 6 a_{n-1}(n+r-1)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n = \sum_{n=2}^{\infty} a_{n-2} x^{n+r}$$

$$\sum_{n=0}^{\infty} 6 x^{1+n+r} a_n = \sum_{n=1}^{\infty} 6 a_{n-1} x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers

of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} a_{n-1}(n+r-1)(n+r-2)\,x^{n+r}\right) + \left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)(n+r-1)\right) + \left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)\,x^{n+r}\right) + \left(\sum_{n=1}^{\infty} 6a_{n-1}(n+r-1)\,x^{n+r}\right) + \sum_{n=0}^{\infty}\left(-x^{n+r} a_n(n+r)\right) + \left(\sum_{n=2}^{\infty} a_{n-2} x^{n+r}\right) + \left(\sum_{n=1}^{\infty} 6a_{n-1} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r} a_n(n+r)(n+r-1) - x^{n+r} a_n(n+r) + a_n x^{n+r} = 0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r) - x^r a_0 r + a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) - x^r r + x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(-1+r)^2\, x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$(-1+r)^2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = 1$$
$$r_2 = 1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(-1+r)^2\, x^r = 0$$

Solving for r gives the roots of the indicial equation as Since the root of the indicial equation is repeated, then we can construct two linearly independent solutions. The first solution has the form

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n+r} \tag{1A}$$

Now the second solution y_2 is found using

$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right) \tag{1B}$$

Then the general solution will be

$$y = c_1 y_1(x) + c_2 y_2(x)$$

In Eq (1B) the sum starts from 1 and not zero. In Eq (1A), a_0 is never zero, and is arbitrary and is typically taken as $a_0 = 1$, and $\{c_1, c_2\}$ are two arbitray constants of integration which can be found from initial conditions. Using the value of the indicial root found earlier, $r = 1$, Eqs (1A,1B) become

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{1+n}$$
$$y_2(x) = y_1(x) \ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{1+n}\right)$$

We start by finding the first solution $y_1(x)$. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = \frac{-r^2 - 5r - 6}{r^2}$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} &a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) + a_{n-2}(n+r-2) \\ &+ 6a_{n-1}(n+r-1) - a_n(n+r) + a_{n-2} + 6a_{n-1} + a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{n^2 a_{n-1} + 2nr a_{n-1} + r^2 a_{n-1} + n a_{n-2} + 3n a_{n-1} + r a_{n-2} + 3r a_{n-1} - a_{n-2} + 2a_{n-1}}{n^2 + 2nr + r^2 - 2n - 2r + 1} \tag{4}$$

Which for the root $r = 1$ becomes

$$a_n = \frac{-n^2 a_{n-1} + (-a_{n-2} - 5a_{n-1})\, n - 6a_{n-1}}{n^2} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2-5r-6}{r^2}$	-12

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{r^4 + 11r^3 + 52r^2 + 102r + 72}{r^2 (1 + r)^2}$$

Which for the root $r = 1$ becomes

$$a_2 = \frac{119}{2}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2-5r-6}{r^2}$	-12
a_2	$\frac{r^4+11r^3+52r^2+102r+72}{r^2(1+r)^2}$	$\frac{119}{2}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-r^6 - 19r^5 - 162r^4 - 759r^3 - 1979r^2 - 2648r - 1428}{r^2 (1 + r)^2 (r + 2)^2}$$

Which for the root $r = 1$ becomes

$$a_3 = -\frac{583}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2-5r-6}{r^2}$	-12
a_2	$\frac{r^4+11r^3+52r^2+102r+72}{r^2(1+r)^2}$	$\frac{119}{2}$
a_3	$\frac{-r^6-19r^5-162r^4-759r^3-1979r^2-2648r-1428}{r^2(1+r)^2(r+2)^2}$	$-\frac{583}{3}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r^8 + 29r^7 + 383r^6 + 2966r^5 + 14534r^4 + 45437r^3 + 87166r^2 + 92772r + 41976}{r^2 (1+r)^2 (r+2)^2 (r+3)^2}$$

Which for the root $r = 1$ becomes

$$a_4 = \frac{1981}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2-5r-6}{r^2}$	-12
a_2	$\frac{r^4+11r^3+52r^2+102r+72}{r^2(1+r)^2}$	$\frac{119}{2}$
a_3	$\frac{-r^6-19r^5-162r^4-759r^3-1979r^2-2648r-1428}{r^2(1+r)^2(r+2)^2}$	$-\frac{583}{3}$
a_4	$\frac{r^8+29r^7+383r^6+2966r^5+14534r^4+45437r^3+87166r^2+92772r+41976}{r^2(1+r)^2(r+2)^2(r+3)^2}$	$\frac{1981}{4}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-r^{10} - 41r^9 - 773r^8 - 8778r^7 - 66136r^6 - 343352r^5 - 1234958r^4 - 3013745r^3 - 4736076r^2 - 429}{r^2 (1+r)^2 (r+2)^2 (r+3)^2 (r+4)^2}$$

Which for the root $r = 1$ becomes

$$a_5 = -\frac{80287}{75}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	$\frac{-r^2-5r-6}{r^2}$	-12
a_2	$\frac{r^4+11r^3+52r^2+102r+72}{r^2(1+r)^2}$	$\frac{119}{2}$
a_3	$\frac{-r^6-19r^5-162r^4-759r^3-1979r^2-2648r-1428}{r^2(1+r)^2(r+2)^2}$	$-\frac{583}{3}$
a_4	$\frac{r^8+29r^7+383r^6+2966r^5+14534r^4+45437r^3+87166r^2+92772r+41976}{r^2(1+r)^2(r+2)^2(r+3)^2}$	$\frac{1981}{4}$
a_5	$\frac{-r^{10}-41r^9-773r^8-8778r^7-66136r^6-343352r^5-1234958r^4-3013745r^3-4736076r^2-4299660r-1711584}{r^2(1+r)^2(r+2)^2(r+3)^2(r+4)^2}$	$-\frac{80287}{75}$

Using the above table, then the first solution $y_1(x)$ is

$$
\begin{aligned}
y_1(x) &= x\left(a_0 + a_1x + a_2x^2 + a_3x^3 + a_4x^4 + a_5x^5 + a_6x^6 \dots\right) \\
&= x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right)
\end{aligned}
$$

Now the second solution is found. The second solution is given by

$$
y_2(x) = y_1(x)\ln(x) + \left(\sum_{n=1}^{\infty} b_n x^{n+r}\right)
$$

Where b_n is found using

$$
b_n = \frac{d}{dr} a_{n,r}
$$

And the above is then evaluated at $r = 1$. The above table for $a_{n,r}$ is used for this purpose. Computing the derivatives gives the following table

n	$b_{n,r}$	a_n	$b_{n,r} = \frac{d}{dr}a$
b_0	1	1	N/A since
b_1	$\frac{-r^2-5r-6}{r^2}$	-12	$\frac{5r+12}{r^3}$
b_2	$\frac{r^4+11r^3+52r^2+102r+72}{r^2(1+r)^2}$	$\frac{119}{2}$	$\frac{-9r^4-93r^3-}{r^3(}$
b_3	$\frac{-r^6-19r^5-162r^4-759r^3-1979r^2-2648r-1428}{r^2(1+r)^2(r+2)^2}$	$-\frac{583}{3}$	$13r^7+259r^6+$
b_4	$\frac{r^8+29r^7+383r^6+2966r^5+14534r^4+45437r^3+87166r^2+92772r+41976}{r^2(1+r)^2(r+2)^2(r+3)^2}$	$\frac{1981}{4}$	$-17r^{10}-548r$
b_5	$\frac{-r^{10}-41r^9-773r^8-8778r^7-66136r^6-343352r^5-1234958r^4-3013745r^3-4736076r^2-4299660r-1711584}{r^2(1+r)^2(r+2)^2(r+3)^2(r+4)^2}$	$-\frac{80287}{75}$	$21r^{13}+996r^{12}$

The above table gives all values of b_n needed. Hence the second solution is

$$\begin{aligned}
y_2(x) &= y_1(x)\ln(x) + b_0 + b_1x + b_2x^2 + b_3x^3 + b_4x^4 + b_5x^5 + b_6x^6 \ldots \\
&= x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right)\ln(x) \\
&\quad + x\left(17x - \frac{471x^2}{4} + 445x^3 - \frac{118285x^4}{96} + \frac{702451x^5}{250} + O(x^6)\right)
\end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned}
y_h(x) &= c_1y_1(x) + c_2y_2(x) \\
&= c_1x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right) \\
&\quad + c_2\left(x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right)\ln(x)\right. \\
&\qquad \left. + x\left(17x - \frac{471x^2}{4} + 445x^3 - \frac{118285x^4}{96} + \frac{702451x^5}{250} + O(x^6)\right)\right)
\end{aligned}$$

Hence the final solution is

$$\begin{aligned}
y &= y_h \\
&= c_1x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right) \\
&\quad + c_2\left(x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right)\ln(x)\right. \\
&\qquad \left. + x\left(17x - \frac{471x^2}{4} + 445x^3 - \frac{118285x^4}{96} + \frac{702451x^5}{250} + O(x^6)\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned}
y &= c_1x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right) \\
&\quad + c_2\left(x\left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right)\ln(x)\right. \\
&\qquad \left. + x\left(17x - \frac{471x^2}{4} + 445x^3 - \frac{118285x^4}{96} + \frac{702451x^5}{250} + O(x^6)\right)\right)
\end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 x \left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right)$$
$$+ c_2 \left(x \left(1 - 12x + \frac{119x^2}{2} - \frac{583x^3}{3} + \frac{1981x^4}{4} - \frac{80287x^5}{75} + O(x^6)\right) \ln(x) + x \left(17x - \frac{471x^2}{4} + 445x^3 - \frac{118285x^4}{96} + \frac{702451x^5}{250} + O(x^6)\right)\right)$$

Verified OK.

11.12.1 Maple step by step solution

Let's solve

$x^2(x+1)\, y'' + (x^3 + 6x^2 - x)\, y' + (x^2 + 6x + 1)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(x^2+6x+1)y}{x^2(x+1)} - \frac{(x^2+6x-1)y'}{x(x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x^2+6x-1)y'}{x(x+1)} + \frac{(x^2+6x+1)y}{x^2(x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{x^2+6x-1}{x(x+1)}, P_3(x) = \frac{x^2+6x+1}{x^2(x+1)}\right]$

  ◦ $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

    $\left((x+1) \cdot P_2(x)\right)\Big|_{x=-1} = 6$

  ◦ $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

    $\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

$x^2(x+1)\,y''+x(x^2+6x-1)\,y'+(x^2+6x+1)\,y=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^3-2u^2+u)\left(\frac{d^2}{du^2}y(u)\right)+(u^3+3u^2-10u+6)\left(\frac{d}{du}y(u)\right)+(u^2+4u-4)\,y(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

  $u^m\cdot y(u)=\sum_{k=0}^{\infty} a_k u^{k+r+m}$

  ◦ Shift index using $k->k-m$

  $u^m\cdot y(u)=\sum_{k=m}^{\infty} a_{k-m}u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..3$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ◦ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

  ◦ Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

Rewrite ODE with series expansions

$a_0r(5+r)\,u^{-1+r}+\left(a_1(1+r)\,(6+r)-2a_0(r^2+4r+2)\right)u^r+\left(a_2(2+r)\,(7+r)-2a_1(r^2+6r+$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(5+r)=0$

- Values of r that satisfy the indicial equation

$r\in\{-5,0\}$

- The coefficients of each power of u must be 0

$[a_1(1+r)(6+r) - 2a_0(r^2+4r+2) = 0, a_2(2+r)(7+r) - 2a_1(r^2+6r+7) + a_0(r^2+2r+4)$

- Solve for the dependent coefficient(s)

$\left\{a_1 = \frac{2a_0(r^2+4r+2)}{r^2+7r+6}, a_2 = \frac{a_0(3r^4+31r^3+108r^2+120r+32)}{r^4+16r^3+83r^2+152r+84}\right\}$

- Each term in the series must be 0, giving the recursion relation

$(-2a_k + a_{k-1} + a_{k+1})k^2 + ((-4a_k + 2a_{k-1} + 2a_{k+1})r - 8a_k + a_{k-2} + 7a_{k+1})k + (-2a_k + a_{k-1}$

- Shift index using $k->k+2$

$(-2a_{k+2} + a_{k+1} + a_{k+3})(k+2)^2 + ((-4a_{k+2} + 2a_{k+1} + 2a_{k+3})r - 8a_{k+2} + a_k + 7a_{k+3})(k+2) +$

- Recursion relation that defines series solution to ODE

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{x^2(3x+1)\,y''+x\left(x^2+12x+2\right)y'+2x(x+3)\,y=0}$$

With the expansion point for the power series method at $x=0$.

