The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 f(x) + ax \ln(x) f(x) y = a \ln(x) + a}$$

19.27.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x) y^2 - ax \ln(x) f(x) y + a \ln(x) + a \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x) y^2 - ax \ln(x) f(x) y + a \ln(x) + a$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = a \ln(x) + a$, $f_1(x) = -f(x) \ln(x) ax$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x) u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$f_2' = f'(x)$$
$$f_1f_2 = -xf(x)^2 \ln(x)\,a$$
$$f_2^2f_0 = f(x)^2\,(a\ln(x) + a)$$

Substituting the above terms back in equation (2) gives

$$f(x)\,u''(x) - \left(-xf(x)^2 \ln(x)\,a + f'(x)\right) u'(x) + f(x)^2\,(a\ln(x) + a)\,u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \text{DESol}\left(\left\{\_Y''(x) - \frac{\left(-xf(x)^2 \ln(x)\,a + f'(x)\right)\_Y'(x)}{f(x)} + a(1+\ln(x))\,f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x}\text{DESol}\left(\left\{\_Y''(x) - \frac{\left(-xf(x)^2 \ln(x)\,a + f'(x)\right)\_Y'(x)}{f(x)} + a(1+\ln(x))\,f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x}\text{DESol}\left(\left\{\_Y''(x) - \frac{\left(-xf(x)^2 \ln(x)a + f'(x)\right)\_Y'(x)}{f(x)} + a(1+\ln(x))\,f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)}{f(x)\,\text{DESol}\left(\left\{\_Y''(x) - \frac{\left(-xf(x)^2 \ln(x)a + f'(x)\right)\_Y'(x)}{f(x)} + a(1+\ln(x))\,f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\frac{\_Y''(x) f(x)+\left(x f(x)^{2} \ln(x) a-f'(x)\right)\_Y'(x)+a(1+\ln(x)) f(x)^{2}\_Y(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{f(x) \operatorname{DESol}\left(\left\{\frac{\_Y''(x) f(x)+\left(x f(x)^{2} \ln(x) a-f'(x)\right)\_Y'(x)+a(1+\ln(x)) f(x)^{2}\_Y(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\frac{\_Y''(x) f(x)+\left(x f(x)^{2} \ln(x) a-f'(x)\right)\_Y'(x)+a(1+\ln(x)) f(x)^{2}\_Y(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{f(x) \operatorname{DESol}\left(\left\{\frac{\_Y''(x) f(x)+\left(x f(x)^{2} \ln(x) a-f'(x)\right)\_Y'(x)+a(1+\ln(x)) f(x)^{2}\_Y(x)}{f(x)}\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\frac{\_Y''(x) f(x)+\left(x f(x)^{2} \ln(x) a-f'(x)\right)\_Y'(x)+a(1+\ln(x)) f(x)^{2}\_Y(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{f(x) \operatorname{DESol}\left(\left\{\frac{\_Y''(x) f(x)+\left(x f(x)^{2} \ln(x) a-f'(x)\right)\_Y'(x)+a(1+\ln(x)) f(x)^{2}\_Y(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-1. Equations containing arbitrary functions (but not containing their derivatives).
Problem number: 28.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' + a\ln(x)\,y^2 - af(x)\,(\ln(x)\,x - x)\,y = -f(x)}$$

19.28.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= ax\ln(x)\,f(x)\,y - f(x)\,axy - a\ln(x)\,y^2 - f(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = ax\ln(x)\,f(x)\,y - f(x)\,axy - a\ln(x)\,y^2 - f(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -f(x)$, $f_1(x) = f(x)\ln(x)\,ax - axf(x)$ and $f_2(x) = -a\ln(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-a\ln(x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{a}{x} \\ f_1 f_2 &= -(f(x)\ln(x) a x - a x f(x)) a \ln(x) \\ f_2^2 f_0 &= -a^2 f(x) \ln(x)^2 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-a\ln(x) u''(x) - \left(-(f(x)\ln(x) a x - a x f(x)) a \ln(x) - \frac{a}{x}\right) u'(x) - a^2 f(x) \ln(x)^2 u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = x(\ln(x) - 1)\left(c_2\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_1\right)$$

The above shows that

$$u'(x) = \frac{x c_2 \ln(x)(\ln(x)-1)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_2 e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx} + c_1 x \ln(x)(\ln}{x(\ln(x)-1)}$$

Using the above in (1) gives the solution

$$y = \frac{x c_2 \ln(x)(\ln(x)-1)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_2 e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx} + c_1 x \ln(x)(\ln}{x^2(\ln(x)-1)^2 a\ln(x)\left(c_2\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_1\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{x \ln(x)(\ln(x)-1)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_3 x \ln(x)^2 - \ln(x) c_3 x + e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x)a}{x\ln(x)}}}{x^2(\ln(x)-1)^2 a \ln(x)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx + c_3\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{x \ln(x)(\ln(x)-1)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_3 x \ln(x)^2 - \ln(x) c_3 x + e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x)a}{x\ln(x)}}}{x^2(\ln(x)-1)^2 a \ln(x)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx + c_3\right)} \tag{1}$$

Verification of solutions

$$y = \frac{x \ln(x)(\ln(x)-1)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx\right) + c_3 x \ln(x)^2 - \ln(x) c_3 x + e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x)a}{x\ln(x)}}}{x^2(\ln(x)-1)^2 a \ln(x)\left(\int \frac{e^{\int \frac{f(x)\ln(x)^2 a x^2 - f(x)\ln(x) a x^2 + 1}{x\ln(x)}dx}}{x^2(\ln(x)-1)^2}dx + c_3\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-1. Equations containing arbitrary functions (but not containing their derivatives).
Problem number: 29.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - \lambda \sin(\lambda x)\, y^2 - f(x) \cos(\lambda x)\, y = -f(x)}$$

19.29.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \lambda \sin(\lambda x)\, y^2 + f(x) \cos(\lambda x)\, y - f(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \lambda \sin(\lambda x)\, y^2 + f(x) \cos(\lambda x)\, y - f(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -f(x)$, $f_1(x) = \cos(\lambda x)\, f(x)$ and $f_2(x) = \lambda \sin(\lambda x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\lambda \sin(\lambda x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned}
f_2' &= \lambda^2 \cos(\lambda x) \\
f_1 f_2 &= \cos(\lambda x) f(x) \lambda \sin(\lambda x) \\
f_2^2 f_0 &= -\lambda^2 \sin(\lambda x)^2 f(x)
\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\lambda \sin(\lambda x) u''(x) - \left(\cos(\lambda x) f(x) \lambda \sin(\lambda x) + \lambda^2 \cos(\lambda x)\right) u'(x) - \lambda^2 \sin(\lambda x)^2 f(x) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = -\cos(\lambda x)\left(c_2 \lambda \left(\int e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \sin(\lambda x)\, dx\right) - c_1\right)$$

The above shows that

$$\begin{aligned}
u'(x) = -\lambda \sin(\lambda x) \Bigg(&\cos(\lambda x)\, c_2 e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \\
&- c_2 \lambda \left(\int e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \sin(\lambda x)\, dx\right) + c_1\Bigg)
\end{aligned}$$

Using the above in (1) gives the solution

$$y = -\frac{\cos(\lambda x)\, c_2 e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} - c_2 \lambda \left(\int e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \sin(\lambda x)\, dx\right) + c_1}{\cos(\lambda x)\left(c_2 \lambda \left(\int e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \sin(\lambda x)\, dx\right) - c_1\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\sec(\lambda x) \lambda \left(\int e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \sin(\lambda x)\, dx\right) - \sec(\lambda x) c_3 - e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx}}{\lambda \left(\int e^{\int (\cos(\lambda x) f(x) + 2\tan(\lambda x)\lambda) dx} \sin(\lambda x)\, dx\right) - c_3}$$

Summary
The solution(s) found are the following

$$y = \frac{\sec(\lambda x)\,\lambda\left(\int e^{\int (\cos(\lambda x) f(x)+2\tan(\lambda x)\lambda)dx}\sin(\lambda x)\,dx\right) - \sec(\lambda x)\,c_3 - e^{\int (\cos(\lambda x) f(x)+2\tan(\lambda x)\lambda)dx}}{\lambda\left(\int e^{\int (\cos(\lambda x) f(x)+2\tan(\lambda x)\lambda)dx}\sin(\lambda x)\,dx\right) - c_3} \tag{1}$$

Verification of solutions

$$y = \frac{\sec(\lambda x)\,\lambda\left(\int e^{\int (\cos(\lambda x) f(x)+2\tan(\lambda x)\lambda)dx}\sin(\lambda x)\,dx\right) - \sec(\lambda x)\,c_3 - e^{\int (\cos(\lambda x) f(x)+2\tan(\lambda x)\lambda)dx}}{\lambda\left(\int e^{\int (\cos(\lambda x) f(x)+2\tan(\lambda x)\lambda)dx}\sin(\lambda x)\,dx\right) - c_3}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-1. Equations containing arbitrary functions (but not containing their derivatives).
Problem number: 30.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 f(x) = -f(x)\, a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2}$$

19.30.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)\, y^2 - f(x)\, a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x)\, y^2 - f(x)\, a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -f(x)\, a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2$, $f_1(x) = 0$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f'(x) \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= f(x)^2 \left(-f(x) a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2\right) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f(x) u''(x) - f'(x) u'(x) + f(x)^2 \left(-f(x) a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$\begin{aligned} u(x) = \mathrm{DESol}\Bigg(\bigg\{ & \_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} \\ & + f(x) \left(-f(x) a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2\right) \_Y(x)\bigg\}, \{\_Y(x)\}\Bigg) \end{aligned}$$

The above shows that

$$\begin{aligned} u'(x) = \frac{\partial}{\partial x} \mathrm{DESol}\Bigg(\bigg\{ & \_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} \\ & + f(x) \left(-f(x) a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2\right) \_Y(x)\bigg\}, \{\_Y(x)\}\Bigg) \end{aligned}$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} + f(x) \left(-f(x) a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2\right) \_Y(x)\right\}, \{\_\right.}{f(x) \mathrm{DESol}\left(\left\{\_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} + f(x) \left(-f(x) a^2 + a\lambda \sin(\lambda x) + a^2 f(x) \sin(\lambda x)^2\right) \_Y(x)\right\}, \right.}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\frac{f(x)^2 \sin(\lambda x)\_Y(x) a\lambda - f(x)^3 \_Y(x) a^2 \cos(\lambda x)^2 + \_Y''(x) f(x) - f'(x)\_Y'(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{f(x)^2 \sin(\lambda x)\_Y(x) a\lambda - f(x)^3 \_Y(x) a^2 \cos(\lambda x)^2 + \_Y''(x) f(x) - f'(x)\_Y'(x)}{f(x)}\right\}, \{\_Y(x)\}\right) f(x)}$$

Summary
The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{f(x)^{2}\sin(\lambda x)\_Y(x)a\lambda - f(x)^{3}\_Y(x)a^{2}\cos(\lambda x)^{2} + \_Y''(x)f(x) - f'(x)\_Y'(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{f(x)^{2}\sin(\lambda x)\_Y(x)a\lambda - f(x)^{3}\_Y(x)a^{2}\cos(\lambda x)^{2} + \_Y''(x)f(x) - f'(x)\_Y'(x)}{f(x)}\right\}, \{\_Y(x)\}\right)f(x)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{f(x)^{2}\sin(\lambda x)\_Y(x)a\lambda - f(x)^{3}\_Y(x)a^{2}\cos(\lambda x)^{2} + \_Y''(x)f(x) - f'(x)\_Y'(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{f(x)^{2}\sin(\lambda x)\_Y(x)a\lambda - f(x)^{3}\_Y(x)a^{2}\cos(\lambda x)^{2} + \_Y''(x)f(x) - f'(x)\_Y'(x)}{f(x)}\right\}, \{\_Y(x)\}\right)f(x)}$$

Verified OK.

Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-1. Equations containing arbitrary functions (but not containing their derivatives).
Problem number: 31.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{y' - f(x)\, y^2 = -a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2}$$

19.31.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= f(x)\, y^2 - a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2 \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x)\, y^2 - a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2$, $f_1(x) = 0$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f'(x) \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= f(x)^2 \left(-a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2\right) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f(x)\, u''(x) - f'(x)\, u'(x) + f(x)^2 \left(-a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$\begin{aligned} u(x) = \mathrm{DESol}\Bigg(\Bigg\{&\_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} \\ &+ f(x)\left(-a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2\right)\_Y(x)\Bigg\}, \{\_Y(x)\}\Bigg) \end{aligned}$$

The above shows that

$$\begin{aligned} u'(x) = \frac{d}{dx} \mathrm{DESol}\Bigg(\Bigg\{&\_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} \\ &+ f(x)\left(-a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2\right)\_Y(x)\Bigg\}, \{\_Y(x)\}\Bigg) \end{aligned}$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{d}{dx} \mathrm{DESol}\left(\left\{\_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} + f(x)\left(-a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2\right)\_Y(x)\right\}, \{\_\right.}{f(x)\, \mathrm{DESol}\left(\left\{\_Y''(x) - \frac{f'(x)\_Y'(x)}{f(x)} + f(x)\left(-a^2 f(x) + a\lambda \cos(\lambda x) + a^2 f(x) \cos(\lambda x)^2\right)\_Y(x)\right\},\right.}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{d}{dx} \mathrm{DESol}\left(\left\{\frac{-f(x)^3 \sin(\lambda x)^2 \_Y(x) a^2 + \cos(\lambda x) f(x)^2 \_Y(x) a\lambda - f'(x)\_Y'(x) + \_Y''(x) f(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}{f(x)\, \mathrm{DESol}\left(\left\{\frac{-f(x)^3 \sin(\lambda x)^2 \_Y(x) a^2 + \cos(\lambda x) f(x)^2 \_Y(x) a\lambda - f'(x)\_Y'(x) + \_Y''(x) f(x)}{f(x)}\right\}, \{\_Y(x)\}\right)}$$

Summary
The solution(s) found are the following

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{-f(x)^3\sin(\lambda x)^2\_\_Y(x)a^2+\cos(\lambda x)f(x)^2\_\_Y(x)a\lambda-f'(x)\_\_Y'(x)+\_\_Y''(x)f(x)}{f(x)}\right\},\{\_\_Y(x)\}\right)}{f(x)\operatorname{DESol}\left(\left\{\frac{-f(x)^3\sin(\lambda x)^2\_\_Y(x)a^2+\cos(\lambda x)f(x)^2\_\_Y(x)a\lambda-f'(x)\_\_Y'(x)+\_\_Y''(x)f(x)}{f(x)}\right\},\{\_\_Y(x)\}\right)} \quad (1)$$

Verification of solutions

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{-f(x)^3\sin(\lambda x)^2\_\_Y(x)a^2+\cos(\lambda x)f(x)^2\_\_Y(x)a\lambda-f'(x)\_\_Y'(x)+\_\_Y''(x)f(x)}{f(x)}\right\},\{\_\_Y(x)\}\right)}{f(x)\operatorname{DESol}\left(\left\{\frac{-f(x)^3\sin(\lambda x)^2\_\_Y(x)a^2+\cos(\lambda x)f(x)^2\_\_Y(x)a\lambda-f'(x)\_\_Y'(x)+\_\_Y''(x)f(x)}{f(x)}\right\},\{\_\_Y(x)\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-1. Equations containing arbitrary functions (but not containing their derivatives).
Problem number: 32.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

Unable to solve or complete the solution.

$$\boxed{y' - f(x)\, y^2 = -a \tan(\lambda x)^2 \,(a f(x) - \lambda) + a\lambda}$$

19.32.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -f(x) \tan(\lambda x)^2 \, a^2 + \tan(\lambda x)^2 \, a\lambda + f(x)\, y^2 + a\lambda \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -f(x) \tan(\lambda x)^2 \, a^2 + \tan(\lambda x)^2 \, a\lambda + f(x)\, y^2 + a\lambda$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -f(x)\tan(\lambda x)^2 a^2 + \tan(\lambda x)^2 a\lambda + a\lambda$, $f_1(x) = 0$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f'(x) \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= f(x)^2 \left(-f(x)\tan(\lambda x)^2 a^2 + \tan(\lambda x)^2 a\lambda + a\lambda\right) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f(x)\, u''(x) - f'(x)\, u'(x) + f(x)^2 \left(-f(x)\tan(\lambda x)^2 a^2 + \tan(\lambda x)^2 a\lambda + a\lambda\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives Unable to solve. Terminating.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-1. Equations containing arbitrary functions (but not containing their derivatives).
Problem number: 33.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

Unable to solve or complete the solution.

$$\boxed{y' - f(x)\,y^2 = -a\cot(\lambda x)^2\,(af(x) - \lambda) + a\lambda}$$

19.33.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= -f(x)\cot(\lambda x)^2\,a^2 + \cot(\lambda x)^2\,a\lambda + f(x)\,y^2 + a\lambda \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -f(x)\cot(\lambda x)^2\,a^2 + \cot(\lambda x)^2\,a\lambda + f(x)\,y^2 + a\lambda$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -f(x)\cot(\lambda x)^2 a^2 + \cot(\lambda x)^2 a\lambda + a\lambda$, $f_1(x) = 0$ and $f_2(x) = f(x)$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{f(x)\, u}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= f'(x) \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= f(x)^2 \left(-f(x)\cot(\lambda x)^2 a^2 + \cot(\lambda x)^2 a\lambda + a\lambda\right)
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
f(x)\, u''(x) - f'(x)\, u'(x) + f(x)^2 \left(-f(x)\cot(\lambda x)^2 a^2 + \cot(\lambda x)^2 a\lambda + a\lambda\right) u(x) = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives Unable to solve. Terminating.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{y' - y^2 = -f(x)^2 + f'(x)}$$

20.1.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= y^2 - f(x)^2 + f'(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 - f(x)^2 + f'(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -f(x)^2 + f'(x)$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned}
f_2' &= 0 \\
f_1f_2 &= 0 \\
f_2^2 f_0 &= -f(x)^2 + f'(x)
\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \left(-f(x)^2 + f'(x)\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \left(\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx + c_1\right) \mathrm{e}^{-\left(\int f(x)dx\right)} c_2$$

The above shows that

$$u'(x) = c_2\left(\mathrm{e}^{\int f(x)dx} - f(x)\, c_1\mathrm{e}^{-\left(\int f(x)dx\right)} - f(x)\left(\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx\right) \mathrm{e}^{-\left(\int f(x)dx\right)}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\left(\mathrm{e}^{\int f(x)dx} - f(x)\, c_1\mathrm{e}^{-\left(\int f(x)dx\right)} - f(x)\left(\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx\right) \mathrm{e}^{-\left(\int f(x)dx\right)}\right) \mathrm{e}^{\int f(x)dx}}{\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx + c_1}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-\mathrm{e}^{2\left(\int f(x)dx\right)} + c_3f(x) + \left(\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx\right) f(x)}{\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx + c_3}$$

Summary

The solution(s) found are the following

$$y = \frac{-\mathrm{e}^{2\left(\int f(x)dx\right)} + c_3f(x) + \left(\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx\right) f(x)}{\int \mathrm{e}^{2\left(\int f(x)dx\right)}dx + c_3} \tag{1}$$

Verification of solutions

$$y = \frac{-e^{2\left(\int f(x)dx\right)} + c_3 f(x) + \left(\int e^{2\left(\int f(x)dx\right)}dx\right) f(x)}{\int e^{2\left(\int f(x)dx\right)}dx + c_3}$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{y' - f(x)\,y^2 + f(x)\,g(x)\,y = g'(x)}$$

20.2.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)\,y^2 - f(x)\,g(x)\,y + g'(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x)\,y^2 - f(x)\,g(x)\,y + g'(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = g'(x)$, $f_1(x) = -f(x)\,g(x)$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f'(x) \\ f_1 f_2 &= -f(x)^2 g(x) \\ f_2^2 f_0 &= f(x)^2 g'(x) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f(x) u''(x) - \left(f'(x) - f(x)^2 g(x)\right) u'(x) + f(x)^2 g'(x) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} \left(c_1 + \left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx} dx\right) c_2\right)$$

The above shows that

$$u'(x) \\ = f(x) \left(-g(x)\, \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} \left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx} dx\right) c_2 - g(x)\, \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} c_1 + c_2\right)$$

Using the above in (1) gives the solution

$$y = \\ -\frac{\left(-g(x)\, \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} \left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx} dx\right) c_2 - g(x)\, \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} c_1 + c_2\right) \mathrm{e}^{\int f(x)g(x)dx}}{c_1 + \left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx} dx\right) c_2}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx} dx\right) g(x) + c_3 g(x) - \mathrm{e}^{\int f(x)g(x)dx}}{c_3 + \int f(x)\, \mathrm{e}^{\int f(x)g(x)dx} dx}$$

Summary

The solution(s) found are the following

$$y = \frac{\left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx}dx\right) g(x) + c_3 g(x) - \mathrm{e}^{\int f(x)g(x)dx}}{c_3 + \int f(x)\, \mathrm{e}^{\int f(x)g(x)dx}dx} \tag{1}$$

Verification of solutions

$$y = \frac{\left(\int f(x)\, \mathrm{e}^{\int f(x)g(x)dx}dx\right) g(x) + c_3 g(x) - \mathrm{e}^{\int f(x)g(x)dx}}{c_3 + \int f(x)\, \mathrm{e}^{\int f(x)g(x)dx}dx}$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' + f'(x)\, y^2 - f(x)\, g(x)\, y = -g(x)}$$

20.3.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= -f'(x)\, y^2 + f(x)\, g(x)\, y - g(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -f'(x)\, y^2 + f(x)\, g(x)\, y - g(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -g(x)$, $f_1(x) = f(x)\, g(x)$ and $f_2(x) = -f'(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{-f'(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -f''(x) \\ f_1f_2 &= -f(x)\,g(x)\,f'(x) \\ f_2^2 f_0 &= -f'(x)^2 g(x) \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$-f'(x)\,u''(x) - (-f''(x) - f(x)\,g(x)\,f'(x))\,u'(x) - f'(x)^2 g(x)\,u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = f(x)\left(c_1 + c_2\left(\int \frac{e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2}dx\right)\right)$$

The above shows that

$$u'(x) = \frac{f'(x)\,f(x)\left(\int \frac{e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2}dx\right)c_2 + f'(x)\,f(x)\,c_1 + c_2 e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)}$$

Using the above in (1) gives the solution

$$y = \frac{f'(x)\,f(x)\left(\int \frac{e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2}dx\right)c_2 + f'(x)\,f(x)\,c_1 + c_2 e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2 f'(x)\left(c_1 + c_2\left(\int \frac{e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2}dx\right)\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{\left(\int \frac{e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2}dx\right)f(x)\,f'(x) + f'(x)\,f(x)\,c_3 + e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2 f'(x)\left(c_3 + \int \frac{e^{\int \frac{f(x)g(x)f'(x)+f''(x)}{f'(x)}dx}}{f(x)^2}dx\right)}$$

Summary
The solution(s) found are the following

$$y = \frac{\left(\int \frac{e^{\int \frac{f(x) g(x) f'(x)+f''(x)}{f'(x)}dx}}{f(x)^{2}}dx\right) f(x) f'(x) + f'(x) f(x) c_{3} + e^{\int \frac{f(x) g(x) f'(x)+f''(x)}{f'(x)}dx}}{f\left(x\right)^{2} f'\left(x\right) \left(c_{3} + \int \frac{e^{\int \frac{f(x) g(x) f'(x)+f''(x)}{f'(x)}dx}}{f(x)^{2}}dx\right)} \tag{1}$$

Verification of solutions

$$y = \frac{\left(\int \frac{e^{\int \frac{f(x) g(x) f'(x)+f''(x)}{f'(x)}dx}}{f(x)^{2}}dx\right) f(x) f'(x) + f'(x) f(x) c_{3} + e^{\int \frac{f(x) g(x) f'(x)+f''(x)}{f'(x)}dx}}{f\left(x\right)^{2} f'\left(x\right) \left(c_{3} + \int \frac{e^{\int \frac{f(x) g(x) f'(x)+f''(x)}{f'(x)}dx}}{f(x)^{2}}dx\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-2. Equations containing arbitrary functions and their derivatives.
Problem number: 37.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[[_1st_order, `_with_symmetry_[F(x),G(x)]`], _Riccati]
```

$$\boxed{y' - g(x)\,(y - f(x))^2 = f'(x)}$$

20.4.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)^2\, g(x) - 2f(x)\, g(x)\, y + g(x)\, y^2 + f'(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x)^2\, g(x) - 2f(x)\, g(x)\, y + g(x)\, y^2 + f'(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = f(x)^2\, g(x) + f'(x)$, $f_1(x) = -2f(x)\, g(x)$ and $f_2(x) = g(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{g(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned}
f_2' &= g'(x) \\
f_1 f_2 &= -2f(x)\, g(x)^2 \\
f_2^2 f_0 &= g(x)^2 \left(f(x)^2 g(x) + f'(x)\right)
\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$g(x)\, u''(x) - \left(g'(x) - 2f(x)\, g(x)^2\right) u'(x) + g(x)^2 \left(f(x)^2 g(x) + f'(x)\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \left(c_1 + \int g(x)\, dx\right) \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} c_2$$

The above shows that

$$u'(x) = g(x)\, \mathrm{e}^{-\left(\int f(x)g(x)dx\right)} c_2 \left(1 - f(x) \left(\int g(x)\, dx\right) - c_1 f(x)\right)$$

Using the above in (1) gives the solution

$$y = -\frac{1 - f(x) \left(\int g(x)\, dx\right) - c_1 f(x)}{c_1 + \int g\,(x)\, dx}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-1 + f(x) \left(\int g(x)\, dx\right) + c_3 f(x)}{c_3 + \int g\,(x)\, dx}$$

Summary
The solution(s) found are the following

$$y = \frac{-1 + f(x) \left(\int g(x)\, dx\right) + c_3 f(x)}{c_3 + \int g\,(x)\, dx} \tag{1}$$

Verification of solutions

$$y = \frac{-1 + f(x) \left(\int g(x) \, dx\right) + c_3 f(x)}{c_3 + \int g(x) \, dx}$$

Verified OK.

20.5 problem 38

Internal problem ID [10631]
Internal file name [`OUTPUT/9578_Monday_June_06_2022_03_10_47_PM_6587525/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-2. Equations containing arbitrary functions and their derivatives.
Problem number: 38.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - \frac{f'(x)\, y^2}{g\left(x\right)} = -\frac{g'(x)}{f\left(x\right)}}$$

20.5.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{f'(x)\, y^2 f(x) - g(x)\, g'(x)}{g\left(x\right) f\left(x\right)} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{f'(x)\, y^2}{g\left(x\right)} - \frac{g'(x)}{f\left(x\right)}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = -\frac{g'(x)}{f(x)}$, $f_1(x) = 0$ and $f_2(x) = \frac{f'(x)}{g(x)}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{f'(x)u}{g(x)}}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= -\frac{f'(x)\, g'(x)}{g(x)^2} + \frac{f''(x)}{g(x)} \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= -\frac{f'(x)^2 g'(x)}{g(x)^2 f(x)}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{f'(x)\, u''(x)}{g(x)} - \left(-\frac{f'(x)\, g'(x)}{g(x)^2} + \frac{f''(x)}{g(x)}\right) u'(x) - \frac{f'(x)^2 g'(x)\, u(x)}{g(x)^2 f(x)} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = \mathrm{DESol}\left(\left\{\_Y''(x) - \frac{\left(-\frac{f'(x)g'(x)}{g(x)^2} + \frac{f''(x)}{g(x)}\right) g(x)\_Y'(x)}{f'(x)} - \frac{f'(x)\, g'(x)\_Y(x)}{g(x)\, f(x)}\right\}, \{\_Y(x)\}\right)
$$

The above shows that

$$
u'(x) = \frac{d}{dx}\mathrm{DESol}\left(\left\{\_Y''(x) - \frac{\left(-\frac{f'(x)g'(x)}{g(x)^2} + \frac{f''(x)}{g(x)}\right) g(x)\_Y'(x)}{f'(x)} - \frac{f'(x)\, g'(x)\_Y(x)}{g(x)\, f(x)}\right\}, \{\_Y(x)\}\right)
$$

Using the above in (1) gives the solution

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\_Y''(x) - \frac{\left(-\frac{f'(x)g'(x)}{g(x)^2} + \frac{f''(x)}{g(x)}\right)g(x)\_Y'(x)}{f'(x)} - \frac{f'(x)g'(x)\_Y(x)}{g(x)f(x)}\right\}, \{\_Y(x)\}\right)\right)g(x)}{f'(x)\operatorname{DESol}\left(\left\{\_Y''(x) - \frac{\left(-\frac{f'(x)g'(x)}{g(x)^2} + \frac{f''(x)}{g(x)}\right)g(x)\_Y'(x)}{f'(x)} - \frac{f'(x)g'(x)\_Y(x)}{g(x)f(x)}\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x)g(x)f(x)f'(x) - f(x)g(x)f''(x)\_Y'(x) + f'(x)g'(x)\left(\_Y'(x)f(x) - \_Y(x)f'(x)\right)}{g(x)f'(x)f(x)}\right\}, \{\_Y(x)\}\right)\right)g(x)}{f'(x)\operatorname{DESol}\left(\left\{\frac{\_Y''(x)g(x)f(x)f'(x) - f(x)g(x)f''(x)\_Y'(x) + f'(x)g'(x)\left(\_Y'(x)f(x) - \_Y(x)f'(x)\right)}{g(x)f'(x)f(x)}\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x)g(x)f(x)f'(x) - f(x)g(x)f''(x)\_Y'(x) + f'(x)g'(x)\left(\_Y'(x)f(x) - \_Y(x)f'(x)\right)}{g(x)f'(x)f(x)}\right\}, \{\_Y(x)\}\right)\right)g(x)}{f'(x)\operatorname{DESol}\left(\left\{\frac{\_Y''(x)g(x)f(x)f'(x) - f(x)g(x)f''(x)\_Y'(x) + f'(x)g'(x)\left(\_Y'(x)f(x) - \_Y(x)f'(x)\right)}{g(x)f'(x)f(x)}\right\}, \{\_Y(x)\}\right)} \quad (1)$$

Verification of solutions

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x)g(x)f(x)f'(x) - f(x)g(x)f''(x)\_Y'(x) + f'(x)g'(x)\left(\_Y'(x)f(x) - \_Y(x)f'(x)\right)}{g(x)f'(x)f(x)}\right\}, \{\_Y(x)\}\right)\right)g(x)}{f'(x)\operatorname{DESol}\left(\left\{\frac{\_Y''(x)g(x)f(x)f'(x) - f(x)g(x)f''(x)\_Y'(x) + f'(x)g'(x)\left(\_Y'(x)f(x) - \_Y(x)f'(x)\right)}{g(x)f'(x)f(x)}\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-2. Equations containing arbitrary functions and their derivatives.
Problem number: 39.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{f(x)^2 y' - f'(x) y^2 + g(x) (y - f(x)) = 0}$$

20.6.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{f'(x) y^2 + f(x) g(x) - y g(x)}{f(x)^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{f'(x) y^2}{f(x)^2} + \frac{g(x)}{f(x)} - \frac{g(x) y}{f(x)^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{g(x)}{f(x)}$, $f_1(x) = -\frac{g(x)}{f(x)^2}$ and $f_2(x) = \frac{f'(x)}{f(x)^2}$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{\frac{f'(x)u}{f(x)^2}} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= -\frac{2f'(x)^2}{f(x)^3} + \frac{f''(x)}{f(x)^2} \\ f_1 f_2 &= -\frac{g(x)\, f'(x)}{f(x)^4} \\ f_2^2 f_0 &= \frac{f'(x)^2 g(x)}{f(x)^5} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$\frac{f'(x)\, u''(x)}{f(x)^2} - \left(-\frac{2f'(x)^2}{f(x)^3} + \frac{f''(x)}{f(x)^2} - \frac{g(x)\, f'(x)}{f(x)^4}\right) u'(x) + \frac{f'(x)^2 g(x)\, u(x)}{f(x)^5} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_Y'(x) + \_Y''(x)\, f(x)^3 f'(x) - f(x)^3 f''(x) \_Y'(x) + f'(x)^2 g(x) \_Y(x) + f'(x}{f(x)^3 f'(x)}\right.\right.$$

The above shows that

$$u'(x) = \frac{d}{dx} \mathrm{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_Y'(x) + \_Y''(x)\, f(x)^3 f'(x) - f(x)^3 f''(x) \_Y'(x) + f'(x)^2 g(x) \_Y(x) + f}{f(x)^3 f'(x)}\right.\right.$$

Using the above in (1) gives the solution

$$y = -\frac{\left(\frac{d}{dx} \mathrm{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_Y'(x) + \_Y''(x) f(x)^3 f'(x) - f(x)^3 f''(x) \_Y'(x) + f'(x)^2 g(x) \_Y(x) + f'(x) f(x) g(x) \_Y'(x)}{f(x)^3 f'(x)}\right\}, \{\_\right.\right.}{f'(x)\, \mathrm{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_Y'(x) + \_Y''(x) f(x)^3 f'(x) - f(x)^3 f''(x) \_Y'(x) + f'(x)^2 g(x) \_Y(x) + f'(x) f(x) g(x) \_Y'(x)}{f(x)^3 f'(x)}\right\}\right.}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_\_Y'(x)+\_\_Y''(x) f(x)^3 f'(x)-f(x)^3 f''(x) \_\_Y'(x)+f'(x)^2 g(x) \_\_Y(x)+f'(x) f(x) g(x) \_\_Y'(x)}{f(x)^3 f'(x)}\right\}, \{\_\right.\right.}{f'(x)\operatorname{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_\_Y'(x)+\_\_Y''(x) f(x)^3 f'(x)-f(x)^3 f''(x) \_\_Y'(x)+f'(x)^2 g(x) \_\_Y(x)+f'(x) f(x) g(x) \_\_Y'(x)}{f(x)^3 f'(x)}\right\}\right.}$$

Summary

The solution(s) found are the following

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_\_Y'(x)+\_\_Y''(x) f(x)^3 f'(x)-f(x)^3 f''(x) \_\_Y'(x)+f'(x)^2 g(x) \_\_Y(x)+f'(x) f(x) g(x) \_\_Y'(x)}{f(x)^3 f'(x)}\right\}, \{\_\right.\right.}{f'(x)\operatorname{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_\_Y'(x)+\_\_Y''(x) f(x)^3 f'(x)-f(x)^3 f''(x) \_\_Y'(x)+f'(x)^2 g(x) \_\_Y(x)+f'(x) f(x) g(x) \_\_Y'(x)}{f(x)^3 f'(x)}\right\}\right.} \tag{1}$$

Verification of solutions

$$y = -\frac{\left(\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_\_Y'(x)+\_\_Y''(x) f(x)^3 f'(x)-f(x)^3 f''(x) \_\_Y'(x)+f'(x)^2 g(x) \_\_Y(x)+f'(x) f(x) g(x) \_\_Y'(x)}{f(x)^3 f'(x)}\right\}, \{\_\right.\right.}{f'(x)\operatorname{DESol}\left(\left\{\frac{2f'(x)^2 f(x)^2 \_\_Y'(x)+\_\_Y''(x) f(x)^3 f'(x)-f(x)^3 f''(x) \_\_Y'(x)+f'(x)^2 g(x) \_\_Y(x)+f'(x) f(x) g(x) \_\_Y'(x)}{f(x)^3 f'(x)}\right\}\right.}$$

Verified OK.

Internal file name [OUTPUT/9580_Monday_June_06_2022_03_10_52_PM_112628/index.tex]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-2. Equations containing arbitrary functions and their derivatives.
Problem number: 40.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{y' - f'(x)\, y^2 - a\, e^{\lambda x} f(x)\, y = a\, e^{\lambda x}}$$

20.7.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f'(x)\, y^2 + a\, e^{\lambda x} f(x)\, y + a\, e^{\lambda x} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f'(x)\, y^2 + a\, e^{\lambda x} f(x)\, y + a\, e^{\lambda x}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = a\, e^{\lambda x}$, $f_1(x) = a\, e^{\lambda x} f(x)$ and $f_2(x) = f'(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f'(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f''(x) \\ f_1 f_2 &= a\,e^{\lambda x} f(x) f'(x) \\ f_2^2 f_0 &= f'(x)^2 a\,e^{\lambda x} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f'(x) u''(x) - \left(f''(x) + a\,e^{\lambda x} f(x) f'(x)\right) u'(x) + f'(x)^2 a\,e^{\lambda x} u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = f(x)\left(c_1 + c_2\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right)\right)$$

The above shows that

$$u'(x) = \frac{f'(x) f(x)\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right) c_2 + f'(x) f(x) c_1 + c_2 e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)}$$

Using the above in (1) gives the solution

$$y = -\frac{f'(x) f(x)\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right) c_2 + f'(x) f(x) c_1 + c_2 e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2 f'(x)\left(c_1 + c_2\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right)\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = \frac{-\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right) f(x) f'(x) - f'(x) f(x) c_3 - e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2 f'(x)\left(c_3 + \int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right)}$$

Summary

The solution(s) found are the following

$$y = \frac{-\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right) f(x)\, f'(x) - f'(x)\, f(x)\, c_3 - e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f\left(x\right)^2 f'\left(x\right) \left(c_3 + \int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right)} \tag{1}$$

Verification of solutions

$$y = \frac{-\left(\int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right) f(x)\, f'(x) - f'(x)\, f(x)\, c_3 - e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f\left(x\right)^2 f'\left(x\right) \left(c_3 + \int \frac{e^{\int \frac{f''(x)+a\,e^{\lambda x} f(x) f'(x)}{f'(x)}dx}}{f(x)^2}dx\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.8-2. Equations containing arbitrary functions and their derivatives.
Problem number: 41.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - f(x)\, y^2 - g'(x)\, y = a f(x)\, \mathrm{e}^{2g(x)}}$$

20.8.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)\, y^2 + g'(x)\, y + a f(x)\, \mathrm{e}^{2g(x)} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x)\, y^2 + g'(x)\, y + a f(x)\, \mathrm{e}^{2g(x)}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = a f(x)\, \mathrm{e}^{2g(x)}$, $f_1(x) = g'(x)$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x)\, u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f'(x) \\ f_1f_2 &= f(x)\, g'(x) \\ f_2^2 f_0 &= f(x)^3\, a\, \mathrm{e}^{2g(x)} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f(x)\, u''(x) - (f'(x) + f(x)\, g'(x))\, u'(x) + f(x)^3\, a\, \mathrm{e}^{2g(x)} u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = c_1 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} + c_2 \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}$$

The above shows that

$$u'(x) = i\sqrt{a}\, f(x)\, \mathrm{e}^{g(x)} \left(c_1 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} - c_2 \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{i\sqrt{a}\, \mathrm{e}^{g(x)} \left(c_1 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} - c_2 \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}\right)}{c_1 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} + c_2 \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{i\sqrt{a}\, \mathrm{e}^{g(x)} \left(c_3 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} - \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}\right)}{c_3 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} + \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}}$$

Summary

The solution(s) found are the following

$$y = -\frac{i\sqrt{a}\, \mathrm{e}^{g(x)} \left(c_3 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} - \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}\right)}{c_3 \mathrm{e}^{i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)} + \mathrm{e}^{-i\sqrt{a}\,\left(\int f(x)\mathrm{e}^{g(x)}dx\right)}} \tag{1}$$

Verification of solutions

$$y = -\frac{i\sqrt{a}\, e^{g(x)} \left(c_3 e^{i\sqrt{a}\,\left(\int f(x) e^{g(x)} dx\right)} - e^{-i\sqrt{a}\,\left(\int f(x) e^{g(x)} dx\right)}\right)}{c_3 e^{i\sqrt{a}\,\left(\int f(x) e^{g(x)} dx\right)} + e^{-i\sqrt{a}\,\left(\int f(x) e^{g(x)} dx\right)}}$$

Verified OK.

Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{y' - y^2 = a^2 f(ax + b)}$$

21.1.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= y^2 + a^2 f(ax + b) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + a^2 f(ax + b)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = a^2 f(ax + b)$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$f_2' = 0$$
$$f_1 f_2 = 0$$
$$f_2^2 f_0 = a^2 f(ax + b)$$

Substituting the above terms back in equation (2) gives

$$u''(x) + a^2 f(ax + b) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x} \operatorname{DESol}\left(\left\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\right\}, \left\{\_Y(x)\right\}\right)}{\operatorname{DESol}\left(\left\{a^2 f(ax+b)\_Y(x) + \_Y''(x)\right\}, \left\{\_Y(x)\right\}\right)}$$

Verified OK.

Internal file name [`OUTPUT/9584_Monday_June_06_2022_03_10_58_PM_85596946/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = \frac{f\left(\frac{1}{x}\right)}{x^4}}$$

21.2.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{y^2x^4 + f\left(\frac{1}{x}\right)}{x^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + \frac{f\left(\frac{1}{x}\right)}{x^4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{f\left(\frac{1}{x}\right)}{x^4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= 0 \\ f_2^2f_0 &= \frac{f\left(\frac{1}{x}\right)}{x^4} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \frac{f\left(\frac{1}{x}\right)u(x)}{x^4} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\frac{f\left(\frac{1}{x}\right)\_Y(x)}{x^4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{d}{dx}\,\mathrm{DESol}\left(\left\{\frac{f\left(\frac{1}{x}\right)\_Y(x)}{x^4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{d}{dx}\,\mathrm{DESol}\left(\left\{\frac{f\left(\frac{1}{x}\right)\_Y(x)}{x^4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{f\left(\frac{1}{x}\right)\_Y(x)}{x^4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{d}{dx}\,\mathrm{DESol}\left(\left\{\frac{\_Y''(x)x^4 + f\left(\frac{1}{x}\right)\_Y(x)}{x^4}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{\_Y''(x)x^4 + f\left(\frac{1}{x}\right)\_Y(x)}{x^4}\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x)\,x^4 + f\left(\frac{1}{x}\right)\_Y(x)}{x^4}\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\frac{\_Y''(x)\,x^4 + f\left(\frac{1}{x}\right)\_Y(x)}{x^4}\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x)\,x^4 + f\left(\frac{1}{x}\right)\_Y(x)}{x^4}\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\frac{\_Y''(x)\,x^4 + f\left(\frac{1}{x}\right)\_Y(x)}{x^4}\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

21.3 problem 3

Internal problem ID [10638]
Internal file name [`OUTPUT/9585_Monday_June_06_2022_03_10_59_PM_98380475/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 3.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = \frac{f\left(\frac{ax+b}{cx+d}\right)}{(cx+d)^4}}$$

21.3.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{c^4x^4y^2 + 4c^3d\,x^3y^2 + 6c^2d^2x^2y^2 + 4c\,d^3x\,y^2 + d^4y^2 + f\left(\frac{ax+b}{cx+d}\right)}{(cx+d)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{c^4x^4y^2}{(cx+d)^4} + \frac{4c^3d\,x^3y^2}{(cx+d)^4} + \frac{6c^2d^2x^2y^2}{(cx+d)^4} + \frac{4c\,d^3x\,y^2}{(cx+d)^4} + \frac{d^4y^2}{(cx+d)^4} + \frac{f\left(\frac{ax+b}{cx+d}\right)}{(cx+d)^4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{f\left(\frac{ax+b}{cx+d}\right)}{(cx+d)^4}$, $f_1(x) = 0$ and $f_2(x) = \frac{c^4x^4+4c^3d\,x^3+6c^2d^2x^2+4c\,d^3x+d^4}{(cx+d)^4}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{(c^4x^4+4c^3d\,x^3+6c^2d^2x^2+4c\,d^3x+d^4)u}{(cx+d)^4}}
\end{aligned}
\tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
\begin{aligned}
f_2' &= \frac{4c^4x^3+12c^3d\,x^2+12c^2d^2x+4c\,d^3}{(cx+d)^4} - \frac{4(c^4x^4+4c^3d\,x^3+6c^2d^2x^2+4c\,d^3x+d^4)\,c}{(cx+d)^5} \\
f_1f_2 &= 0 \\
f_2^2f_0 &= \frac{(c^4x^4+4c^3d\,x^3+6c^2d^2x^2+4c\,d^3x+d^4)^2 f\left(\frac{ax+b}{cx+d}\right)}{(cx+d)^{12}}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{(c^4x^4+4c^3d\,x^3+6c^2d^2x^2+4c\,d^3x+d^4)\,u''(x)}{(cx+d)^4} - \left(\frac{4c^4x^3+12c^3d\,x^2+12c^2d^2x+4c\,d^3}{(cx+d)^4} - \frac{4(c^4x^4+4c^3d\,x
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = \mathrm{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x) + \_Y''(x)\,(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)
$$

The above shows that

$$
u'(x) = \frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x) + \_Y''(x)\,(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)
$$

Using the above in (1) gives the solution

$$
y = -\frac{\left(\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)\right)(cx+d)^4}{(c^4x^4+4c^3d\,x^3+6c^2d^2x^2+4c\,d^3x+d^4)\,\mathrm{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \operatorname{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \operatorname{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x} \operatorname{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\frac{f\left(\frac{ax+b}{cx+d}\right)\_Y(x)+\_Y''(x)(cx+d)^4}{(cx+d)^4}\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

21.4 problem 4

Internal problem ID [10639]
Internal file name [`OUTPUT/9586_Monday_June_06_2022_03_11_01_PM_74540310/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 4.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{x^2y' - x^4f(x)\,y^2 = 1}$$

21.4.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{x^4f(x)\,y^2+1}{x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x^2f(x)\,y^2 + \frac{1}{x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{1}{x^2}$, $f_1(x) = 0$ and $f_2(x) = x^2f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2u} \\ &= \frac{-u'}{x^2f\,(x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned}
f_2' &= 2f(x)\,x + x^2 f'(x)\\
f_1f_2 &= 0\\
f_2^2 f_0 &= x^2 f(x)^2
\end{aligned}$$

Substituting the above terms back in equation (2) gives

$$x^2 f(x)\,u''(x) - \left(2f(x)\,x + x^2 f'(x)\right) u'(x) + x^2 f(x)^2\, u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\_Y''(x) - \frac{(2f(x)\,x + x^2 f'(x))\_Y'(x)}{x^2 f(x)} + f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{d}{dx}\,\mathrm{DESol}\left(\left\{\_Y''(x) - \frac{(2f(x)\,x + x^2 f'(x))\_Y'(x)}{x^2 f(x)} + f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{d}{dx}\,\mathrm{DESol}\left(\left\{\_Y''(x) - \frac{(2f(x)x + x^2 f'(x))\_Y'(x)}{x^2 f(x)} + f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)}{x^2 f(x)\,\mathrm{DESol}\left(\left\{\_Y''(x) - \frac{(2f(x)x + x^2 f'(x))\_Y'(x)}{x^2 f(x)} + f(x)\_Y(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{d}{dx}\,\mathrm{DESol}\left(\left\{\frac{\_Y''(x)xf(x) + (-xf'(x) - 2f(x))\_Y'(x) + f(x)^2\_Y(x)x}{xf(x)}\right\}, \{\_Y(x)\}\right)}{x^2 f(x)\,\mathrm{DESol}\left(\left\{\frac{\_Y''(x)xf(x) + (-xf'(x) - 2f(x))\_Y'(x) + f(x)^2\_Y(x)x}{xf(x)}\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x) x f(x)+(-x f'(x)-2 f(x))\_Y'(x)+f(x)^{2}\_Y(x) x}{x f(x)}\right\}, \{\_Y(x)\}\right)}{x^{2} f(x) \operatorname{DESol}\left(\left\{\frac{\_Y''(x) x f(x)+(-x f'(x)-2 f(x))\_Y'(x)+f(x)^{2}\_Y(x) x}{x f(x)}\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{\frac{\_Y''(x) x f(x)+(-x f'(x)-2 f(x))\_Y'(x)+f(x)^{2}\_Y(x) x}{x f(x)}\right\}, \{\_Y(x)\}\right)}{x^{2} f(x) \operatorname{DESol}\left(\left\{\frac{\_Y''(x) x f(x)+(-x f'(x)-2 f(x))\_Y'(x)+f(x)^{2}\_Y(x) x}{x f(x)}\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

21.5 problem 5

Internal problem ID [10640]
Internal file name [`OUTPUT/9587_Monday_June_06_2022_03_11_03_PM_91047867/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 5.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{x^2 y' - y^2 x^4 = x^{2n} f(a\,x^n + b) - \frac{n^2}{4} + \frac{1}{4}}$$

21.5.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{4y^2x^4 + 4x^{2n} f(a\,x^n + b) - n^2 + 1}{4x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = x^2 y^2 + \frac{x^{2n} f(a\,x^n + b)}{x^2} - \frac{n^2}{4x^2} + \frac{1}{4x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{4x^{2n} f(a\,x^n+b) - n^2+1}{4x^2}$, $f_1(x) = 0$ and $f_2(x) = x^2$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{x^2 u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 2x \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= \frac{x^2(4x^{2n} f(a\,x^n + b) - n^2 + 1)}{4} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$x^2 u''(x) - 2xu'(x) + \frac{x^2(4x^{2n} f(a\,x^n + b) - n^2 + 1)\, u(x)}{4} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\left(x^{2n} f(a\,x^n + b) - \frac{n^2}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\left(x^{2n} f(a\,x^n + b) - \frac{n^2}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\left(x^{2n} f(a\,x^n + b) - \frac{n^2}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{x^2\,\mathrm{DESol}\left(\left\{\left(x^{2n} f(a\,x^n + b) - \frac{n^2}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\left(x^{2n} f(a\,x^n + b) - \frac{n^2}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{x^2\,\mathrm{DESol}\left(\left\{\frac{4x^{2n+1}\_Y(x) f(a\,x^n+b) + 4\_Y''(x)x - 8\_Y'(x) + x(-n^2+1)\_Y(x)}{4x}\right\}, \{\_Y(x)\}\right)}$$

Summary
The solution(s) found are the following

$$
y = -\frac{\frac{\partial}{\partial x} \operatorname{DESol}\left(\left\{\left(x^{2n} f(a\,x^{n}+b) - \frac{n^{2}}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{x^{2} \operatorname{DESol}\left(\left\{\frac{4x^{2n+1}\_Y(x) f(a\,x^{n}+b)+4\_Y''(x)x-8\_Y'(x)+x(-n^{2}+1)\_Y(x)}{4x}\right\}, \{\_Y(x)\}\right)} \tag{1}
$$

Verification of solutions

$$
y = -\frac{\frac{\partial}{\partial x} \operatorname{DESol}\left(\left\{\left(x^{2n} f(a\,x^{n}+b) - \frac{n^{2}}{4} + \frac{1}{4}\right)\_Y(x) - \frac{2\_Y'(x)}{x} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{x^{2} \operatorname{DESol}\left(\left\{\frac{4x^{2n+1}\_Y(x) f(a\,x^{n}+b)+4\_Y''(x)x-8\_Y'(x)+x(-n^{2}+1)\_Y(x)}{4x}\right\}, \{\_Y(x)\}\right)}
$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 6.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - f(x)\,y^2 - g(x)\,y = h(x)}$$

21.6.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= f(x)\,y^2 + yg(x) + h(x) \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = f(x)\,y^2 + yg(x) + h(x)$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = h(x)$, $f_1(x) = g(x)$ and $f_2(x) = f(x)$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{f(x)\,u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= f'(x) \\ f_1f_2 &= f(x)\,g(x) \\ f_2^2 f_0 &= h(x)\,f(x)^2 \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$f(x)\,u''(x) - (f(x)\,g(x) + f'(x))\,u'(x) + h(x)\,f(x)^2\,u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{h(x)\,f(x)\_Y(x) - \frac{(f(x)\,g(x) + f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{d}{dx}\mathrm{DESol}\left(\left\{h(x)\,f(x)\_Y(x) - \frac{(f(x)\,g(x) + f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{d}{dx}\mathrm{DESol}\left(\left\{h(x)\,f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{f(x)\,\mathrm{DESol}\left(\left\{h(x)\,f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{d}{dx}\mathrm{DESol}\left(\left\{h(x)\,f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{f(x)\,\mathrm{DESol}\left(\left\{h(x)\,f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{h(x)\, f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{f(x)\operatorname{DESol}\left(\left\{h(x)\, f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{d}{dx}\operatorname{DESol}\left(\left\{h(x)\, f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{f(x)\operatorname{DESol}\left(\left\{h(x)\, f(x)\_Y(x) - \frac{(f(x)g(x)+f'(x))\_Y'(x)}{f(x)} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

21.7 problem 7

Internal problem ID [10642]
Internal file name [`OUTPUT/9589_Monday_June_06_2022_03_11_07_PM_128411/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 7.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = e^{2\lambda x} f\left(e^{\lambda x}\right) - \frac{\lambda^2}{4}}$$

21.7.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= y^2 + e^{2\lambda x} f\left(e^{\lambda x}\right) - \frac{\lambda^2}{4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + e^{2\lambda x} f\left(e^{\lambda x}\right) - \frac{\lambda^2}{4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = e^{2\lambda x} f\left(e^{\lambda x}\right) - \frac{\lambda^2}{4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= e^{2\lambda x} f(e^{\lambda x}) - \frac{\lambda^2}{4} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \left(e^{2\lambda x} f(e^{\lambda x}) - \frac{\lambda^2}{4}\right) u(x) = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\_Y(x)\, e^{2\lambda x} f(e^{\lambda x}) - \frac{\_Y(x)\, \lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\, e^{2\lambda x} f(e^{\lambda x}) - \frac{\_Y(x)\, \lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\, e^{2\lambda x} f(e^{\lambda x}) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\, e^{2\lambda x} f(e^{\lambda x}) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\, e^{2\lambda x} f(e^{\lambda x}) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\, e^{2\lambda x} f(e^{\lambda x}) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\_Y(x)\,\mathrm{e}^{2\lambda x} f\left(\mathrm{e}^{\lambda x}\right) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\_Y(x)\,\mathrm{e}^{2\lambda x} f\left(\mathrm{e}^{\lambda x}\right) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\_Y(x)\,\mathrm{e}^{2\lambda x} f\left(\mathrm{e}^{\lambda x}\right) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{\_Y(x)\,\mathrm{e}^{2\lambda x} f\left(\mathrm{e}^{\lambda x}\right) - \frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

Internal problem ID [10643]
Internal file name [`OUTPUT/9590_Monday_June_06_2022_03_11_12_PM_76019185/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 8.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$y' - y^2 = -\frac{\lambda^2}{4} + \frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)}{\left(c\,e^{\lambda x}+d\right)^4}$$

21.8.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{-e^{4\lambda x}c^4\lambda^2 + 4\,e^{4\lambda x}c^4y^2 - 4\,e^{3\lambda x}c^3d\,\lambda^2 + 16\,e^{3\lambda x}c^3d\,y^2 - 6\,e^{2\lambda x}c^2d^2\lambda^2 + 24\,e^{2\lambda x}c^2d^2y^2 - 4\,e^{\lambda x}c\,d^3\lambda^2 + 1}{4\left(c\,e^{\lambda x}+d\right)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = -\frac{3\,e^{2\lambda x}c^2d^2\lambda^2}{2\left(c\,e^{\lambda x}+d\right)^4} + \frac{6\,e^{2\lambda x}c^2d^2y^2}{\left(c\,e^{\lambda x}+d\right)^4} - \frac{e^{\lambda x}c\,d^3\lambda^2}{\left(c\,e^{\lambda x}+d\right)^4} + \frac{4\,e^{\lambda x}c\,d^3y^2}{\left(c\,e^{\lambda x}+d\right)^4} - \frac{e^{4\lambda x}c^4\lambda^2}{4\left(c\,e^{\lambda x}+d\right)^4} + \frac{e^{4\lambda x}c^4y^2}{\left(c\,e^{\lambda x}+d\right)^4} - \frac{e^{3\lambda x}c^3d\,\lambda^2}{\left(c\,e^{\lambda x}+d\right)^4} +$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{-\mathrm{e}^{4\lambda x} c^4 \lambda^2 - 4\,\mathrm{e}^{3\lambda x} c^3 d\,\lambda^2 - 6\,\mathrm{e}^{2\lambda x} c^2 d^2 \lambda^2 - 4\,\mathrm{e}^{\lambda x} c\, d^3 \lambda^2 - d^4 \lambda^2 + 4\,\mathrm{e}^{2\lambda x} f\left(\frac{a\,\mathrm{e}^{\lambda x}+b}{c\,\mathrm{e}^{\lambda x}+d}\right)}{4\left(c\,\mathrm{e}^{\lambda x}+d\right)^4}$, $f_1(x) = 0$ and $f_2(x) = \frac{16c\,\mathrm{e}^{\lambda x} d^3 + 4\,\mathrm{e}^{4\lambda x} c^4 + 16\,\mathrm{e}^{3\lambda x} c^3 d + 24c^2 d^2 \mathrm{e}^{2\lambda x} + 4d^4}{4\left(c\,\mathrm{e}^{\lambda x}+d\right)^4}$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{\frac{\left(16c\,\mathrm{e}^{\lambda x} d^3 + 4\,\mathrm{e}^{4\lambda x} c^4 + 16\,\mathrm{e}^{3\lambda x} c^3 d + 24c^2 d^2 \mathrm{e}^{2\lambda x} + 4d^4\right) u}{4\left(c\,\mathrm{e}^{\lambda x}+d\right)^4}}
\end{aligned} \tag{1}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - \left(f_2' + f_1 f_2\right) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}
$$

But

$$
f_2' = \frac{16\,\mathrm{e}^{4\lambda x} c^4 \lambda + 48\,\mathrm{e}^{3\lambda x} c^3 d\lambda + 48\,\mathrm{e}^{2\lambda x} c^2 d^2 \lambda + 16c\,\mathrm{e}^{\lambda x} d^3 \lambda}{4\left(c\,\mathrm{e}^{\lambda x}+d\right)^4} - \frac{\left(16c\,\mathrm{e}^{\lambda x} d^3 + 4\,\mathrm{e}^{4\lambda x} c^4 + 16\,\mathrm{e}^{3\lambda x} c^3 d + 24c^2 d\right.}{\left(c\,\mathrm{e}^{\lambda x}+d\right)^5}
$$

$$
f_1 f_2 = 0
$$

$$
f_2^2 f_0 = \frac{\left(16c\,\mathrm{e}^{\lambda x} d^3 + 4\,\mathrm{e}^{4\lambda x} c^4 + 16\,\mathrm{e}^{3\lambda x} c^3 d + 24c^2 d^2 \mathrm{e}^{2\lambda x} + 4d^4\right)^2 \left(-\mathrm{e}^{4\lambda x} c^4 \lambda^2 - 4\,\mathrm{e}^{3\lambda x} c^3 d\,\lambda^2 - 6\,\mathrm{e}^{2\lambda x} c^2 d^2 \lambda^2 -\right.}{64\left(c\,\mathrm{e}^{\lambda x}+d\right)^{12}}
$$

Substituting the above terms back in equation (2) gives

$$
\frac{\left(16c\,\mathrm{e}^{\lambda x} d^3 + 4\,\mathrm{e}^{4\lambda x} c^4 + 16\,\mathrm{e}^{3\lambda x} c^3 d + 24c^2 d^2 \mathrm{e}^{2\lambda x} + 4d^4\right) u''(x)}{4\left(c\,\mathrm{e}^{\lambda x}+d\right)^4} - \left(\frac{16\,\mathrm{e}^{4\lambda x} c^4 \lambda + 48\,\mathrm{e}^{3\lambda x} c^3 d\lambda + 48\,\mathrm{e}^{2\lambda x} c^2 d^2 \lambda}{4\left(c\,\mathrm{e}^{\lambda x}+d\right)^4}\right.
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
u(x) = \mathrm{DESol}\left(\left\{\frac{\mathrm{e}^{2\lambda x} f\left(\frac{a\,\mathrm{e}^{\lambda x}+b}{c\,\mathrm{e}^{\lambda x}+d}\right) \_Y(x) + 6\left(c^2 d^2 \mathrm{e}^{2\lambda x} + \frac{2\,\mathrm{e}^{3\lambda x} c^3 d}{3} + \frac{\mathrm{e}^{4\lambda x} c^4}{6} + \frac{2d^3\left(c\,\mathrm{e}^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4} + \_Y''(x)\right.}{\mathrm{e}^{4\lambda x} c^4 + 4\,\mathrm{e}^{3\lambda x} c^3 d + 6c^2 d^2 \mathrm{e}^{2\lambda x} + 4c\,\mathrm{e}^{\lambda x} d^3 + d^4}\right.\right.
$$

The above shows that

$$
u'(x) = \frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{\mathrm{e}^{2\lambda x} f\left(\frac{a\,\mathrm{e}^{\lambda x}+b}{c\,\mathrm{e}^{\lambda x}+d}\right) \_Y(x) + 6\left(c^2 d^2 \mathrm{e}^{2\lambda x} + \frac{2\,\mathrm{e}^{3\lambda x} c^3 d}{3} + \frac{\mathrm{e}^{4\lambda x} c^4}{6} + \frac{2d^3\left(c\,\mathrm{e}^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4} + \_Y\right.}{\mathrm{e}^{4\lambda x} c^4 + 4\,\mathrm{e}^{3\lambda x} c^3 d + 6c^2 d^2 \mathrm{e}^{2\lambda x} + 4c\,\mathrm{e}^{\lambda x} d^3 + d^4}\right.\right.
$$

Using the above in (1) gives the solution

$$y = -\frac{4\left(\frac{\partial}{\partial x}\operatorname{DESol}\left(\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}\cdots\right.}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right.\right.\right.\cdots\right.}{\left(16c\,e^{\lambda x}d^3+4\,e^{4\lambda x}c^4+16\,e^{3\lambda x}c^3d+24c^2d^2e^{2\lambda x}+4d^4\right)\operatorname{DESol}\left(\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3}{3}\cdots\right.}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+\cdots}\right.\right.\right.\cdots}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1}=c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}+\_Y''(x)\right)}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right\},\{\_Y(x\cdots\right.}{\operatorname{DESol}\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}+\_Y''(x)\right)}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right\},\{\_Y(x)\cdots\right.}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}+\_Y''(x)\right)}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right\},\{\_Y(x\cdots\right.}{\operatorname{DESol}\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}+\_Y''(x)\right)}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right\},\{\_Y(x)\cdots\right.} \quad (1)$$

Verification of solutions

$y =$

$$-\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}+\_Y''(x)\right)}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right\}, \{\_Y(x\right.}{\operatorname{DESol}\left(\left\{\frac{e^{2\lambda x} f\left(\frac{a\,e^{\lambda x}+b}{c\,e^{\lambda x}+d}\right)\_Y(x)+6\left(c^2d^2e^{2\lambda x}+\frac{2\,e^{3\lambda x}c^3d}{3}+\frac{e^{4\lambda x}c^4}{6}+\frac{2d^3\left(c\,e^{\lambda x}+\frac{d}{4}\right)}{3}\right)\left(-\frac{\_Y(x)\lambda^2}{4}+\_Y''(x)\right)}{e^{4\lambda x}c^4+4\,e^{3\lambda x}c^3d+6c^2d^2e^{2\lambda x}+4c\,e^{\lambda x}d^3+d^4}\right\}, \{\_Y(x)\right.}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 9.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = -\lambda^2 + \frac{f(\coth(\lambda x))}{\sinh(\lambda x)^4}}$$

21.9.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{-\lambda^2 \sinh(\lambda x)^4 + y^2 \sinh(\lambda x)^4 + f(\coth(\lambda x))}{\sinh(\lambda x)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 - \lambda^2 + \frac{f(\coth(\lambda x))}{\sinh(\lambda x)^4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{-\lambda^2 \sinh(\lambda x)^4 + f(\coth(\lambda x))}{\sinh(\lambda x)^4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$f_2' = 0$$
$$f_1 f_2 = 0$$
$$f_2^2 f_0 = \frac{-\lambda^2 \sinh(\lambda x)^4 + f(\coth(\lambda x))}{\sinh(\lambda x)^4}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \frac{\left(-\lambda^2 \sinh(\lambda x)^4 + f(\coth(\lambda x))\right) u(x)}{\sinh(\lambda x)^4} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x} \text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x} \text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\text{DESol}\left(\left\{f(\coth(\lambda x)) \operatorname{csch}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{f(\coth(\lambda x))\,\mathrm{csch}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{f(\coth(\lambda x))\,\mathrm{csch}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 10.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = -\lambda^2 + \frac{f(\tanh(\lambda x))}{\cosh(\lambda x)^4}}$$

21.10.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{-\cosh(\lambda x)^4 \lambda^2 + \cosh(\lambda x)^4 y^2 + f(\tanh(\lambda x))}{\cosh(\lambda x)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 - \lambda^2 + \frac{f(\tanh(\lambda x))}{\cosh(\lambda x)^4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{-\cosh(\lambda x)^4\lambda^2 + f(\tanh(\lambda x))}{\cosh(\lambda x)^4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= 0 \\ f_2^2f_0 &= \frac{-\cosh(\lambda x)^4\,\lambda^2 + f(\tanh(\lambda x))}{\cosh(\lambda x)^4} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \frac{(-\cosh(\lambda x)^4\,\lambda^2 + f(\tanh(\lambda x)))\,u(x)}{\cosh(\lambda x)^4} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x}\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x}\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x}\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x}\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\text{DESol}\left(\left\{f(\tanh(\lambda x))\,\text{sech}(\lambda x)^4\,\_Y(x) - \_Y(x)\,\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{f(\tanh(\lambda x)) \operatorname{sech}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{f(\tanh(\lambda x)) \operatorname{sech}(\lambda x)^4 \_Y(x) - \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