The ODE is

$$\left(3x^3+x^2\right)y''+\left(x^3+12x^2+2x\right)y'+\left(2x^2+6x\right)y=0$$

Or

$$x\left(y'x^2+3x^2y''+2yx+12y'x+xy''+6y+2y'\right)=0$$

For $x\neq 0$ the above simplifies to

$$\left(3x^2+x\right)y''+y'\left(x^2+12x+2\right)+2y(x+3)=0$$

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$\left(3x^3+x^2\right)y''+\left(x^3+12x^2+2x\right)y'+\left(2x^2+6x\right)y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$
\begin{aligned}
p(x) &= \frac{x^2+12x+2}{x(3x+1)} \\
q(x) &= \frac{2x+6}{x(3x+1)}
\end{aligned}
$$

Table 454: Table $p(x), q(x)$ singularites.

$p(x) = \frac{x^2+12x+2}{x(3x+1)}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{1}{3}$	"regular"

$q(x) = \frac{2x+6}{x(3x+1)}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{1}{3}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, -\frac{1}{3}\right]$

Irregular singular points : $[\infty]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$
x^2(3x+1)\, y'' + \left(x^3+12x^2+2x\right) y' + \left(2x^2+6x\right) y = 0
$$

Let the solution be represented as Frobenius power series of the form

$$
y = \sum_{n=0}^{\infty} a_n x^{n+r}
$$

Then

$$
\begin{aligned}
y' &= \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1} \\
y'' &= \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\, a_n x^{n+r-2}
\end{aligned}
$$

Substituting the above back into the ode gives

$$x^2(3x+1)\left(\sum_{n=0}^{\infty}(n+r)(n+r-1)a_n x^{n+r-2}\right) + (x^3+12x^2+2x)\left(\sum_{n=0}^{\infty}(n+r)a_n x^{n+r-1}\right) + (2x^2+6x)\left(\sum_{n=0}^{\infty}a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty}3x^{1+n+r}a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty}x^{n+r}a_n(n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty}x^{n+r+2}a_n(n+r)\right) + \left(\sum_{n=0}^{\infty}12x^{1+n+r}a_n(n+r)\right) + \left(\sum_{n=0}^{\infty}2x^{n+r}a_n(n+r)\right) + \left(\sum_{n=0}^{\infty}2x^{n+r+2}a_n\right) + \left(\sum_{n=0}^{\infty}6x^{1+n+r}a_n\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty}3x^{1+n+r}a_n(n+r)(n+r-1) = \sum_{n=1}^{\infty}3a_{n-1}(n+r-1)(n+r-2)\,x^{n+r}$$

$$\sum_{n=0}^{\infty}x^{n+r+2}a_n(n+r) = \sum_{n=2}^{\infty}a_{n-2}(n+r-2)\,x^{n+r}$$

$$\sum_{n=0}^{\infty}12x^{1+n+r}a_n(n+r) = \sum_{n=1}^{\infty}12a_{n-1}(n+r-1)\,x^{n+r}$$

$$\sum_{n=0}^{\infty}2x^{n+r+2}a_n = \sum_{n=2}^{\infty}2a_{n-2}x^{n+r}$$

$$\sum_{n=0}^{\infty}6x^{1+n+r}a_n = \sum_{n=1}^{\infty}6a_{n-1}x^{n+r}$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=1}^{\infty} 3a_{n-1}(n+r-1)(n+r-2)\,x^{n+r}\right)+\left(\sum_{n=0}^{\infty} x^{n+r}a_n(n+r)(n+r-1)\right)$$
$$+\left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)\,x^{n+r}\right)+\left(\sum_{n=1}^{\infty} 12a_{n-1}(n+r-1)\,x^{n+r}\right) \tag{2B}$$
$$+\left(\sum_{n=0}^{\infty} 2x^{n+r}a_n(n+r)\right)+\left(\sum_{n=2}^{\infty} 2a_{n-2}x^{n+r}\right)+\left(\sum_{n=1}^{\infty} 6a_{n-1}x^{n+r}\right)=0$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$x^{n+r}a_n(n+r)(n+r-1)+2x^{n+r}a_n(n+r)=0$$

When $n=0$ the above becomes

$$x^r a_0 r(-1+r)+2x^r a_0 r=0$$

Or

$$(x^r r(-1+r)+2x^r r)\,a_0=0$$

Since $a_0 \neq 0$ then the above simplifies to

$$x^r r(1+r)=0$$

Since the above is true for all x then the indicial equation becomes

$$r(1+r)=0$$

Solving for r gives the roots of the indicial equation as

$$r_1=0$$
$$r_2=-1$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$x^r r(1+r)=0$$

Solving for r gives the roots of the indicial equation as Since $r_1-r_2=1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x)=x^{r_1}\left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x)=Cy_1(x)\ln(x)+x^{r_2}\left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$

$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^n$$

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-1}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = -3$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} &3a_{n-1}(n+r-1)(n+r-2) + a_n(n+r)(n+r-1) + a_{n-2}(n+r-2) \\ &+ 12a_{n-1}(n+r-1) + 2a_n(n+r) + 2a_{n-2} + 6a_{n-1} = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{3na_{n-1} + 3ra_{n-1} + a_{n-2} + 3a_{n-1}}{1+n+r} \tag{4}$$

Which for the root $r = 0$ becomes

$$a_n = \frac{(-3n-3)a_{n-1} - a_{n-2}}{1+n} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = 0$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-3	-3

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{9r + 26}{3 + r}$$

Which for the root $r = 0$ becomes

$$a_2 = \frac{26}{3}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-3	-3
a_2	$\frac{9r+26}{3+r}$	$\frac{26}{3}$

For $n = 3$, using the above recursive equation gives

$$a_3 = \frac{-27r^2 - 183r - 303}{(3 + r)(4 + r)}$$

Which for the root $r = 0$ becomes

$$a_3 = -\frac{101}{4}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-3	-3
a_2	$\frac{9r+26}{3+r}$	$\frac{26}{3}$
a_3	$\frac{-27r^2-183r-303}{(3+r)(4+r)}$	$-\frac{101}{4}$

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{81r^3 + 945r^2 + 3592r + 4441}{(3 + r)(4 + r)(5 + r)}$$

Which for the root $r = 0$ becomes

$$a_4 = \frac{4441}{60}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-3	-3
a_2	$\frac{9r+26}{3+r}$	$\frac{26}{3}$
a_3	$\frac{-27r^2-183r-303}{(3+r)(4+r)}$	$-\frac{101}{4}$
a_4	$\frac{81r^3+945r^2+3592r+4441}{(3+r)(4+r)(5+r)}$	$\frac{4441}{60}$

For $n = 5$, using the above recursive equation gives

$$a_5 = \frac{-243r^4 - 4266r^3 - 27468r^2 - 76761r - 78423}{(3+r)(4+r)(5+r)(6+r)}$$

Which for the root $r = 0$ becomes

$$a_5 = -\frac{26141}{120}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	-3	-3
a_2	$\frac{9r+26}{3+r}$	$\frac{26}{3}$
a_3	$\frac{-27r^2-183r-303}{(3+r)(4+r)}$	$-\frac{101}{4}$
a_4	$\frac{81r^3+945r^2+3592r+4441}{(3+r)(4+r)(5+r)}$	$\frac{4441}{60}$
a_5	$\frac{-243r^4-4266r^3-27468r^2-76761r-78423}{(3+r)(4+r)(5+r)(6+r)}$	$-\frac{26141}{120}$

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots \\ &= 1 - 3x + \frac{26x^2}{3} - \frac{101x^3}{4} + \frac{4441x^4}{60} - \frac{26141x^5}{120} + O(x^6) \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_1 \\ &= -3 \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} -3 &= \lim_{r \to -1} -3 \\ &= -3 \end{aligned}$$

The limit is -3. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^{n-1} \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = -3$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} &3b_{n-1}(n+r-1)(n+r-2) + b_n(n+r)(n+r-1) + b_{n-2}(n+r-2) \\ &+ 12b_{n-1}(n+r-1) + 2b_n(n+r) + 2b_{n-2} + 6b_{n-1} = 0 \end{aligned} \tag{4}$$

Which for for the root $r = -1$ becomes

$$\begin{aligned} &3b_{n-1}(n-2)(n-3) + b_n(n-1)(n-2) + b_{n-2}(n-3) \\ &+ 12b_{n-1}(n-2) + 2b_n(n-1) + 2b_{n-2} + 6b_{n-1} = 0 \end{aligned} \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{3nb_{n-1} + 3rb_{n-1} + b_{n-2} + 3b_{n-1}}{1 + n + r} \tag{5}$$

Which for the root $r = -1$ becomes

$$b_n = -\frac{3nb_{n-1} + b_{n-2}}{n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-3	-3

For $n = 2$, using the above recursive equation gives

$$b_2 = \frac{9r + 26}{3 + r}$$

Which for the root $r = -1$ becomes

$$b_2 = \frac{17}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-3	-3
b_2	$\frac{9r+26}{3+r}$	$\frac{17}{2}$

For $n = 3$, using the above recursive equation gives

$$b_3 = -\frac{3(9r^2 + 61r + 101)}{(3 + r)(4 + r)}$$

Which for the root $r = -1$ becomes

$$b_3 = -\frac{49}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-3	-3
b_2	$\frac{9r+26}{3+r}$	$\frac{17}{2}$
b_3	$\frac{-27r^2-183r-303}{(3+r)(4+r)}$	$-\frac{49}{2}$

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{81r^3 + 945r^2 + 3592r + 4441}{(3 + r)(4 + r)(5 + r)}$$

Which for the root $r = -1$ becomes

$$b_4 = \frac{571}{8}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-3	-3
b_2	$\frac{9r+26}{3+r}$	$\frac{17}{2}$
b_3	$\frac{-27r^2-183r-303}{(3+r)(4+r)}$	$-\frac{49}{2}$
b_4	$\frac{81r^3+945r^2+3592r+4441}{(3+r)(4+r)(5+r)}$	$\frac{571}{8}$