```
[_Riccati]
```

$$\boxed{x^2y' - x^2y^2 = f(a\ln(x) + b) + \frac{1}{4}}$$

21.11.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{4x^2y^2 + 4f(a\ln(x) + b) + 1}{4x^2} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + \frac{f(a\ln(x) + b)}{x^2} + \frac{1}{4x^2}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{4f(a\ln(x)+b)+1}{4x^2}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\,u'(x) + f_2^2f_0u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= 0 \\ f_2^2f_0 &= \frac{4f(a\ln(x)+b)+1}{4x^2} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \frac{(4f(a\ln(x)+b)+1)\,u(x)}{4x^2} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\frac{(4f(a\ln(x)+b)+1)\_Y(x)}{4x^2} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{(4f(a\ln(x)+b)+1)\_Y(x)}{4x^2} + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{(4f(a\ln(x)+b)+1)\_Y(x)}{4x^2} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{(4f(a\ln(x)+b)+1)\_Y(x)}{4x^2} + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\left\{\frac{4\_Y''(x)x^2+4\_Y(x)f(a\ln(x)+b)+\_Y(x)}{4x^2}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{4\_Y''(x)x^2+4\_Y(x)f(a\ln(x)+b)+\_Y(x)}{4x^2}\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\frac{4\_Y''(x)\,x^2+4\_Y(x)\,f(a\ln(x)+b)+\_Y(x)}{4x^2}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{4\_Y''(x)\,x^2+4\_Y(x)\,f(a\ln(x)+b)+\_Y(x)}{4x^2}\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\frac{4\_Y''(x)\,x^2+4\_Y(x)\,f(a\ln(x)+b)+\_Y(x)}{4x^2}\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\frac{4\_Y''(x)\,x^2+4\_Y(x)\,f(a\ln(x)+b)+\_Y(x)}{4x^2}\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 12.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = \lambda^2 + \frac{f(\cot(\lambda x))}{\sin(\lambda x)^4}}$$

21.12.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{\lambda^2 \sin(\lambda x)^4 + y^2 \sin(\lambda x)^4 + f(\cot(\lambda x))}{\sin(\lambda x)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + \lambda^2 + \frac{f(\cot(\lambda x))}{\sin(\lambda x)^4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{\lambda^2 \sin(\lambda x)^4 + f(\cot(\lambda x))}{\sin(\lambda x)^4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2u''(x) - (f_2' + f_1f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1f_2 &= 0 \\ f_2^2 f_0 &= \frac{\lambda^2 \sin(\lambda x)^4 + f(\cot(\lambda x))}{\sin(\lambda x)^4} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \frac{(\lambda^2 \sin(\lambda x)^4 + f(\cot(\lambda x)))\, u(x)}{\sin(\lambda x)^4} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x)^4 f(\cot(\lambda x))\_Y(x)\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{\_Y(x)\,\lambda^2+\_Y''(x)+\csc(\lambda x)^4 f(\cot(\lambda x))\,\_Y(x)\right\},\left\{\_Y(x)\right\}\right)}{\operatorname{DESol}\left(\left\{\_Y(x)\,\lambda^2+\_Y''(x)+\csc(\lambda x)^4 f(\cot(\lambda x))\,\_Y(x)\right\},\left\{\_Y(x)\right\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 13.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = \lambda^2 + \frac{f(\tan(\lambda x))}{\cos(\lambda x)^4}}$$

21.13.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x, y) \\ &= \frac{\cos(\lambda x)^4 \lambda^2 + \cos(\lambda x)^4 y^2 + f(\tan(\lambda x))}{\cos(\lambda x)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = y^2 + \lambda^2 + \frac{f(\tan(\lambda x))}{\cos(\lambda x)^4}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{\cos(\lambda x)^4 \lambda^2 + f(\tan(\lambda x))}{\cos(\lambda x)^4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$\begin{aligned} y &= \frac{-u'}{f_2 u} \\ &= \frac{-u'}{u} \end{aligned} \tag{1}$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$f_2 u''(x) - (f_2' + f_1 f_2)\, u'(x) + f_2^2 f_0 u(x) = 0 \tag{2}$$

But

$$\begin{aligned} f_2' &= 0 \\ f_1 f_2 &= 0 \\ f_2^2 f_0 &= \frac{\cos(\lambda x)^4 \lambda^2 + f(\tan(\lambda x))}{\cos(\lambda x)^4} \end{aligned}$$

Substituting the above terms back in equation (2) gives

$$u''(x) + \frac{(\cos(\lambda x)^4 \lambda^2 + f(\tan(\lambda x)))\, u(x)}{\cos(\lambda x)^4} = 0$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$u(x) = \mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

The above shows that

$$u'(x) = \frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)$$

Using the above in (1) gives the solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\left\{f(\tan(\lambda x)) \sec(\lambda x)^4 \_Y(x) + \_Y(x)\, \lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)} \tag{1}$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x}\operatorname{DESol}\left(\left\{f(\tan(\lambda x))\sec(\lambda x)^4 \_Y(x) + \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}{\operatorname{DESol}\left(\left\{f(\tan(\lambda x))\sec(\lambda x)^4 \_Y(x) + \_Y(x)\lambda^2 + \_Y''(x)\right\}, \{\_Y(x)\}\right)}$$

Verified OK.

21.14 problem 14

Internal problem ID [10649]
Internal file name [`OUTPUT/9596_Monday_June_06_2022_03_11_50_PM_77761706/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.2. Riccati Equation. subsection 1.2.9. Some Transformations
Problem number: 14.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"riccati"**

Maple gives the following as the ode type

`[_Riccati]`

$$\boxed{y' - y^2 = \lambda^2 + \frac{f\left(\frac{\sin(\lambda x+a)}{\sin(\lambda x+b)}\right)}{\sin(\lambda x+b)^4}}$$

21.14.1 Solving as riccati ode

In canonical form the ODE is

$$\begin{aligned} y' &= F(x,y) \\ &= \frac{\lambda^2 \sin(\lambda x+b)^4 + y^2 \sin(\lambda x+b)^4 + f\left(\frac{\sin(\lambda x+a)}{\sin(\lambda x+b)}\right)}{\sin(\lambda x+b)^4} \end{aligned}$$

This is a Riccati ODE. Comparing the ODE to solve

$$y' = \frac{\lambda^2 \sin(\lambda x)^4 \cos(b)^4}{(\sin(\lambda x)\cos(b)+\cos(\lambda x)\sin(b))^4} + \frac{4\lambda^2 \sin(\lambda x)^3 \cos(b)^3 \cos(\lambda x)\sin(b)}{(\sin(\lambda x)\cos(b)+\cos(\lambda x)\sin(b))^4} + \frac{6\lambda^2 \sin(\lambda x)^2 \cos(b)^2 \cos(}{(\sin(\lambda x)\cos(b)+\cos(\lambda}$$

With Riccati ODE standard form

$$y' = f_0(x) + f_1(x)y + f_2(x)y^2$$

Shows that $f_0(x) = \frac{\lambda^2 \sin(\lambda x+b)^4 + f\left(\frac{\sin(\lambda x+a)}{\sin(\lambda x+b)}\right)}{\sin(\lambda x+b)^4}$, $f_1(x) = 0$ and $f_2(x) = 1$. Let

$$
\begin{aligned}
y &= \frac{-u'}{f_2 u} \\
&= \frac{-u'}{u} \qquad (1)
\end{aligned}
$$

Using the above substitution in the given ODE results (after some simplification)in a second order ODE to solve for $u(x)$ which is

$$
f_2 u''(x) - (f_2' + f_1 f_2) u'(x) + f_2^2 f_0 u(x) = 0 \qquad (2)
$$

But

$$
\begin{aligned}
f_2' &= 0 \\
f_1 f_2 &= 0 \\
f_2^2 f_0 &= \frac{\lambda^2 \sin(\lambda x+b)^4 + f\left(\frac{\sin(\lambda x+a)}{\sin(\lambda x+b)}\right)}{\sin(\lambda x+b)^4}
\end{aligned}
$$

Substituting the above terms back in equation (2) gives

$$
u''(x) + \frac{\left(\lambda^2 \sin(\lambda x+b)^4 + f\left(\frac{\sin(\lambda x+a)}{\sin(\lambda x+b)}\right)\right) u(x)}{\sin(\lambda x+b)^4} = 0
$$

Solving the above ODE (this ode solved using Maple, not this program), gives

$$
\begin{aligned}
u(x) = \mathrm{DESol}\Big(\{&\_Y(x)\,\lambda^2 + \_Y''(x) \\
&+ \csc(\lambda x+b)^4 f(\csc(\lambda x+b)\sin(\lambda x+a))\,\_Y(x)\}, \{\_Y(x)\}\Big)
\end{aligned}
$$

The above shows that

$$
\begin{aligned}
u'(x) = \frac{\partial}{\partial x}\mathrm{DESol}\Big(\{&\_Y(x)\,\lambda^2 + \_Y''(x) \\
&+ \csc(\lambda x+b)^4 f(\csc(\lambda x+b)\sin(\lambda x+a))\,\_Y(x)\}, \{\_Y(x)\}\Big)
\end{aligned}
$$

Using the above in (1) gives the solution

$$
y = -\frac{\frac{\partial}{\partial x}\mathrm{DESol}\left(\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x+b)^4 f(\csc(\lambda x+b)\sin(\lambda x+a))\,\_Y(x)\}, \{\_Y(x)\}\right)}{\mathrm{DESol}\left(\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc(\lambda x+b)^4 f(\csc(\lambda x+b)\sin(\lambda x+a))\,\_Y(x)\}, \{\_Y(x)\}\right)}
$$

Dividing both numerator and denominator by c_1 gives, after renaming the constant $\frac{c_2}{c_1} = c_3$ the following solution

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc\left(\lambda x + b\right)^4 f\left(\csc\left(\lambda x + b\right)\sin\left(\lambda x + a\right)\right)\_Y(x)\right\}, \left\{\_Y(x)\right\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc\left(\lambda x + b\right)^4 f\left(\csc\left(\lambda x + b\right)\sin\left(\lambda x + a\right)\right)\_Y(x)\right\}, \left\{\_Y(x)\right\}\right)}$$

Summary

The solution(s) found are the following

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc\left(\lambda x + b\right)^4 f\left(\csc\left(\lambda x + b\right)\sin\left(\lambda x + a\right)\right)\_Y(x)\right\}, \left\{\_Y(x)\right\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc\left(\lambda x + b\right)^4 f\left(\csc\left(\lambda x + b\right)\sin\left(\lambda x + a\right)\right)\_Y(x)\right\}, \left\{\_Y(x)\right\}\right)} \quad (1)$$

Verification of solutions

$$y = -\frac{\frac{\partial}{\partial x} \mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc\left(\lambda x + b\right)^4 f\left(\csc\left(\lambda x + b\right)\sin\left(\lambda x + a\right)\right)\_Y(x)\right\}, \left\{\_Y(x)\right\}\right)}{\mathrm{DESol}\left(\left\{\_Y(x)\,\lambda^2 + \_Y''(x) + \csc\left(\lambda x + b\right)^4 f\left(\csc\left(\lambda x + b\right)\sin\left(\lambda x + a\right)\right)\_Y(x)\right\}, \left\{\_Y(x)\right\}\right)}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. Form $yy' - y = f(x)$. subsection 1.3.1-2. Solvable equations and their solutions
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"quadrature"**

Maple gives the following as the ode type

`[_quadrature]`

$$\boxed{yy' - y = A}$$

22.1.1 Solving as quadrature ode

Integrating both sides gives

$$\int \frac{y}{y+A} dy = x + c_1$$
$$y - A\ln(y + A) = x + c_1$$

Solving for y gives these solutions

$$y_1 = -A\left(\text{LambertW}\left(-\frac{e^{-\frac{A+c_1+x}{A}}}{A}\right) + 1\right)$$
$$= -A\left(\text{LambertW}\left(-\frac{e^{\frac{-A-x}{A}}}{c_1 A}\right) + 1\right)$$

Summary
The solution(s) found are the following

$$y = -A\left(\text{LambertW}\left(-\frac{e^{\frac{-A-x}{A}}}{c_1 A}\right) + 1\right) \tag{1}$$

Verification of solutions

$$y = -A\left(\mathrm{LambertW}\left(-\frac{e^{\frac{-A-x}{A}}}{c_1 A}\right)+1\right)$$

Verified OK.

22.1.2 Maple step by step solution

Let's solve

$yy' - y = A$

- Highest derivative means the order of the ODE is 1

  y'

- Separate variables

  $\frac{y'y}{y+A} = 1$

- Integrate both sides with respect to x

  $\int \frac{y'y}{y+A}dx = \int 1dx + c_1$

- Evaluate integral

  $y - A\ln(y+A) = x + c_1$

- Solve for y

  $y = -A\left(\mathit{LambertW}\left(-\frac{e^{-\frac{A+c_1+x}{A}}}{A}\right)+1\right)$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. Form $yy' - y = f(x)$. subsection 1.3.1-2. Solvable equations and their solutions
Problem number: 2.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{yy' - y = Ax + B}$$

22.2.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{Ax + B + y}{y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{(Ax+B+y)(b_3-a_2)}{y} - \frac{(Ax+B+y)^2 a_3}{y^2} - \frac{A(xa_2+ya_3+a_1)}{y} - \left(\frac{1}{y} - \frac{Ax+B+y}{y^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{A^2x^2a_3 + 2ABxa_3 - A\,x^2b_2 + 2Axya_2 + 2Axya_3 - 2Axyb_3 + A\,y^2a_3 - Axb_1 + Aya_1 + B^2a_3 - Bxb_2 +}{y^2}$$
$$= 0$$

Setting the numerator to zero gives

$$-A^2x^2a_3 - 2ABxa_3 + A\,x^2b_2 - 2Axya_2 - 2Axya_3 + 2Axyb_3 - A\,y^2a_3 + Axb_1 - Aya_1 - B^2a_3 + Bxb_2 - Bya_2 - 2Bya_3 + 2Byb_3 - y^2a_2 - y^2a_3 + b_2y^2 + y^2b_3 + Bb_1 = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$-A^2a_3v_1^2 - 2ABa_3v_1 - 2Aa_2v_1v_2 - 2Aa_3v_1v_2 - Aa_3v_2^2 + Ab_2v_1^2 + 2Ab_3v_1v_2 - Aa_1v_2 + Ab_1v_1 - B^2a_3 - Ba_2v_2 - 2Ba_3v_2 + Bb_2v_1 + 2Bb_3v_2 - a_2v_2^2 - a_3v_2^2 + b_2v_2^2 + b_3v_2^2 + Bb_1 = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\begin{aligned}
&(-A^2a_3 + Ab_2)\, v_1^2 + (-2Aa_2 - 2Aa_3 + 2Ab_3)\, v_1v_2 \\
&+ (-2ABa_3 + Ab_1 + Bb_2)\, v_1 + (-Aa_3 - a_2 - a_3 + b_2 + b_3)\, v_2^2 \\
&+ (-Aa_1 - Ba_2 - 2Ba_3 + 2Bb_3)\, v_2 - B^2a_3 + Bb_1 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
-A^2a_3 + Ab_2 &= 0 \\
-B^2a_3 + Bb_1 &= 0 \\
-2Aa_2 - 2Aa_3 + 2Ab_3 &= 0 \\
-2ABa_3 + Ab_1 + Bb_2 &= 0 \\
-Aa_1 - Ba_2 - 2Ba_3 + 2Bb_3 &= 0 \\
-Aa_3 - a_2 - a_3 + b_2 + b_3 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned}
a_1 &= a_1 \\
a_2 &= \frac{Aa_1}{B} \\
a_3 &= a_3 \\
b_1 &= Ba_3 \\
b_2 &= Aa_3 \\
b_3 &= \frac{Aa_1 + Ba_3}{B}
\end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned}
\xi &= \frac{Ax + B}{B} \\
\eta &= \frac{Ay}{B}
\end{aligned}$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= \frac{Ay}{B} - \left(\frac{Ax+B+y}{y}\right)\left(\frac{Ax+B}{B}\right) \\
&= \frac{-A^2x^2 - 2ABx - Axy + A\,y^2 - B^2 - By}{By} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{-A^2x^2-2ABx-Axy+A\,y^2-B^2-By}{By}} dy
\end{aligned}
$$

Which results in

$$
S = B\left(\frac{\ln\left(A^2x^2 + 2ABx + Axy - A\,y^2 + B^2 + By\right)}{2A} + \frac{(Ax+B)\operatorname{arctanh}\left(\frac{Ax-2Ay+B}{\sqrt{4A^3x^2+8A^2Bx+A^2x^2+4A\,B^2+2AB}}\right.}{A\sqrt{4A^3x^2 + 8A^2Bx + A^2x^2 + 4A\,B^2 + 2ABx}}\right.
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{Ax + B + y}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{B(Ax + B + y)}{A^2x^2 + (2Bx + y(x-y))A + B(B+y)} \\
S_y &= -\frac{By}{A^2x^2 + (2Bx + y(x-y))A + B(B+y)}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{B\left(\ln\left(A^2x^2 + (2Bx + y(x-y))A + B(B+y)\right)\sqrt{4A+1} + 2\,\mathrm{arctanh}\left(\frac{(x-2y)A+B}{\sqrt{4A+1}\,(Ax+B)}\right)\right)}{2\sqrt{4A+1}\,A} = c_1$$

Which simplifies to

$$\frac{B\left(\ln\left(A^2x^2 + (2Bx + y(x-y))A + B(B+y)\right)\sqrt{4A+1} + 2\,\mathrm{arctanh}\left(\frac{(x-2y)A+B}{\sqrt{4A+1}\,(Ax+B)}\right)\right)}{2\sqrt{4A+1}\,A} = c_1$$

Summary

The solution(s) found are the following

$$
\frac{B\left(\ln\left(A^2x^2+(2Bx+y(x-y))A+B(B+y)\right)\sqrt{4A+1}+2\operatorname{arctanh}\left(\frac{(x-2y)A+B}{\sqrt{4A+1}\,(Ax+B)}\right)\right)}{2\sqrt{4A+1}\,A} = c_1 \tag{1}
$$

Verification of solutions

$$
\frac{B\left(\ln\left(A^2x^2+(2Bx+y(x-y))A+B(B+y)\right)\sqrt{4A+1}+2\operatorname{arctanh}\left(\frac{(x-2y)A+B}{\sqrt{4A+1}\,(Ax+B)}\right)\right)}{2\sqrt{4A+1}\,A} = c_1
$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. Form $yy' - y = f(x)$. subsection 1.3.1-2. Solvable equations and their solutions
Problem number: 35.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class B`]]
```

Unable to solve or complete the solution.

$$yy' - y = A(2+n)\left(\sqrt{x} + 2(2+n)\,A + \frac{(3+2n)\,A^2}{\sqrt{x}}\right)$$

Unable to determine ODE type.

Maple trace

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. Form $yy' - y = f(x)$. subsection 1.3.1-2. Solvable equations and their solutions
Problem number: 62.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class B`]]
```

Unable to solve or complete the solution.

$$yy' - y = -\frac{5x}{36} + \frac{A}{x^{\frac{3}{5}}} - \frac{B}{x^{\frac{7}{5}}}$$

Unable to determine ODE type.

Maple trace

```

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_1st_order, _with_linear_symmetries], [_Abel, `2nd type`, `
   class B`]]
```

$$\boxed{yy' - \frac{y}{\sqrt{ax+b}} = 1}$$

23.4.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$\begin{aligned} y' &= \frac{y + \sqrt{ax+b}}{\sqrt{ax+b}\, y} \\ y' &= \omega(x, y) \end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + y a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + y b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + \frac{\left(y+\sqrt{ax+b}\right)(b_3-a_2)}{\sqrt{ax+b}\,y} - \frac{\left(y+\sqrt{ax+b}\right)^2 a_3}{(ax+b)\,y^2} - \left(\frac{a}{2\,(ax+b)\,y} - \frac{\left(y+\sqrt{ax+b}\right)a}{2\,(ax+b)^{\frac{3}{2}}\,y}\right)(xa_2+ya_3+a_1) - \left(\frac{1}{y\sqrt{ax+b}} - \frac{y+\sqrt{ax+b}}{\sqrt{ax+b}\,y^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{a^2x^2y^2a_2 - a^2x\,y^3a_3 - a^2x\,y^2a_1 - ab\,y^3a_3 - ab\,y^2a_1 - 2(ax+b)^{\frac{3}{2}}\,a\,x^2b_2 + (ax+b)^{\frac{3}{2}}\,a\,y^2a_3 - 2(ax+b)^{\frac{3}{2}} \cdots}{\cdots}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&-a^2x^2y^2a_2+a^2x\,y^3a_3+a^2x\,y^2a_1+ab\,y^3a_3+ab\,y^2a_1+2(ax+b)^{\frac{3}{2}}\,a\,x^2b_2 \\
&-(ax+b)^{\frac{3}{2}}\,a\,y^2a_3+2(ax+b)^{\frac{3}{2}}\,b\,y^2b_2+2(ax+b)^{\frac{3}{2}}\,axb_1-(ax+b)^{\frac{3}{2}}\,aya_1 \\
&+2(ax+b)^{\frac{3}{2}}\,bxb_2-2(ax+b)^{\frac{3}{2}}\,bya_2+4(ax+b)^{\frac{3}{2}}\,byb_3+2a^2x^2y^2b_3 \\
&-4a^2x^2ya_3+\sqrt{ax+b}\,abxya_2-2(ax+b)^{\frac{3}{2}}\,y^2a_3+2(ax+b)^{\frac{3}{2}}\,bb_1 \\
&-2b^2y^2a_2+2b^2y^2b_3-4b^2ya_3+4abx\,y^2b_3-8abxya_3-3abx\,y^2a_2 \\
&+2(ax+b)^{\frac{3}{2}}\,ax\,y^2b_2-3(ax+b)^{\frac{3}{2}}\,axya_2+4(ax+b)^{\frac{3}{2}}\,axyb_3 \\
&+\sqrt{ax+b}\,a^2x^2ya_2+\sqrt{ax+b}\,a^2x\,y^2a_3+\sqrt{ax+b}\,a^2xya_1 \\
&+\sqrt{ax+b}\,ab\,y^2a_3+\sqrt{ax+b}\,abya_1-2(ax+b)^{\frac{5}{2}}\,a_3=0
\end{aligned} \tag{6E}$$

Simplifying the above gives

$$
\begin{aligned}
&a^{2}x^{2}y^{2}a_{2}+a^{2}x\,y^{3}a_{3}+a^{2}x\,y^{2}a_{1}+ab\,y^{3}a_{3}+ab\,y^{2}a_{1}+2(ax+b)^{\frac{3}{2}}\,a\,x^{2}b_{2}\\
&-(ax+b)^{\frac{3}{2}}\,a\,y^{2}a_{3}+2(ax+b)^{\frac{3}{2}}\,b\,y^{2}b_{2}+2(ax+b)^{\frac{3}{2}}\,axb_{1}-(ax+b)^{\frac{3}{2}}\,aya_{1}\\
&+2(ax+b)^{\frac{3}{2}}\,bxb_{2}-2(ax+b)^{\frac{3}{2}}\,bya_{2}+4(ax+b)^{\frac{3}{2}}\,byb_{3}-2(ax+b)\,b\,y^{2}a_{2}\\
&+2(ax+b)\,b\,y^{2}b_{3}+\sqrt{ax+b}\,abxya_{2}-4(ax+b)^{2}\,ya_{3}-2(ax+b)^{\frac{3}{2}}\,y^{2}a_{3}\\
&+2(ax+b)^{\frac{3}{2}}\,bb_{1}+abx\,y^{2}a_{2}+2(ax+b)^{\frac{3}{2}}\,ax\,y^{2}b_{2}-3(ax+b)^{\frac{3}{2}}\,axya_{2}\\
&+4(ax+b)^{\frac{3}{2}}\,axyb_{3}-2(ax+b)\,ax\,y^{2}a_{2}+2(ax+b)\,ax\,y^{2}b_{3}\\
&+\sqrt{ax+b}\,a^{2}x^{2}ya_{2}+\sqrt{ax+b}\,a^{2}x\,y^{2}a_{3}+\sqrt{ax+b}\,a^{2}xya_{1}\\
&+\sqrt{ax+b}\,ab\,y^{2}a_{3}+\sqrt{ax+b}\,abya_{1}-2(ax+b)^{\frac{5}{2}}\,a_{3}=0
\end{aligned}
\tag{6E}
$$

Since the PDE has radicals, simplifying gives

$$
\begin{aligned}
&-2b^{2}\sqrt{ax+b}\,ya_{2}+4b^{2}\sqrt{ax+b}\,yb_{3}-2b\sqrt{ax+b}\,y^{2}a_{3}+2a^{2}x^{3}\sqrt{ax+b}\,b_{2}\\
&-2a^{2}x^{2}\sqrt{ax+b}\,a_{3}+2a^{2}x^{2}\sqrt{ax+b}\,b_{1}+2b^{2}\sqrt{ax+b}\,y^{2}b_{2}\\
&+2b^{2}x\sqrt{ax+b}\,b_{2}-a^{2}x^{2}y^{2}a_{2}+a^{2}x\,y^{3}a_{3}+a^{2}x\,y^{2}a_{1}+ab\,y^{3}a_{3}+ab\,y^{2}a_{1}\\
&+2a^{2}x^{2}y^{2}b_{3}-4a^{2}x^{2}ya_{3}+4abx\sqrt{ax+b}\,y^{2}b_{2}+8abx\sqrt{ax+b}\,yb_{3}\\
&-4\sqrt{ax+b}\,abxya_{2}-2b^{2}y^{2}a_{2}+2b^{2}y^{2}b_{3}-4b^{2}ya_{3}+2b^{2}\sqrt{ax+b}\,b_{1}\\
&-2b^{2}\sqrt{ax+b}\,a_{3}+4abx\,y^{2}b_{3}-8abxya_{3}-3abx\,y^{2}a_{2}-2\sqrt{ax+b}\,a^{2}x^{2}ya_{2}\\
&+2a^{2}x^{2}\sqrt{ax+b}\,y^{2}b_{2}+4a^{2}x^{2}\sqrt{ax+b}\,yb_{3}+4ab\,x^{2}\sqrt{ax+b}\,b_{2}\\
&-2ax\sqrt{ax+b}\,y^{2}a_{3}-4abx\sqrt{ax+b}\,a_{3}+4abx\sqrt{ax+b}\,b_{1}=0
\end{aligned}
$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$
\left\{x, y, \sqrt{ax+b}\right\}
$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$
\left\{x=v_{1}, y=v_{2}, \sqrt{ax+b}=v_{3}\right\}
$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&2a^{2}v_{1}^{2}v_{3}v_{2}^{2}b_{2}-a^{2}v_{1}^{2}v_{2}^{2}a_{2}-2v_{3}a^{2}v_{1}^{2}v_{2}a_{2}+a^{2}v_{1}v_{2}^{3}a_{3}+2a^{2}v_{1}^{3}v_{3}b_{2}\\
&+2a^{2}v_{1}^{2}v_{2}^{2}b_{3}+4a^{2}v_{1}^{2}v_{3}v_{2}b_{3}+4abv_{1}v_{3}v_{2}^{2}b_{2}+a^{2}v_{1}v_{2}^{2}a_{1}-4a^{2}v_{1}^{2}v_{2}a_{3}\\
&-2a^{2}v_{1}^{2}v_{3}a_{3}+2a^{2}v_{1}^{2}v_{3}b_{1}-3abv_{1}v_{2}^{2}a_{2}-4v_{3}abv_{1}v_{2}a_{2}+abv_{2}^{3}a_{3}\\
&+4abv_{1}^{2}v_{3}b_{2}+4abv_{1}v_{2}^{2}b_{3}+8abv_{1}v_{3}v_{2}b_{3}-2av_{1}v_{3}v_{2}^{2}a_{3}+2b^{2}v_{3}v_{2}^{2}b_{2}+abv_{2}^{2}a_{1}\\
&-8abv_{1}v_{2}a_{3}-4abv_{1}v_{3}a_{3}+4abv_{1}v_{3}b_{1}-2b^{2}v_{2}^{2}a_{2}-2b^{2}v_{3}v_{2}a_{2}+2b^{2}v_{1}v_{3}b_{2}\\
&+2b^{2}v_{2}^{2}b_{3}+4b^{2}v_{3}v_{2}b_{3}-2bv_{3}v_{2}^{2}a_{3}-4b^{2}v_{2}a_{3}-2b^{2}v_{3}a_{3}+2b^{2}v_{3}b_{1}=0
\end{aligned}
\tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3\}$$

Equation (7E) now becomes

$$\begin{aligned}
&2a^2v_1^3v_3b_2 + 2a^2v_1^2v_3v_2^2b_2 + \left(-a^2a_2 + 2a^2b_3\right)v_1^2v_2^2 \\
&+ \left(-2a^2a_2 + 4a^2b_3\right)v_1^2v_2v_3 - 4a^2v_1^2v_2a_3 + \left(-2a^2a_3 + 2a^2b_1 + 4abb_2\right)v_1^2v_3 \\
&+ a^2v_1v_2^3a_3 + (4abb_2 - 2aa_3)v_1v_2^2v_3 + \left(a^2a_1 - 3aba_2 + 4abb_3\right)v_1v_2^2 \\
&+ (-4aba_2 + 8abb_3)v_1v_2v_3 - 8abv_1v_2a_3 + \left(-4aba_3 + 4abb_1 + 2b^2b_2\right)v_1v_3 \\
&+ abv_2^3a_3 + \left(2b^2b_2 - 2ba_3\right)v_2^2v_3 + \left(aba_1 - 2b^2a_2 + 2b^2b_3\right)v_2^2 \\
&+ \left(-2b^2a_2 + 4b^2b_3\right)v_2v_3 - 4b^2v_2a_3 + \left(-2b^2a_3 + 2b^2b_1\right)v_3 = 0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned}
a^2a_3 &= 0 \\
aba_3 &= 0 \\
-4a^2a_3 &= 0 \\
2a^2b_2 &= 0 \\
-4b^2a_3 &= 0 \\
-8aba_3 &= 0 \\
-2a^2a_2 + 4a^2b_3 &= 0 \\
-a^2a_2 + 2a^2b_3 &= 0 \\
-2b^2a_2 + 4b^2b_3 &= 0 \\
-2b^2a_3 + 2b^2b_1 &= 0 \\
2b^2b_2 - 2ba_3 &= 0 \\
-4aba_2 + 8abb_3 &= 0 \\
4abb_2 - 2aa_3 &= 0 \\
aba_1 - 2b^2a_2 + 2b^2b_3 &= 0 \\
a^2a_1 - 3aba_2 + 4abb_3 &= 0 \\
-4aba_3 + 4abb_1 + 2b^2b_2 &= 0 \\
-2a^2a_3 + 2a^2b_1 + 4abb_2 &= 0
\end{aligned}$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= \frac{2bb_3}{a} \\
a_2 &= 2b_3 \\
a_3 &= 0 \\
b_1 &= 0 \\
b_2 &= 0 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{2ax + 2b}{a} \\
\eta &= y
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x, y)\,\xi \\
&= y - \left(\frac{y + \sqrt{ax + b}}{\sqrt{ax + b}\,y}\right)\left(\frac{2ax + 2b}{a}\right) \\
&= \frac{a\,y^2 - 2ax - 2b - 2\sqrt{ax + b}\,y}{ay} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, y) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial y}\right) S(x, y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{a\,y^2-2ax-2b-2\sqrt{ax+b}\,y}{ay}} dy \end{aligned}$$

Which results in

$$S = \frac{\ln\left(-a\,y^2+2ax+2b+2\sqrt{ax+b}\,y\right)}{2} + \frac{\sqrt{ax+b}\,\operatorname{arctanh}\left(\frac{-2ay+2\sqrt{ax+b}}{2\sqrt{2a^2x+2ab+ax+b}}\right)}{\sqrt{2a^2x+2ab+ax+b}}$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{y+\sqrt{ax+b}}{\sqrt{ax+b}\,y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_y &= 0 \\ S_x &= \frac{4a\left(\frac{\left(\left(-\frac{y^2}{2}+x\right)a+y^2+b\right)\sqrt{ax+b}}{2} + \left(\left(-\frac{y^2}{4}+x\right)a+b\right)y\right)}{\sqrt{ax+b}\,\left(-a\,y^2+2ax+2b+2\sqrt{ax+b}\,y\right)^2} \\ S_y &= -\frac{2\left(\left(\left(-\frac{y^2}{2}+x\right)a+b\right)\sqrt{ax+b}+(ax+b)\,y\right)ay}{\sqrt{ax+b}\,\left(-a\,y^2+2ax+2b+2\sqrt{ax+b}\,y\right)^2} \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\sqrt{ax+b}\, \operatorname{arctanh}\left(\frac{-ay+\sqrt{ax+b}}{\sqrt{(2a+1)(ax+b)}}\right)}{\sqrt{(2a+1)\,(ax+b)}} + \frac{\ln\left(2y\sqrt{ax+b}+(-y^2+2x)\,a+2b\right)}{2} = c_1$$

Which simplifies to

$$\frac{\sqrt{ax+b}\, \operatorname{arctanh}\left(\frac{-ay+\sqrt{ax+b}}{\sqrt{(2a+1)(ax+b)}}\right)}{\sqrt{(2a+1)\,(ax+b)}} + \frac{\ln\left(2y\sqrt{ax+b}+(-y^2+2x)\,a+2b\right)}{2} = c_1$$

Summary

The solution(s) found are the following

$$\frac{\sqrt{ax+b}\, \operatorname{arctanh}\left(\frac{-ay+\sqrt{ax+b}}{\sqrt{(2a+1)(ax+b)}}\right)}{\sqrt{(2a+1)\,(ax+b)}} + \frac{\ln\left(2y\sqrt{ax+b}+(-y^2+2x)\,a+2b\right)}{2} = c_1 \tag{1}$$

Verification of solutions

$$\frac{\sqrt{ax+b}\, \operatorname{arctanh}\left(\frac{-ay+\sqrt{ax+b}}{\sqrt{(2a+1)(ax+b)}}\right)}{\sqrt{(2a+1)\,(ax+b)}} + \frac{\ln\left(2y\sqrt{ax+b}+(-y^2+2x)\,a+2b\right)}{2} = c_1$$

Verified OK.

ODE degree: 1.

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class A`]]
```

$$\boxed{yy' - (3ax + b)\, y = -x^3a^2 - ab\, x^2 + cx}$$

24.2.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{-x^3a^2 - ab\, x^2 + 3axy + by + cx}{y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2\xi_y - \omega_x\xi - \omega_y\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 3 to use as anstaz gives

$$\xi = x^3a_7 + x^2ya_8 + x\, y^2a_9 + y^3a_{10} + x^2a_4 + xya_5 + y^2a_6 + xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = x^3b_7 + x^2yb_8 + x\, y^2b_9 + y^3b_{10} + x^2b_4 + xyb_5 + y^2b_6 + xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, a_4, a_5, a_6, a_7, a_8, a_9, a_{10}, b_1, b_2, b_3, b_4, b_5, b_6, b_7, b_8, b_9, b_{10}\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned}
&3x^2b_7 + 2xyb_8 + y^2b_9 + 2xb_4 + yb_5 + b_2 \\
&+ \frac{(-x^3a^2 - ab\,x^2 + 3axy + by + cx)\,(-3x^2a_7 + x^2b_8 - 2xya_8 + 2xyb_9 - y^2a_9 + 3y^2b_{10} - 2xa_4 + xb_5 - ya_5}{y} \\
&- \frac{(-x^3a^2 - ab\,x^2 + 3axy + by + cx)^2\,(x^2a_8 + 2xya_9 + 3y^2a_{10} + xa_5 + 2ya_6 + a_3)}{y^2} \\
&- \frac{(-3a^2x^2 - 2abx + 3ay + c)\,(x^3a_7 + x^2ya_8 + x\,y^2a_9 + y^3a_{10} + x^2a_4 + xya_5 + y^2a_6 + xa_2 + ya_3 + a_1)}{y} \\
&- \left(\frac{3ax + b}{y} - \frac{-x^3a^2 - ab\,x^2 + 3axy + by + cx}{y^2}\right)(x^3b_7 + x^2yb_8 \\
&+ x\,y^2b_9 + y^3b_{10} + x^2b_4 + xyb_5 + y^2b_6 + xb_2 + yb_3 + b_1) = 0
\end{aligned} \tag{5E}$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

$$\text{Expression too large to display} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$\text{Expression too large to display} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2\}$$

Equation (7E) now becomes

$$\text{Expression too large to display} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$-a^4a_5$$

$$-6a^3ba_{10}$$

$$-2a^4a_6 - 4a^3ba$$

$$-16aba_{10} - 6aa$$

$$24a^2ba_{10} - 14a^2a_9$$

$$-abb_1 - c$$

$$2aba_1 - 2bca_3 - 2c$$

$$-a^4a_3 - 2a^3ba_5 - a^2b^2a_8 + 2a^2c$$

$$2abca_3 - a^2b_1 - abb_2 - c$$

$$-b^2a_3 - 3aa_1 - ba_2 + bb_3 -$$

$$-2b^2a_6 - 3aa_3 - ba_5 + 2bb_6 -$$

$$-2a^3ba_3 - a^2b^2a_5 + 2a^2ca_5 + 2abca_8 - a^2$$

$$-3a^2b^2a_{10} + 12a^3a_6 + 16a^2ba_9 + 6a^2ca_{10} - 4a^2a$$

$$-3b^2a_{10} - 3aa_6 - ba_9 + 3bb_{10} -$$

$$-a^2b^2a_3 + 2a^2ca_3 + 2abca_5 - a^2b_2 - abb_4 - c$$

$$-4a^3ba_6 - 2a^2b^2a_9 + 6a^3a_5 + 8a^2ba_8 + 4a^2ca_9 + 6a^2a$$

$$6a\,b^2a_{10} - 15a^2a_6 - 9aba_9 - 4abb_{10} - 18aca_{10} - 9a$$

$$2a\,b^2a_3 + 3a^2a_1 + 3aba_2 - 2abb_3 - 6aca_3 - 2bca_5 - 2c^2a_6 - 3c$$

$$-4aba_3 - b^2a_5 - 4bca_6 - 6aa_2 + 3ab_3 - 2ba_4 + bb_5 - 2ca_5 + 3$$

$$16a^2ba_6 + 4a\,b^2a_9 + 6abca_{10} - 5a^2a_5 - 3a^2b_6 - 2aba_8 - 3abb_9 - 12aca_9 - 12a$$

$$-10aba_6 - 2b^2a_9 - 6bca_{10} - 6aa_5 + 6ab_6 - 2ba_8 + 2bb_9 - 2ca_9 + 4c$$

$$-2a^2b^2a_6 + 6a^3a_3 + 8a^2ba_5 + 4a^2ca_6 + 2a\,b^2a_8 + 4abca_9 + 5a^2a_4 - 2a^2b_5 + 5aba_7 - 2abb$$

$$8a^2ba_3 + 2a\,b^2a_5 + 4abca_6 + 4a^2a_2 - 2a^2b_3 + 4aba_4 - 2abb_5 - 6aca_5 - 2bca_8 - 2c^2a_9 - 4c$$

$$4a\,b^2a_6 - 6a^2a_3 - 3aba_5 - 3abb_6 - 12aca_6 - b^2a_8 - 4bca_9 - 3c^2a_{10} - 9aa_4 + 3ab_5 - 3ba_7 + bb_8 - 3ca_8 + 3$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= \frac{cb_6}{a} \\
a_3 &= a_3 \\
a_4 &= -bb_6 \\
a_5 &= 0 \\
a_6 &= 0 \\
a_7 &= -ab_6 \\
a_8 &= 0 \\
a_9 &= 0 \\
a_{10} &= 0 \\
b_1 &= 0 \\
b_2 &= ca_3 \\
b_3 &= \frac{aba_3 + cb_6}{a} \\
b_4 &= -aba_3 \\
b_5 &= 3aa_3 - 2bb_6 \\
b_6 &= b_6 \\
b_7 &= -a^2a_3 \\
b_8 &= -3ab_6 \\
b_9 &= 0 \\
b_{10} &= 0
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= -\frac{x(a^2x^2 + abx - c)}{a} \\
\eta &= -\frac{y(3a^2x^2 + 2abx - ay - c)}{a}
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= -\frac{y(3a^2x^2+2abx-ay-c)}{a} - \left(\frac{-x^3a^2-ab\,x^2+3axy+by+cx}{y}\right)\left(-\frac{x(a^2x^2+abx-c)}{a}\right) \\
&= \frac{-a^4x^6-2a^3b\,x^5+3a^3x^4y-a^2b^2x^4+4a^2b\,x^3y+2a^2c\,x^4-3a^2x^2y^2+a\,b^2x^2y+2abc\,x^3-2abx\,y^2-}{ay} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta}dy \\
&= \int \frac{1}{\frac{-a^4x^6-2a^3b\,x^5+3a^3x^4y-a^2b^2x^4+4a^2b\,x^3y+2a^2c\,x^4-3a^2x^2y^2+a\,b^2x^2y+2abc\,x^3-2abx\,y^2-3ac\,x^2y+a\,y^3-bcxy-c^2x^2+c\,y^2}{ay}}dy
\end{aligned}
$$

Which results in

$$
S = a\left(-\frac{\ln\left(-a^2x^2-abx+ay+c\right)}{c} + \frac{\frac{\ln\left(a^2x^4+ab\,x^3-2a\,x^2y-bxy-c\,x^2+y^2\right)}{2} - \frac{bx\,\operatorname{arctanh}\left(\frac{-2a\,x^2-bx+2y}{\sqrt{b^2x^2+4c\,x^2}}\right)}{\sqrt{b^2x^2+4c\,x^2}}}{c}\right)
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{-x^3a^2 - ab\,x^2 + 3axy + by + cx}{y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}
R_x &= 1\\
R_y &= 0\\
S_x &= -\frac{a(x^3a^2 + ab\,x^2 + (-3ay - c)\,x - by)}{(a^2x^4 + ab\,x^3 + (-2ay - c)\,x^2 - bxy + y^2)\,(a^2x^2 + abx - ay - c)}\\
S_y &= -\frac{ay}{(a^2x^4 + ab\,x^3 + (-2ay - c)\,x^2 - bxy + y^2)\,(a^2x^2 + abx - ay - c)}
\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{a\left(2b \operatorname{arctanh}\left(\frac{2a\,x^2+bx-2y}{x\sqrt{b^2+4c}}\right) - 2\ln\left(-a^2x^2 + (-bx+y)\,a + c\right)\sqrt{b^2+4c} + \ln\left(a^2x^4 + ab\,x^3 + (-2ay - c)\,x^2\right.}{2\sqrt{b^2+4c}\,c}$$

Which simplifies to

$$\frac{a\left(2b \operatorname{arctanh}\left(\frac{2a\,x^2+bx-2y}{x\sqrt{b^2+4c}}\right) - 2\ln\left(-a^2x^2 + (-bx+y)\,a + c\right)\sqrt{b^2+4c} + \ln\left(a^2x^4 + ab\,x^3 + (-2ay - c)\,x^2\right.}{2\sqrt{b^2+4c}\,c}$$

Summary
The solution(s) found are the following

$$\frac{a\left(2b \operatorname{arctanh}\left(\frac{2a\,x^2+bx-2y}{x\sqrt{b^2+4c}}\right)-2\ln\left(-a^2x^2+(-bx+y)\,a+c\right)\sqrt{b^2+4c}+\ln\left(a^2x^4+ab\,x^3+(-2ay-c)\,x^2\right.\right.}{2\sqrt{b^2+4c}\,c} \tag{1}$$

$= c_1$

Verification of solutions

$$\frac{a\left(2b \operatorname{arctanh}\left(\frac{2a\,x^2+bx-2y}{x\sqrt{b^2+4c}}\right)-2\ln\left(-a^2x^2+(-bx+y)\,a+c\right)\sqrt{b^2+4c}+\ln\left(a^2x^4+ab\,x^3+(-2ay-c)\,x^2\right.\right.}{2\sqrt{b^2+4c}\,c}$$

$= c_1$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. subsection 1.3.3-2. Equations of the form $yy' = f_1(x)y + f_0(x)$
Problem number: 25.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class B`]]
```

Unable to solve or complete the solution.

$$yy' + \frac{a(5x+1)\,y}{2\sqrt{x}} = a^2(-x^2+1)$$

Unable to determine ODE type.

✗ Solution by Maple

```
dsolve(y(x)*diff(y(x),x)+1/2*a*(5*x+1)*x^(-1/2)*y(x)=a^2*(1-x^2),y(x), singsol=all)
```

No solution found

✗ Solution by Mathematica
Time used: 0.0 (sec). Leaf size: 0

```
DSolve[y[x]*y'[x]+1/2*a*(5*x+1)*x^(-1/2)*y[x]==a^2*(1-x^2),y[x],x,IncludeSingularSolutions -
```

Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. subsection 1.3.3-2. Equations of the form $yy' = f_1(x)y + f_0(x)$
Problem number: 50.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[_rational, [_Abel, `2nd type`, `class B`]]
```

Unable to solve or complete the solution.

$$\boxed{yy' - \frac{a(x+4)\,y}{5x^{\frac{8}{5}}} = \frac{a^2(x-1)\,(3x+7)}{5x^{\frac{3}{5}}}}$$

Unable to determine ODE type.

Maple trace

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 1, section 1.3. Abel Equations of the Second Kind. subsection 1.3.4-2. Equations of the form $(g_1(x) + g_0(x))y' = f_2(x)y^2 + f_1(x)y + f_0(x)$
Problem number: 1.
ODE order: 1.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact", "first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _exact, _rational, [_Abel, `2nd
   type`, `class A`]]
```

$$\boxed{(Ay + Bx + a)\, y' + By = -kx - b}$$

25.1.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = -\frac{By + kx + b}{Ay + Bx + a}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 - \frac{(By+kx+b)(b_3-a_2)}{Ay+Bx+a} - \frac{(By+kx+b)^2 a_3}{(Ay+Bx+a)^2} - \left(-\frac{k}{Ay+Bx+a} + \frac{(By+kx+b)B}{(Ay+Bx+a)^2}\right)(xa_2+ya_3+a_1) - \left(-\frac{B}{Ay+Bx+a} + \frac{(By+kx+b)A}{(Ay+Bx+a)^2}\right)(xb_2+yb_3+b_1) = 0 \tag{5E}$$

Putting the above in normal form gives

$$\frac{A^2y^2b_2 + 2ABxyb_2 + AB\,y^2a_2 - AB\,y^2b_3 - Ak\,x^2b_2 + 2Akxya_2 - 2Akxyb_3 + Ak\,y^2a_3 + 2B^2x^2b_2 - 2B^2y}{}$$

$= 0$

Setting the numerator to zero gives

$$\begin{aligned} &A^2y^2b_2+2ABxyb_2+AB\,y^2a_2-AB\,y^2b_3-Ak\,x^2b_2+2Akxya_2-2Akxyb_3 \\ &+Ak\,y^2a_3+2B^2x^2b_2-2B^2y^2a_3+Bk\,x^2a_2-Bk\,x^2b_3-2Bkxya_3-k^2x^2a_3 \\ &+2Aayb_2-Abxb_2+Abya_2-2Abyb_3-Akxb_1+Akya_1+B^2xb_1-B^2ya_1 \\ &+3Baxb_2+Baya_2-Bbxb_3-3Bbya_3+2akxa_2-akxb_3+akya_3 \\ &-2bkxa_3-Abb_1+Bab_1-Bba_1+a^2b_2+aba_2-abb_3+aka_1-b^2a_3=0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&A^2b_2v_2^2 + ABa_2v_2^2 + 2ABb_2v_1v_2 - ABb_3v_2^2 + 2Aka_2v_1v_2 + Aka_3v_2^2 \\
&- Akb_2v_1^2 - 2Akb_3v_1v_2 - 2B^2a_3v_2^2 + 2B^2b_2v_1^2 + Bka_2v_1^2 - 2Bka_3v_1v_2 \\
&- Bkb_3v_1^2 - k^2a_3v_1^2 + 2Aab_2v_2 + Aba_2v_2 - Abb_2v_1 - 2Abb_3v_2 \\
&+ Aka_1v_2 - Akb_1v_1 - B^2a_1v_2 + B^2b_1v_1 + Baa_2v_2 + 3Bab_2v_1 \\
&- 3Bba_3v_2 - Bbb_3v_1 + 2aka_2v_1 + aka_3v_2 - akb_3v_1 - 2bka_3v_1 \\
&- Abb_1 + Bab_1 - Bba_1 + a^2b_2 + aba_2 - abb_3 + aka_1 - b^2a_3 = 0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&(-Akb_2 + 2B^2b_2 + Bka_2 - Bkb_3 - k^2a_3)\, v_1^2 \\
&+ (2ABb_2 + 2Aka_2 - 2Akb_3 - 2Bka_3)\, v_1v_2 \\
&+ (-Abb_2 - Akb_1 + B^2b_1 + 3Bab_2 - Bbb_3 + 2aka_2 - akb_3 - 2bka_3)\, v_1 \\
&+ (A^2b_2 + ABa_2 - ABb_3 + Aka_3 - 2B^2a_3)\, v_2^2 \\
&+ (2Aab_2 + Aba_2 - 2Abb_3 + Aka_1 - B^2a_1 + Baa_2 - 3Bba_3 + aka_3)\, v_2 \\
&- Abb_1 + Bab_1 - Bba_1 + a^2b_2 + aba_2 - abb_3 + aka_1 - b^2a_3 = 0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
2ABb_2 + 2Aka_2 - 2Akb_3 - 2Bka_3 &= 0 \\
-Akb_2 + 2B^2b_2 + Bka_2 - Bkb_3 - k^2a_3 &= 0 \\
A^2b_2 + ABa_2 - ABb_3 + Aka_3 - 2B^2a_3 &= 0 \\
2Aab_2 + Aba_2 - 2Abb_3 + Aka_1 - B^2a_1 + Baa_2 - 3Bba_3 + aka_3 &= 0 \\
-Abb_2 - Akb_1 + B^2b_1 + 3Bab_2 - Bbb_3 + 2aka_2 - akb_3 - 2bka_3 &= 0 \\
-Abb_1 + Bab_1 - Bba_1 + a^2b_2 + aba_2 - abb_3 + aka_1 - b^2a_3 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= -\frac{ABbb_2 + Aakb_2 - Abkb_3 - 2B^2ab_2 + Bakb_3}{k\,(Ak - B^2)} \\
a_2 &= -\frac{2Bb_2 - kb_3}{k} \\
a_3 &= -\frac{Ab_2}{k} \\
b_1 &= \frac{Abb_2 - Bab_2 - Bbb_3 + akb_3}{Ak - B^2} \\
b_2 &= b_2 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{Akx - B^2x + Ab - Ba}{Ak - B^2} \\
\eta &= \frac{Aky - B^2y - Bb + ak}{Ak - B^2}
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= \frac{Aky - B^2y - Bb + ak}{Ak - B^2} - \left(-\frac{By + kx + b}{Ay + Bx + a}\right)\left(\frac{Akx - B^2x + Ab - Ba}{Ak - B^2}\right) \\
&= \frac{A^2k\,y^2 - A\,B^2y^2 + 2ABkxy + A\,k^2x^2 - 2B^3xy - B^2k\,x^2 + 2Aaky + 2Abkx - 2B^2ay - 2B^2bx + A\,b}{A^2ky - A\,B^2y + ABkx - x\,B^3 + Aak - B^2a} \\
\xi &= 0
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right)S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{\frac{A^2k\,y^2-A\,B^2y^2+2ABkxy+A\,k^2x^2-2B^3xy-B^2k\,x^2+2Aaky+2Abkx-2B^2ay-2B^2bx+A\,b^2-2Bab+a^2k}{A^2ky-A\,B^2y+ABkx-x\,B^3+Aak-B^2a}} dy
\end{aligned}
$$

Which results in

$$
S = \frac{\ln\left(A^2k\,y^2 - A\,B^2y^2 + 2ABkxy + A\,k^2x^2 - 2B^3xy - B^2k\,x^2 + 2Aaky + 2Abkx - 2B^2ay - 2B^2bx + \right.}{2}
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}
$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$
\omega(x,y) = -\frac{By + kx + b}{Ay + Bx + a}
$$

Evaluating all the partial derivatives gives

$$
\begin{aligned}
R_x &= 1 \\
R_y &= 0 \\
S_x &= \frac{(By + kx + b)\,(Ak - B^2)}{A^2k\,y^2 + (-B^2y^2 + 2Bkxy + k^2x^2 + (2ay + 2bx)\,k + b^2)\,A - 2\left(B^2y + \left(\frac{kx}{2} + b\right)B - \frac{ak}{2}\right)(Bx + a)} \\
S_y &= \frac{(Ak - B^2)\,(Ay + Bx + a)}{A^2k\,y^2 + (-B^2y^2 + 2Bkxy + k^2x^2 + (2ay + 2bx)\,k + b^2)\,A - 2\left(B^2y + \left(\frac{kx}{2} + b\right)B - \frac{ak}{2}\right)(Bx + a)}
\end{aligned}
$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$
\frac{dS}{dR} = 0 \tag{2A}
$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$
\frac{dS}{dR} = 0
$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\ln \left(A\,k^2 x^2+\left(-B^2 x^2+2ABxy+2Abx+\left(Ay+a\right)^2\right) k-\left(By+b\right)\left(2B^2 x+\left(Ay+2a\right) B-Ab\right)\right)}{2} = c_1$$

Which simplifies to

$$\frac{\ln \left(A\,k^2 x^2+\left(-B^2 x^2+2ABxy+2Abx+\left(Ay+a\right)^2\right) k-\left(By+b\right)\left(2B^2 x+\left(Ay+2a\right) B-Ab\right)\right)}{2} = c_1$$

Summary
The solution(s) found are the following

$$\frac{\ln \left(A\,k^2 x^2+\left(-B^2 x^2+2ABxy+2Abx+\left(Ay+a\right)^2\right) k-\left(By+b\right)\left(2B^2 x+\left(Ay+2a\right) B-Ab\right)\right)}{2} = c_1 \tag{1}$$

Verification of solutions

$$\frac{\ln \left(A\,k^2 x^2+\left(-B^2 x^2+2ABxy+2Abx+\left(Ay+a\right)^2\right) k-\left(By+b\right)\left(2B^2 x+\left(Ay+2a\right) B-Ab\right)\right)}{2} = c_1$$

Verified OK.

25.1.2 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y)+N(x,y)\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial \phi}{\partial x}+\frac{\partial \phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$
\begin{aligned}
\frac{\partial \phi}{\partial x} &= M \\
\frac{\partial \phi}{\partial y} &= N
\end{aligned}
$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$
M(x, y) \, \mathrm{d}x + N(x, y) \, \mathrm{d}y = 0 \tag{1A}
$$

Therefore

$$
\begin{aligned}
(Ay + Bx + a) \, \mathrm{d}y &= (-By - kx - b) \, \mathrm{d}x \\
(By + kx + b) \, \mathrm{d}x + (Ay + Bx + a) \, \mathrm{d}y &= 0 \qquad (2A)
\end{aligned}
$$

Comparing (1A) and (2A) shows that

$$
\begin{aligned}
M(x, y) &= By + kx + b \\
N(x, y) &= Ay + Bx + a
\end{aligned}
$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$
\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}
$$

Using result found above gives

$$
\begin{aligned}
\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}(By + kx + b) \\
&= B
\end{aligned}
$$

And

$$
\begin{aligned}
\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(Ay + Bx + a) \\
&= B
\end{aligned}
$$

Since $\frac{\partial M}{\partial y}=\frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x,y)$

$$\frac{\partial \phi}{\partial x}=M \tag{1}$$
$$\frac{\partial \phi}{\partial y}=N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int M\,\mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x}\,\mathrm{d}x=\int By+kx+b\,\mathrm{d}x$$
$$\phi=\frac{k\,x^2}{2}+(By+b)\,x+f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y}=Bx+f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y}=Ay+Bx+a$. Therefore equation (4) becomes

$$Ay+Bx+a=Bx+f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y)=Ay+a$$

Integrating the above w.r.t y gives

$$\int f'(y)\,\mathrm{d}y=\int (Ay+a)\,\mathrm{d}y$$
$$f(y)=\frac{1}{2}A\,y^2+ay+c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = \frac{k\,x^2}{2} + (By + b)\,x + \frac{A\,y^2}{2} + ay + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = \frac{k\,x^2}{2} + (By + b)\,x + \frac{A\,y^2}{2} + ay$$

Summary

The solution(s) found are the following

$$\frac{k\,x^2}{2} + (By + b)\,x + \frac{Ay^2}{2} + ay = c_1 \tag{1}$$

Verification of solutions

$$\frac{k\,x^2}{2} + (By + b)\,x + \frac{Ay^2}{2} + ay = c_1$$

Verified OK.

25.1.3 Maple step by step solution

Let's solve

$(Ay + Bx + a)\,y' + By = -kx - b$

- Highest derivative means the order of the ODE is 1

  y'

□ Check if ODE is exact

  ◦ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  ◦ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

  ◦ Evaluate derivatives

    $B = B$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y)=c_1, M(x,y)=F'(x,y), N(x,y)=\frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y)=\int (By+kx+b)\,dx+f_1(y)$

- Evaluate integral

  $F(x,y)=Bxy+\frac{k\,x^2}{2}+bx+f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y)=\frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $Ay+Bx+a=Bx+\frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y)=Ay+a$

- Solve for $f_1(y)$

  $f_1(y)=\frac{1}{2}A\,y^2+ay$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y)=Bxy+\frac{1}{2}k\,x^2+bx+\frac{1}{2}A\,y^2+ay$

- Substitute $F(x,y)$ into the solution of the ODE

  $Bxy+\frac{1}{2}k\,x^2+bx+\frac{1}{2}A\,y^2+ay=c_1$

- Solve for y

  $\left\{y=-\frac{Bx-\sqrt{-Ak\,x^2+B^2x^2-2Abx+2Bax+2Ac_1+a^2}+a}{A}, y=-\frac{Bx+\sqrt{-Ak\,x^2+B^2x^2-2Abx+2Bax+2Ac_1+a^2}+a}{A}\right\}$

The type(s) of ODE detected by this program : **"first_order_ode_lie_symmetry_calculated"**

Maple gives the following as the ode type

```
[[_homogeneous, `class C`], _rational, [_Abel, `2nd type`, `
   class A`]]
```

$$\boxed{(y + ax + b)\, y' - \alpha y = \beta x + \gamma}$$

25.2.1 Solving as first order ode lie symmetry calculated ode

Writing the ode as

$$y' = \frac{\alpha y + \beta x + \gamma}{ax + b + y}$$
$$y' = \omega(x, y)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_y - \xi_x) - \omega^2 \xi_y - \omega_x \xi - \omega_y \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + ya_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + yb_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$\begin{aligned} b_2 &+ \frac{(\alpha y + \beta x + \gamma)(b_3 - a_2)}{ax + b + y} - \frac{(\alpha y + \beta x + \gamma)^2 a_3}{(ax + b + y)^2} \\ &- \left(\frac{\beta}{ax + b + y} - \frac{(\alpha y + \beta x + \gamma) a}{(ax + b + y)^2}\right)(xa_2 + ya_3 + a_1) \\ &- \left(\frac{\alpha}{ax + b + y} - \frac{\alpha y + \beta x + \gamma}{(ax + b + y)^2}\right)(xb_2 + yb_3 + b_1) = 0 \end{aligned} \tag{5E}$$

Putting the above in normal form gives

$$\frac{a^2x^2b_2 - a\alpha\, x^2b_2 + a\alpha\, y^2a_3 - a\beta\, x^2a_2 + a\beta\, x^2b_3 - \alpha^2y^2a_3 - 2\alpha\beta xya_3 - \beta^2x^2a_3 - a\alpha xb_1 + a\alpha ya_1 + 2abx}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned} &a^2x^2b_2 - a\alpha\, x^2b_2 + a\alpha\, y^2a_3 - a\beta\, x^2a_2 + a\beta\, x^2b_3 - \alpha^2y^2a_3 - 2\alpha\beta xya_3 \\ &- \beta^2x^2a_3 - a\alpha xb_1 + a\alpha ya_1 + 2abxb_2 + a\gamma xb_3 + a\gamma ya_3 + 2axyb_2 - \alpha bxb_2 \\ &- \alpha bya_2 - 2\alpha\gamma ya_3 - \alpha\, y^2a_2 + \alpha\, y^2b_3 - 2b\beta xa_2 + b\beta xb_3 - b\beta ya_3 - 2\beta\gamma xa_3 \\ &+ \beta\, x^2b_2 - 2\beta xya_2 + 2\beta xyb_3 - \beta\, y^2a_3 + a\gamma a_1 - \alpha bb_1 + b^2b_2 - b\beta a_1 - b\gamma a_2 \\ &+ b\gamma b_3 + 2byb_2 + \beta xb_1 - \beta ya_1 - \gamma^2a_3 + \gamma xb_2 - \gamma ya_2 + 2\gamma yb_3 + y^2b_2 + \gamma b_1 = 0 \end{aligned} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, y\}$ in them.

$$\{x, y\}$$

The following substitution is now made to be able to collect on all terms with $\{x, y\}$ in them

$$\{x = v_1, y = v_2\}$$

The above PDE (6E) now becomes

$$
\begin{aligned}
&a^{2} b_{2} v_{1}^{2}+a \alpha a_{3} v_{2}^{2}-a \alpha b_{2} v_{1}^{2}-a \beta a_{2} v_{1}^{2}+a \beta b_{3} v_{1}^{2}-\alpha^{2} a_{3} v_{2}^{2}-2 \alpha \beta a_{3} v_{1} v_{2} \\
&-\beta^{2} a_{3} v_{1}^{2}+a \alpha a_{1} v_{2}-a \alpha b_{1} v_{1}+2 a b b_{2} v_{1}+a \gamma a_{3} v_{2}+a \gamma b_{3} v_{1}+2 a b_{2} v_{1} v_{2} \\
&-\alpha b a_{2} v_{2}-\alpha b b_{2} v_{1}-2 \alpha \gamma a_{3} v_{2}-\alpha a_{2} v_{2}^{2}+\alpha b_{3} v_{2}^{2}-2 b \beta a_{2} v_{1}-b \beta a_{3} v_{2} \\
&+b \beta b_{3} v_{1}-2 \beta \gamma a_{3} v_{1}-2 \beta a_{2} v_{1} v_{2}-\beta a_{3} v_{2}^{2}+\beta b_{2} v_{1}^{2}+2 \beta b_{3} v_{1} v_{2} \\
&+a \gamma a_{1}-\alpha b b_{1}+b^{2} b_{2}-b \beta a_{1}-b \gamma a_{2}+b \gamma b_{3}+2 b b_{2} v_{2}-\beta a_{1} v_{2} \\
&+\beta b_{1} v_{1}-\gamma^{2} a_{3}-\gamma a_{2} v_{2}+\gamma b_{2} v_{1}+2 \gamma b_{3} v_{2}+b_{2} v_{2}^{2}+\gamma b_{1}=0
\end{aligned} \tag{7E}
$$

Collecting the above on the terms v_i introduced, and these are

$$
\{v_1, v_2\}
$$

Equation (7E) now becomes

$$
\begin{aligned}
&\left(a^{2} b_{2}-a \alpha b_{2}-a \beta a_{2}+a \beta b_{3}-\beta^{2} a_{3}+\beta b_{2}\right) v_{1}^{2} \\
&+\left(-2 \alpha \beta a_{3}+2 a b_{2}-2 \beta a_{2}+2 \beta b_{3}\right) v_{1} v_{2} \\
&+\left(-a \alpha b_{1}+2 a b b_{2}+a \gamma b_{3}-\alpha b b_{2}-2 b \beta a_{2}+b \beta b_{3}-2 \beta \gamma a_{3}+\beta b_{1}+\gamma b_{2}\right) v_{1} \\
&+\left(a \alpha a_{3}-\alpha^{2} a_{3}-\alpha a_{2}+\alpha b_{3}-\beta a_{3}+b_{2}\right) v_{2}^{2} \\
&+\left(a \alpha a_{1}+a \gamma a_{3}-\alpha b a_{2}-2 \alpha \gamma a_{3}-b \beta a_{3}+2 b b_{2}-\beta a_{1}-\gamma a_{2}+2 \gamma b_{3}\right) v_{2} \\
&+a \gamma a_{1}-\alpha b b_{1}+b^{2} b_{2}-b \beta a_{1}-b \gamma a_{2}+b \gamma b_{3}-\gamma^{2} a_{3}+\gamma b_{1}=0
\end{aligned} \tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
-2 \alpha \beta a_{3}+2 a b_{2}-2 \beta a_{2}+2 \beta b_{3} &=0 \\
a \alpha a_{3}-\alpha^{2} a_{3}-\alpha a_{2}+\alpha b_{3}-\beta a_{3}+b_{2} &=0 \\
a^{2} b_{2}-a \alpha b_{2}-a \beta a_{2}+a \beta b_{3}-\beta^{2} a_{3}+\beta b_{2} &=0 \\
a \gamma a_{1}-\alpha b b_{1}+b^{2} b_{2}-b \beta a_{1}-b \gamma a_{2}+b \gamma b_{3}-\gamma^{2} a_{3}+\gamma b_{1} &=0 \\
a \alpha a_{1}+a \gamma a_{3}-\alpha b a_{2}-2 \alpha \gamma a_{3}-b \beta a_{3}+2 b b_{2}-\beta a_{1}-\gamma a_{2}+2 \gamma b_{3} &=0 \\
-a \alpha b_{1}+2 a b b_{2}+a \gamma b_{3}-\alpha b b_{2}-2 b \beta a_{2}+b \beta b_{3}-2 \beta \gamma a_{3}+\beta b_{1}+\gamma b_{2} &=0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= \frac{a\alpha b a_3 - \alpha^2 b a_3 + \alpha b b_3 + \alpha\gamma a_3 - b\beta a_3 - \gamma b_3}{a\alpha - \beta} \\
a_2 &= a a_3 - \alpha a_3 + b_3 \\
a_3 &= a_3 \\
b_1 &= \frac{\alpha b\beta a_3 + a\gamma b_3 - b\beta b_3 - \beta\gamma a_3}{a\alpha - \beta} \\
b_2 &= \beta a_3 \\
b_3 &= b_3
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= \frac{a\alpha x + b\alpha - \beta x - \gamma}{a\alpha - \beta} \\
\eta &= \frac{a\alpha y + a\gamma - b\beta - \beta y}{a\alpha - \beta}
\end{aligned}
$$

Shifting is now applied to make $\xi = 0$ in order to simplify the rest of the computation

$$
\begin{aligned}
\eta &= \eta - \omega(x,y)\,\xi \\
&= \frac{a\alpha y + a\gamma - b\beta - \beta y}{a\alpha - \beta} - \left(\frac{\alpha y + \beta x + \gamma}{a x + b + y}\right)\left(\frac{a\alpha x + b\alpha - \beta x - \gamma}{a\alpha - \beta}\right) \\
&= \frac{a^2\alpha x y - a\,\alpha^2 x y - a\alpha\beta\, x^2 + a^2\gamma x + a\alpha b y - a\alpha\gamma x + a\alpha\, y^2 - ab\beta x - a\beta x y - \alpha^2 b y - \alpha b\beta x + \alpha\beta x y +}{a^2\alpha x + a\alpha b + a\alpha y - a\beta x - b\beta - \beta}
\end{aligned}
$$

$$
\xi = 0
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,y) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dy}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial y}\right) S(x,y) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$\begin{aligned}S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{\frac{a^2\alpha xy - a\,\alpha^2 xy - a\alpha\beta\, x^2 + a^2\gamma x + a\alpha by - a\alpha\gamma x + a\alpha\, y^2 - ab\beta x - a\beta xy - \alpha^2 by - \alpha b\beta x + \alpha\beta xy + \beta^2 x^2 + b\gamma a + a\gamma y - b\gamma\alpha + \alpha\gamma y - b^2\beta - 2b\beta y + 2\beta\gamma}{a^2\alpha x + a\alpha b + a\alpha y - a\beta x - b\beta - \beta y}}\end{aligned}$$

Which results in

$$S = (a\alpha - \beta)\left(\frac{\ln\left(a^2\alpha xy - a\,\alpha^2 xy - a\alpha\beta\, x^2 + a^2\gamma x + a\alpha by - a\alpha\gamma x + a\alpha\, y^2 - ab\beta x - a\beta xy - \alpha^2 by - \alpha\right.}{2a\alpha - 2}\right.$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,y)S_y}{R_x + \omega(x,y)R_y} \tag{2}$$

Where in the above R_x, R_y, S_x, S_y are all partial derivatives and $\omega(x,y)$ is the right hand side of the original ode given by

$$\omega(x,y) = \frac{\alpha y + \beta x + \gamma}{ax + b + y}$$

Evaluating all the partial derivatives gives

$$\begin{aligned}R_x &= 1 \\ R_y &= 0 \\ S_x &= -\frac{(\alpha y + \beta x + \gamma)(a\alpha - \beta)}{-y(ax+b)\alpha^2 + (a^2xy + (-x^2\beta - \gamma x + y(b+y))a - (\beta x + \gamma)(b - y))\alpha + a^2\gamma x - (\beta x - \gamma)(b -} \\ S_y &= \frac{(a\alpha - \beta)(ax + b + y)}{-y(ax+b)\alpha^2 + (a^2xy + (-x^2\beta - \gamma x + y(b+y))a - (\beta x + \gamma)(b - y))\alpha + a^2\gamma x - (\beta x - \gamma)(b +}\end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = 0 \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, y in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = 0$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by

integration when the ode is in the canonical coordinates R, S. Integrating the above gives

$$S(R) = c_1 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, y coordinates. This results in

$$\frac{\frac{\ln\left((-a\alpha\beta+\beta^2)x^2+(((-a+\alpha)y+2\gamma+(-\alpha-a)b)\beta+a(\alpha y+\gamma)(a-\alpha))x-(b+y)^2\beta+(ay+\gamma+b(a-\alpha))(\alpha y+\gamma)\right)\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}{2}+\arctan\left(\right.}{\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}$$

Which simplifies to

$$\frac{\frac{\ln\left((-a\alpha\beta+\beta^2)x^2+(((-a+\alpha)y+2\gamma+(-\alpha-a)b)\beta+a(\alpha y+\gamma)(a-\alpha))x-(b+y)^2\beta+(ay+\gamma+b(a-\alpha))(\alpha y+\gamma)\right)\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}{2}+\arctan\left(\right.}{\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}$$

Summary

The solution(s) found are the following

$$\frac{\frac{\ln\left((-a\alpha\beta+\beta^2)x^2+(((-a+\alpha)y+2\gamma+(-\alpha-a)b)\beta+a(\alpha y+\gamma)(a-\alpha))x-(b+y)^2\beta+(ay+\gamma+b(a-\alpha))(\alpha y+\gamma)\right)\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}{2}+\arctan\left(\right.}{\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}} \tag{1}$$
$$= c_1$$

Verification of solutions

$$\frac{\frac{\ln\left((-a\alpha\beta+\beta^2)x^2+(((-a+\alpha)y+2\gamma+(-\alpha-a)b)\beta+a(\alpha y+\gamma)(a-\alpha))x-(b+y)^2\beta+(ay+\gamma+b(a-\alpha))(\alpha y+\gamma)\right)\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}{2}+\arctan\left(\right.}{\sqrt{-a^2+2a\alpha-\alpha^2-4\beta}}$$
$$= c_1$$

Verified OK.

The type(s) of ODE detected by this program : **"exact"**

Maple gives the following as the ode type