For $n = 5$, using the above recursive equation gives

$$b_5 = -\frac{3(81r^4 + 1422r^3 + 9156r^2 + 25587r + 26141)}{(3 + r)(4 + r)(6 + r)(5 + r)}$$

Which for the root $r = -1$ becomes

$$b_5 = -\frac{8369}{40}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	-3	-3
b_2	$\frac{9r+26}{3+r}$	$\frac{17}{2}$
b_3	$\frac{-27r^2-183r-303}{(3+r)(4+r)}$	$-\frac{49}{2}$
b_4	$\frac{81r^3+945r^2+3592r+4441}{(3+r)(4+r)(5+r)}$	$\frac{571}{8}$
b_5	$\frac{-243r^4-4266r^3-27468r^2-76761r-78423}{(3+r)(4+r)(5+r)(6+r)}$	$-\frac{8369}{40}$

Using the above table, then the solution $y_2(x)$ is

$$
\begin{aligned}
y_2(x) &= 1\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\
&= \frac{1 - 3x + \frac{17x^2}{2} - \frac{49x^3}{2} + \frac{571x^4}{8} - \frac{8369x^5}{40} + O(x^6)}{x}
\end{aligned}
$$

Therefore the homogeneous solution is

$$
\begin{aligned}
y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\
&= c_1 \left(1 - 3x + \frac{26x^2}{3} - \frac{101x^3}{4} + \frac{4441x^4}{60} - \frac{26141x^5}{120} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 - 3x + \frac{17x^2}{2} - \frac{49x^3}{2} + \frac{571x^4}{8} - \frac{8369x^5}{40} + O(x^6)\right)}{x}
\end{aligned}
$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= c_1 \left(1 - 3x + \frac{26x^2}{3} - \frac{101x^3}{4} + \frac{4441x^4}{60} - \frac{26141x^5}{120} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 - 3x + \frac{17x^2}{2} - \frac{49x^3}{2} + \frac{571x^4}{8} - \frac{8369x^5}{40} + O(x^6)\right)}{x}
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 \left(1 - 3x + \frac{26x^2}{3} - \frac{101x^3}{4} + \frac{4441x^4}{60} - \frac{26141x^5}{120} + O(x^6)\right) \\
&\quad + \frac{c_2 \left(1 - 3x + \frac{17x^2}{2} - \frac{49x^3}{2} + \frac{571x^4}{8} - \frac{8369x^5}{40} + O(x^6)\right)}{x}
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1\left(1 - 3x + \frac{26x^2}{3} - \frac{101x^3}{4} + \frac{4441x^4}{60} - \frac{26141x^5}{120} + O(x^6)\right) + \frac{c_2\left(1 - 3x + \frac{17x^2}{2} - \frac{49x^3}{2} + \frac{571x^4}{8} - \frac{8369x^5}{40} + O(x^6)\right)}{x}$$

Verified OK.

11.13.1 Maple step by step solution

Let's solve

$x^2(3x+1)\, y'' + (x^3 + 12x^2 + 2x)\, y' + (2x^2 + 6x)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2(x+3)y}{x(3x+1)} - \frac{(x^2+12x+2)y'}{x(3x+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x^2+12x+2)y'}{x(3x+1)} + \frac{2(x+3)y}{x(3x+1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{x^2+12x+2}{x(3x+1)}, P_3(x) = \frac{2(x+3)}{x(3x+1)}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 2$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x(3x+1)\, y'' + y'(x^2 + 12x + 2) + (2x + 6)\, y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

  ◦ Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$$

  ◦ Shift index using $k- >k + 1 - m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

  ◦ Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

$$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$$

  ◦ Shift index using $k- >k + 2 - m$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(1+r)\, x^{-1+r} + (a_1(1+r)\,(2+r) + 3a_0(2+r)\,(1+r))\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+r+1)\,(k+r+2$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- Each term must be 0

$$a_1(1+r)\,(2+r) + 3a_0(2+r)\,(1+r) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$3\left(\frac{a_{k+1}(k+r+2)}{3}+a_k(k+r+2)+\frac{a_{k-1}}{3}\right)(k+r+1)=0$$

- Shift index using $k->k+1$

$$3\left(\frac{a_{k+2}(k+3+r)}{3}+a_{k+1}(k+3+r)+\frac{a_k}{3}\right)(k+r+2)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{3ka_{k+1}+3ra_{k+1}+a_k+9a_{k+1}}{k+3+r}$$

- Recursion relation for $r=-1$

$$a_{k+2}=-\frac{3ka_{k+1}+a_k+6a_{k+1}}{k+2}$$

- Solution for $r=-1$

$$\left[y=\sum_{k=0}^{\infty}a_kx^{k-1}, a_{k+2}=-\frac{3ka_{k+1}+a_k+6a_{k+1}}{k+2}, 0=0\right]$$

- Recursion relation for $r=0$

$$a_{k+2}=-\frac{3ka_{k+1}+a_k+9a_{k+1}}{k+3}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty}a_kx^{k}, a_{k+2}=-\frac{3ka_{k+1}+a_k+9a_{k+1}}{k+3}, 2a_1+6a_0=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}a_kx^{k-1}\right)+\left(\sum_{k=0}^{\infty}b_kx^{k}\right), a_{k+2}=-\frac{3ka_{1+k}+a_k+6a_{1+k}}{k+2}, 0=0, b_{k+2}=-\frac{3kb_{1+k}+b_k+9b_{1+k}}{k+3}, 2b_1 \right.$$

Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(2x^2+1)\,y''+x(2x^2+4)\,y'+2(-x^2+1)\,y=0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(2x^4+x^2)\,y''+(2x^3+4x)\,y'+(-2x^2+2)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{2x^2+4}{x\,(2x^2+1)}$$
$$q(x)=-\frac{2(x^2-1)}{x^2\,(2x^2+1)}$$

Table 456: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2x^2+4}{x(2x^2+1)}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{i\sqrt{2}}{2}$	"regular"
$x = \frac{i\sqrt{2}}{2}$	"regular"

$q(x) = -\frac{2(x^2-1)}{x^2(2x^2+1)}$	
singularity	type
$x = 0$	"regular"
$x = -\frac{i\sqrt{2}}{2}$	"regular"
$x = \frac{i\sqrt{2}}{2}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $\left[0, -\frac{i\sqrt{2}}{2}, \frac{i\sqrt{2}}{2}, \infty\right]$

Irregular singular points : []

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(2x^2+1)\,y'' + (2x^3+4x)\,y' + (-2x^2+2)\,y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(2x^2+1)\left(\sum_{n=0}^{\infty} (n+r)\,(n+r-1)\,a_n x^{n+r-2}\right) + (2x^3+4x)\left(\sum_{n=0}^{\infty} (n+r)\,a_n x^{n+r-1}\right) + (-2x^2+2)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$
\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2x^{n+r+2} a_n(n+r)\,(n+r-1)\right)+\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\,(n+r-1)\right) \\
&+\left(\sum_{n=0}^{\infty} 2x^{n+r+2} a_n(n+r)\right)+\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n(n+r)\right) \\
&+\sum_{n=0}^{\infty}\left(-2x^{n+r+2} a_n\right)+\left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right)=0
\end{aligned}
\tag{2A}
$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$
\begin{aligned}
\sum_{n=0}^{\infty} 2x^{n+r+2} a_n(n+r)\,(n+r-1) &= \sum_{n=2}^{\infty} 2a_{n-2}(n+r-2)\,(n-3+r)\,x^{n+r} \\
\sum_{n=0}^{\infty} 2x^{n+r+2} a_n(n+r) &= \sum_{n=2}^{\infty} 2a_{n-2}(n+r-2)\,x^{n+r} \\
\sum_{n=0}^{\infty}\left(-2x^{n+r+2} a_n\right) &= \sum_{n=2}^{\infty}\left(-2a_{n-2} x^{n+r}\right)
\end{aligned}
$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$
\begin{aligned}
&\left(\sum_{n=2}^{\infty} 2a_{n-2}(n+r-2)\,(n-3+r)\,x^{n+r}\right) \\
&+\left(\sum_{n=0}^{\infty} x^{n+r} a_n(n+r)\,(n+r-1)\right)+\left(\sum_{n=2}^{\infty} 2a_{n-2}(n+r-2)\,x^{n+r}\right) \\
&+\left(\sum_{n=0}^{\infty} 4x^{n+r} a_n(n+r)\right)+\sum_{n=2}^{\infty}\left(-2a_{n-2} x^{n+r}\right)+\left(\sum_{n=0}^{\infty} 2a_n x^{n+r}\right)=0
\end{aligned}
\tag{2B}
$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$
x^{n+r} a_n(n+r)\,(n+r-1)+4x^{n+r} a_n(n+r)+2a_n x^{n+r}=0
$$

When $n = 0$ the above becomes

$$x^r a_0 r(-1+r) + 4x^r a_0 r + 2a_0 x^r = 0$$

Or

$$\left(x^r r(-1+r) + 4x^r r + 2x^r\right) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$\left(r^2 + 3r + 2\right) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$r^2 + 3r + 2 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -1$$
$$r_2 = -2$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$\left(r^2 + 3r + 2\right) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 1$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n\right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n\right)$$

Or

$$y_1(x) = \frac{\sum_{n=0}^{\infty} a_n x^n}{x}$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^2}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n-1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-2}\right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} &2a_{n-2}(n+r-2)(n-3+r) + a_n(n+r)(n+r-1) \\ &+ 2a_{n-2}(n+r-2) + 4a_n(n+r) - 2a_{n-2} + 2a_n = 0 \end{aligned} \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{2a_{n-2}(n^2 + 2nr + r^2 - 4n - 4r + 3)}{n^2 + 2nr + r^2 + 3n + 3r + 2} \tag{4}$$

Which for the root $r = -1$ becomes

$$a_n = -\frac{2a_{n-2}(n^2 - 6n + 8)}{n(n+1)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-2r^2 + 2}{r^2 + 7r + 12}$$

Which for the root $r = -1$ becomes

$$a_2 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-2r^2+2}{r^2+7r+12}$	0

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-2r^2+2}{r^2+7r+12}$	0
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{4(-1+r)\,(1+r)^2}{(r+6)\,(r+5)\,(r+4)}$$

Which for the root $r = -1$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-2r^2+2}{r^2+7r+12}$	0
a_3	0	0
a_4	$\frac{4(-1+r)(1+r)^2}{(r+6)(r+5)(r+4)}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-2r^2+2}{r^2+7r+12}$	0
a_3	0	0
a_4	$\frac{4(-1+r)(1+r)^2}{(r+6)(r+5)(r+4)}$	0
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \frac{1}{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= \frac{1 + O(x^6)}{x} \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 1$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r\to r_2} a_1(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_1 \\ &= 0 \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r\to r_2} 0 &= \lim_{r\to -2} 0 \\ &= 0 \end{aligned}$$

The limit is 0. Since the limit exists then the log term is not needed and we can set $C = 0$. Therefore the second solution has the form

$$\begin{aligned} y_2(x) &= \sum_{n=0}^{\infty} b_n x^{n+r} \\ &= \sum_{n=0}^{\infty} b_n x^{n-2} \end{aligned}$$

Eq (3) derived above is used to find all b_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. b_0 is arbitrary and taken as $b_0 = 1$. Substituting $n = 1$ in Eq(3) gives

$$b_1 = 0$$

For $2 \leq n$ the recursive equation is

$$\begin{aligned} &2b_{n-2}(n+r-2)(n-3+r)+b_n(n+r)(n+r-1) \\ &+2b_{n-2}(n+r-2)+4b_n(n+r)-2b_{n-2}+2b_n=0 \end{aligned} \tag{4}$$

Which for for the root $r = -2$ becomes

$$2b_{n-2}(n-4)(n-5)+b_n(n-2)(n-3)+2b_{n-2}(n-4)+4b_n(n-2)-2b_{n-2}+2b_n=0 \tag{4A}$$

Solving for b_n from the recursive equation (4) gives

$$b_n = -\frac{2b_{n-2}(n^2+2nr+r^2-4n-4r+3)}{n^2+2nr+r^2+3n+3r+2} \tag{5}$$

Which for the root $r = -2$ becomes

$$b_n = -\frac{2b_{n-2}(n^2-8n+15)}{n^2-n} \tag{6}$$

At this point, it is a good idea to keep track of b_n in a table both before substituting $r = -2$ and after as more terms are found using the above recursive equation.