```
[_exact, _rational, [_1st_order, `_with_symmetry_[F(x),G(x)]`],
    [_Abel, `2nd type`, `class A`]]
```

$$\boxed{(y + A\,x^n + a)\,y' + nA\,x^{n-1}y = -k\,x^m - b}$$

25.4.1 Solving as exact ode

Entering Exact first order ODE solver. (Form one type)

To solve an ode of the form

$$M(x,y) + N(x,y)\,\frac{dy}{dx} = 0 \tag{A}$$

We assume there exists a function $\phi(x,y) = c$ where c is constant, that satisfies the ode. Taking derivative of ϕ w.r.t. x gives

$$\frac{d}{dx}\phi(x,y) = 0$$

Hence

$$\frac{\partial\phi}{\partial x} + \frac{\partial\phi}{\partial y}\frac{dy}{dx} = 0 \tag{B}$$

Comparing (A,B) shows that

$$\frac{\partial \phi}{\partial x} = M$$
$$\frac{\partial \phi}{\partial y} = N$$

But since $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ then for the above to be valid, we require that

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

If the above condition is satisfied, then the original ode is called exact. We still need to determine $\phi(x, y)$ but at least we know now that we can do that since the condition $\frac{\partial^2 \phi}{\partial x \partial y} = \frac{\partial^2 \phi}{\partial y \partial x}$ is satisfied. If this condition is not satisfied then this method will not work and we have to now look for an integrating factor to force this condition, which might or might not exist. The first step is to write the ODE in standard form to check for exactness, which is

$$M(x, y)\,\mathrm{d}x + N(x, y)\,\mathrm{d}y = 0 \tag{1A}$$

Therefore

$$(y + A\,x^{n} + a)\,\mathrm{d}y = \left(-nA\,x^{n-1}y - k\,x^{m} - b\right)\mathrm{d}x$$
$$\left(nA\,x^{n-1}y + k\,x^{m} + b\right)\mathrm{d}x + (y + A\,x^{n} + a)\,\mathrm{d}y = 0 \tag{2A}$$

Comparing (1A) and (2A) shows that

$$M(x, y) = nA\,x^{n-1}y + k\,x^{m} + b$$
$$N(x, y) = y + A\,x^{n} + a$$

The next step is to determine if the ODE is is exact or not. The ODE is exact when the following condition is satisfied

$$\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$$

Using result found above gives

$$\begin{aligned}\frac{\partial M}{\partial y} &= \frac{\partial}{\partial y}\left(nA\,x^{n-1}y + k\,x^{m} + b\right)\\ &= A\,x^{n-1}n\end{aligned}$$

And

$$\begin{aligned}\frac{\partial N}{\partial x} &= \frac{\partial}{\partial x}(y + A\,x^{n} + a)\\ &= A\,x^{n-1}n\end{aligned}$$

Since $\frac{\partial M}{\partial y} = \frac{\partial N}{\partial x}$, then the ODE is exact The following equations are now set up to solve for the function $\phi(x, y)$

$$\frac{\partial \phi}{\partial x} = M \tag{1}$$
$$\frac{\partial \phi}{\partial y} = N \tag{2}$$

Integrating (1) w.r.t. x gives

$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int M \, \mathrm{d}x$$
$$\int \frac{\partial \phi}{\partial x} \, \mathrm{d}x = \int nA\, x^{n-1} y + k\, x^{m} + b \, \mathrm{d}x$$
$$\phi = bx + \frac{k\, x^{m+1}}{m+1} + Ay\, x^{n} + f(y) \tag{3}$$

Where $f(y)$ is used for the constant of integration since ϕ is a function of both x and y. Taking derivative of equation (3) w.r.t y gives

$$\frac{\partial \phi}{\partial y} = A\, x^{n} + f'(y) \tag{4}$$

But equation (2) says that $\frac{\partial \phi}{\partial y} = y + A\, x^{n} + a$. Therefore equation (4) becomes

$$y + A\, x^{n} + a = A\, x^{n} + f'(y) \tag{5}$$

Solving equation (5) for $f'(y)$ gives

$$f'(y) = a + y$$

Integrating the above w.r.t y gives

$$\int f'(y) \, \mathrm{d}y = \int (a + y) \, \mathrm{d}y$$
$$f(y) = ay + \frac{1}{2} y^{2} + c_1$$

Where c_1 is constant of integration. Substituting result found above for $f(y)$ into equation (3) gives ϕ

$$\phi = bx + \frac{k\,x^{m+1}}{m+1} + Ay\,x^n + ay + \frac{y^2}{2} + c_1$$

But since ϕ itself is a constant function, then let $\phi = c_2$ where c_2 is new constant and combining c_1 and c_2 constants into new constant c_1 gives the solution as

$$c_1 = bx + \frac{k\,x^{m+1}}{m+1} + Ay\,x^n + ay + \frac{y^2}{2}$$

Summary

The solution(s) found are the following

$$bx + \frac{k\,x^{m+1}}{m+1} + Ayx^n + ay + \frac{y^2}{2} = c_1 \tag{1}$$

Verification of solutions

$$bx + \frac{k\,x^{m+1}}{m+1} + Ayx^n + ay + \frac{y^2}{2} = c_1$$

Verified OK.

25.4.2 Maple step by step solution

Let's solve

$(y + A\,x^n + a)\,y' + nA\,x^{n-1}y = -k\,x^m - b$

- Highest derivative means the order of the ODE is 1

  y'

- □ Check if ODE is exact

  - ∘ ODE is exact if the lhs is the total derivative of a C^2 function

    $F'(x, y) = 0$

  - ∘ Compute derivative of lhs

    $F'(x, y) + \left(\frac{\partial}{\partial y}F(x, y)\right) y' = 0$

  - ∘ Evaluate derivatives

    $A\,x^{n-1}n = \frac{A\,x^n n}{x}$

- Simplify

  $A\,x^{n-1}n = A\,x^{n-1}n$

- Condition met, ODE is exact

- Exact ODE implies solution will be of this form

  $\left[F(x,y) = c_1, M(x,y) = F'(x,y)\,, N(x,y) = \frac{\partial}{\partial y}F(x,y)\right]$

- Solve for $F(x,y)$ by integrating $M(x,y)$ with respect to x

  $F(x,y) = \int (nA\,x^{n-1}y + k\,x^m + b)\,dx + f_1(y)$

- Evaluate integral

  $F(x,y) = bx + \frac{k\,x^{m+1}}{m+1} + Ay\,x^n + f_1(y)$

- Take derivative of $F(x,y)$ with respect to y

  $N(x,y) = \frac{\partial}{\partial y}F(x,y)$

- Compute derivative

  $y + A\,x^n + a = A\,x^n + \frac{d}{dy}f_1(y)$

- Isolate for $\frac{d}{dy}f_1(y)$

  $\frac{d}{dy}f_1(y) = a + y$

- Solve for $f_1(y)$

  $f_1(y) = ay + \frac{1}{2}y^2$

- Substitute $f_1(y)$ into equation for $F(x,y)$

  $F(x,y) = bx + \frac{k\,x^{m+1}}{m+1} + Ay\,x^n + ay + \frac{y^2}{2}$

- Substitute $F(x,y)$ into the solution of the ODE

  $bx + \frac{k\,x^{m+1}}{m+1} + Ay\,x^n + ay + \frac{y^2}{2} = c_1$

- Solve for y

  $\left\{y = -\frac{Am\,x^n + A\,x^n + am - \sqrt{A^2(x^n)^2m^2 + 2A^2(x^n)^2m + 2A\,x^n a\,m^2 + A^2(x^n)^2 + 4A\,x^n am + m^2a^2 - 2b\,m^2x + 2A\,x^n a - 2x^{m+1}km +}}{m+1}\right.$

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff", "second_order_ode_can_be_made_integrable"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + ay = 0}$$

26.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = 0, C = a$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda x} + a\, e^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$\lambda^2 + a = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = a$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(a)} \\ &= \pm\sqrt{-a}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-a} \\ \lambda_2 &= -\sqrt{-a}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-a} \\ \lambda_2 &= -\sqrt{-a}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ y &= c_1 e^{(\sqrt{-a})x} + c_2 e^{(-\sqrt{-a})x}\end{aligned}$$

Or

$$y = c_1 \mathrm{e}^{\sqrt{-a}\,x} + c_2 \mathrm{e}^{-\sqrt{-a}\,x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\sqrt{-a}\,x} + c_2 \mathrm{e}^{-\sqrt{-a}\,x} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\sqrt{-a}\,x} + c_2 \mathrm{e}^{-\sqrt{-a}\,x}$$

Verified OK.

26.1.2 Solving as second order ode can be made integrable ode

Multiplying the ode by y' gives

$$y'y'' + ay'y = 0$$

Integrating the above w.r.t x gives

$$\int (y'y'' + ay'y)\,dx = 0$$
$$\frac{y'^2}{2} + \frac{y^2 a}{2} = c_2$$

Which is now solved for y. Solving the given ode for y' results in 2 differential equations to solve. Each one of these will generate a solution. The equations generated are

$$y' = \sqrt{-y^2 a + 2c_1} \tag{1}$$
$$y' = -\sqrt{-y^2 a + 2c_1} \tag{2}$$

Now each one of the above ODE is solved.

Solving equation (1)

Integrating both sides gives

$$\int \frac{1}{\sqrt{-a\,y^2 + 2c_1}} dy = \int dx$$
$$\frac{\arctan\left(\frac{\sqrt{a}\,y}{\sqrt{-y^2 a + 2c_1}}\right)}{\sqrt{a}} = x + c_2$$

Solving equation (2)

Integrating both sides gives

$$\int -\frac{1}{\sqrt{-a\,y^2 + 2c_1}} dy = \int dx$$
$$-\frac{\arctan\left(\frac{\sqrt{a}\,y}{\sqrt{-y^2 a + 2c_1}}\right)}{\sqrt{a}} = x + c_3$$

Summary

The solution(s) found are the following

$$\frac{\arctan\left(\frac{\sqrt{a}\, y}{\sqrt{-y^{2} a+2 c_{1}}}\right)}{\sqrt{a}} = x + c_2 \tag{1}$$

$$-\frac{\arctan\left(\frac{\sqrt{a}\, y}{\sqrt{-y^{2} a+2 c_{1}}}\right)}{\sqrt{a}} = x + c_3 \tag{2}$$

Verification of solutions

$$\frac{\arctan\left(\frac{\sqrt{a}\, y}{\sqrt{-y^{2} a+2 c_{1}}}\right)}{\sqrt{a}} = x + c_2$$

Verified OK.

$$-\frac{\arctan\left(\frac{\sqrt{a}\, y}{\sqrt{-y^{2} a+2 c_{1}}}\right)}{\sqrt{a}} = x + c_3$$

Verified OK.

26.1.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + ay = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = -a$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = (-a)\, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 17: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -a$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{-a}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \mathrm{e}^{\sqrt{-a}\, x} \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-a}\, x}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\ &= \mathrm{e}^{\sqrt{-a}\, x} \int \frac{1}{\mathrm{e}^{2\sqrt{-a}\, x}}\, dx \\ &= \mathrm{e}^{\sqrt{-a}\, x} \left(-\frac{\mathrm{e}^{-2\sqrt{-a}\, x}}{2\sqrt{-a}}\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{\sqrt{-a}\,x}\right) + c_2\left(\mathrm{e}^{\sqrt{-a}\,x}\left(-\frac{\mathrm{e}^{-2\sqrt{-a}\,x}}{2\sqrt{-a}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{\sqrt{-a}\,x} - \frac{c_2 \mathrm{e}^{-\sqrt{-a}\,x}}{2\sqrt{-a}} \tag{1}
$$

Verification of solutions

$$
y = c_1 \mathrm{e}^{\sqrt{-a}\,x} - \frac{c_2 \mathrm{e}^{-\sqrt{-a}\,x}}{2\sqrt{-a}}
$$

Verified OK.

26.1.4 Maple step by step solution

Let's solve

$y'' + ay = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $r^2 + a = 0$

- Use quadratic formula to solve for r

  $r = \frac{0 \pm (\sqrt{-4a})}{2}$

- Roots of the characteristic polynomial

  $r = \left(\sqrt{-a}, -\sqrt{-a}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{\sqrt{-a}\,x}$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{-\sqrt{-a}\,x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 e^{\sqrt{-a}\, x} + c_2 e^{-\sqrt{-a}\, x}$

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - (ax + b)\, y = 0}$$

26.2.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + \left(-a\, x^3 - b\, x^2\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha} (c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = -1$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = -c_1\sqrt{x}\ \text{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\ \text{BesselY}\left(1, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = -c_1\sqrt{x}\ \text{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\ \text{BesselY}\left(1, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = -c_1\sqrt{x}\ \text{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\ \text{BesselY}\left(1, 2\sqrt{x}\right)$$

Verified OK.

26.2.2 Maple step by step solution

Let's solve

$y'' + (-ax - b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- > k - m$

$$x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$-a_0 b + 2a_2 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a_k b - a_{k-1} a\right) x^k\right) = 0$$

- Each term must be 0

$$-a_0 b + 2a_2 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} - a_{k-1} a - a_k b = 0$$

- Shift index using $k->k+1$

$$\left((k+1)^2 + 3k + 5\right) a_{k+3} - a_k a - a_{k+1} b = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = \frac{a_k a + a_{k+1} b}{k^2 + 5k + 6}, -a_0 b + 2a_2 = 0\right]$$

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - \left(a^2x^2 + a\right) y = 0}$$

26.3.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(-a^2x^4 - a\,x^2\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1\,\text{BesselJ}\,(n, \beta\,x^\gamma) + c_2\,\text{BesselY}\,(n, \beta\,x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = -1$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = -c_1\sqrt{x}\ \text{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\ \text{BesselY}\left(1, 2\sqrt{x}\right)$$

Summary
The solution(s) found are the following

$$y = -c_1\sqrt{x}\ \text{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\ \text{BesselY}\left(1, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = -c_1\sqrt{x}\ \text{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\ \text{BesselY}\left(1, 2\sqrt{x}\right)$$

Verified OK.

26.3.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(-a^2x^2 - a\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 0 \\ C &= -a^2x^2 - a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a(a\,x^2 + 1)}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = a(a\,x^2 + 1)$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = \left(a(a\,x^2 + 1)\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 20: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 2 \\
&= -2
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$
v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1
$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{1} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx ax + \frac{1}{2x} - \frac{1}{8a\,x^3} + \frac{1}{16a^2x^5} - \frac{5}{128a^3x^7} + \frac{7}{256a^4x^9} - \frac{21}{1024a^5x^{11}} + \frac{33}{2048a^6x^{13}} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = a
$$

From Eq. (9) the sum up to $v = 1$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= ax
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = a^2x^2
$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a(a\,x^2+1)}{1} \\ &= Q + \frac{R}{1} \\ &= (a^2x^2 + a) + (0) \\ &= a^2x^2 + a \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is a. Now b can be found.

$$\begin{aligned} b &= (a) - (0) \\ &= a \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= ax \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{a}{a} - 1\right) &= 0 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{a}{a} - 1\right) &= -1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = a\left(a\,x^2+1\right)$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	ax	0	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + (ax) \\ &= ax \\ &= ax \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2(ax)(0) + \left((a) + (ax)^2 - \left(a\left(a\,x^2 + 1\right)\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int ax dx} \\ &= \mathrm{e}^{\frac{a\,x^2}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= e^{\frac{a x^2}{2}} \end{aligned}$$

Which simplifies to

$$y_1 = e^{\frac{a x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\ &= e^{\frac{a x^2}{2}} \int \frac{1}{e^{a x^2}} \, dx \\ &= e^{\frac{a x^2}{2}} \left(\frac{\sqrt{\pi} \, \operatorname{erf}\left(\sqrt{a}\, x\right)}{2\sqrt{a}} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(e^{\frac{a x^2}{2}} \right) + c_2 \left(e^{\frac{a x^2}{2}} \left(\frac{\sqrt{\pi} \, \operatorname{erf}\left(\sqrt{a}\, x\right)}{2\sqrt{a}} \right) \right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 e^{\frac{a x^2}{2}} + \frac{c_2 e^{\frac{a x^2}{2}} \sqrt{\pi} \, \operatorname{erf}\left(\sqrt{a}\, x\right)}{2\sqrt{a}} \tag{1}$$

Verification of solutions

$$y = c_1 e^{\frac{a x^2}{2}} + \frac{c_2 e^{\frac{a x^2}{2}} \sqrt{\pi} \, \operatorname{erf}\left(\sqrt{a}\, x\right)}{2\sqrt{a}}$$

Verified OK.

26.3.3 Maple step by step solution

Let's solve

$y'' + (-a^2x^2 - a)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- >k + 2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$-a_0 a + 2a_2 + (6a_3 - a_1 a)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) - a a_k - a_{k-2}a^2\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_2 - a_0 a = 0, 6a_3 - a_1 a = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = \frac{a_0 a}{2}, a_3 = \frac{a_1 a}{6}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(k^2 + 3k + 2)\, a_{k+2} - a_{k-2}a^2 - a a_k = 0$

- Shift index using $k- >k + 2$

$$\left((k+2)^2+3k+8\right) a_{k+4} - a_k a^2 - a a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = \frac{a(a a_k + a_{k+2})}{k^2+7k+12}, a_2 = \frac{a_0 a}{2}, a_3 = \frac{a_1 a}{6}\right]$$

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - \left(a\,x^2 + b\right) y = 0}$$

26.4.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + \left(-a\,x^4 - b\,x^2\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha} (c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = -1$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + a^3 x(-ax+2)\, y = 0}$$

26.5.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' + \left(-a^4 x^4 + 2a^3 x^3\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1-2\alpha)\, x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= \frac{1}{2}\\ \beta &= 2\\ n &= -1\\ \gamma &= \frac{1}{2}\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right)$$

Summary
The solution(s) found are the following

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right)$$

Verified OK.

26.5.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(-a^4x^2 + 2a^3x\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= 1\\ B &= 0\\ C &= -a^4x^2 + 2a^3x\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^3x(ax-2)}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = a^3x(ax-2)$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = \left(a^3x(ax-2)\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 23: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx a^2 x - a - \frac{1}{2x} - \frac{1}{2a\,x^2} - \frac{5}{8a^2x^3} - \frac{7}{8a^3x^4} - \frac{21}{16a^4x^5} - \frac{33}{16a^5x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = a^2$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= a^2 x - a \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = a^4x^2 - 2a^3x + a^2$$

This shows that the coefficient of 1 in the above is a^2. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a^3x(ax-2)}{1} \\ &= Q + \frac{R}{1} \\ &= \left(a^4x^2 - 2a^3x\right) + (0) \\ &= a^4x^2 - 2a^3x \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - \left(a^2\right) \\ &= -a^2 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= a^2x - a \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-a^2}{a^2} - 1\right) &= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-a^2}{a^2} - 1\right) &= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = a^3x(ax-2)$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$a^2x - a$	-1	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(a^2 x - a\right) \\ &= -a^2 x + a \\ &= -a^2 x + a \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(-a^2 x + a\right)(0) + \left(\left(-a^2\right) + \left(-a^2 x + a\right)^2 - \left(a^3 x (a x - 2)\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int (-a^2 x + a) dx} \\ &= \mathrm{e}^{-\frac{a x (a x - 2)}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= \mathrm{e}^{-\frac{ax(ax-2)}{2}}
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{ax(ax-2)}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \mathrm{e}^{-\frac{ax(ax-2)}{2}} \int \frac{1}{\mathrm{e}^{-ax(ax-2)}}\, dx \\
&= \mathrm{e}^{-\frac{ax(ax-2)}{2}} \left(-\frac{i\sqrt{\pi}\, \mathrm{e}^{-1} \operatorname{erf}(iax - i)}{2a}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{ax(ax-2)}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{ax(ax-2)}{2}} \left(-\frac{i\sqrt{\pi}\, \mathrm{e}^{-1} \operatorname{erf}(iax - i)}{2a}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{ax(ax-2)}{2}} - \frac{ic_2 \mathrm{e}^{-1-\frac{1}{2}a^2x^2+ax} \sqrt{\pi}\, \operatorname{erf}(iax - i)}{2a} \tag{1}
$$

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{ax(ax-2)}{2}} - \frac{ic_2 \mathrm{e}^{-1-\frac{1}{2}a^2x^2+ax} \sqrt{\pi}\, \operatorname{erf}(iax - i)}{2a}
$$

Verified OK.

26.5.3 Maple step by step solution

Let's solve

$y'' + (-a^4x^2 + 2a^3x)\, y = 0$

- Highest derivative means the order of the ODE is 2

y''

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 1..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

  ◦ Shift index using $k- > k + 2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$2a_2 + (2a_0a^3 + 6a_3)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + 2a^3a_{k-1} - a_{k-2}a^4)\, x^k\right) = 0$

- The coefficients of each power of x must be 0

$[2a_2 = 0, 2a_0a^3 + 6a_3 = 0]$

- Solve for the dependent coefficient(s)

$\left\{a_2 = 0, a_3 = -\frac{a_0a^3}{3}\right\}$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2 Equations Containing Power Functions. page 213
Problem number: 6.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - \left(a\,x^2 + bcx\right) y = 0}$$

26.6.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(-a\,x^4 - bc\,x^3\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}\left(n, \beta\,x^\gamma\right) + c_2 \operatorname{BesselY}\left(n, \beta\,x^\gamma\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = -1$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right) \quad (1)$$

Verification of solutions

$$y = -c_1\sqrt{x}\,\mathrm{BesselJ}\left(1, 2\sqrt{x}\right) - c_2\sqrt{x}\,\mathrm{BesselY}\left(1, 2\sqrt{x}\right)$$

Verified OK.

26.6.2 Maple step by step solution

Let's solve

$y'' + (-a\,x^2 - bcx)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 1..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  - Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- > k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + (6a_3 - a_0 bc)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) - a_{k-1}bc - a_{k-2}a)\, x^k\right) = 0$$

- The coefficients of each power of x must be 0

$$[2a_2 = 0, 6a_3 - a_0 bc = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = 0, a_3 = \frac{a_0 bc}{6}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} - a_{k-1}bc - a_{k-2}a = 0$$

- Shift index using $k- > k+2$

$$\left((k+2)^2 + 3k + 8\right) a_{k+4} - a_{k+1}bc - a_k a = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = \frac{a_{k+1}bc + a_k a}{k^2 + 7k + 12}, a_2 = 0, a_3 = \frac{a_0 bc}{6}\right]$$

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2 Equations Containing Power Functions. page 213
Problem number: 7.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{y'' - a\,x^n y = 0}$$

26.7.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' - a\,x^2 x^n y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, x y' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = \frac{2\sqrt{-a}}{2+n}$$
$$n = -\frac{1}{2+n}$$
$$\gamma = 1 + \frac{n}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(-\frac{1}{2+n}, \frac{2\sqrt{-a}\,x^{1+\frac{n}{2}}}{2+n}\right) + c_2\sqrt{x}\,\text{BesselY}\left(-\frac{1}{2+n}, \frac{2\sqrt{-a}\,x^{1+\frac{n}{2}}}{2+n}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(-\frac{1}{2+n}, \frac{2\sqrt{-a}\,x^{1+\frac{n}{2}}}{2+n}\right) + c_2\sqrt{x}\,\text{BesselY}\left(-\frac{1}{2+n}, \frac{2\sqrt{-a}\,x^{1+\frac{n}{2}}}{2+n}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(-\frac{1}{2+n}, \frac{2\sqrt{-a}\,x^{1+\frac{n}{2}}}{2+n}\right) + c_2\sqrt{x}\,\text{BesselY}\left(-\frac{1}{2+n}, \frac{2\sqrt{-a}\,x^{1+\frac{n}{2}}}{2+n}\right)$$

Verified OK.

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 11.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_linear_constant_coeff"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_x]]
```

$$\boxed{y'' + ay' + yb = 0}$$

27.1.1 Solving as second order linear constant coeff ode

This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(x) + By'(x) + Cy(x) = 0$$

Where in the above $A = 1, B = a, C = b$. Let the solution be $y = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + a\lambda\, \mathrm{e}^{\lambda x} + b\, \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$a\lambda + \lambda^2 + b = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = a, C = b$ into the above gives

$$\lambda_{1,2} = \frac{-a}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{a^2 - (4)(1)(b)}$$
$$= -\frac{a}{2} \pm \frac{\sqrt{a^2 - 4b}}{2}$$

Hence

$$\lambda_1 = -\frac{a}{2} + \frac{\sqrt{a^2 - 4b}}{2}$$
$$\lambda_2 = -\frac{a}{2} - \frac{\sqrt{a^2 - 4b}}{2}$$

Which simplifies to

$$\lambda_1 = -\frac{a}{2} + \frac{\sqrt{a^2 - 4b}}{2}$$
$$\lambda_2 = -\frac{a}{2} - \frac{\sqrt{a^2 - 4b}}{2}$$

Since roots are real and distinct, then the solution is

$$y = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$y = c_1 e^{\left(-\frac{a}{2} + \frac{\sqrt{a^2-4b}}{2}\right)x} + c_2 e^{\left(-\frac{a}{2} - \frac{\sqrt{a^2-4b}}{2}\right)x}$$

Or

$$y = c_1 \mathrm{e}^{\left(-\frac{a}{2} + \frac{\sqrt{a^2-4b}}{2}\right)x} + c_2 \mathrm{e}^{\left(-\frac{a}{2} - \frac{\sqrt{a^2-4b}}{2}\right)x}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\left(-\frac{a}{2} + \frac{\sqrt{a^2-4b}}{2}\right)x} + c_2 \mathrm{e}^{\left(-\frac{a}{2} - \frac{\sqrt{a^2-4b}}{2}\right)x} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\left(-\frac{a}{2} + \frac{\sqrt{a^2-4b}}{2}\right)x} + c_2 \mathrm{e}^{\left(-\frac{a}{2} - \frac{\sqrt{a^2-4b}}{2}\right)x}$$

Verified OK.

27.1.2 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y'' + ay' + yb &= 0 \tag{1} \\
Ay'' + By' + Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= 1 \\
B &= a \tag{3} \\
C &= b
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r &= \frac{s}{t} \tag{5} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{align*}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{a^2 - 4b}{4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{align*}
s &= a^2 - 4b \\
t &= 4
\end{align*}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{a^2}{4} - b\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x) \, e^{-\int \frac{B}{2A} \, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 26: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = \frac{a^2}{4} - b$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$
z_1(x) = e^{\frac{x\sqrt{a^2-4b}}{2}}
$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}
$$

$$
\begin{aligned}
&= z_1 e^{-\int \frac{1}{2}\frac{a}{1}\,dx} \\
&= z_1 e^{-\frac{ax}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{ax}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{\left(-a+\sqrt{a^2-4b}\right)x}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-ax}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{e}^{-x\sqrt{a^2-4b}}}{\sqrt{a^2-4b}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\frac{\left(-a+\sqrt{a^2-4b}\right)x}{2}}\right) + c_2 \left(\mathrm{e}^{\frac{\left(-a+\sqrt{a^2-4b}\right)x}{2}} \left(-\frac{\mathrm{e}^{-x\sqrt{a^2-4b}}}{\sqrt{a^2-4b}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{\frac{\left(-a+\sqrt{a^2-4b}\right)x}{2}} - \frac{c_2 \mathrm{e}^{-\frac{\left(a+\sqrt{a^2-4b}\right)x}{2}}}{\sqrt{a^2-4b}} \tag{1}
$$

Verification of solutions

$$
y = c_1 \mathrm{e}^{\frac{\left(-a+\sqrt{a^2-4b}\right)x}{2}} - \frac{c_2 \mathrm{e}^{-\frac{\left(a+\sqrt{a^2-4b}\right)x}{2}}}{\sqrt{a^2-4b}}
$$

Verified OK.

27.1.3 Maple step by step solution

Let's solve

$y'' + ay' + yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Characteristic polynomial of ODE

  $ar + r^2 + b = 0$

- Use quadratic formula to solve for r

  $r = \frac{(-a)\pm\left(\sqrt{a^2-4b}\right)}{2}$

- Roots of the characteristic polynomial

  $r = \left(-\frac{a}{2} - \frac{\sqrt{a^2-4b}}{2}, -\frac{a}{2} + \frac{\sqrt{a^2-4b}}{2}\right)$

- 1st solution of the ODE

  $y_1(x) = \mathrm{e}^{\left(-\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)x}$

- 2nd solution of the ODE

  $y_2(x) = \mathrm{e}^{\left(-\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)x}$

- General solution of the ODE

  $y = c_1 y_1(x) + c_2 y_2(x)$

- Substitute in solutions

  $y = c_1 \mathrm{e}^{\left(-\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)x} + c_2 \mathrm{e}^{\left(-\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)x}$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 14.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{y'' + ay' + b\left(-b\,x^2 + ax + 1\right) y = 0}$$

27.4.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + ay' + \left(-b^2x^2 + abx + b\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a \\ C &= -b^2x^2 + abx + b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4b^2x^2 - 4abx + a^2 - 4b}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4b^2x^2 - 4abx + a^2 - 4b \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(b^2x^2 - abx + \frac{1}{4}a^2 - b\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 30: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx bx - \frac{a}{2} - \frac{1}{2x} - \frac{a}{4b\,x^2} - \frac{a^2}{8b^2x^3} - \frac{a^3}{16b^3x^4} - \frac{1}{8b\,x^3} - \frac{a^4}{32b^4x^5} - \frac{3a}{16b^2x^4} - \frac{a^5}{64b^5x^6} - \frac{3a^2}{16b^3x^5} - \frac{5a^3}{32b^4x^6} - \frac{1}{16b^2x^5} - \cdots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = b$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= -\frac{a}{2} + bx \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2 - abx + b^2x^2$$

This shows that the coefficient of 1 in the above is $\frac{a^2}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{4b^2x^2 - 4abx + a^2 - 4b}{4} \\
&= Q + \frac{R}{4} \\
&= \left(b^2x^2 - abx + \frac{1}{4}a^2 - b\right) + (0) \\
&= b^2x^2 - abx + \frac{1}{4}a^2 - b
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{a^2}{4} - b$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{a^2}{4} - b\right) - \left(\frac{a^2}{4}\right) \\
&= -b
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{a}{2} + bx \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-b}{b} - 1\right) &= -1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-b}{b} - 1\right) &= 0
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = b^2x^2 - abx + \frac{1}{4}a^2 - b$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$-\frac{a}{2}+bx$	-1	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(-\frac{a}{2} + bx\right) \\ &= \frac{a}{2} - bx \\ &= \frac{a}{2} - bx \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{a}{2} - bx\right)(0) + \left((-b) + \left(\frac{a}{2} - bx\right)^2 - \left(b^2x^2 - abx + \frac{1}{4}a^2 - b\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{a}{2} - bx\right) dx} \\
&= \mathrm{e}^{\frac{x(-bx+a)}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{a}{1} \, dx} \\
&= z_1 e^{-\frac{ax}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{ax}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{b x^2}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-ax}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{\sqrt{\pi}\, \mathrm{e}^{-\frac{a^2}{4b}} \operatorname{erf}\left(\frac{-2bx+a}{2\sqrt{-b}}\right)}{2\sqrt{-b}} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{b x^2}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{b x^2}{2}} \left(\frac{\sqrt{\pi}\, \mathrm{e}^{-\frac{a^2}{4b}} \operatorname{erf}\left(\frac{-2bx+a}{2\sqrt{-b}}\right)}{2\sqrt{-b}} \right) \right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{b\,x^2}{2}} + \frac{c_2 \sqrt{\pi}\, \mathrm{e}^{-\frac{2b^2x^2+a^2}{4b}} \operatorname{erf}\left(\frac{-2bx+a}{2\sqrt{-b}}\right)}{2\sqrt{-b}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{b\,x^2}{2}} + \frac{c_2 \sqrt{\pi}\, \mathrm{e}^{-\frac{2b^2x^2+a^2}{4b}} \operatorname{erf}\left(\frac{-2bx+a}{2\sqrt{-b}}\right)}{2\sqrt{-b}}$$

Verified OK.

27.4.2 Maple step by step solution

Let's solve

$y'' + ay' + (-b^2x^2 + abx + b)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  - Convert y' to series expansion

    $y' = \sum_{k=1}^{\infty} a_k k\, x^{k-1}$

  - Shift index using $k- >k + 1$

    $y' = \sum_{k=0}^{\infty} a_{k+1}(k+1)\, x^k$

  - Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$a_1 a + a_0 b + 2a_2 + (a_0 ab + 2aa_2 + a_1 b + 6a_3)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + aa_{k+1}(k+1) + a_k b$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_1 a + a_0 b = 0, a_0 ab + 2aa_2 + a_1 b + 6a_3 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{a_1 a}{2} - \frac{a_0 b}{2}, a_3 = \frac{1}{6}a_1 a^2 - \frac{1}{6}a_1 b\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + (ba_{k-1} + a_{k+1}(k+1))\, a - a_{k-2}b^2 + a_k b = 0$$

- Shift index using $k- >k+2$

$$\left((k+2)^2 + 3k + 8\right) a_{k+4} + (ba_{k+1} + a_{k+3}(k+3))\, a - a_k b^2 + a_{k+2} b = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{aba_{k+1} + aka_{k+3} - a_k b^2 + 3aa_{k+3} + a_{k+2} b}{k^2 + 7k + 12}, a_2 = -\frac{a_1 a}{2} - \frac{a_0 b}{2}, a_3 = \frac{1}{6}a_1 a^2 - \frac{1}{6}a_1 b\right]$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 15.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{y'' + ay' + bx\left(-x^3b + ax + 2\right) y = 0}$$

27.5.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + ay' + bx\left(-x^3b + ax + 2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a \\ C &= bx\left(-x^3b + ax + 2\right) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4b^2x^4 - 4ab\,x^2 + a^2 - 8bx}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4b^2x^4 - 4ab\,x^2 + a^2 - 8bx \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{4}a^2 + b^2x^4 - ab\,x^2 - 2bx\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 32: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx b\,x^2 - \frac{a}{2} - \frac{1}{x} - \frac{a}{2b\,x^3} - \frac{a^2}{4b^2x^5} - \frac{1}{2b\,x^4} - \frac{a^3}{8b^3x^7} - \frac{3a}{4b^2x^6} - \frac{1}{2b^2x^7} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = b$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= -\frac{a}{2} + b\,x^2 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2 - ab\,x^2 + b^2x^4$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4b^2x^4 - 4ab\,x^2 + a^2 - 8bx}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{1}{4}a^2 + b^2x^4 - ab\,x^2 - 2bx\right) + (0) \\ &= \frac{1}{4}a^2 + b^2x^4 - ab\,x^2 - 2bx \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-2b$. Now b can be found.

$$\begin{aligned} b &= (-2b) - (0) \\ &= -2b \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= -\frac{a}{2} + b\,x^2 \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-2b}{b} - 2\right) &&= -2 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-2b}{b} - 2\right) &&= 0 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{4}a^2 + b^2x^4 - ab\,x^2 - 2bx$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-4	$-\frac{a}{2}+b\,x^2$	-2	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 0$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^{-} \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(-\frac{a}{2} + b\,x^2\right) \\ &= \frac{a}{2} - b\,x^2 \\ &= \frac{a}{2} - b\,x^2 \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{a}{2} - b\,x^2\right)(0) + \left((-2bx) + \left(\frac{a}{2} - b\,x^2\right)^2 - \left(\frac{1}{4}a^2 + b^2x^4 - ab\,x^2 - 2bx\right)\right) &= 0 \\ 0 &= 0 \end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{a}{2} - b\,x^2\right) dx} \\
&= \mathrm{e}^{\frac{1}{2} a x - \frac{1}{3} x^3 b}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{a}{1} \, dx} \\
&= z_1 e^{-\frac{ax}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{ax}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{x^3 b}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-ax}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \mathrm{e}^{-ax + \frac{2}{3} x^3 b} dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x^3 b}{3}}\right) + c_2 \left(\mathrm{e}^{-\frac{x^3 b}{3}} \left(\int \mathrm{e}^{-ax + \frac{2}{3} x^3 b} dx \right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{x^3 b}{3}} + c_2 \mathrm{e}^{-\frac{x^3 b}{3}} \left(\int \mathrm{e}^{-ax+\frac{2}{3}x^3 b} dx \right) \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{x^3 b}{3}} + c_2 \mathrm{e}^{-\frac{x^3 b}{3}} \left(\int \mathrm{e}^{-ax+\frac{2}{3}x^3 b} dx \right)$$

Verified OK.

27.5.2 Maple step by step solution

Let's solve

$y'' + ay' + bx(-x^3 b + ax + 2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 1..4$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert y' to series expansion

  $y' = \sum_{k=1}^{\infty} a_k k\, x^{k-1}$

- ○ Shift index using $k- > k + 1$

  $y' = \sum_{k=0}^{\infty} a_{k+1}(k+1)\, x^k$

- ○ Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^{k}$$

Rewrite ODE with series expansions

$$a_1a + 2a_2 + (2aa_2 + 2a_0b + 6a_3)\, x + (a_0ab + 3aa_3 + 2a_1b + 12a_4)\, x^2 + (a_1ab + 4aa_4 + 2ba_2 + 20$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_1a = 0, 2aa_2 + 2a_0b + 6a_3 = 0, a_0ab + 3aa_3 + 2a_1b + 12a_4 = 0, a_1ab + 4aa_4 + 2ba_2 + 20a$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{a_1a}{2}, a_3 = \frac{a_1a^2}{6} - \frac{a_0b}{3}, a_4 = -\frac{1}{24}a_1a^3 - \frac{1}{6}a_1b, a_5 = \frac{1}{120}a_1a^4 + \frac{1}{30}a_1ab\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + (ba_{k-2} + a_{k+1}(k+1))\, a - a_{k-4}b^2 + 2ba_{k-1} = 0$$

- Shift index using $k- >k+4$

$$\left((k+4)^2 + 3k + 14\right) a_{k+6} + (ba_{k+2} + a_{k+5}(k+5))\, a - a_k b^2 + 2ba_{k+3} = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+6} = -\frac{aba_{k+2} + aka_{k+5} - a_k b^2 + 5aa_{k+5} + 2ba_{k+3}}{k^2 + 11k + 30}, a_2 = -\frac{a_1a}{2}, a_3 = \frac{a_1a^2}{6} - \frac{a_0b}{3}, a_4 = -\frac{1}{24}a_1a\right.$$

□ Rewrite ODE with series expansions

  ∘ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$$

- Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k k\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$a_0 c + 2a_2 + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k(ak+c) + b a_{k-1}\right) x^k\right) = 0$$

- Each term must be 0

$$a_0 c + 2a_2 = 0$$

- Each term in the series must be 0, giving the recursion relation

$$(k^2 + 3k + 2)\, a_{k+2} + a a_k k + b a_{k-1} + a_k c = 0$$

- Shift index using $k->k+1$

$$\left((k+1)^2 + 3k + 5\right) a_{k+3} + a a_{k+1}(k+1) + b a_k + a_{k+1} c = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{ak a_{k+1} + a a_{k+1} + b a_k + a_{k+1} c}{k^2 + 5k + 6}, a_0 c + 2a_2 = 0\right]$$

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + (ax + b)\, y' - ay = 0}$$

27.14.1 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B+2v'B'+B''v)+B(B'v+v'B)+CBv&=0\\
ABv''+\left(2AB'+B^2\right)v'+\left(AB''+BB'+CB\right)v&=0 \qquad (1)
\end{aligned}
$$

If the term $AB''+BB'+CB$ is zero, then this method works and can be used to solve

$$
ABv''+\left(2AB'+B^2\right)v'=0
$$

By Using $u=v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu'+\left(2AB'+B^2\right)u=0
$$

The above ode is first order ode which is solved for u. Now a new ode $v'=u$ is solved for v as first order ode. Then the final solution is obtain from $y=Bv$.

This method works only if the term $AB''+BB'+CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A&=1\\
B&=ax+b\\
C&=-a\\
F&=0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB''+BB'+CB&=(1)\,(0)+(ax+b)\,(a)+(-a)\,(ax+b)\\
&=0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
ax+bv''+\left(2a+(ax+b)^2\right)v'=0
$$

Now by applying $v'=u$ the above becomes

$$
(ax+b)\,u'(x)+\left(a^2x^2+2abx+b^2+2a\right)u(x)=0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u'&=F(x,u)\\
&=f(x)g(u)\\
&=-\frac{\left(a^2x^2+2abx+b^2+2a\right)u}{ax+b}
\end{aligned}
$$

Where $f(x) = -\frac{a^2x^2+2abx+b^2+2a}{ax+b}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\, du &= -\frac{a^2x^2+2abx+b^2+2a}{ax+b}\, dx \\
\int \frac{1}{u}\, du &= \int -\frac{a^2x^2+2abx+b^2+2a}{ax+b}\, dx \\
\ln(u) &= -\frac{a\,x^2}{2} - bx - 2\ln(ax+b) + c_1 \\
u &= e^{-\frac{a\,x^2}{2} - bx - 2\ln(ax+b) + c_1} \\
&= c_1 e^{-\frac{a\,x^2}{2} - bx - 2\ln(ax+b)}
\end{aligned}$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= c_1 e^{-\frac{a\,x^2}{2} - bx - 2\ln(ax+b)}
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int c_1 e^{-\frac{a\,x^2}{2} - bx - 2\ln(ax+b)}\, \mathrm{d}x \\
&= c_1 \left(-\frac{e^{-\frac{(ax+b)^2}{2a} + \frac{b^2}{2a}}}{a\,(ax+b)} - \frac{\sqrt{\pi}\, e^{\frac{b^2}{2a}} \sqrt{2}\, \operatorname{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)}{2a^{\frac{3}{2}}} \right) + c_2
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y(x) &= Bv \\
&= (ax+b) \left(c_1 \left(-\frac{e^{-\frac{(ax+b)^2}{2a} + \frac{b^2}{2a}}}{a\,(ax+b)} - \frac{\sqrt{\pi}\, e^{\frac{b^2}{2a}} \sqrt{2}\, \operatorname{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)}{2a^{\frac{3}{2}}} \right) + c_2 \right) \\
&= -\frac{\sqrt{\pi}\, e^{\frac{b^2}{2a}} c_1 \sqrt{2}\,(ax+b)\, \operatorname{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right) + 2\, e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{a} - 2c_2 \left(a^{\frac{3}{2}} b + a^{\frac{5}{2}} x\right)}{2a^{\frac{3}{2}}}
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = -\frac{\sqrt{\pi}\, e^{\frac{b^2}{2a}} c_1 \sqrt{2}\,(ax+b)\, \operatorname{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right) + 2\, e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{a} - 2c_2 \left(a^{\frac{3}{2}} b + a^{\frac{5}{2}} x\right)}{2a^{\frac{3}{2}}} \tag{1}$$

Verification of solutions

$$y = -\frac{\sqrt{\pi}\, e^{\frac{b^2}{2a}} c_1 \sqrt{2}\,(ax+b)\, \operatorname{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right) + 2\, e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{a} - 2c_2 \left(a^{\frac{3}{2}} b + a^{\frac{5}{2}} x\right)}{2a^{\frac{3}{2}}}$$

Verified OK.

27.14.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + (ax + b)\, y' - ay = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= ax + b \\ C &= -a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^2 + 2abx + b^2 + 6a}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^2 + 2abx + b^2 + 6a \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 40: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞.

Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ax}{2}+\frac{b}{2}+\frac{3}{2x}-\frac{3b}{2a\,x^2}+\frac{3b^2}{2a^2x^3}-\frac{9}{4a\,x^3}-\frac{3b^3}{2a^3x^4}+\frac{27b}{4a^2x^4}+\frac{3b^4}{2a^4x^5}-\frac{27b^2}{2a^3x^5}-\frac{3b^5}{2a^5x^6}+\frac{27}{4a^2x^5}+\frac{45b^3}{2a^4x^6}-\frac{135b}{4a^3x^6}+ \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{ax}{2} + \frac{b}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2$$

This shows that the coefficient of 1 in the above is $\frac{b^2}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^2 + 2abx + b^2 + 6a}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{3}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\right) + (0) \\
&= \frac{3}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{3a}{2} + \frac{b^2}{4}$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{3a}{2} + \frac{b^2}{4}\right) - \left(\frac{b^2}{4}\right) \\
&= \frac{3a}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{ax}{2} + \frac{b}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) &= 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) &= -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{3}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{ax}{2} + \frac{b}{2}$	1	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$
\begin{aligned}
d &= \alpha_\infty^+ \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= (+)[\sqrt{r}]_\infty \\
&= 0 + \left(\frac{ax}{2} + \frac{b}{2} \right) \\
&= \frac{ax}{2} + \frac{b}{2} \\
&= \frac{ax}{2} + \frac{b}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{ax}{2} + \frac{b}{2}\right)(1) + \left(\left(\frac{a}{2}\right) + \left(\frac{ax}{2} + \frac{b}{2}\right)^2 - \left(\frac{3}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\right) \right) &= 0 \\
-aa_0 + b &= 0
\end{aligned}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{ a_0 = \frac{b}{a} \right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + \frac{b}{a}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x+\frac{b}{a}\right) \mathrm{e}^{\int \left(\frac{ax}{2}+\frac{b}{2}\right)dx} \\
&= \left(x+\frac{b}{a}\right) \mathrm{e}^{\frac{1}{4}a\,x^2+\frac{1}{2}bx} \\
&= \frac{(ax+b)\,\mathrm{e}^{\frac{x(ax+2b)}{4}}}{a}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{ax+b}{1}\,dx} \\
&= z_1 e^{-\frac{1}{4}a\,x^2-\frac{1}{2}bx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x(ax+2b)}{4}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{ax+b}{a}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{ax+b}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{1}{2}a\,x^2-bx}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\left(\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{b^2}{2a}}(ax+b)\operatorname{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)+2\,\mathrm{e}^{-\frac{x(ax+2b)}{2}}\sqrt{a}\right)\sqrt{a}}{2ax+2b}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{a x + b}{a}\right) \\
&\quad + c_2 \left(\frac{a x + b}{a} \left(-\frac{\left(\sqrt{2}\, \sqrt{\pi}\, \mathrm{e}^{\frac{b^2}{2a}} (a x + b) \operatorname{erf}\left(\frac{\sqrt{2}\, (a x + b)}{2 \sqrt{a}}\right) + 2\, \mathrm{e}^{-\frac{x(a x + 2b)}{2}} \sqrt{a}\right) \sqrt{a}}{2 a x + 2 b}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 (a x + b)}{a} - \frac{c_2 \left(\sqrt{2}\, \sqrt{\pi}\, \mathrm{e}^{\frac{b^2}{2a}} (a x + b) \operatorname{erf}\left(\frac{\sqrt{2}\, (a x + b)}{2 \sqrt{a}}\right) + 2\, \mathrm{e}^{-\frac{x(a x + 2b)}{2}} \sqrt{a}\right)}{2 \sqrt{a}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 (a x + b)}{a} - \frac{c_2 \left(\sqrt{2}\, \sqrt{\pi}\, \mathrm{e}^{\frac{b^2}{2a}} (a x + b) \operatorname{erf}\left(\frac{\sqrt{2}\, (a x + b)}{2 \sqrt{a}}\right) + 2\, \mathrm{e}^{-\frac{x(a x + 2b)}{2}} \sqrt{a}\right)}{2 \sqrt{a}}
$$

Verified OK.

27.14.3 Maple step by step solution

Let's solve

$y'' + (a x + b) y' - a y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

    $x^m \cdot y' = \sum_{k=\max(0, 1-m)}^{\infty} a_k k\, x^{k-1+m}$

  ◦ Shift index using $k- > k + 1 - m$

    $x^m \cdot y' = \sum_{k=\max(0, 1-m)+m-1}^{\infty} a_{k+1-m} (k + 1 - m)\, x^k$

- Convert y'' to series expansion

  $$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

  $$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^{k}$$

  Rewrite DE with series expansions

  $$\sum_{k=0}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k+1}(k+1)\, b + a a_k(k-1)\right) x^k = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$k^2 a_{k+2} + (a a_k + a_{k+1} b + 3a_{k+2})\, k - a a_k + a_{k+1} b + 2a_{k+2} = 0$$

- Recursion relation that defines the series solution to the ODE

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a a_k k + a_{k+1} b k - a a_k + a_{k+1} b}{k^2 + 3k + 2}\right]$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 25.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' + (ax + b)\,y' + ay = 0}$$

27.15.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + (ax + b)\,y' + ay)\,dx = 0$$
$$(ax + b)\,y + y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= ax + b \\
q(x) &= c_1
\end{aligned}
$$

Hence the ode is

$$
(ax + b)\, y + y' = c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int (ax+b)dx} \\
&= \mathrm{e}^{\frac{1}{2}a\,x^2+bx}
\end{aligned}
$$

Which simplifies to

$$
\mu = \mathrm{e}^{\frac{x(ax+2b)}{2}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\,(c_1) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{x(ax+2b)}{2}} y\right) &= \left(\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)(c_1) \\
\mathrm{d}\left(\mathrm{e}^{\frac{x(ax+2b)}{2}} y\right) &= \left(c_1 \mathrm{e}^{\frac{x(ax+2b)}{2}}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{\frac{x(ax+2b)}{2}} y &= \int c_1 \mathrm{e}^{\frac{x(ax+2b)}{2}}\,\mathrm{d}x \\
\mathrm{e}^{\frac{x(ax+2b)}{2}} y &= -\frac{c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{x(ax+2b)}{2}}$ results in

$$
y = -\frac{\mathrm{e}^{-\frac{x(ax+2b)}{2}} c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + \mathrm{e}^{-\frac{x(ax+2b)}{2}} c_2
$$

Summary

The solution(s) found are the following

$$
y = -\frac{\mathrm{e}^{-\frac{x(ax+2b)}{2}} c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + \mathrm{e}^{-\frac{x(ax+2b)}{2}} c_2 \tag{1}
$$

Verification of solutions

$$y = -\frac{e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{\pi}\, e^{-\frac{b^2}{2a}} \operatorname{erf}\left(-\frac{\sqrt{-2a}\, x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + e^{-\frac{x(ax+2b)}{2}} c_2$$

Verified OK.

27.15.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + (ax + b)\, y' + ay = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (y'' + (ax + b)\, y' + ay)\, dx = 0$$
$$(ax + b)\, y + y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = ax + b$$
$$q(x) = c_1$$

Hence the ode is

$$(ax + b)\, y + y' = c_1$$

The integrating factor μ is

$$\mu = e^{\int (ax+b)dx}$$
$$= e^{\frac{1}{2} a\, x^2 + bx}$$

Which simplifies to

$$\mu = e^{\frac{x(ax+2b)}{2}}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)(c_1)$$
$$\frac{d}{dx}\left(e^{\frac{x(ax+2b)}{2}} y\right) = \left(e^{\frac{x(ax+2b)}{2}}\right)(c_1)$$
$$d\left(e^{\frac{x(ax+2b)}{2}} y\right) = \left(c_1 e^{\frac{x(ax+2b)}{2}}\right) dx$$

Integrating gives

$$e^{\frac{x(ax+2b)}{2}} y = \int c_1 e^{\frac{x(ax+2b)}{2}} dx$$
$$e^{\frac{x(ax+2b)}{2}} y = -\frac{c_1 \sqrt{\pi}\, e^{-\frac{b^2}{2a}} \operatorname{erf}\left(-\frac{\sqrt{-2a}\, x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + c_2$$

Dividing both sides by the integrating factor $\mu = e^{\frac{x(ax+2b)}{2}}$ results in

$$y = -\frac{e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{\pi}\, e^{-\frac{b^2}{2a}} \operatorname{erf}\left(-\frac{\sqrt{-2a}\, x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + e^{-\frac{x(ax+2b)}{2}} c_2$$

Summary
The solution(s) found are the following

$$y = -\frac{e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{\pi}\, e^{-\frac{b^2}{2a}} \operatorname{erf}\left(-\frac{\sqrt{-2a}\, x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + e^{-\frac{x(ax+2b)}{2}} c_2 \tag{1}$$

Verification of solutions

$$y = -\frac{e^{-\frac{x(ax+2b)}{2}} c_1 \sqrt{\pi}\, e^{-\frac{b^2}{2a}} \operatorname{erf}\left(-\frac{\sqrt{-2a}\, x}{2} + \frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + e^{-\frac{x(ax+2b)}{2}} c_2$$

Verified OK.

27.15.3 Solving using Kovacic algorithm

Writing the ode as

$$y'' + (ax+b)\, y' + ay = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= ax + b \\ C &= a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^2 + 2abx + b^2 - 2a}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^2 + 2abx + b^2 - 2a \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 42: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ax}{2}+\frac{b}{2}-\frac{1}{2x}+\frac{b}{2a\,x^2}-\frac{b^2}{2a^2x^3}-\frac{1}{4a\,x^3}+\frac{b^3}{2a^3x^4}+\frac{3b}{4a^2x^4}-\frac{b^4}{2a^4x^5}-\frac{3b^2}{2a^3x^5}+\frac{b^5}{2a^5x^6}-\frac{1}{4a^2x^5}+\frac{5b^3}{2a^4x^6}+\frac{5b}{4a^3x^6}+ \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{ax}{2} + \frac{b}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2$$

This shows that the coefficient of 1 in the above is $\frac{b^2}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{a^2x^2 + 2abx + b^2 - 2a}{4} \\ &= Q + \frac{R}{4} \\ &= \left(-\frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\right) + (0) \\ &= -\frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{a}{2} + \frac{b^2}{4}$. Now b can be found.

$$\begin{aligned}b &= \left(-\frac{a}{2} + \frac{b^2}{4}\right) - \left(\frac{b^2}{4}\right) \\ &= -\frac{a}{2}\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{ax}{2} + \frac{b}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{a}{2}}{\frac{a}{2}} - 1\right) &&= -1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{a}{2}}{\frac{a}{2}} - 1\right) &&= 0
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2
$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{ax}{2} + \frac{b}{2}$	-1	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 0$, and since there are no poles then

$$
\begin{aligned}
d &= \alpha_\infty^{-} \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= (-)[\sqrt{r}]_\infty \\
&= 0 + (-)\left(\frac{ax}{2} + \frac{b}{2}\right) \\
&= -\frac{ax}{2} - \frac{b}{2} \\
&= -\frac{ax}{2} - \frac{b}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{ax}{2} - \frac{b}{2}\right)(0) + \left(\left(-\frac{a}{2}\right) + \left(-\frac{ax}{2} - \frac{b}{2}\right)^2 - \left(-\frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2\right)\right) = 0$$
$$0 = 0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= e^{\int \left(-\frac{ax}{2} - \frac{b}{2}\right) dx} \\ &= e^{-\frac{x(ax+2b)}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{ax+b}{1} \, dx} \\ &= z_1 e^{-\frac{1}{4}a\,x^2 - \frac{1}{2}bx} \\ &= z_1 \left(e^{-\frac{x(ax+2b)}{4}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = e^{-\frac{x(ax+2b)}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{ax+b}{1} dx}}{(y_1)^2} dx$$

$$= y_1 \int \frac{e^{-\frac{1}{2}a x^2 - bx}}{(y_1)^2} dx$$

$$= y_1 \left(-\frac{\sqrt{\pi}\, \mathrm{e}^{-\frac{b^2}{2a}} \sqrt{2}\, \mathrm{erf}\left(\frac{(ax+b)\sqrt{2}}{2\sqrt{-a}}\right)}{2\sqrt{-a}} \right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(\mathrm{e}^{-\frac{x(ax+2b)}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{x(ax+2b)}{2}} \left(-\frac{\sqrt{\pi}\, \mathrm{e}^{-\frac{b^2}{2a}} \sqrt{2}\, \mathrm{erf}\left(\frac{(ax+b)\sqrt{2}}{2\sqrt{-a}}\right)}{2\sqrt{-a}} \right)\right)$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{x(ax+2b)}{2}} - \frac{c_2 \sqrt{2}\, \sqrt{\pi}\, \mathrm{e}^{-\frac{(ax+b)^2}{2a}}\, \mathrm{erf}\left(\frac{(ax+b)\sqrt{2}}{2\sqrt{-a}}\right)}{2\sqrt{-a}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{x(ax+2b)}{2}} - \frac{c_2 \sqrt{2}\, \sqrt{\pi}\, \mathrm{e}^{-\frac{(ax+b)^2}{2a}}\, \mathrm{erf}\left(\frac{(ax+b)\sqrt{2}}{2\sqrt{-a}}\right)}{2\sqrt{-a}}$$

Verified OK.

27.15.4 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1 \\
q(x) &= ax + b \\
r(x) &= a \\
s(x) &= 0
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0 \\
q'(x) &= a
\end{aligned}$$

Therefore (1) becomes

$$0 - (a) + (a) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\; dx$$

Substituting the above values for p, q, r, s gives

$$(ax + b)\, y + y' = c_1$$

We now have a first order ode to solve which is

$$(ax + b)\, y + y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}
p(x) &= ax + b \\
q(x) &= c_1
\end{aligned}$$

Hence the ode is

$$(ax + b)\, y + y' = c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int (ax+b)dx}$$
$$= \mathrm{e}^{\frac{1}{2}a\,x^2+bx}$$

Which simplifies to

$$\mu = \mathrm{e}^{\frac{x(ax+2b)}{2}}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\,(c_1)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{x(ax+2b)}{2}} y\right) = \left(\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)(c_1)$$
$$\mathrm{d}\left(\mathrm{e}^{\frac{x(ax+2b)}{2}} y\right) = \left(c_1\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)\,\mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{\frac{x(ax+2b)}{2}} y = \int c_1\mathrm{e}^{\frac{x(ax+2b)}{2}}\,\mathrm{d}x$$
$$\mathrm{e}^{\frac{x(ax+2b)}{2}} y = -\frac{c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2}+\frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + c_2$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{x(ax+2b)}{2}}$ results in

$$y = -\frac{\mathrm{e}^{-\frac{x(ax+2b)}{2}} c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2}+\frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + \mathrm{e}^{-\frac{x(ax+2b)}{2}} c_2$$

Summary

The solution(s) found are the following

$$y = -\frac{\mathrm{e}^{-\frac{x(ax+2b)}{2}} c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2}+\frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + \mathrm{e}^{-\frac{x(ax+2b)}{2}} c_2 \tag{1}$$

Verification of solutions

$$y = -\frac{\mathrm{e}^{-\frac{x(ax+2b)}{2}} c_1\sqrt{\pi}\,\mathrm{e}^{-\frac{b^2}{2a}}\,\mathrm{erf}\left(-\frac{\sqrt{-2a}\,x}{2}+\frac{b}{\sqrt{-2a}}\right)}{\sqrt{-2a}} + \mathrm{e}^{-\frac{x(ax+2b)}{2}} c_2$$

Verified OK.

27.15.5 Maple step by step solution

Let's solve

$y'' + (ax + b)\, y' + ay = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite DE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

  ◦ Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k + 1 - m)\, x^k$

  ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k - 1)\, x^{k-2}$

  ◦ Shift index using $k- >k + 2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k + 2)\,(k + 1)\, x^k$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} (a_{k+2}(k + 2)\,(k + 1) + a_{k+1}(k + 1)\, b + a a_k(k + 1))\, x^k = 0$

- Each term in the series must be 0, giving the recursion relation

  $(k + 1)\,(a_{k+2}(k + 2) + a_{k+1}b + a a_k) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a a_k + a_{k+1} b}{k+2}\right]$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 26.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + (ax + b)\, y' + c(ax + b - c)\, y = 0}$$

27.16.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + (ax + b)\, y' + c(ax + b - c)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= ax + b \\ C &= c(ax + b - c) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^2 + 2abx - 4acx + b^2 - 4bc + 4c^2 + 2a}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^2 + 2abx - 4acx + b^2 - 4bc + 4c^2 + 2a \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 - acx - bc + c^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 44: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{b}{2} - c + \frac{ax}{2} + \frac{1}{2x} - \frac{2bc}{a^2x^3} + \frac{3b^2c}{a^3x^4} - \frac{6b\,c^2}{a^3x^4} - \frac{4b^3c}{a^4x^5} + \frac{12b^2c^2}{a^4x^5} - \frac{16b\,c^3}{a^4x^5} + \frac{6bc}{a^3x^5} + \frac{5b^4c}{a^5x^6} - \frac{20b^3c^2}{a^5x^6} + \frac{40b^2c^3}{a^5x^6} - \frac{40b\,c^4}{a^5x^6} - \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{b}{2} - c + \frac{ax}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2 - bc + \frac{1}{2}abx + c^2 - acx + \frac{1}{4}a^2x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{4}b^2 - bc + c^2$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^2 + 2abx - 4acx + b^2 - 4bc + 4c^2 + 2a}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{a^2x^2}{4} + \left(\frac{1}{2}ab - ac\right)x + \frac{a}{2} + \frac{b^2}{4} - bc + c^2\right) + (0) \\
&= \frac{a^2x^2}{4} + \left(\frac{1}{2}ab - ac\right)x + \frac{a}{2} + \frac{b^2}{4} - bc + c^2
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{1}{2}a + \frac{1}{4}b^2 - bc + c^2$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{1}{2}a + \frac{1}{4}b^2 - bc + c^2\right) - \left(\frac{1}{4}b^2 - bc + c^2\right) \\
&= \frac{a}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{b}{2} - c + \frac{ax}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{a}{2}}{\frac{a}{2}} - 1\right) &= 0 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{a}{2}}{\frac{a}{2}} - 1\right) &= -1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{2}a + \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 - acx - bc + c^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{b}{2}-c+\frac{ax}{2}$	0	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=0$, and since there are no poles, then

$$\begin{aligned}d&=\alpha_\infty^{+}\\&=0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega&=(+)[\sqrt{r}]_\infty\\&=0+\left(\frac{b}{2}-c+\frac{ax}{2}\right)\\&=\frac{b}{2}-c+\frac{ax}{2}\\&=\frac{b}{2}-c+\frac{ax}{2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{b}{2}-c+\frac{ax}{2}\right)(0)+\left(\left(\frac{a}{2}\right)+\left(\frac{b}{2}-c+\frac{ax}{2}\right)^2-\left(\frac{1}{2}a+\frac{1}{4}a^2x^2+\frac{1}{2}abx+\frac{1}{4}b^2-acx-bc+c^2\right)\right)$$
$$0=0$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{b}{2} - c + \frac{ax}{2}\right) dx} \\
&= \mathrm{e}^{\frac{x(ax+2b-4c)}{4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{ax+b}{1} \, dx} \\
&= z_1 e^{-\frac{1}{4} a x^2 - \frac{1}{2} bx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x(ax+2b)}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-cx}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{ax+b}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{1}{2} a x^2 - bx}}{(y_1)^2} \, dx \\
&= y_1 \left(\frac{\sqrt{\pi}\, \mathrm{e}^{\frac{(b-2c)^2}{2a}} \sqrt{2}\, \mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b-2c)}{2\sqrt{a}}\right)}{2\sqrt{a}} \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\mathrm{e}^{-cx}\right) + c_2\left(\mathrm{e}^{-cx}\left(\frac{\sqrt{\pi}\,\mathrm{e}^{\frac{(b-2c)^2}{2a}}\sqrt{2}\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b-2c)}{2\sqrt{a}}\right)}{2\sqrt{a}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1\mathrm{e}^{-cx} + \frac{c_2\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{-2acx+(b-2c)^2}{2a}}\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b-2c)}{2\sqrt{a}}\right)}{2\sqrt{a}} \tag{1}
$$

Verification of solutions

$$
y = c_1\mathrm{e}^{-cx} + \frac{c_2\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{-2acx+(b-2c)^2}{2a}}\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b-2c)}{2\sqrt{a}}\right)}{2\sqrt{a}}
$$

Verified OK.