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0

For $n = 2$, using the above recursive equation gives

$$b_2 = -\frac{2(r^2-1)}{r^2+7r+12}$$

Which for the root $r = -2$ becomes

$$b_2 = -3$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{-2r^2+2}{r^2+7r+12}$	-3

For $n = 3$, using the above recursive equation gives

$$b_3 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{-2r^2+2}{r^2+7r+12}$	-3
b_3	0	0

For $n = 4$, using the above recursive equation gives

$$b_4 = \frac{4r^3 + 4r^2 - 4r - 4}{(r^2 + 11r + 30)(r + 4)}$$

Which for the root $r = -2$ becomes

$$b_4 = -\frac{1}{2}$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{-2r^2+2}{r^2+7r+12}$	-3
b_3	0	0
b_4	$\frac{4(-1+r)(1+r)^2}{(r+6)(r+5)(r+4)}$	$-\frac{1}{2}$

For $n = 5$, using the above recursive equation gives

$$b_5 = 0$$

And the table now becomes

n	$b_{n,r}$	b_n
b_0	1	1
b_1	0	0
b_2	$\frac{-2r^2+2}{r^2+7r+12}$	-3
b_3	0	0
b_4	$\frac{4(-1+r)(1+r)^2}{(r+6)(r+5)(r+4)}$	$-\frac{1}{2}$
b_5	0	0

Using the above table, then the solution $y_2(x)$ is

$$\begin{aligned} y_2(x) &= \frac{1}{x}\left(b_0 + b_1 x + b_2 x^2 + b_3 x^3 + b_4 x^4 + b_5 x^5 + b_6 x^6 \dots\right) \\ &= \frac{1 - 3x^2 - \frac{x^4}{2} + O(x^6)}{x^2} \end{aligned}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{c_1(1 + O(x^6))}{x} + \frac{c_2\left(1 - 3x^2 - \frac{x^4}{2} + O(x^6)\right)}{x^2} \end{aligned}$$

Hence the final solution is

$$\begin{aligned} y &= y_h \\ &= \frac{c_1(1 + O(x^6))}{x} + \frac{c_2\left(1 - 3x^2 - \frac{x^4}{2} + O(x^6)\right)}{x^2} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1(1 + O(x^6))}{x} + \frac{c_2\left(1 - 3x^2 - \frac{x^4}{2} + O(x^6)\right)}{x^2} \tag{1}$$

Verification of solutions

$$y = \frac{c_1(1 + O(x^6))}{x} + \frac{c_2\left(1 - 3x^2 - \frac{x^4}{2} + O(x^6)\right)}{x^2}$$

Verified OK.

11.14.1 Maple step by step solution

Let's solve

$x^2(2x^2+1)\,y''+(2x^3+4x)\,y'+(-2x^2+2)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{2(x^2-1)y}{x^2(2x^2+1)}-\frac{2(x^2+2)y'}{x(2x^2+1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2(x^2+2)y'}{x(2x^2+1)}-\frac{2(x^2-1)y}{x^2(2x^2+1)}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{2(x^2+2)}{x(2x^2+1)}, P_3(x)=-\frac{2(x^2-1)}{x^2(2x^2+1)}\right]$

  - $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=4$

  - $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=2$

  - $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $x^2(2x^2+1)\,y''+2(x^2+2)\,xy'+(-2x^2+2)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m\cdot y$ to series expansion for $m=0..2$

    $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

- Shift index using $k->k-m$

  $x^{m}\cdot y=\sum_{k=m}^{\infty} a_{k-m}x^{k+r}$

- Convert $x^{m}\cdot y'$ to series expansion for $m=1..3$

  $x^{m}\cdot y'=\sum_{k=0}^{\infty} a_{k}(k+r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^{m}\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^{m}\cdot y''$ to series expansion for $m=2..4$

  $x^{m}\cdot y''=\sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $x^{m}\cdot y''=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(2+r)\,(1+r)\, x^{r}+a_{1}(3+r)\,(2+r)\, x^{1+r}+\left(\sum_{k=2}^{\infty} (a_{k}(k+r+2)\,(k+r+1)+2a_{k-2}(k+r-1$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(1+r)=0$

- Values of r that satisfy the indicial equation

  $r\in\{-2,-1\}$

- Each term must be 0

  $a_{1}(3+r)\,(2+r)=0$

- Solve for the dependent coefficient(s)

  $a_{1}=0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k}(k+r+2)\,(k+r+1)+2a_{k-2}(k+r-1)\,(k-3+r)=0$

- Shift index using $k->k+2$

  $a_{k+2}(k+4+r)\,(k+3+r)+2a_{k}(k+r+1)\,(k+r-1)=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{2a_{k}(k+r+1)(k+r-1)}{(k+4+r)(k+3+r)}$

- Recursion relation for $r = -2$

$$a_{k+2} = -\frac{2a_k(k-1)(k-3)}{(k+2)(k+1)}$$

- Solution for $r = -2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = -\frac{2a_k(k-1)(k-3)}{(k+2)(k+1)}, a_1 = 0\right]$$

- Recursion relation for $r = -1$; series terminates at $k = 2$

$$a_{k+2} = -\frac{2a_k k(k-2)}{(k+3)(k+2)}$$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{2a_k k(k-2)}{(k+3)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), a_{k+2} = -\frac{2a_k(k-1)(k-3)}{(k+2)(1+k)}, a_1 = 0, b_{k+2} = -\frac{2b_k k(k-2)}{(k+3)(k+2)}, b_1 = 0\right]$$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.1 Exercises. Page 318
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Regular singular point. Difference is integer"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(x^2+2)\,y''+2x(x^2+5)\,y'+2(-x^2+3)\,y=0}$$

With the expansion point for the power series method at $x = 0$.

The type of the expansion point is first determined. This is done on the homogeneous part of the ODE.

$$(x^4+2x^2)\,y''+(2x^3+10x)\,y'+(-2x^2+6)\,y=0$$

The following is summary of singularities for the above ode. Writing the ode as

$$y''+p(x)y'+q(x)y=0$$

Where

$$p(x)=\frac{2x^2+10}{(x^2+2)\,x}$$
$$q(x)=-\frac{2(x^2-3)}{x^2\,(x^2+2)}$$

Table 458: Table $p(x), q(x)$ singularites.

$p(x) = \frac{2x^2+10}{(x^2+2)x}$	
singularity	type
$x = 0$	"regular"
$x = -i\sqrt{2}$	"regular"
$x = i\sqrt{2}$	"regular"

$q(x) = -\frac{2(x^2-3)}{x^2(x^2+2)}$	
singularity	type
$x = 0$	"regular"
$x = -i\sqrt{2}$	"regular"
$x = i\sqrt{2}$	"regular"

Combining everything together gives the following summary of singularities for the ode as

Regular singular points : $[0, -i\sqrt{2}, i\sqrt{2}, \infty]$

Irregular singular points : $[]$

Since $x = 0$ is regular singular point, then Frobenius power series is used. The ode is normalized to be

$$x^2(x^2+2)\,y'' + (2x^3+10x)\,y' + (-2x^2+6)\,y = 0$$

Let the solution be represented as Frobenius power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^{n+r}$$

Then

$$y' = \sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}$$

$$y'' = \sum_{n=0}^{\infty} (n+r)(n+r-1)\, a_n x^{n+r-2}$$

Substituting the above back into the ode gives

$$x^2(x^2+2)\left(\sum_{n=0}^{\infty} (n+r)(n+r-1)\, a_n x^{n+r-2}\right) + (2x^3+10x)\left(\sum_{n=0}^{\infty} (n+r)\, a_n x^{n+r-1}\right) + (-2x^2+6)\left(\sum_{n=0}^{\infty} a_n x^{n+r}\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r+2} a_n (n+r)\right) + \left(\sum_{n=0}^{\infty} 10x^{n+r} a_n (n+r)\right) + \sum_{n=0}^{\infty} \left(-2x^{n+r+2} a_n\right) + \left(\sum_{n=0}^{\infty} 6a_n x^{n+r}\right) = 0 \tag{2A}$$

The next step is to make all powers of x be $n+r$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n+r} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} x^{n+r+2} a_n (n+r)(n+r-1) = \sum_{n=2}^{\infty} a_{n-2}(n+r-2)(n-3+r)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} 2x^{n+r+2} a_n (n+r) = \sum_{n=2}^{\infty} 2a_{n-2}(n+r-2)\, x^{n+r}$$

$$\sum_{n=0}^{\infty} \left(-2x^{n+r+2} a_n\right) = \sum_{n=2}^{\infty} \left(-2a_{n-2} x^{n+r}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n+r$.

$$\left(\sum_{n=2}^{\infty} a_{n-2}(n+r-2)(n-3+r)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 2x^{n+r} a_n (n+r)(n+r-1)\right) + \left(\sum_{n=2}^{\infty} 2a_{n-2}(n+r-2)\, x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 10x^{n+r} a_n (n+r)\right) + \sum_{n=2}^{\infty} \left(-2a_{n-2} x^{n+r}\right) + \left(\sum_{n=0}^{\infty} 6a_n x^{n+r}\right) = 0 \tag{2B}$$

The indicial equation is obtained from $n=0$. From Eq (2B) this gives

$$2x^{n+r} a_n (n+r)(n+r-1) + 10x^{n+r} a_n (n+r) + 6a_n x^{n+r} = 0$$

When $n = 0$ the above becomes

$$2x^r a_0 r(-1+r) + 10x^r a_0 r + 6a_0 x^r = 0$$

Or

$$(2x^r r(-1+r) + 10x^r r + 6x^r) a_0 = 0$$

Since $a_0 \neq 0$ then the above simplifies to

$$(2r^2 + 8r + 6) x^r = 0$$

Since the above is true for all x then the indicial equation becomes

$$2r^2 + 8r + 6 = 0$$

Solving for r gives the roots of the indicial equation as

$$r_1 = -1$$
$$r_2 = -3$$

Since $a_0 \neq 0$ then the indicial equation becomes

$$(2r^2 + 8r + 6) x^r = 0$$

Solving for r gives the roots of the indicial equation as Since $r_1 - r_2 = 2$ is an integer, then we can construct two linearly independent solutions

$$y_1(x) = x^{r_1} \left(\sum_{n=0}^{\infty} a_n x^n \right)$$
$$y_2(x) = C y_1(x) \ln(x) + x^{r_2} \left(\sum_{n=0}^{\infty} b_n x^n \right)$$

Or

$$y_1(x) = \frac{\sum_{n=0}^{\infty} a_n x^n}{x}$$
$$y_2(x) = C y_1(x) \ln(x) + \frac{\sum_{n=0}^{\infty} b_n x^n}{x^3}$$

Or

$$y_1(x) = \sum_{n=0}^{\infty} a_n x^{n-1}$$
$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n-3} \right)$$

Where C above can be zero. We start by finding y_1. Eq (2B) derived above is now used to find all a_n coefficients. The case $n = 0$ is skipped since it was used to find the roots of the indicial equation. a_0 is arbitrary and taken as $a_0 = 1$. Substituting $n = 1$ in Eq. (2B) gives

$$a_1 = 0$$

For $2 \leq n$ the recursive equation is

$$a_{n-2}(n+r-2)(n-3+r) + 2a_n(n+r)(n+r-1) + 2a_{n-2}(n+r-2) + 10a_n(n+r) - 2a_{n-2} + 6a_n = 0 \tag{3}$$

Solving for a_n from recursive equation (4) gives

$$a_n = -\frac{a_{n-2}(n^2+2nr+r^2-3n-3r)}{2(n^2+2nr+r^2+4n+4r+3)} \tag{4}$$

Which for the root $r = -1$ becomes

$$a_n = -\frac{a_{n-2}(n^2-5n+4)}{2n(n+2)} \tag{5}$$

At this point, it is a good idea to keep track of a_n in a table both before substituting $r = -1$ and after as more terms are found using the above recursive equation.