27.16.2 Maple step by step solution

Let's solve

$y'' + (ax+b)\,y' + c(ax+b-c)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + a_1 b + a_0(bc - c^2) + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_{k+1}(k+1)\, b + a_k(ak + bc - c^2) + a_{k-1}ac\right.\right.$$

- Each term must be 0

$$2a_2 + a_1 b + a_0(bc - c^2) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$k^2 a_{k+2} + (a a_k + a_{k+1} b + 3a_{k+2})\, k + 2a_{k+2} + (bc - c^2)\, a_k + a_{k-1}ac + a_{k+1}b = 0$$

- Shift index using $k- >k+1$

$$(k+1)^2 a_{k+3} + (a a_{k+1} + a_{k+2} b + 3a_{k+3})\,(k+1) + 2a_{k+3} + (bc - c^2)\, a_{k+1} + a_k ac + a_{k+2}b = 0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{a_k ac + ak a_{k+1} + bc a_{k+1} + bk a_{k+2} - c^2 a_{k+1} + a a_{k+1} + 2a_{k+2} b}{k^2 + 5k + 6}, 2a_2 + a_1 b + a_0(bc - c^2) = 0\right]$$

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + (ax + 2b)\, y' + \left(abx + b^2 - a\right) y = 0}$$

27.17.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + (ax + 2b)\, y' + \left(abx + b^2 - a\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= ax + 2b \\ C &= abx + b^2 - a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a(a\,x^2 + 6)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a\left(a\,x^2 + 6\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a(a\,x^2 + 6)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 46: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ax}{2} + \frac{3}{2x} - \frac{9}{4a\,x^3} + \frac{27}{4a^2x^5} - \frac{405}{16a^3x^7} + \frac{1701}{16a^4x^9} - \frac{15309}{32a^5x^{11}} + \frac{72171}{32a^6x^{13}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{ax}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{a^2x^2}{4}$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a(a\,x^2+6)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{3}{2}a + \frac{1}{4}a^2x^2\right) + (0) \\
&= \frac{3}{2}a + \frac{1}{4}a^2x^2
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{3a}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{3a}{2}\right) - (0) \\
&= \frac{3a}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{ax}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) &= 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) &= -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a(a\,x^2+6)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{ax}{2}$	1	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{ax}{2}\right) \\ &= \frac{ax}{2} \\ &= \frac{ax}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{ax}{2}\right)(1) + \left(\left(\frac{a}{2}\right) + \left(\frac{ax}{2}\right)^2 - \left(\frac{a(a\,x^2+6)}{4}\right)\right) = 0$$
$$-aa_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x) \, e^{\int \frac{ax}{2} dx} \\ &= (x) \, e^{\frac{a x^2}{4}} \\ &= x \, e^{\frac{a x^2}{4}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{ax+2b}{1} \, dx} \\ &= z_1 e^{-\frac{1}{4} a x^2 - bx} \\ &= z_1 \left(e^{-\frac{x(ax+4b)}{4}} \right) \end{aligned}$$

Which simplifies to

$$y_1 = x \, e^{-bx}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{ax+2b}{1} \, dx}}{(y_1)^2} \, dx \\ &= y_1 \int \frac{e^{-\frac{1}{2} a x^2 - 2bx}}{(y_1)^2} \, dx \\ &= y_1 \left(\frac{-\sqrt{a}\, \sqrt{\pi}\, \sqrt{2}\, \operatorname{erf}\left(\frac{\sqrt{2}\, \sqrt{a}\, x}{2}\right) x - 2 \, e^{-\frac{a x^2}{2}}}{2x} \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\,\mathrm{e}^{-bx}\right) + c_2 \left(x\,\mathrm{e}^{-bx} \left(\frac{-\sqrt{a}\,\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,\sqrt{a}\,x}{2}\right) x - 2\,\mathrm{e}^{-\frac{a\,x^2}{2}}}{2x}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\,\mathrm{e}^{-bx} - \frac{c_2 \mathrm{e}^{-bx} \left(\sqrt{a}\,\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,\sqrt{a}\,x}{2}\right) x + 2\,\mathrm{e}^{-\frac{a\,x^2}{2}}\right)}{2} \tag{1}
$$

Verification of solutions

$$
y = c_1 x\,\mathrm{e}^{-bx} - \frac{c_2 \mathrm{e}^{-bx} \left(\sqrt{a}\,\sqrt{\pi}\,\sqrt{2}\,\operatorname{erf}\left(\frac{\sqrt{2}\,\sqrt{a}\,x}{2}\right) x + 2\,\mathrm{e}^{-\frac{a\,x^2}{2}}\right)}{2}
$$

Verified OK.

27.17.2 Maple step by step solution

Let's solve

$y'' + (ax + 2b)\,y' + (abx + b^2 - a)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

☐ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_2 + 2a_1 b + a_0(b^2-a) + \left(\sum_{k=1}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + 2a_{k+1}(k+1)\, b + a_k(ak+b^2-a) + a_{k-1}ab\right.\right.$$

- Each term must be 0

$$2a_2 + 2a_1 b + a_0(b^2-a) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_k b^2 + (a a_{k-1} + 2k a_{k+1} + 2a_{k+1})\, b + k^2 a_{k+2} + (a a_k + 3a_{k+2})\, k - a a_k + 2a_{k+2} = 0$$

- Shift index using $k->k+1$

$$a_{k+1} b^2 + (a a_k + 2(k+1)\, a_{k+2} + 2a_{k+2})\, b + (k+1)^2 a_{k+3} + (a a_{k+1} + 3a_{k+3})\,(k+1) - a a_{k+1} + 2a$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{a_k ab + ak a_{k+1} + a_{k+1} b^2 + 2bk a_{k+2} + 4b a_{k+2}}{k^2+5k+6}, 2a_2 + 2a_1 b + a_0(b^2-a) = 0\right]$$

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= a^2x^2 + 2abx + c - \frac{(2ax+2b)'}{2} - \frac{(2ax+2b)^2}{4} \\
&= a^2x^2 + 2abx + c - \frac{(2a)}{2} - \frac{\left((2ax+2b)^2\right)}{4} \\
&= a^2x^2 + 2abx + c - (a) - \frac{(2ax+2b)^2}{4} \\
&= -b^2 - a + c
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\, z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{2ax+2b}{2}} \\
&= \mathrm{e}^{-\frac{x(ax+2b)}{2}}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\, \mathrm{e}^{-\frac{x(ax+2b)}{2}} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
-\mathrm{e}^{-\frac{x(ax+2b)}{2}} \left(v(x)\, b^2 + av(x) - v(x)\, c - v''(x)\right) = 0
$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = 0
$$

Where in the above $A = -1, B = 0, C = b^2 + a - c$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$
-\lambda^2 \mathrm{e}^{\lambda x} + \left(b^2 + a - c\right) \mathrm{e}^{\lambda x} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$b^2 - \lambda^2 + a - c = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = -1, B = 0, C = b^2 + a - c$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(-1)} \pm \frac{1}{(2)(-1)}\sqrt{0^2 - (4)(-1)(b^2 + a - c)} \\ &= \pm - \sqrt{b^2 + a - c}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= + - \sqrt{b^2 + a - c} \\ \lambda_2 &= - - \sqrt{b^2 + a - c}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -\sqrt{b^2 + a - c} \\ \lambda_2 &= \sqrt{b^2 + a - c}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ v(x) &= c_1 e^{\left(-\sqrt{b^2+a-c}\right)x} + c_2 e^{\left(\sqrt{b^2+a-c}\right)x}\end{aligned}$$

Or

$$v(x) = c_1 \mathrm{e}^{-\sqrt{b^2+a-c}\,x} + c_2 \mathrm{e}^{\sqrt{b^2+a-c}\,x}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x) \\ &= \left(c_1 \mathrm{e}^{-\sqrt{b^2+a-c}\,x} + c_2 \mathrm{e}^{\sqrt{b^2+a-c}\,x}\right)(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \mathrm{e}^{-\frac{x(ax+2b)}{2}}$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{-\sqrt{b^2+a-c}\,x} + c_2 \mathrm{e}^{\sqrt{b^2+a-c}\,x}\right) \mathrm{e}^{-\frac{x(ax+2b)}{2}}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \left(c_1 \mathrm{e}^{-\sqrt{b^2+a-c}\,x} + c_2 \mathrm{e}^{\sqrt{b^2+a-c}\,x}\right) \mathrm{e}^{-\frac{x(ax+2b)}{2}} \tag{1}$$

<u>Verification of solutions</u>

$$y = \left(c_1 \mathrm{e}^{-\sqrt{b^2+a-c}\,x} + c_2 \mathrm{e}^{\sqrt{b^2+a-c}\,x}\right) \mathrm{e}^{-\frac{x(ax+2b)}{2}}$$

Verified OK.

27.20.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + (2ax + 2b)\, y' + \left(a^2x^2 + 2abx + c\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2ax + 2b \\ C &= a^2x^2 + 2abx + c \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{b^2 + a - c}{1} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= b^2 + a - c \\
t &= 1
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(b^2 + a - c\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 50: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$
L = [1]
$$

Since $r = b^2 + a - c$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{b^2+a-c}\,x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2ax+2b}{1}\,dx} \\
&= z_1 e^{-\frac{1}{2}a\,x^2 - bx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x(ax+2b)}{2}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x\left(ax-2\sqrt{b^2+a-c}+2b\right)}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2ax+2b}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-a\,x^2-2bx}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{e}^{-2\sqrt{b^2+a-c}\,x}}{2\sqrt{b^2+a-c}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x\left(ax-2\sqrt{b^2+a-c}+2b\right)}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{x\left(ax-2\sqrt{b^2+a-c}+2b\right)}{2}} \left(-\frac{\mathrm{e}^{-2\sqrt{b^2+a-c}\,x}}{2\sqrt{b^2+a-c}}\right)\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{x\left(ax-2\sqrt{b^2+a-c}+2b\right)}{2}} - \frac{c_2 \mathrm{e}^{-\frac{x\left(ax+2\sqrt{b^2+a-c}+2b\right)}{2}}}{2\sqrt{b^2+a-c}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{x\left(ax-2\sqrt{b^2+a-c}+2b\right)}{2}} - \frac{c_2 \mathrm{e}^{-\frac{x\left(ax+2\sqrt{b^2+a-c}+2b\right)}{2}}}{2\sqrt{b^2+a-c}}$$

Verified OK.

27.20.3 Maple step by step solution

Let's solve

$y'' + (2ax + 2b)\, y' + (a^2x^2 + 2abx + c)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ∘ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ∘ Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ∘ Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

    $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

  ∘ Shift index using $k- >k + 1 - m$

    $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k + 1 - m)\, x^k$

  ∘ Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$2a_1b + a_0c + 2a_2 + (6a_3 + 4a_2b + a_1(2a + c) + 2a_0ab)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + 2a_{k+1}(k +$$

- The coefficients of each power of x must be 0

$$[2a_2 + 2a_1b + a_0c = 0, 6a_3 + 4a_2b + a_1(2a + c) + 2a_0ab = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -a_1b - \frac{a_0c}{2}, a_3 = -\frac{1}{3}a_0ab + \frac{2}{3}a_1b^2 + \frac{1}{3}a_0bc - \frac{1}{3}a_1a - \frac{1}{6}a_1c\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$k^2a_{k+2} + (2aa_k + 2a_{k+1}b + 3a_{k+2})\, k + a_{k-2}a^2 + 2a_{k-1}ab + 2a_{k+1}b + a_kc + 2a_{k+2} = 0$$

- Shift index using $k- >k+2$

$$(k+2)^2\, a_{k+4} + (2aa_{k+2} + 2a_{k+3}b + 3a_{k+4})\,(k+2) + a_ka^2 + 2a_{k+1}ab + 2a_{k+3}b + a_{k+2}c + 2a_{k+4} =$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_kx^k, a_{k+4} = -\frac{a_ka^2 + 2a_{k+1}ab + 2aka_{k+2} + 2bka_{k+3} + 4aa_{k+2} + 6a_{k+3}b + a_{k+2}c}{k^2+7k+12}, a_2 = -a_1b - \frac{a_0c}{2}, a_3 = -\frac{1}{3}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 33.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + a\left(-b^2 + x^2\right) y' - a(x + b)\, y = 0}$$

27.23.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + a\left(-b^2 + x^2\right) y' - a(x + b)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \left(-b^2 + x^2\right) a \\ C &= -a(x + b) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a(a\,b^4 - 2a\,b^2x^2 + a\,x^4 + 4b + 8x)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a\left(a\,b^4 - 2a\,b^2x^2 + a\,x^4 + 4b + 8x\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a(a\,b^4 - 2a\,b^2x^2 + a\,x^4 + 4b + 8x)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 53: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx -\frac{a\,b^2}{2} + \frac{a\,x^2}{2} + \frac{b^5}{x^6} + \frac{2b^4}{x^5} + \frac{b^3}{x^4} + \frac{2b^2}{x^3} + \frac{b}{x^2} + \frac{2}{x} - \frac{13b^2}{a\,x^6} - \frac{4b}{a\,x^5} - \frac{4}{a\,x^4} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= -\frac{1}{2} a\,b^2 + \frac{1}{2} a\,x^2 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2b^4 - \frac{1}{2}a^2b^2x^2 + \frac{1}{4}a^2x^4$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a(a\,b^4 - 2a\,b^2x^2 + a\,x^4 + 4b + 8x)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{a^2x^4}{4} - \frac{a^2b^2x^2}{2} + 2ax + \frac{ab(b^3a+4)}{4}\right) + (0) \\
&= \frac{a^2x^4}{4} - \frac{a^2b^2x^2}{2} + 2ax + \frac{ab(b^3a+4)}{4}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $2a$. Now b can be found.

$$\begin{aligned}
b &= (2a) - (0) \\
&= 2a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{1}{2}a\,b^2 + \frac{1}{2}a\,x^2 \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{2a}{\frac{a}{2}} - 2\right) &&= 1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{2a}{\frac{a}{2}} - 2\right) &&= -3
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a(a\,b^4 - 2a\,b^2x^2 + a\,x^4 + 4b + 8x)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$-\frac{1}{2}a\,b^2+\frac{1}{2}a\,x^2$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=1$, and since there are no poles, then

$$\begin{aligned}d&=\alpha_\infty^+\\&=1\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega&=(+)[\sqrt{r}]_\infty\\&=0+\left(-\frac{1}{2}a\,b^2+\frac{1}{2}a\,x^2\right)\\&=-\frac{1}{2}a\,b^2+\frac{1}{2}a\,x^2\\&=-\frac{a(b^2-x^2)}{2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2}a\,b^2+\frac{1}{2}a\,x^2\right)(1)+\left((ax)+\left(-\frac{1}{2}a\,b^2+\frac{1}{2}a\,x^2\right)^2-\left(\frac{a(a\,b^4-2a\,b^2x^2+a\,x^4+4b+8x)}{4}\right)\right)=$$

$$-a(a_0+b)\,(x+b)=0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = -b\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x - b$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x-b)\, e^{\int \left(-\frac{1}{2} a\, b^2 + \frac{1}{2} a\, x^2\right) dx} \\ &= (x-b)\, e^{-\frac{a\left(b^2 x - \frac{1}{3} x^3\right)}{2}} \\ &= -(-x+b)\, e^{-\frac{a x \left(b^2 - \frac{x^2}{3}\right)}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{\left(-b^2 + x^2\right) a}{1} \, dx} \\ &= z_1 e^{-\frac{a\left(-b^2 x + \frac{1}{3} x^3\right)}{2}} \\ &= z_1 \left(e^{\frac{a x \left(3 b^2 - x^2\right)}{6}} \right) \end{aligned}$$

Which simplifies to

$$y_1 = x - b$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{\left(-b^2 + x^2\right) a}{1} \, dx}}{\left(y_1\right)^2} \, dx \\ &= y_1 \int \frac{e^{a\, b^2 x - \frac{1}{3} a\, x^3}}{\left(y_1\right)^2} \, dx \\ &= y_1 \left(\int \frac{e^{a\, b^2 x - \frac{1}{3} a\, x^3}}{\left(-x+b\right)^2} dx \right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x-b) + c_2\left(x - b\left(\int \frac{e^{a\,b^2 x - \frac{1}{3} a\,x^3}}{(-x+b)^2} dx\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1(x-b) - c_2(-x+b)\left(\int \frac{e^{a\,b^2 x - \frac{1}{3} a\,x^3}}{(-x+b)^2} dx\right) \tag{1}
$$

Verification of solutions

$$
y = c_1(x-b) - c_2(-x+b)\left(\int \frac{e^{a\,b^2 x - \frac{1}{3} a\,x^3}}{(-x+b)^2} dx\right)
$$

Verified OK.

27.23.2 Maple step by step solution

Let's solve

$y'' + a(-b^2 + x^2)\, y' - a(x+b)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = a(x+b)\, y + a(b^2 - x^2)\, y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - a(b^2 - x^2)\, y' - a(x+b)\, y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- Shift index using $k->k-m$

$$x^{m}\cdot y=\sum_{k=\max(0,-m)+m}^{\infty}a_{k-m}x^{k}$$

- Convert $x^{m}\cdot y'$ to series expansion for $m=0..2$

$$x^{m}\cdot y'=\sum_{k=\max(0,1-m)}^{\infty}a_{k}k\,x^{k-1+m}$$

- Shift index using $k->k+1-m$

$$x^{m}\cdot y'=\sum_{k=\max(0,1-m)+m-1}^{\infty}a_{k+1-m}(k+1-m)\,x^{k}$$

- Convert y'' to series expansion

$$y''=\sum_{k=2}^{\infty}a_{k}k(k-1)\,x^{k-2}$$

- Shift index using $k->k+2$

$$y''=\sum_{k=0}^{\infty}a_{k+2}(k+2)\,(k+1)\,x^{k}$$

Rewrite ODE with series expansions

$$-a_{1}a\,b^{2}-aa_{0}b+2a_{2}+\left(\sum_{k=1}^{\infty}\left(a_{k+2}(k+2)\,(k+1)-a_{k+1}(k+1)\,a\,b^{2}-aa_{k}b+a_{k-1}a(k-2)\right)x^{k}\right)$$

- Each term must be 0

$$-a_{1}a\,b^{2}-aa_{0}b+2a_{2}=0$$

- Each term in the series must be 0, giving the recursion relation

$$\left(\left(-b^{2}a_{k+1}+a_{k-1}\right)k-b^{2}a_{k+1}-ba_{k}-2a_{k-1}\right)a+a_{k+2}(k+2)\,(k+1)=0$$

- Shift index using $k->k+1$

$$\left(\left(-b^{2}a_{k+2}+a_{k}\right)(k+1)-b^{2}a_{k+2}-ba_{k+1}-2a_{k}\right)a+a_{k+3}(k+3)\,(k+2)=0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y=\sum_{k=0}^{\infty}a_{k}x^{k},a_{k+3}=\frac{\left(b^{2}ka_{k+2}+2b^{2}a_{k+2}+ba_{k+1}-a_{k}k+a_{k}\right)a}{(k+3)(k+2)},-a_{1}a\,b^{2}-aa_{0}b+2a_{2}=0\right]$$

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(a\,x^2 + b\right) y' + c\left(a\,x^2 + b - c\right) y = 0}$$

27.24.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(a\,x^2 + b\right) y' + c\left(a\,x^2 + b - c\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a\,x^2 + b \\ C &= c\left(a\,x^2 + b - c\right) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^4 + 2ab\,x^2 - 4ac\,x^2 + 4ax + b^2 - 4bc + 4c^2}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^4 + 2ab\,x^2 - 4ac\,x^2 + 4ax + b^2 - 4bc + 4c^2 \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(ax + \frac{1}{4}a^2x^4 + \frac{1}{2}ab\,x^2 + \frac{1}{4}b^2 - ac\,x^2 - bc + c^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 55: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^2}{2} + \frac{b}{2} - c + \frac{1}{x} - \frac{b}{a\,x^3} + \frac{2c}{a\,x^3} - \frac{1}{a\,x^4} + \frac{b^2}{a^2x^5} - \frac{4bc}{a^2x^5} + \frac{4c^2}{a^2x^5} + \frac{3b}{a^2x^6} - \frac{6c}{a^2x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= \frac{b}{2} - c + \frac{a\,x^2}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2 - bc + \frac{1}{2}ab\,x^2 + c^2 - ac\,x^2 + \frac{1}{4}a^2x^4$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^4 + 2ab\,x^2 - 4ac\,x^2 + 4ax + b^2 - 4bc + 4c^2}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{a^2x^4}{4} + \left(\frac{1}{2}ab - ac\right)x^2 + ax + \frac{b^2}{4} - bc + c^2\right) + (0) \\
&= \frac{a^2x^4}{4} + \left(\frac{1}{2}ab - ac\right)x^2 + ax + \frac{b^2}{4} - bc + c^2
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is a. Now b can be found.

$$\begin{aligned}
b &= (a) - (0) \\
&= a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{b}{2} - c + \frac{a\,x^2}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) = \frac{1}{2}\left(\frac{a}{\frac{a}{2}} - 2\right) = 0 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{a}{\frac{a}{2}} - 2\right) = -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = ax + \frac{1}{4}a^2x^4 + \frac{1}{2}ab\,x^2 + \frac{1}{4}b^2 - ac\,x^2 - bc + c^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{b}{2}-c+\frac{a\,x^2}{2}$	0	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=0$, and since there are no poles, then

$$\begin{aligned}d&=\alpha_\infty^+\\&=0\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega&=(+)[\sqrt{r}]_\infty\\&=0+\left(\frac{b}{2}-c+\frac{a\,x^2}{2}\right)\\&=\frac{b}{2}-c+\frac{a\,x^2}{2}\\&=\frac{b}{2}-c+\frac{a\,x^2}{2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{b}{2}-c+\frac{a\,x^2}{2}\right)(0)+\left((ax)+\left(\frac{b}{2}-c+\frac{a\,x^2}{2}\right)^2-\left(ax+\frac{1}{4}a^2x^4+\frac{1}{2}ab\,x^2+\frac{1}{4}b^2-ac\,x^2-bc+c\right.\right.$$

0

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{b}{2} - c + \frac{a\,x^2}{2}\right) dx} \\
&= \mathrm{e}^{\frac{x\left(a\,x^2 + 3b - 6c\right)}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{a\,x^2 + b}{1} \, dx} \\
&= z_1 e^{-\frac{1}{6} a\,x^3 - \frac{1}{2} b x} \\
&= z_1 \left(\mathrm{e}^{-\frac{x\left(a\,x^2 + 3b\right)}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-cx}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^2 + b}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{1}{3} a\,x^3 - bx}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \mathrm{e}^{-\frac{x\left(a\,x^2 + 3b - 6c\right)}{3}} \, dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-cx}\right) + c_2 \left(\mathrm{e}^{-cx} \left(\int \mathrm{e}^{-\frac{x\left(a\,x^2 + 3b - 6c\right)}{3}} \, dx\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 e^{-cx} + c_2 e^{-cx} \left(\int e^{-\frac{x(a\,x^2+3b-6c)}{3}} dx \right) \tag{1}$$

Verification of solutions

$$y = c_1 e^{-cx} + c_2 e^{-cx} \left(\int e^{-\frac{x(a\,x^2+3b-6c)}{3}} dx \right)$$

Verified OK.

27.24.2 Maple step by step solution

Let's solve

$y'' + (a\,x^2 + b)\,y' + c(a\,x^2 + b - c)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

    $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

  ◦ Shift index using $k- >k + 1 - m$

    $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k + 1 - m)\, x^k$

  ◦ Convert y'' to series expansion

$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- Shift index using $k- >k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^{k}$

  Rewrite ODE with series expansions

  $2a_2 + a_1 b + c a_0(b-c) + (6a_3 + 2a_2 b + c a_1(b-c))\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + a_{k+1}(k+1)\, b\right.$

- The coefficients of each power of x must be 0

  $[2a_2 + a_1 b + c a_0(b-c) = 0, 6a_3 + 2a_2 b + c a_1(b-c) = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = -\frac{1}{2}a_0 bc + \frac{1}{2}a_0 c^2 - \frac{1}{2}a_1 b, a_3 = \frac{1}{6}a_0 b^2 c - \frac{1}{6}a_0 b\, c^2 + \frac{1}{6}a_1 b^2 - \frac{1}{6}a_1 bc + \frac{1}{6}a_1 c^2\right\}$

- Each term in the series must be 0, giving the recursion relation

  $k^2 a_{k+2} + (a a_{k-1} + a_{k+1} b + 3a_{k+2})\, k + 2a_{k+2} + (c a_{k-2} - a_{k-1})\, a + (c a_k + a_{k+1})\, b - a_k c^2 = 0$

- Shift index using $k- >k+2$

  $(k+2)^2\, a_{k+4} + (a a_{k+1} + b a_{k+3} + 3a_{k+4})\,(k+2) + 2a_{k+4} + (c a_k - a_{k+1})\, a + (c a_{k+2} + a_{k+3})\, b - a$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{a_k a c + a k a_{k+1} + b c a_{k+2} + b k a_{k+3} - a_{k+2} c^2 + a a_{k+1} + 3b a_{k+3}}{k^2+7k+12}, a_2 = -\frac{1}{2}a_0 bc + \frac{1}{2}a_0 c^2 - \frac{1}{2}a_1 b\right.$

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(a\,x^2 + 2b\right) y' + \left(ab\,x^2 - ax + b^2\right) y = 0}$$

27.25.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(a\,x^2 + 2b\right) y' + \left(\left(b\,x^2 - x\right) a + b^2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a\,x^2 + 2b \\ C &= \left(b\,x^2 - x\right) a + b^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{ax(a\,x^3 + 8)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= ax\left(a\,x^3 + 8\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{ax(a\,x^3 + 8)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 57: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 4 \\
&= -4
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{2} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^2}{2} + \frac{2}{x} - \frac{4}{a\,x^4} + \frac{16}{a^2 x^7} - \frac{80}{a^3 x^{10}} + \frac{448}{a^4 x^{13}} - \frac{2688}{a^5 x^{16}} + \frac{16896}{a^6 x^{19}} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\
&= \frac{a\,x^2}{2} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{a^2x^4}{4}$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{ax(a\,x^3 + 8)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(2ax + \frac{1}{4}a^2x^4\right) + (0) \\
&= 2ax + \frac{1}{4}a^2x^4
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $2a$. Now b can be found.

$$\begin{aligned}
b &= (2a) - (0) \\
&= 2a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{a\,x^2}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{2a}{\frac{a}{2}} - 2\right) &= 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{2a}{\frac{a}{2}} - 2\right) &= -3
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{ax(a\,x^3 + 8)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{a\,x^2}{2}$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{a\,x^2}{2}\right) \\ &= \frac{a\,x^2}{2} \\ &= \frac{a\,x^2}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned} (0) + 2\left(\frac{a\,x^2}{2}\right)(1) + \left((ax) + \left(\frac{a\,x^2}{2}\right)^2 - \left(\frac{ax(a\,x^3+8)}{4}\right)\right) &= 0 \\ -axa_0 &= 0 \end{aligned}$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= (x)\, \mathrm{e}^{\int \frac{a\,x^2}{2} dx} \\ &= (x)\, \mathrm{e}^{\frac{a\,x^3}{6}} \\ &= x\, \mathrm{e}^{\frac{a\,x^3}{6}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{a\,x^2+2b}{1}\, dx} \\ &= z_1 e^{-\frac{1}{6}a\,x^3 - bx} \\ &= z_1 \left(\mathrm{e}^{-\frac{x\left(a\,x^2+6b\right)}{6}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-bx}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^2+2b}{1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{1}{3}a\,x^3 - 2bx}}{(y_1)^2}\, dx \\ &= y_1 \left(\int \frac{\mathrm{e}^{-\frac{a\,x^3}{3}}}{x^2} dx\right) \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(x\,\mathrm{e}^{-bx}\right) + c_2\left(x\,\mathrm{e}^{-bx}\left(\int \frac{\mathrm{e}^{-\frac{a\,x^3}{3}}}{x^2}dx\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1x\,\mathrm{e}^{-bx} + c_2x\,\mathrm{e}^{-bx}\left(\int \frac{\mathrm{e}^{-\frac{a\,x^3}{3}}}{x^2}dx\right) \tag{1}
$$

Verification of solutions

$$
y = c_1x\,\mathrm{e}^{-bx} + c_2x\,\mathrm{e}^{-bx}\left(\int \frac{\mathrm{e}^{-\frac{a\,x^3}{3}}}{x^2}dx\right)
$$

Verified OK.

27.25.2 Maple step by step solution

Let's solve

$y'' + (a\,x^2 + 2b)\,y' + ((b\,x^2 - x)\,a + b^2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = (-ab\,x^2 + ax - b^2)\,y - (a\,x^2 + 2b)\,y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (a\,x^2 + 2b)\,y' + (ab\,x^2 - ax + b^2)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_kx^k$

□ Rewrite ODE with series expansions

  ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_kx^{k+m}$

- Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)(k+1)\, x^k$$

Rewrite ODE with series expansions

$$a_0 b^2 + 2a_1 b + 2a_2 + (a_1 b^2 - a_0 a + 4a_2 b + 6a_3)\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)(k+1) + 2a_{k+1}(k+1)\, b +\right.$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_0 b^2 + 2a_1 b = 0, a_1 b^2 - a_0 a + 4a_2 b + 6a_3 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{1}{2}a_0 b^2 - a_1 b, a_3 = \frac{1}{3}a_0 b^3 + \frac{1}{2}a_1 b^2 + \frac{1}{6}a_0 a\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k b^2 + (a a_{k-2} + 2k a_{k+1} + 2a_{k+1})\, b + k^2 a_{k+2} + (a_{k-1} a + 3a_{k+2})\, k - 2a_{k-1} a + 2a_{k+2} = 0$$

- Shift index using $k->k+2$

$$a_{k+2} b^2 + (a_k a + 2(k+2)\, a_{k+3} + 2a_{k+3})\, b + (k+2)^2\, a_{k+4} + (a_{k+1} a + 3a_{k+4})\,(k+2) - 2a_{k+1} a + 2$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{a_k a b + a k a_{k+1} + a_{k+2} b^2 + 2bk a_{k+3} + 6b a_{k+3}}{k^2 + 7k + 12}, a_2 = -\frac{1}{2}a_0 b^2 - a_1 b, a_3 = \frac{1}{3}a_0 b^3 + \frac{1}{2}a_1 b^2\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 36.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(2x^2 + a\right) y' + \left(x^4 + a\,x^2 + b + 2x\right) y = 0}$$

27.26.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned}p(x) &= 2x^2 + a\\ q(x) &= x^4 + a\,x^2 + b + 2x\end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= x^4 + a\,x^2 + b + 2x - \frac{(2x^2+a)'}{2} - \frac{(2x^2+a)^2}{4} \\
&= x^4 + a\,x^2 + b + 2x - \frac{(4x)}{2} - \frac{\left((2x^2+a)^2\right)}{4} \\
&= x^4 + a\,x^2 + b + 2x - (2x) - \frac{(2x^2+a)^2}{4} \\
&= b - \frac{a^2}{4}
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\,z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2}dx\right)} \\
&= e^{-\int \frac{2x^2+a}{2}} \\
&= \mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\,\mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
-\mathrm{e}^{-\frac{x(2x^2+3a)}{6}}\left(v(x)\,a^2 - 4v(x)\,b - 4v''(x)\right) = 0
$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = 0
$$

Where in the above $A = -4, B = 0, C = a^2 - 4b$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$
-4\lambda^2\mathrm{e}^{\lambda x} + \left(a^2 - 4b\right)\mathrm{e}^{\lambda x} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$a^2 - 4\lambda^2 - 4b = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = -4, B = 0, C = a^2 - 4b$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(-4)} \pm \frac{1}{(2)(-4)}\sqrt{0^2 - (4)(-4)(a^2 - 4b)}\\ &= \pm - \frac{\sqrt{a^2 - 4b}}{2}\end{aligned}$$

Hence

$$\lambda_1 = + - \frac{\sqrt{a^2 - 4b}}{2}$$

$$\lambda_2 = - - \frac{\sqrt{a^2 - 4b}}{2}$$

Which simplifies to

$$\lambda_1 = -\frac{\sqrt{a^2 - 4b}}{2}$$

$$\lambda_2 = \frac{\sqrt{a^2 - 4b}}{2}$$

Since roots are real and distinct, then the solution is

$$v(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$

$$v(x) = c_1 e^{\left(-\frac{\sqrt{a^2-4b}}{2}\right)x} + c_2 e^{\left(\frac{\sqrt{a^2-4b}}{2}\right)x}$$

Or

$$v(x) = c_1 \mathrm{e}^{-\frac{x\sqrt{a^2-4b}}{2}} + c_2 \mathrm{e}^{\frac{x\sqrt{a^2-4b}}{2}}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x)\\ &= \left(c_1 \mathrm{e}^{-\frac{x\sqrt{a^2-4b}}{2}} + c_2 \mathrm{e}^{\frac{x\sqrt{a^2-4b}}{2}}\right)(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax}$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{-\frac{x\sqrt{a^2-4b}}{2}} + c_2 \mathrm{e}^{\frac{x\sqrt{a^2-4b}}{2}}\right) \mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax}$$

Summary

The solution(s) found are the following

$$y = \left(c_1 \mathrm{e}^{-\frac{x\sqrt{a^2-4b}}{2}} + c_2 \mathrm{e}^{\frac{x\sqrt{a^2-4b}}{2}}\right) \mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax} \tag{1}$$

Verification of solutions

$$y = \left(c_1 \mathrm{e}^{-\frac{x\sqrt{a^2-4b}}{2}} + c_2 \mathrm{e}^{\frac{x\sqrt{a^2-4b}}{2}}\right) \mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax}$$

Verified OK.