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0

For $n = 2$, using the above recursive equation gives

$$a_2 = \frac{-r^2-r+2}{2r^2+16r+30}$$

Which for the root $r = -1$ becomes

$$a_2 = \frac{1}{8}$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-r^2-r+2}{2r^2+16r+30}$	$\frac{1}{8}$

For $n = 3$, using the above recursive equation gives

$$a_3 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-r^2-r+2}{2r^2+16r+30}$	$\frac{1}{8}$
a_3	0	0

For $n = 4$, using the above recursive equation gives

$$a_4 = \frac{r^4 + 6r^3 + 7r^2 - 6r - 8}{4\left(r + 5\right)^2 \left(r + 3\right) \left(r + 7\right)}$$

Which for the root $r = -1$ becomes

$$a_4 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-r^2-r+2}{2r^2+16r+30}$	$\frac{1}{8}$
a_3	0	0
a_4	$\frac{r^4+6r^3+7r^2-6r-8}{4(r+5)^2(r+3)(r+7)}$	0

For $n = 5$, using the above recursive equation gives

$$a_5 = 0$$

And the table now becomes

n	$a_{n,r}$	a_n
a_0	1	1
a_1	0	0
a_2	$\frac{-r^2-r+2}{2r^2+16r+30}$	$\frac{1}{8}$
a_3	0	0
a_4	$\frac{r^4+6r^3+7r^2-6r-8}{4(r+5)^2(r+3)(r+7)}$	0
a_5	0	0

Using the above table, then the solution $y_1(x)$ is

$$\begin{aligned} y_1(x) &= \frac{1}{x}\left(a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + a_5 x^5 + a_6 x^6 \dots\right) \\ &= \frac{1 + \frac{x^2}{8} + O(x^6)}{x} \end{aligned}$$

Now the second solution $y_2(x)$ is found. Let

$$r_1 - r_2 = N$$

Where N is positive integer which is the difference between the two roots. r_1 is taken as the larger root. Hence for this problem we have $N = 2$. Now we need to determine if C is zero or not. This is done by finding $\lim_{r \to r_2} a_2(r)$. If this limit exists, then $C = 0$, else we need to keep the log term and $C \neq 0$. The above table shows that

$$\begin{aligned} a_N &= a_2 \\ &= \frac{-r^2 - r + 2}{2r^2 + 16r + 30} \end{aligned}$$

Therefore

$$\begin{aligned} \lim_{r \to r_2} \frac{-r^2 - r + 2}{2r^2 + 16r + 30} &= \lim_{r \to -3} \frac{-r^2 - r + 2}{2r^2 + 16r + 30} \\ &= \textit{undefined} \end{aligned}$$

Since the limit does not exist then the log term is needed. Therefore the second solution has the form

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Therefore

$$\frac{d}{dx}y_2(x) = Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)$$
$$= Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty} x^{-1+n+r_2} b_n(n+r_2)\right)$$
$$\frac{d^2}{dx^2}y_2(x) = Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)$$
$$= Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \left(\sum_{n=0}^{\infty} x^{-2+n+r_2} b_n(n+r_2)(-1+n+r_2)\right)$$

Substituting these back into the given ode $x^2(x^2+2)\,y''+(2x^3+10x)\,y'+(-2x^2+6)\,y = 0$ gives

$$x^2(x^2+2)\left(Cy_1''(x)\ln(x) + \frac{2Cy_1'(x)}{x} - \frac{Cy_1(x)}{x^2} + \sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) + (2x^3+10x)\left(Cy_1'(x)\ln(x) + \frac{Cy_1(x)}{x} + \left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)\right) + (-2x^2+6)\left(Cy_1(x)\ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)\right) = 0$$

Which can be written as

$$\left(\left(x^2(x^2+2)\,y_1''(x) + (2x^3+10x)\,y_1'(x) + (-2x^2+6)\,y_1(x)\right)\ln(x) + x^2(x^2+2)\left(\frac{2y_1'(x)}{x} - \frac{y_1(x)}{x^2}\right) + \frac{(2x^3+10x)\,y_1(x)}{x}\right)C + x^2(x^2+2)\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2} - \frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right) + (2x^3+10x)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right) + (-2x^2+6)\left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right) = 0 \tag{7}$$

But since $y_1(x)$ is a solution to the ode, then

$$x^2(x^2+2)\,y_1''(x)+(2x^3+10x)\,y_1'(x)+(-2x^2+6)\,y_1(x)=0$$

Eq (7) simplifes to

$$\begin{aligned}&\left(x^2(x^2+2)\left(\frac{2y_1'(x)}{x}-\frac{y_1(x)}{x^2}\right)+\frac{(2x^3+10x)\,y_1(x)}{x}\right)C\\&+x^2(x^2+2)\left(\sum_{n=0}^{\infty}\left(\frac{b_n x^{n+r_2}(n+r_2)^2}{x^2}-\frac{b_n x^{n+r_2}(n+r_2)}{x^2}\right)\right)\\&+(2x^3+10x)\left(\sum_{n=0}^{\infty}\frac{b_n x^{n+r_2}(n+r_2)}{x}\right)+(-2x^2+6)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0\end{aligned}\tag{8}$$

Substituting $y_1=\sum_{n=0}^{\infty}a_n x^{n+r_1}$ into the above gives

$$\begin{aligned}&\left(2x(x^2+2)\left(\sum_{n=0}^{\infty}x^{-1+n+r_1}a_n(n+r_1)\right)+(x^2+8)\left(\sum_{n=0}^{\infty}a_n x^{n+r_1}\right)\right)C\\&+(x^4+2x^2)\left(\sum_{n=0}^{\infty}x^{-2+n+r_2}b_n(n+r_2)(-1+n+r_2)\right)\\&+2(x^3+5x)\left(\sum_{n=0}^{\infty}x^{-1+n+r_2}b_n(n+r_2)\right)+2(-x^2+3)\left(\sum_{n=0}^{\infty}b_n x^{n+r_2}\right)=0\end{aligned}\tag{9}$$

Since $r_1=-1$ and $r_2=-3$ then the above becomes

$$\begin{aligned}&\left(2x(x^2+2)\left(\sum_{n=0}^{\infty}x^{n-2}a_n(n-1)\right)+(x^2+8)\left(\sum_{n=0}^{\infty}a_n x^{n-1}\right)\right)C\\&+(x^4+2x^2)\left(\sum_{n=0}^{\infty}x^{-5+n}b_n(n-3)(-4+n)\right)\\&+2(x^3+5x)\left(\sum_{n=0}^{\infty}x^{-4+n}b_n(n-3)\right)+2(-x^2+3)\left(\sum_{n=0}^{\infty}b_n x^{n-3}\right)=0\end{aligned}\tag{10}$$

Which simplifies to

$$\begin{aligned}
&\left(\sum_{n=0}^{\infty} 2C\, x^{1+n} a_n (n-1)\right) + \left(\sum_{n=0}^{\infty} 4C\, x^{n-1} a_n (n-1)\right) + \left(\sum_{n=0}^{\infty} C\, x^{1+n} a_n\right) \\
&+ \left(\sum_{n=0}^{\infty} 8C\, x^{n-1} a_n\right) + \left(\sum_{n=0}^{\infty} x^{n-1} b_n (-4+n)(n-3)\right) \\
&+ \left(\sum_{n=0}^{\infty} 2x^{n-3} b_n (-4+n)(n-3)\right) + \left(\sum_{n=0}^{\infty} 2x^{n-1} b_n (n-3)\right) \\
&+ \left(\sum_{n=0}^{\infty} 10x^{n-3} b_n (n-3)\right) + \sum_{n=0}^{\infty} \left(-2x^{n-1} b_n\right) + \left(\sum_{n=0}^{\infty} 6b_n x^{n-3}\right) = 0
\end{aligned} \tag{2A}$$

The next step is to make all powers of x be $n-3$ in each summation term. Going over each summation term above with power of x in it which is not already x^{n-3} and adjusting the power and the corresponding index gives

$$\sum_{n=0}^{\infty} 2C\, x^{1+n} a_n (n-1) = \sum_{n=4}^{\infty} 2C a_{-4+n} (-5+n)\, x^{n-3}$$

$$\sum_{n=0}^{\infty} 4C\, x^{n-1} a_n (n-1) = \sum_{n=2}^{\infty} 4C a_{n-2} (n-3)\, x^{n-3}$$

$$\sum_{n=0}^{\infty} C\, x^{1+n} a_n = \sum_{n=4}^{\infty} C a_{-4+n} x^{n-3}$$

$$\sum_{n=0}^{\infty} 8C\, x^{n-1} a_n = \sum_{n=2}^{\infty} 8C a_{n-2} x^{n-3}$$

$$\sum_{n=0}^{\infty} x^{n-1} b_n (-4+n)(n-3) = \sum_{n=2}^{\infty} b_{n-2} (-6+n)(-5+n)\, x^{n-3}$$

$$\sum_{n=0}^{\infty} 2x^{n-1} b_n (n-3) = \sum_{n=2}^{\infty} 2b_{n-2} (-5+n)\, x^{n-3}$$

$$\sum_{n=0}^{\infty} \left(-2x^{n-1} b_n\right) = \sum_{n=2}^{\infty} \left(-2b_{n-2} x^{n-3}\right)$$

Substituting all the above in Eq (2A) gives the following equation where now all powers of x are the same and equal to $n-3$.

$$
\begin{aligned}
&\left(\sum_{n=4}^{\infty} 2C a_{-4+n} (-5+n)\, x^{n-3}\right) + \left(\sum_{n=2}^{\infty} 4C a_{n-2} (n-3)\, x^{n-3}\right) \\
&+ \left(\sum_{n=4}^{\infty} C a_{-4+n} x^{n-3}\right) + \left(\sum_{n=2}^{\infty} 8C a_{n-2} x^{n-3}\right) \\
&+ \left(\sum_{n=2}^{\infty} b_{n-2}(-6+n)\,(-5+n)\, x^{n-3}\right) + \left(\sum_{n=0}^{\infty} 2x^{n-3} b_n (-4+n)\,(n-3)\right) \\
&+ \left(\sum_{n=2}^{\infty} 2b_{n-2}(-5+n)\, x^{n-3}\right) + \left(\sum_{n=0}^{\infty} 10x^{n-3} b_n (n-3)\right) \\
&+ \sum_{n=2}^{\infty} \left(-2b_{n-2} x^{n-3}\right) + \left(\sum_{n=0}^{\infty} 6b_n x^{n-3}\right) = 0
\end{aligned} \tag{2B}
$$

For $n=0$ in Eq. (2B), we choose arbitray value for b_0 as $b_0 = 1$. For $n=1$, Eq (2B) gives

$$-2b_1 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-2b_1 = 0$$

Solving the above for b_1 gives

$$b_1 = 0$$

For $n = N$, where $N = 2$ which is the difference between the two roots, we are free to choose $b_2 = 0$. Hence for $n = 2$, Eq (2B) gives

$$4C + 4 = 0$$

Which is solved for C. Solving for C gives

$$C = -1$$

For $n = 3$, Eq (2B) gives

$$8Ca_1 + 6b_3 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$6b_3 = 0$$

Solving the above for b_3 gives

$$b_3 = 0$$

For $n = 4$, Eq (2B) gives

$$(-a_0 + 12a_2)\, C - 2b_2 + 16b_4 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$-\frac{1}{2} + 16b_4 = 0$$

Solving the above for b_4 gives

$$b_4 = \frac{1}{32}$$

For $n = 5$, Eq (2B) gives

$$(a_1 + 16a_3)\, C - 2b_3 + 30b_5 = 0$$

Which when replacing the above values found already for b_n and the values found earlier for a_n and for C, gives

$$30b_5 = 0$$

Solving the above for b_5 gives

$$b_5 = 0$$

Now that we found all b_n and C, we can calculate the second solution from

$$y_2(x) = C y_1(x) \ln(x) + \left(\sum_{n=0}^{\infty} b_n x^{n+r_2}\right)$$

Using the above value found for $C = -1$ and all b_n, then the second solution becomes

$$y_2(x) = (-1) \left(\frac{1 + \frac{x^2}{8} + O(x^6)}{x}\right) \ln(x) + \frac{1 + \frac{x^4}{32} + O(x^6)}{x^3}$$

Therefore the homogeneous solution is

$$\begin{aligned} y_h(x) &= c_1 y_1(x) + c_2 y_2(x) \\ &= \frac{c_1 \left(1 + \frac{x^2}{8} + O(x^6)\right)}{x} + c_2 \left((-1) \left(\frac{1 + \frac{x^2}{8} + O(x^6)}{x}\right) \ln(x) + \frac{1 + \frac{x^4}{32} + O(x^6)}{x^3}\right) \end{aligned}$$

Hence the final solution is

$$
\begin{aligned}
y &= y_h \\
&= \frac{c_1\left(1+\frac{x^2}{8}+O(x^6)\right)}{x}+c_2\left(-\frac{\left(1+\frac{x^2}{8}+O(x^6)\right)\ln(x)}{x}+\frac{1+\frac{x^4}{32}+O(x^6)}{x^3}\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1\left(1+\frac{x^2}{8}+O(x^6)\right)}{x}+c_2\left(-\frac{\left(1+\frac{x^2}{8}+O(x^6)\right)\ln(x)}{x}+\frac{1+\frac{x^4}{32}+O(x^6)}{x^3}\right) \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1\left(1+\frac{x^2}{8}+O(x^6)\right)}{x}+c_2\left(-\frac{\left(1+\frac{x^2}{8}+O(x^6)\right)\ln(x)}{x}+\frac{1+\frac{x^4}{32}+O(x^6)}{x^3}\right)
$$

Verified OK.

11.15.1 Maple step by step solution

Let's solve

$x^2(x^2+2)\,y''+(2x^3+10x)\,y'+(-2x^2+6)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{2(x^2-3)y}{x^2(x^2+2)}-\frac{2(x^2+5)y'}{x(x^2+2)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{2(x^2+5)y'}{x(x^2+2)}-\frac{2(x^2-3)y}{x^2(x^2+2)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{2(x^2+5)}{(x^2+2)x}, P_3(x)=-\frac{2(x^2-3)}{x^2(x^2+2)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 5$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 3$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$x^2(x^2+2)\, y'' + 2x(x^2+5)\, y' + (-2x^2+6)\, y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^m \cdot y''$ to series expansion for $m = 2..4$

  $$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

$$2a_0(3+r)(1+r)x^r + 2a_1(4+r)(2+r)x^{1+r} + \left(\sum_{k=2}^{\infty} (2a_k(k+r+3)(k+r+1) + a_{k-2}(k+r)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$2(3+r)(1+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{-3, -1\}$$

- Each term must be 0

  $$2a_1(4+r)(2+r) = 0$$

- Solve for the dependent coefficient(s)

  $$a_1 = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$2a_k(k+r+3)(k+r+1) + a_{k-2}(k+r)(k-3+r) = 0$$

- Shift index using $k- >k+2$

  $$2a_{k+2}(k+5+r)(k+r+3) + a_k(k+r+2)(k+r-1) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{a_k(k+r+2)(k+r-1)}{2(k+5+r)(k+r+3)}$$

- Recursion relation for $r = -3$; series terminates at $k = 4$

  $$a_{k+2} = -\frac{a_k(k-1)(k-4)}{2(k+2)k}$$

- Solution for $r = -3$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k-3}, a_{k+2} = -\frac{a_k(k-1)(k-4)}{2(k+2)k}, a_1 = 0\right]$$

- Recursion relation for $r = -1$; series terminates at $k = 2$

  $$a_{k+2} = -\frac{a_k(k+1)(k-2)}{2(k+4)(k+2)}$$

- Solution for $r = -1$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a_k(k+1)(k-2)}{2(k+4)(k+2)}, a_1 = 0\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k x^{k-3}\right) + \left(\sum_{k=0}^{\infty} b_k x^{k-1}\right), a_{k+2} = -\frac{a_k(k-1)(-4+k)}{2(k+2)k}, a_1 = 0, b_{k+2} = -\frac{b_k(1+k)(k-2)}{2(4+k)(k+2)}, b_1 = 0\right]$$

Problem number: 1.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\,y''+6y'x+6y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots\\
&= y_0+xy'_0+\frac{x^2}{2}\,f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}\,f'|_{x_0,y_0,y'_0}+\cdots\\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\,\frac{d^nf}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{818}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{819}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)!}F_n\big|_{x_0,y_0,y'_0} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{6(y'x+y)}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{36y'x^2 + 48yx - 12y'}{(x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{240(-x^3+x)\, y' + 120(-3x^2+1)\, y}{(x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{360(5x^4 - 10x^2 + 1)\, y' + 2880(x^3 - x)\, y}{(x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-15120x^5 + 50400x^3 - 15120x)\, y' - 25200y\left(x^4 - 2x^2 + \frac{1}{5}\right)}{(x^2+1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -6y(0) \\
F_1 &= -12y'(0) \\
F_2 &= 120y(0) \\
F_3 &= 360y'(0) \\
F_4 &= -5040y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(-7x^6 + 5x^4 - 3x^2 + 1\right) y(0) + \left(3x^5 - 2x^3 + x\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$\left(x^2+1\right) y'' + 6y'x + 6y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$\left(x^2+1\right)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + 6\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 6\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 6n a_n x^n\right) + \left(\sum_{n=0}^{\infty} 6a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{aligned}\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) \\ + \left(\sum_{n=1}^{\infty} 6n a_n x^n\right) + \left(\sum_{n=0}^{\infty} 6a_n x^n\right) = 0\end{aligned} \tag{3}$$

$n = 0$ gives

$$2a_2 + 6a_0 = 0$$

$$a_2 = -3a_0$$

$n = 1$ gives

$$6a_3 + 12a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -2a_1$$

For $2 \leq n$, the recurrence equation is

$$na_n(n-1) + (n+2)\,a_{n+2}(n+1) + 6na_n + 6a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{(n+3)\,a_n}{n+1} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$20a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = 5a_0$$

For $n = 3$ the recurrence equation gives

$$30a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 3a_1$$

For $n = 4$ the recurrence equation gives

$$42a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = -7a_0$$

For $n = 5$ the recurrence equation gives

$$56a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = -4a_1$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = 3a_1 x^5 + 5a_0 x^4 - 2a_1 x^3 - 3a_0 x^2 + a_1 x + a_0 + \dots$$

Collecting terms, the solution becomes

$$y = (5x^4 - 3x^2 + 1)\, a_0 + (3x^5 - 2x^3 + x)\, a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = (5x^4 - 3x^2 + 1)\, c_1 + (3x^5 - 2x^3 + x)\, c_2 + O(x^6)$$

<u>Summary</u>
The solution(s) found are the following

$$y = (-7x^6 + 5x^4 - 3x^2 + 1)\, y(0) + (3x^5 - 2x^3 + x)\, y'(0) + O(x^6) \tag{1}$$
$$y = (5x^4 - 3x^2 + 1)\, c_1 + (3x^5 - 2x^3 + x)\, c_2 + O(x^6) \tag{2}$$

<u>Verification of solutions</u>

$$y = (-7x^6 + 5x^4 - 3x^2 + 1)\, y(0) + (3x^5 - 2x^3 + x)\, y'(0) + O(x^6)$$

Verified OK.

$$y = (5x^4 - 3x^2 + 1)\, c_1 + (3x^5 - 2x^3 + x)\, c_2 + O(x^6)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.2 SERIES SOLUTIONS NEAR AN ORDINARY POINT I. Exercises 7.2. Page 329
Problem number: 2.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second_order_change_of_variable_on_y_method_2", "second order series method. Taylor series method", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\,y''+2y'x-2y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using

Taylor series gives

$$
\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + x y_0' + \frac{x^2}{2} f|_{x_0, y_0, y_0'} + \frac{x^3}{3!} f'|_{x_0, y_0, y_0'} + \cdots \\
&= y_0 + x y_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)\,!} \frac{d^n f}{dx^n}\bigg|_{x_0, y_0, y_0'}
\end{aligned}
$$

But

$$
\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} y'' && (821) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y} y' + \frac{\partial f}{\partial y'} f && (822) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right) y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right) f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right) y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right) f && (3) \\
&\vdots
\end{aligned}
$$

And so on. Hence if we name $F_0 = f(x, y, y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x, y, y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0, y_0, y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{2(-y+y'x)}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{8(-y+y'x)\, x}{(x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -\frac{8(-y+y'x)\,(5x^2-1)}{(x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{240\left(x^2-\frac{3}{5}\right)(-y+y'x)\, x}{(x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= -\frac{48(-y+y'x)\,(35x^4-42x^2+3)}{(x^2+1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 2y(0) \\
F_1 &= 0 \\
F_2 &= -8y(0) \\
F_3 &= 0 \\
F_4 &= 144y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 + x^2 - \frac{1}{3}x^4 + \frac{1}{5}x^6\right) y(0) + y'(0)\, x + O\!\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x^2+1)\,y''+2y'x-2y=0$$

Let the solution be represented as power series of the form

$$y=\sum_{n=0}^{\infty} a_n x^n$$

Then

$$y'=\sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y''=\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(x^2+1)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+2\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right)x-2\left(\sum_{n=0}^{\infty} a_n x^n\right)=0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right)+\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right)+\left(\sum_{n=1}^{\infty} 2n a_n x^n\right)+\sum_{n=0}^{\infty}(-2a_n x^n)=0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}=\sum_{n=0}^{\infty}(n+2)\,a_{n+2}(n+1)\,x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{gathered}\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right)+\left(\sum_{n=0}^{\infty}(n+2)\,a_{n+2}(n+1)\,x^n\right)\\+\left(\sum_{n=1}^{\infty} 2n a_n x^n\right)+\sum_{n=0}^{\infty}(-2a_n x^n)=0\end{gathered} \tag{3}$$

$n = 0$ gives

$$2a_2 - 2a_0 = 0$$

$$a_2 = a_0$$

For $2 \leq n$, the recurrence equation is

$$na_n(n-1) + (n+2)\, a_{n+2}(n+1) + 2na_n - 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{(n-1)\, a_n}{n+1} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$4a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = -\frac{a_0}{3}$$

For $n = 3$ the recurrence equation gives

$$10a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 0$$

For $n = 4$ the recurrence equation gives

$$18a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = \frac{a_0}{5}$$

For $n = 5$ the recurrence equation gives

$$28a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + a_0 x^2 - \frac{1}{3} a_0 x^4 + \dots$$

Collecting terms, the solution becomes

$$y = \left(1 + x^2 - \frac{1}{3}x^4\right) a_0 + a_1 x + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = \left(1 + x^2 - \frac{1}{3}x^4\right) c_1 + c_2 x + O(x^6)$$

Summary

The solution(s) found are the following

$$y = \left(1 + x^2 - \frac{1}{3}x^4 + \frac{1}{5}x^6\right) y(0) + y'(0)\, x + O(x^6) \tag{1}$$

$$y = \left(1 + x^2 - \frac{1}{3}x^4\right) c_1 + c_2 x + O(x^6) \tag{2}$$

Verification of solutions

$$y = \left(1 + x^2 - \frac{1}{3}x^4 + \frac{1}{5}x^6\right) y(0) + y'(0)\, x + O(x^6)$$

Verified OK.

$$y = \left(1 + x^2 - \frac{1}{3}x^4\right) c_1 + c_2 x + O(x^6)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.2 SERIES SOLUTIONS NEAR AN ORDINARY POINT I. Exercises 7.2. Page 329
Problem number: 3.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^2+1)\, y'' - 8y'x + 20y = 0}$$

With the expansion point for the power series method at $x = 0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y'' = f(x, y, y')$$

Assuming expansion is at $x_0 = 0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x, y, y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0) = y_0$ and $y'(x_0) = y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0) + (x - x_0)\, y'(x_0) + \frac{(x - x_0)^2}{2} y''(x_0) + \frac{(x - x_0)^3}{3!} y'''(x_0) + \cdots \\
&= y_0 + xy'_0 + \frac{x^2}{2} f|_{x_0,y_0,y'_0} + \frac{x^3}{3!} f'|_{x_0,y_0,y'_0} + \cdots \\
&= y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} \frac{d^n f}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (824)\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (825)\\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2)\\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)\\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3)\\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$
y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}F_n|_{x_0,y_0,y_0'} \qquad (7)
$$

To find $y(x)$ series solution around $x = 0$. Hence

$$\begin{aligned}
F_0 &= \frac{8y'x - 20y}{x^2+1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{36y'x^2 - 120yx - 12y'}{(x^2+1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{96x^3y' - 360x^2y - 96y'x + 120y}{(x^2+1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{24(5x^4 - 10x^2 + 1)\, y' + 480(-x^3 + x)\, y}{(x^2+1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= 0
\end{aligned}$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$\begin{aligned}
F_0 &= -20y(0) \\
F_1 &= -12y'(0) \\
F_2 &= 120y(0) \\
F_3 &= 24y'(0) \\
F_4 &= 0
\end{aligned}$$

Substituting all the above in (7) and simplifying gives the solution as

$$y = (5x^4 - 10x^2 + 1)\, y(0) + \left(x - 2x^3 + \frac{1}{5}x^5\right) y'(0) + O(x^6)$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(x^2+1)\,y'' - 8y'x + 20y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(x^2+1)\left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) - 8\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 20\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2}\right) + \sum_{n=1}^{\infty} (-8n a_n x^n) + \left(\sum_{n=0}^{\infty} 20 a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\,a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\,a_{n+2}(n+1)\,x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{aligned}&\left(\sum_{n=2}^{\infty} x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\,a_{n+2}(n+1)\,x^n\right)\\&+\sum_{n=1}^{\infty} (-8n a_n x^n) + \left(\sum_{n=0}^{\infty} 20 a_n x^n\right) = 0\end{aligned} \tag{3}$$

$n = 0$ gives

$$2a_2 + 20a_0 = 0$$

$$a_2 = -10a_0$$

$n = 1$ gives

$$6a_3 + 12a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -2a_1$$

For $2 \leq n$, the recurrence equation is

$$na_n(n-1) + (n+2)\,a_{n+2}(n+1) - 8na_n + 20a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{a_n(n^2 - 9n + 20)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$6a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = 5a_0$$

For $n = 3$ the recurrence equation gives

$$2a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{a_1}{5}$$

For $n = 4$ the recurrence equation gives

$$30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = 0$$

For $n = 5$ the recurrence equation gives

$$42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 0$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x - 10a_0 x^2 - 2a_1 x^3 + 5a_0 x^4 + \frac{1}{5} a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = (5x^4 - 10x^2 + 1)\, a_0 + \left(x - 2x^3 + \frac{1}{5}x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = (5x^4 - 10x^2 + 1)\, c_1 + \left(x - 2x^3 + \frac{1}{5}x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$y = (5x^4 - 10x^2 + 1)\, y(0) + \left(x - 2x^3 + \frac{1}{5}x^5\right) y'(0) + O(x^6) \tag{1}$$

$$y = (5x^4 - 10x^2 + 1)\, c_1 + \left(x - 2x^3 + \frac{1}{5}x^5\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$y = (5x^4 - 10x^2 + 1)\, y(0) + \left(x - 2x^3 + \frac{1}{5}x^5\right) y'(0) + O(x^6)$$

Verified OK.

$$y = (5x^4 - 10x^2 + 1)\, c_1 + \left(x - 2x^3 + \frac{1}{5}x^5\right) c_2 + O(x^6)$$

Verified OK.

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.2 SERIES SOLUTIONS NEAR AN ORDINARY POINT I. Exercises 7.2. Page 329
Problem number: 4.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

`[_Gegenbauer]`

$$\boxed{\left(-x^{2}+1\right) y''-8y'x-12y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\,y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy'_0+\frac{x^2}{2}f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}f'|_{x_0,y_0,y'_0}+\cdots \\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\left.\frac{d^nf}{dx^n}\right|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\frac{df}{dx} = \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} \tag{1}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' \tag{827}$$

$$= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \tag{828}$$

$$\frac{d^2 f}{dx^2} = \frac{d}{dx}\left(\frac{df}{dx}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f \tag{2}$$

$$\frac{d^3 f}{dx^3} = \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right)$$

$$= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f \tag{3}$$

$$\vdots$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$
\begin{aligned}
F_0 &= f(x,y,y') && (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 && (6)
\end{aligned}
$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy_0' + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y_0'} \tag{7}$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{4(2y'x + 3y)}{x^2 - 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{60y'x^2 + 120yx + 20y'}{(x^2 - 1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= -\frac{120(4x^3y' + 9x^2y + 4y'x + 3y)}{(x^2 - 1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(4200x^4 + 8400x^2 + 840)\, y' + 10080xy(x^2 + 1)}{(x^2 - 1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-40320x^5 - 134400x^3 - 40320x)\, y' - 100800\left(x^4 + 2x^2 + \frac{1}{5}\right) y}{(x^2 - 1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= 12y(0) \\
F_1 &= 20y'(0) \\
F_2 &= 360y(0) \\
F_3 &= 840y'(0) \\
F_4 &= 20160y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(28x^6 + 15x^4 + 6x^2 + 1\right) y(0) + \left(x + \frac{10}{3}x^3 + 7x^5\right) y'(0) + O\left(x^6\right)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(-x^2+1)\, y'' - 8y'x - 12y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(-x^2+1)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) - 8\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x - 12\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\sum_{n=2}^{\infty} \left(-x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \sum_{n=1}^{\infty} \left(-8n a_n x^n\right) + \sum_{n=0}^{\infty} \left(-12 a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\sum_{n=2}^{\infty} \left(-x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) + \sum_{n=1}^{\infty} \left(-8n a_n x^n\right) + \sum_{n=0}^{\infty} \left(-12 a_n x^n\right) = 0 \tag{3}$$

$n = 0$ gives

$$2a_2 - 12a_0 = 0$$

$$a_2 = 6a_0$$

$n = 1$ gives

$$6a_3 - 20a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = \frac{10a_1}{3}$$

For $2 \leq n$, the recurrence equation is

$$-na_n(n-1) + (n+2)\,a_{n+2}(n+1) - 8na_n - 12a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = \frac{a_n(n^2 + 7n + 12)}{(n+2)\,(n+1)} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$-30a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = 15a_0$$

For $n = 3$ the recurrence equation gives

$$-42a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = 7a_1$$

For $n = 4$ the recurrence equation gives

$$-56a_4 + 30a_6 = 0$$

Which after substituting the earlier terms found becomes

$$a_6 = 28a_0$$

For $n = 5$ the recurrence equation gives

$$-72a_5 + 42a_7 = 0$$

Which after substituting the earlier terms found becomes

$$a_7 = 12a_1$$

And so on. Therefore the solution is

$$\begin{aligned} y &= \sum_{n=0}^{\infty} a_n x^n \\ &= a_3 x^3 + a_2 x^2 + a_1 x + a_0 + \dots \end{aligned}$$

Substituting the values for a_n found above, the solution becomes

$$y = a_0 + a_1 x + 6a_0 x^2 + \frac{10}{3} a_1 x^3 + 15a_0 x^4 + 7a_1 x^5 + \dots$$

Collecting terms, the solution becomes

$$y = (15x^4 + 6x^2 + 1) a_0 + \left(x + \frac{10}{3}x^3 + 7x^5\right) a_1 + O(x^6) \tag{3}$$

At $x = 0$ the solution above becomes

$$y = (15x^4 + 6x^2 + 1) c_1 + \left(x + \frac{10}{3}x^3 + 7x^5\right) c_2 + O(x^6)$$

Summary

The solution(s) found are the following

$$y = (28x^6 + 15x^4 + 6x^2 + 1) y(0) + \left(x + \frac{10}{3}x^3 + 7x^5\right) y'(0) + O(x^6) \tag{1}$$

$$y = (15x^4 + 6x^2 + 1) c_1 + \left(x + \frac{10}{3}x^3 + 7x^5\right) c_2 + O(x^6) \tag{2}$$

Verification of solutions

$$y = (28x^6 + 15x^4 + 6x^2 + 1)\, y(0) + \left(x + \frac{10}{3}x^3 + 7x^5\right) y'(0) + O(x^6)$$

Verified OK.

$$y = (15x^4 + 6x^2 + 1)\, c_1 + \left(x + \frac{10}{3}x^3 + 7x^5\right) c_2 + O(x^6)$$

Verified OK.

12.4.1 Maple step by step solution

Let's solve

$(-x^2 + 1)\, y'' - 8y'x - 12y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{8xy'}{x^2-1} - \frac{12y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{8xy'}{x^2-1} + \frac{12y}{x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{8x}{x^2-1}, P_3(x) = \frac{12}{x^2-1}\right]$

  ◦ $(x+1) \cdot P_2(x)$ is analytic at $x = -1$

  $\left((x+1) \cdot P_2(x)\right)\Big|_{x=-1} = 4$

  ◦ $(x+1)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $\left((x+1)^2 \cdot P_3(x)\right)\Big|_{x=-1} = 0$

  ◦ $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

$$\left(x^2-1\right) y''+8y'x+12y=0$$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$$\left(u^2-2u\right)\left(\frac{d^2}{du^2}y(u)\right)+(8u-8)\left(\frac{d}{du}y(u)\right)+12y(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

◦ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

◦ Shift index using $k->k+1-m$

$$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

◦ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

◦ Shift index using $k->k+2-m$

$$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0r(3+r)\, u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)\,(k+r+4)+a_k(k+r+4)\,(k+r+3)\right) u^{k+r}\right)=$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2r(3+r)=0$$

- Values of r that satisfy the indicial equation

$$r\in\{-3,0\}$$

- Each term in the series must be 0, giving the recursion relation

$$\left((-2k-2r-2)\, a_{k+1}+a_k(k+r+3)\right)(k+r+4)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{a_k(k+r+3)}{2(k+1+r)}$$

- Recursion relation for $r=-3$

$a_{k+1} = \frac{a_k k}{2(k-2)}$

- Series not valid for $r = -3$, division by 0 in the recursion relation at $k = 2$

  $a_{k+1} = \frac{a_k k}{2(k-2)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(k+3)}{2(k+1)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k+3)}{2(k+1)}\right]$

- Revert the change of variables $u = x + 1$

  $\left[y = \sum_{k=0}^{\infty} a_k(x+1)^k, a_{k+1} = \frac{a_k(k+3)}{2(k+1)}\right]$

Book: Elementary differential equations with boundary value problems. William F. Trench. Brooks/Cole 2001
Section: Chapter 7 Series Solutions of Linear Second Equations. 7.2 SERIES SOLUTIONS NEAR AN ORDINARY POINT I. Exercises 7.2. Page 329
Problem number: 5.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second order series method. Ordinary point", "second order series method. Taylor series method"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(2x^2+1)\, y''+7y'x+2y=0}$$

With the expansion point for the power series method at $x=0$.

Solving ode using Taylor series method. This gives review on how the Taylor series method works for solving second order ode.

Let

$$y''=f(x,y,y')$$

Assuming expansion is at $x_0=0$ (we can always shift the actual expansion point to 0 by change of variables) and assuming $f(x,y,y')$ is analytic at x_0 which must be the case for an ordinary point. Let initial conditions be $y(x_0)=y_0$ and $y'(x_0)=y'_0$. Using Taylor series gives

$$\begin{aligned}
y(x) &= y(x_0)+(x-x_0)\, y'(x_0)+\frac{(x-x_0)^2}{2}y''(x_0)+\frac{(x-x_0)^3}{3!}y'''(x_0)+\cdots \\
&= y_0+xy'_0+\frac{x^2}{2}\, f|_{x_0,y_0,y'_0}+\frac{x^3}{3!}\, f'|_{x_0,y_0,y'_0}+\cdots \\
&= y_0+xy'_0+\sum_{n=0}^{\infty}\frac{x^{n+2}}{(n+2)\,!}\,\frac{d^nf}{dx^n}\bigg|_{x_0,y_0,y'_0}
\end{aligned}$$

But

$$\begin{aligned}
\frac{df}{dx} &= \frac{\partial f}{\partial x}\frac{dx}{dx} + \frac{\partial f}{\partial y}\frac{dy}{dx} + \frac{\partial f}{\partial y'}\frac{dy'}{dx} && (1) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y'' && (830) \\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f && (831) \\
\frac{d^2 f}{dx^2} &= \frac{d}{dx}\left(\frac{df}{dx}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{df}{dx}\right) + \frac{\partial}{\partial y}\left(\frac{df}{dx}\right)y' + \frac{\partial}{\partial y'}\left(\frac{df}{dx}\right)f && (2) \\
\frac{d^3 f}{dx^3} &= \frac{d}{dx}\left(\frac{d^2 f}{dx^2}\right) \\
&= \frac{\partial}{\partial x}\left(\frac{d^2 f}{dx^2}\right) + \left(\frac{\partial}{\partial y}\frac{d^2 f}{dx^2}\right)y' + \frac{\partial}{\partial y'}\left(\frac{d^2 f}{dx^2}\right)f && (3) \\
&\vdots
\end{aligned}$$

And so on. Hence if we name $F_0 = f(x,y,y')$ then the above can be written as

$$\begin{aligned}
F_0 &= f(x,y,y') \qquad (4)\\
F_1 &= \frac{df}{dx}\\
&= \frac{dF_0}{dx}\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}y''\\
&= \frac{\partial f}{\partial x} + \frac{\partial f}{\partial y}y' + \frac{\partial f}{\partial y'}f \qquad (5)\\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y}y' + \frac{\partial F_0}{\partial y'}F_0\\
F_2 &= \frac{d}{dx}\left(\frac{d}{dx}f\right)\\
&= \frac{d}{dx}(F_1)\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_1 + \left(\frac{\partial F_1}{\partial y}\right)y' + \left(\frac{\partial F_1}{\partial y'}\right)F_0\\
&\vdots\\
F_n &= \frac{d}{dx}(F_{n-1})\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)y''\\
&= \frac{\partial}{\partial x}F_{n-1} + \left(\frac{\partial F_{n-1}}{\partial y}\right)y' + \left(\frac{\partial F_{n-1}}{\partial y'}\right)F_0 \qquad (6)
\end{aligned}$$

Therefore (6) can be used from now on along with

$$y(x) = y_0 + xy'_0 + \sum_{n=0}^{\infty} \frac{x^{n+2}}{(n+2)!} F_n|_{x_0,y_0,y'_0} \qquad (7)$$

To find $y(x)$ series solution around $x = 0$. Hence

$$
\begin{aligned}
F_0 &= -\frac{7y'x + 2y}{2x^2 + 1} \\
F_1 &= \frac{dF_0}{dx} \\
&= \frac{\partial F_0}{\partial x} + \frac{\partial F_0}{\partial y} y' + \frac{\partial F_0}{\partial y'} F_0 \\
&= \frac{59y'x^2 + 22yx - 9y'}{(2x^2 + 1)^2} \\
F_2 &= \frac{dF_1}{dx} \\
&= \frac{\partial F_1}{\partial x} + \frac{\partial F_1}{\partial y} y' + \frac{\partial F_1}{\partial y'} F_1 \\
&= \frac{-605x^3y' - 250x^2y + 275y'x + 40y}{(2x^2 + 1)^3} \\
F_3 &= \frac{dF_2}{dx} \\
&= \frac{\partial F_2}{\partial x} + \frac{\partial F_2}{\partial y} y' + \frac{\partial F_2}{\partial y'} F_2 \\
&= \frac{(7365x^4 - 6660x^2 + 315)\, y' + (3210x^3 - 1530x)\, y}{(2x^2 + 1)^4} \\
F_4 &= \frac{dF_3}{dx} \\
&= \frac{\partial F_3}{\partial x} + \frac{\partial F_3}{\partial y} y' + \frac{\partial F_3}{\partial y'} F_3 \\
&= \frac{(-104055x^5 + 156150x^3 - 22095x)\, y' + (-46830x^4 + 44370x^2 - 2160)\, y}{(2x^2 + 1)^5}
\end{aligned}
$$

And so on. Evaluating all the above at initial conditions $x = 0$ and $y(0) = y(0)$ and $y'(0) = y'(0)$ gives

$$
\begin{aligned}
F_0 &= -2y(0) \\
F_1 &= -9y'(0) \\
F_2 &= 40y(0) \\
F_3 &= 315y'(0) \\
F_4 &= -2160y(0)
\end{aligned}
$$

Substituting all the above in (7) and simplifying gives the solution as

$$
y = \left(1 - x^2 + \frac{5}{3}x^4 - 3x^6\right) y(0) + \left(x - \frac{3}{2}x^3 + \frac{21}{8}x^5\right) y'(0) + O(x^6)
$$

Since the expansion point $x = 0$ is an ordinary, we can also solve this using standard power series The ode is normalized to be

$$(2x^2+1)\, y'' + 7y'x + 2y = 0$$

Let the solution be represented as power series of the form

$$y = \sum_{n=0}^{\infty} a_n x^n$$

Then

$$y' = \sum_{n=1}^{\infty} n a_n x^{n-1}$$
$$y'' = \sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}$$

Substituting the above back into the ode gives

$$(2x^2+1)\left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + 7\left(\sum_{n=1}^{\infty} n a_n x^{n-1}\right) x + 2\left(\sum_{n=0}^{\infty} a_n x^n\right) = 0 \tag{1}$$

Which simplifies to

$$\left(\sum_{n=2}^{\infty} 2x^n a_n n(n-1)\right) + \left(\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2}\right) + \left(\sum_{n=1}^{\infty} 7n a_n x^n\right) + \left(\sum_{n=0}^{\infty} 2a_n x^n\right) = 0 \tag{2}$$

The next step is to make all powers of x be n in each summation term. Going over each summation term above with power of x in it which is not already x^n and adjusting the power and the corresponding index gives

$$\sum_{n=2}^{\infty} n(n-1)\, a_n x^{n-2} = \sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n$$

Substituting all the above in Eq (2) gives the following equation where now all powers of x are the same and equal to n.

$$\begin{aligned}\left(\sum_{n=2}^{\infty} 2x^n a_n n(n-1)\right) + \left(\sum_{n=0}^{\infty} (n+2)\, a_{n+2}(n+1)\, x^n\right) \\ + \left(\sum_{n=1}^{\infty} 7n a_n x^n\right) + \left(\sum_{n=0}^{\infty} 2a_n x^n\right) = 0\end{aligned} \tag{3}$$

$n = 0$ gives

$$2a_2 + 2a_0 = 0$$

$$a_2 = -a_0$$

$n = 1$ gives

$$6a_3 + 9a_1 = 0$$

Which after substituting earlier equations, simplifies to

$$a_3 = -\frac{3a_1}{2}$$

For $2 \leq n$, the recurrence equation is

$$2na_n(n-1) + (n+2)\, a_{n+2}(n+1) + 7na_n + 2a_n = 0 \tag{4}$$

Solving for a_{n+2}, gives

$$a_{n+2} = -\frac{(2n+1)\, a_n}{n+1} \tag{5}$$

For $n = 2$ the recurrence equation gives

$$20a_2 + 12a_4 = 0$$

Which after substituting the earlier terms found becomes

$$a_4 = \frac{5a_0}{3}$$

For $n = 3$ the recurrence equation gives

$$35a_3 + 20a_5 = 0$$

Which after substituting the earlier terms found becomes

$$a_5 = \frac{21a_1}{8}$$