27.26.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' + (2x^2 + a) y' + (x^4 + a x^2 + b + 2x) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2x^2 + a \\ C &= x^4 + a x^2 + b + 2x \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2 - 4b}{4} \tag{6}$$

Comparing the above to (5) shows that

$$s = a^2 - 4b$$
$$t = 4$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2}{4} - b\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 59: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = \frac{a^2}{4} - b$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\frac{x\sqrt{a^2-4b}}{2}}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^2+a}{1}\,dx} \\
&= z_1 e^{-\frac{1}{3}x^3-\frac{1}{2}ax} \\
&= z_1 \left(\mathrm{e}^{-\frac{1}{3}x^3-\frac{1}{2}ax}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{x^3}{3}-\frac{ax}{2}+\frac{x\sqrt{a^2-4b}}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2+a}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{2}{3}x^3-ax}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{e}^{-x\sqrt{a^2-4b}}}{\sqrt{a^2-4b}}\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x^3}{3}-\frac{ax}{2}+\frac{x\sqrt{a^2-4b}}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{x^3}{3}-\frac{ax}{2}+\frac{x\sqrt{a^2-4b}}{2}} \left(-\frac{\mathrm{e}^{-x\sqrt{a^2-4b}}}{\sqrt{a^2-4b}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{-\frac{x^3}{3}-\frac{ax}{2}+\frac{x\sqrt{a^2-4b}}{2}} - \frac{c_2 \mathrm{e}^{-\frac{x\left(2x^2+3\sqrt{a^2-4b}+3a\right)}{6}}}{\sqrt{a^2-4b}} \tag{1}
$$

Verification of solutions

$$
y = c_1 \mathrm{e}^{-\frac{x^3}{3}-\frac{ax}{2}+\frac{x\sqrt{a^2-4b}}{2}} - \frac{c_2 \mathrm{e}^{-\frac{x\left(2x^2+3\sqrt{a^2-4b}+3a\right)}{6}}}{\sqrt{a^2-4b}}
$$

Verified OK.

27.26.3 Maple step by step solution

Let's solve

$y'' + (2x^2 + a)\, y' + (x^4 + a\, x^2 + b + 2x)\, y = 0$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 38.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(ab\,x^2 + bx + 2a\right)y' + a^2\left(b\,x^2 + 1\right)y = 0}$$

27.28.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(\left(a\,x^2 + x\right)b + 2a\right)y' + a^2\left(b\,x^2 + 1\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \left(a\,x^2 + x\right)b + 2a \\ C &= a^2\left(b\,x^2 + 1\right) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{b(a^2 b\, x^4 + 2ab\, x^3 + b\, x^2 + 8ax + 2)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= b\left(a^2 b\, x^4 + 2ab\, x^3 + b\, x^2 + 8ax + 2\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{b(a^2 b\, x^4 + 2ab\, x^3 + b\, x^2 + 8ax + 2)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 62: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ab\,x^2}{2} + \frac{bx}{2} + \frac{2}{x} - \frac{3}{2a\,x^2} + \frac{3}{2a^2x^3} - \frac{4}{ab\,x^4} - \frac{3}{2a^3x^4} + \frac{10}{a^2b\,x^5} + \frac{3}{2a^4x^5} - \frac{73}{4a^3b\,x^6} - \frac{3}{2a^5x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{ab}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= \frac{1}{2}bx + \frac{1}{2}ab\,x^2 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2x^2 + \frac{1}{2}a\,b^2x^3 + \frac{1}{4}a^2b^2x^4$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{b(a^2b\,x^4 + 2ab\,x^3 + b\,x^2 + 8ax + 2)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(2abx + \frac{1}{2}b + \frac{1}{4}a^2b^2x^4 + \frac{1}{2}a\,b^2x^3 + \frac{1}{4}b^2x^2\right) + (0) \\
&= 2abx + \frac{1}{2}b + \frac{1}{4}a^2b^2x^4 + \frac{1}{2}a\,b^2x^3 + \frac{1}{4}b^2x^2
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $2ab$. Now b can be found.

$$\begin{aligned}
b &= (2ab) - (0) \\
&= 2ab
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2}bx + \frac{1}{2}ab\,x^2 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{2ab}{\frac{ab}{2}} - 2\right) &&= 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{2ab}{\frac{ab}{2}} - 2\right) &&= -3
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{b(a^2b\,x^4 + 2ab\,x^3 + b\,x^2 + 8ax + 2)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-4	$\frac{1}{2}bx+\frac{1}{2}ab\,x^2$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+}=1$, and since there are no poles, then

$$\begin{aligned} d&=\alpha_\infty^{+}\\ &=1 \end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega&=(+)[\sqrt{r}]_\infty\\ &=0+\left(\frac{1}{2}bx+\frac{1}{2}ab\,x^2\right)\\ &=\frac{1}{2}bx+\frac{1}{2}ab\,x^2\\ &=\frac{bx(ax+1)}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2}bx+\frac{1}{2}ab\,x^2\right)(1)+\left(\left(abx+\frac{1}{2}b\right)+\left(\frac{1}{2}bx+\frac{1}{2}ab\,x^2\right)^2-\left(\frac{b(a^2b\,x^4+2ab\,x^3+b\,x^2+8ax+2)}{4}\right.\right.$$

$$-bx(aa_0-1)$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{1}{a}\right) e^{\int \left(\frac{1}{2}bx + \frac{1}{2}ab\,x^2\right) dx} \\
&= \left(x + \frac{1}{a}\right) e^{\frac{b\left(\frac{1}{3}a\,x^3 + \frac{1}{2}x^2\right)}{2}} \\
&= \frac{(ax+1)\, e^{\frac{1}{6}ab\,x^3 + \frac{1}{4}b\,x^2}}{a}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{\left(a\,x^2 + x\right)b + 2a}{1} \, dx} \\
&= z_1 e^{-\frac{1}{6}ab\,x^3 - \frac{1}{4}b\,x^2 - ax} \\
&= z_1 \left(e^{-\frac{x\left(ab\,x^2 + \frac{3}{2}bx + 6a\right)}{6}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(ax+1)\, e^{-ax}}{a}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{\left(a\,x^2+x\right)b+2a}{1}\,dx}}{\left(y_1\right)^2}\,dx$$
$$= y_1 \int \frac{e^{-\frac{x\left(ab\,x^2+\frac{3}{2}bx+6a\right)}{3}}}{\left(y_1\right)^2}\,dx$$
$$= y_1 \left(\int \frac{a^2 \mathrm{e}^{-\frac{x^2\left(ax+\frac{3}{2}\right)b}{3}}}{\left(ax+1\right)^2}dx\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a}\right) + c_2 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a} \left(\int \frac{a^2 \mathrm{e}^{-\frac{x^2\left(ax+\frac{3}{2}\right)b}{3}}}{\left(ax+1\right)^2}dx\right)\right)$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a} + c_2(ax+1)\,\mathrm{e}^{-ax} a \left(\int \frac{\mathrm{e}^{-\frac{x^2\left(ax+\frac{3}{2}\right)b}{3}}}{\left(ax+1\right)^2}dx\right) \tag{1}$$

<u>Verification of solutions</u>

$$y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a} + c_2(ax+1)\,\mathrm{e}^{-ax} a \left(\int \frac{\mathrm{e}^{-\frac{x^2\left(ax+\frac{3}{2}\right)b}{3}}}{\left(ax+1\right)^2}dx\right)$$

Verified OK.

27.28.2 Maple step by step solution

Let's solve

$y'' + ((a\,x^2+x)\,b+2a)\,y' + a^2(b\,x^2+1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -(ab\,x^2+bx+2a)\,y' - a^2(b\,x^2+1)\,y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (ab\,x^2+bx+2a)\,y' + a^2(b\,x^2+1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ○ Shift index using $k- > k-m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ○ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

- ○ Shift index using $k- > k+1-m$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$

- ○ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ○ Shift index using $k- > k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$$a_0a^2 + 2a_1a + 2a_2 + (6a_3 + 4aa_2 + a_1(a^2 + b))\, x + \left(\sum_{k=2}^{\infty} (a_{k+2}(k+2)\,(k+1) + 2aa_{k+1}(k+1) + \right.$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_0a^2 + 2a_1a = 0, 6a_3 + 4aa_2 + a_1(a^2 + b) = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{1}{2}a_0a^2 - a_1a, a_3 = \frac{1}{3}a_0a^3 + \frac{1}{2}a_1a^2 - \frac{1}{6}a_1b\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(ba_{k-2} + a_k)\, a^2 + ((ba_{k-1} + 2a_{k+1})\, k - ba_{k-1} + 2a_{k+1})\, a + k^2a_{k+2} + (ba_k + 3a_{k+2})\, k + 2a_{k+2} = 0$$

- Shift index using $k- >k+2$

$$(ba_k + a_{k+2})\, a^2 + ((ba_{k+1} + 2a_{k+3})\,(k+2) - ba_{k+1} + 2a_{k+3})\, a + (k+2)^2\, a_{k+4} + (ba_{k+2} + 3a_{k+4})$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_kx^k, a_{k+4} = -\frac{a_ka^2b + abka_{k+1} + a^2a_{k+2} + aba_{k+1} + 2aka_{k+3} + bka_{k+2} + 6aa_{k+3} + 2ba_{k+2}}{k^2 + 7k + 12}, a_2 = -\frac{1}{2}a_0a^2 - a_1\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 39.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + \left(a\,x^2 + bx + c\right) y' + x\left(ab\,x^2 + bc + 2a\right) y = 0}$$

27.29.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(a\,x^2 + bx + c\right) y' + x\left(\left(a\,x^2 + c\right) b + 2a\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a\,x^2 + bx + c \\ C &= x\left(\left(a\,x^2 + c\right) b + 2a\right) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^4 - 2ab\,x^3 + 2ac\,x^2 + b^2x^2 - 2bcx - 4ax + c^2 + 2b}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^4 - 2ab\,x^3 + 2ac\,x^2 + b^2x^2 - 2bcx - 4ax + c^2 + 2b \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-ax + \frac{1}{2}b + \frac{1}{4}a^2x^4 - \frac{1}{2}ab\,x^3 + \frac{1}{2}ac\,x^2 + \frac{1}{4}b^2x^2 - \frac{1}{2}bcx + \frac{1}{4}c^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 64: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 4 \\
&= -4
\end{aligned}
$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{2} a_i x^i \qquad (8)
\end{aligned}
$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^2}{2} - \frac{bx}{2} + \frac{c}{2} - \frac{1}{x} - \frac{b}{2a\,x^2} + \frac{c}{a\,x^3} - \frac{b^2}{2a^2x^3} + \frac{3bc}{2a^2x^4} - \frac{b^3}{2a^3x^4} - \frac{1}{a\,x^4} - \frac{c^2}{a^2x^5} + \frac{2b^2c}{a^3x^5} - \frac{b^4}{2a^4x^5} - \frac{2b}{a^2x^5} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\
&= \frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2 \qquad (10)
\end{aligned}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}c^2 - \frac{1}{2}bcx + \frac{1}{2}ac\,x^2 + \frac{1}{4}b^2x^2 - \frac{1}{2}ab\,x^3 + \frac{1}{4}a^2x^4$$

This shows that the coefficient of x in the above is $-\frac{bc}{2}$. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^4 - 2ab\,x^3 + 2ac\,x^2 + b^2x^2 - 2bcx - 4ax + c^2 + 2b}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{a^2x^4}{4} - \frac{ab\,x^3}{2} + \left(\frac{ac}{2} + \frac{b^2}{4}\right)x^2 + \left(-a - \frac{bc}{2}\right)x + \frac{b}{2} + \frac{c^2}{4}\right) + (0) \\
&= \frac{a^2x^4}{4} - \frac{ab\,x^3}{2} + \left(\frac{ac}{2} + \frac{b^2}{4}\right)x^2 + \left(-a - \frac{bc}{2}\right)x + \frac{b}{2} + \frac{c^2}{4}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-a - \frac{bc}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(-a - \frac{bc}{2}\right) - \left(-\frac{bc}{2}\right) \\
&= -a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-a}{\frac{a}{2}} - 2\right) &&= -2 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-a}{\frac{a}{2}} - 2\right) &&= 0
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -ax + \frac{1}{2}b + \frac{1}{4}a^2x^4 - \frac{1}{2}ab\,x^3 + \frac{1}{2}ac\,x^2 + \frac{1}{4}b^2x^2 - \frac{1}{2}bcx + \frac{1}{4}c^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2$	-2	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 0$, and since there are no poles then

$$\begin{aligned} d &= \alpha_\infty^- \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= (-)[\sqrt{r}]_\infty \\ &= 0 + (-)\left(\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2\right) \\ &= -\frac{1}{2}c + \frac{1}{2}bx - \frac{1}{2}a\,x^2 \\ &= -\frac{1}{2}c + \frac{1}{2}bx - \frac{1}{2}a\,x^2 \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2}c + \frac{1}{2}bx - \frac{1}{2}a\,x^2\right)(0) + \left(\left(\frac{b}{2} - ax\right) + \left(-\frac{1}{2}c + \frac{1}{2}bx - \frac{1}{2}a\,x^2\right)^2 - \left(-ax + \frac{1}{2}b + \frac{1}{4}a^2x^4 - \frac{1}{2}c\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2}c+\frac{1}{2}bx-\frac{1}{2}a\,x^2\right) dx} \\
&= \mathrm{e}^{-\frac{\left(a\,x^2-\frac{3}{2}bx+3c\right)x}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{a\,x^2+bx+c}{1} \, dx} \\
&= z_1 e^{-\frac{1}{6}a\,x^3-\frac{1}{4}b\,x^2-\frac{1}{2}cx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x\left(a\,x^2+\frac{3}{2}bx+3c\right)}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{1}{3}a\,x^3-cx}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^2+bx+c}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x\left(a\,x^2+\frac{3}{2}bx+3c\right)}{3}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \mathrm{e}^{\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2+cx} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{1}{3}a\,x^3-cx}\right) + c_2 \left(\mathrm{e}^{-\frac{1}{3}a\,x^3-cx} \left(\int \mathrm{e}^{\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2+cx} dx\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = c_1 e^{-\frac{1}{3} a x^3 - c x} + c_2 e^{-\frac{x(a x^2 + 3c)}{3}} \left(\int e^{\frac{1}{3} a x^3 - \frac{1}{2} b x^2 + c x} dx\right) \tag{1}$$

Verification of solutions

$$y = c_1 e^{-\frac{1}{3} a x^3 - c x} + c_2 e^{-\frac{x(a x^2 + 3c)}{3}} \left(\int e^{\frac{1}{3} a x^3 - \frac{1}{2} b x^2 + c x} dx\right)$$

Verified OK.

27.29.2 Maple step by step solution

Let's solve

$y'' + (a x^2 + b x + c) y' + x((a x^2 + c) b + 2a) y = 0$

- Highest derivative means the order of the ODE is 2

y''

- Isolate 2nd derivative

$y'' = -(a x^2 + b x + c) y' - x(a b x^2 + b c + 2a) y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' + (a x^2 + b x + c) y' + x(a b x^2 + b c + 2a) y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 1..3$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

- Shift index using $k->k+1-m$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k->k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$a_1c + 2a_2 + (6a_3 + 2a_2c + a_1b + a_0(bc+2a))\, x + (12a_4 + 3a_3c + 2a_2b + a_1(bc+3a))\, x^2 + \left(\sum_{k=3}^{\infty} (\right.$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_1c = 0, 6a_3 + 2a_2c + a_1b + a_0(bc+2a) = 0, 12a_4 + 3a_3c + 2a_2b + a_1(bc+3a) = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{a_1c}{2}, a_3 = -\frac{1}{6}a_0bc + \frac{1}{6}a_1c^2 - \frac{1}{3}a_0a - \frac{1}{6}a_1b, a_4 = \frac{1}{24}a_0b\,c^2 - \frac{1}{24}a_1c^3 + \frac{1}{12}a_0ac + \frac{1}{24}a_1bc - \frac{1}{4}a\right.$$

- Each term in the series must be 0, giving the recursion relation

$$k^2a_{k+2} + (aa_{k-1} + ba_k + a_{k+1}c + 3a_{k+2})\, k + (bc+a)\, a_{k-1} + a_{k-3}ab + a_{k+1}c + 2a_{k+2} = 0$$

- Shift index using $k->k+3$

$$(k+3)^2\, a_{k+5} + (aa_{k+2} + ba_{k+3} + a_{k+4}c + 3a_{k+5})\,(k+3) + (bc+a)\, a_{k+2} + a_kab + a_{k+4}c + 2a_{k+5}$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_kx^k, a_{k+5} = -\frac{a_kab + aka_{k+2} + bca_{k+2} + bka_{k+3} + cka_{k+4} + 4aa_{k+2} + 3ba_{k+3} + 4a_{k+4}c}{k^2+9k+20}, a_2 = -\frac{a_1c}{2}, a_3 = -\frac{1}{6}a\right.$$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(a\,x^2 + bx + c\right) y' + \left(ab\,x^3 + ac\,x^2 + b\right) y = 0}$$

27.30.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(a\,x^2 + bx + c\right) y' + \left(x^2(bx + c)\,a + b\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a\,x^2 + bx + c \\ C &= x^2(bx + c)\,a + b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^4 - 2ab\,x^3 - 2ac\,x^2 + b^2x^2 + 2bcx + 4ax + c^2 - 2b}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^4 - 2ab\,x^3 - 2ac\,x^2 + b^2x^2 + 2bcx + 4ax + c^2 - 2b \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(ax - \frac{1}{2}b + \frac{1}{4}a^2x^4 - \frac{1}{2}ab\,x^3 - \frac{1}{2}ac\,x^2 + \frac{1}{4}b^2x^2 + \frac{1}{2}bcx + \frac{1}{4}c^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 66: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^2}{2} - \frac{bx}{2} - \frac{c}{2} + \frac{1}{x} + \frac{b}{2a\,x^2} + \frac{c}{a\,x^3} + \frac{b^2}{2a^2x^3} + \frac{3bc}{2a^2x^4} + \frac{b^3}{2a^3x^4} - \frac{1}{a\,x^4} + \frac{c^2}{a^2x^5} + \frac{2b^2c}{a^3x^5} + \frac{b^4}{2a^4x^5} - \frac{2b}{a^2x^5} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= -\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}c^2 + \frac{1}{2}bcx - \frac{1}{2}ac\,x^2 + \frac{1}{4}b^2x^2 - \frac{1}{2}ab\,x^3 + \frac{1}{4}a^2x^4$$

This shows that the coefficient of x in the above is $\frac{bc}{2}$. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^4 - 2ab\,x^3 - 2ac\,x^2 + b^2x^2 + 2bcx + 4ax + c^2 - 2b}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{a^2x^4}{4} - \frac{ab\,x^3}{2} + \left(-\frac{ac}{2} + \frac{b^2}{4}\right)x^2 + \left(\frac{bc}{2} + a\right)x - \frac{b}{2} + \frac{c^2}{4}\right) + (0) \\
&= \frac{a^2x^4}{4} - \frac{ab\,x^3}{2} + \left(-\frac{ac}{2} + \frac{b^2}{4}\right)x^2 + \left(\frac{bc}{2} + a\right)x - \frac{b}{2} + \frac{c^2}{4}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{bc}{2} + a$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{bc}{2} + a\right) - \left(\frac{bc}{2}\right) \\
&= a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{a}{\frac{a}{2}} - 2\right) &&= 0 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{a}{\frac{a}{2}} - 2\right) &&= -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = ax - \frac{1}{2}b + \frac{1}{4}a^2x^4 - \frac{1}{2}ab\,x^3 - \frac{1}{2}ac\,x^2 + \frac{1}{4}b^2x^2 + \frac{1}{2}bcx + \frac{1}{4}c^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$-\frac{1}{2}c-\frac{1}{2}bx+\frac{1}{2}a\,x^2$	0	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 0$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(-\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2\right) \\ &= -\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2 \\ &= -\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2 \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2\right)(0) + \left(\left(ax - \frac{b}{2}\right) + \left(-\frac{1}{2}c - \frac{1}{2}bx + \frac{1}{2}a\,x^2\right)^2 - \left(ax - \frac{1}{2}b + \frac{1}{4}a^2x^4 - \frac{1}{2}ab\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2}c-\frac{1}{2}bx+\frac{1}{2}a\,x^2\right) dx} \\
&= \mathrm{e}^{-\frac{1}{2}cx-\frac{1}{4}b\,x^2+\frac{1}{6}a\,x^3}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{a\,x^2+bx+c}{1} \, dx} \\
&= z_1 e^{-\frac{1}{6}a\,x^3-\frac{1}{4}b\,x^2-\frac{1}{2}cx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x\left(a\,x^2+\frac{3}{2}bx+3c\right)}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{-\frac{x(bx+2c)}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^2+bx+c}{1} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{x\left(a\,x^2+\frac{3}{2}bx+3c\right)}{3}}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \mathrm{e}^{-\frac{\left(a\,x^2-\frac{3}{2}bx-3c\right)x}{3}} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{x(bx+2c)}{2}}\right) + c_2 \left(\mathrm{e}^{-\frac{x(bx+2c)}{2}} \left(\int \mathrm{e}^{-\frac{\left(a\,x^2-\frac{3}{2}bx-3c\right)x}{3}} dx\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{x(bx+2c)}{2}} + c_2 \mathrm{e}^{-\frac{x(bx+2c)}{2}} \left(\int \mathrm{e}^{-\frac{\left(a\,x^2-\frac{3}{2}bx-3c\right)x}{3}} dx\right) \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{x(bx+2c)}{2}} + c_2 \mathrm{e}^{-\frac{x(bx+2c)}{2}} \left(\int \mathrm{e}^{-\frac{\left(a\,x^2-\frac{3}{2}bx-3c\right)x}{3}} dx\right)$$

Verified OK.

27.30.2 Maple step by step solution

Let's solve

$y'' + (a\,x^2 + bx + c)\,y' + (x^2(bx + c)\,a + b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = (-ab\,x^3 - ac\,x^2 - b)\,y - (a\,x^2 + bx + c)\,y'$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (a\,x^2 + bx + c)\,y' + (ab\,x^3 + ac\,x^2 + b)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..3$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ◦ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

- Shift index using $k->k+1-m$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$
- Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$
- Shift index using $k->k+2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

  Rewrite ODE with series expansions

  $a_0 b + a_1 c + 2a_2 + (2a_1 b + 2a_2 c + 6a_3)\, x + (a_0 ac + a_1 a + 3a_2 b + 3a_3 c + 12a_4)\, x^2 + \left(\sum_{k=3}^{\infty} (a_{k+2}(k\right.$

- The coefficients of each power of x must be 0

  $[2a_2 + a_1 c + a_0 b = 0, 2a_1 b + 2a_2 c + 6a_3 = 0, a_0 ac + a_1 a + 3a_2 b + 3a_3 c + 12a_4 = 0]$
- Solve for the dependent coefficient(s)

  $\left\{a_2 = -\frac{a_0 b}{2} - \frac{a_1 c}{2}, a_3 = \frac{1}{6}a_0 bc + \frac{1}{6}a_1 c^2 - \frac{1}{3}a_1 b, a_4 = -\frac{1}{24}a_0 b\, c^2 - \frac{1}{24}a_1 c^3 - \frac{1}{12}a_0 ac + \frac{1}{8}a_0 b^2 + \frac{5}{24}a_1 b\right.$
- Each term in the series must be 0, giving the recursion relation

  $k^2 a_{k+2} + (a a_{k-1} + a_k b + a_{k+1} c + 3a_{k+2})\, k + (b a_{k-3} + c a_{k-2} - a_{k-1})\, a + a_k b + a_{k+1} c + 2a_{k+2} = 0$
- Shift index using $k->k+3$

  $(k+3)^2\, a_{k+5} + (a a_{k+2} + a_{k+3} b + a_{k+4} c + 3a_{k+5})\,(k+3) + (a_k b + a_{k+1} c - a_{k+2})\, a + a_{k+3} b + a_{k+4}$
- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+5} = -\frac{a_k ab + ac a_{k+1} + ak a_{k+2} + bk a_{k+3} + ck a_{k+4} + 2a a_{k+2} + 4a_{k+3} b + 4a_{k+4} c}{k^2 + 9k + 20}, a_2 = -\frac{a_0 b}{2} - \frac{a_1 c}{2}, a_3 =\right.$

ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(a\,x^3 + 2b\right) y' + \left(ab\,x^3 - a\,x^2 + b^2\right) y = 0}$$

27.31.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(a\,x^3 + 2b\right) y' + \left(ab\,x^3 - a\,x^2 + b^2\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= a\,x^3 + 2b \\ C &= ab\,x^3 - a\,x^2 + b^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a\,x^2(a\,x^4 + 10)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a\,x^2\left(a\,x^4 + 10\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a\,x^2(a\,x^4 + 10)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 68: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 6 \\ &= -6 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -6 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -6$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{6}{2} = 3$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{3} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^3$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^3}{2} + \frac{5}{2x} - \frac{25}{4a\,x^5} + \frac{125}{4a^2x^9} - \frac{3125}{16a^3x^{13}} + \frac{21875}{16a^4x^{17}} - \frac{328125}{32a^5x^{21}} + \frac{2578125}{32a^6x^{25}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 3$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{3} a_i x^i \\ &= \frac{a\,x^3}{2} \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^2 = x^2$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{a^2 x^6}{4}$$

This shows that the coefficient of x^2 in the above is 0. Now we need to find the coefficient of x^2 in r. How this is done depends on if $v = 0$ or not. Since $v = 3$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^2 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a\,x^2(a\,x^4 + 10)}{4} \\ &= Q + \frac{R}{4} \\ &= \left(\frac{5}{2}a\,x^2 + \frac{1}{4}a^2x^6\right) + (0) \\ &= \frac{5}{2}a\,x^2 + \frac{1}{4}a^2x^6 \end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{5a}{2}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{5a}{2}\right) - (0) \\ &= \frac{5a}{2} \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{a\,x^3}{2} \\ \alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{5a}{2}}{\frac{a}{2}} - 3\right) &= 1 \\ \alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{\frac{5a}{2}}{\frac{a}{2}} - 3\right) &= -4 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a\,x^2(a\,x^4 + 10)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-6	$\frac{a\,x^3}{2}$	1	-4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{a\,x^3}{2}\right) \\ &= \frac{a\,x^3}{2} \\ &= \frac{a\,x^3}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{a\,x^3}{2}\right)(1) + \left(\left(\frac{3a\,x^2}{2}\right) + \left(\frac{a\,x^3}{2}\right)^2 - \left(\frac{a\,x^2(a\,x^4+10)}{4}\right)\right) = 0$$

$$-a\,x^2 a_0 = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= pe^{\int \omega \, dx} \\
&= (x) \, \mathrm{e}^{\int \frac{a\,x^3}{2} dx} \\
&= (x) \, \mathrm{e}^{\frac{a\,x^4}{8}} \\
&= x \, \mathrm{e}^{\frac{a\,x^4}{8}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{a\,x^3+2b}{1}\, dx} \\
&= z_1 e^{-\frac{1}{8}a\,x^4 - bx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x\left(a\,x^3+8b\right)}{8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = x \, \mathrm{e}^{-bx}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^3+2b}{1}\, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{1}{4}a\,x^4 - 2bx}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{a\,x^4}{4}}}{x^2} dx\right)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x \,\mathrm{e}^{-bx}\right) + c_2 \left(x \,\mathrm{e}^{-bx} \left(\int \frac{\mathrm{e}^{-\frac{a\,x^4}{4}}}{x^2} dx\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 x \,\mathrm{e}^{-bx} + c_2 x \,\mathrm{e}^{-bx} \left(\int \frac{\mathrm{e}^{-\frac{a\,x^4}{4}}}{x^2} dx\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x \,\mathrm{e}^{-bx} + c_2 x \,\mathrm{e}^{-bx} \left(\int \frac{\mathrm{e}^{-\frac{a\,x^4}{4}}}{x^2} dx\right)
$$

Verified OK.

27.31.2 Maple step by step solution

Let's solve

$y'' + (a\,x^3 + 2b)\,y' + (ab\,x^3 - a\,x^2 + b^2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

  ∘ Convert $x^m \cdot y$ to series expansion for $m = 0..3$

    $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  ∘ Shift index using $k- > k - m$

    $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

  ∘ Convert $x^m \cdot y'$ to series expansion for $m = 0..3$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$$

- Shift index using $k- >k+1-m$

$$x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$$

- Convert y'' to series expansion

$$y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$$

- Shift index using $k- >k+2$

$$y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$$

Rewrite ODE with series expansions

$$a_0 b^2 + 2a_1 b + 2a_2 + (a_1 b^2 + 4a_2 b + 6a_3)\, x + (a_2 b^2 - a_0 a + 6a_3 b + 12a_4)\, x^2 + \left(\sum_{k=3}^{\infty} (a_{k+2}(k+2)\,(\right.$$

- The coefficients of each power of x must be 0

$$[2a_2 + a_0 b^2 + 2a_1 b = 0, a_1 b^2 + 4a_2 b + 6a_3 = 0, a_2 b^2 - a_0 a + 6a_3 b + 12a_4 = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2 = -\frac{1}{2} a_0 b^2 - a_1 b, a_3 = \frac{1}{3} a_0 b^3 + \frac{1}{2} a_1 b^2, a_4 = -\frac{1}{8} a_0 b^4 - \frac{1}{6} a_1 b^3 + \frac{1}{12} a_0 a\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k b^2 + (a a_{k-3} + 2k a_{k+1} + 2a_{k+1})\, b + k^2 a_{k+2} + (a_{k-2} a + 3a_{k+2})\, k - 3a_{k-2} a + 2a_{k+2} = 0$$

- Shift index using $k- >k+3$

$$a_{k+3} b^2 + (a_k a + 2(k+3)\, a_{k+4} + 2a_{k+4})\, b + (k+3)^2\, a_{k+5} + (a_{k+1} a + 3a_{k+5})\,(k+3) - 3a_{k+1} a + 2$$

- Recursion relation that defines the series solution to the ODE

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+5} = -\frac{a_k ab + ak a_{k+1} + a_{k+3} b^2 + 2bk a_{k+4} + 8b a_{k+4}}{k^2 + 9k + 20}, a_2 = -\frac{1}{2} a_0 b^2 - a_1 b, a_3 = \frac{1}{3} a_0 b^3 + \frac{1}{2} a_1 b^2,\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y''+f(x)y'+g(x)y=0$
Problem number: 42.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y''+\left(a\,x^{3}+bx\right)y'+2\left(2a\,x^{2}+b\right)y=0}$$

27.32.1 Solving using Kovacic algorithm

Writing the ode as

$$y''+x\left(a\,x^{2}+b\right)y'+\left(4a\,x^{2}+2b\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=1\\ B&=x\left(a\,x^{2}+b\right)\\ C&=4a\,x^{2}+2b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^6 + 2ab\,x^4 + b^2x^2 - 10a\,x^2 - 6b}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^6 + 2ab\,x^4 + b^2x^2 - 10a\,x^2 - 6b \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{5}{2}a\,x^2 - \frac{3}{2}b + \frac{1}{4}a^2x^6 + \frac{1}{2}ab\,x^4 + \frac{1}{4}b^2x^2\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 70: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 6 \\ &= -6 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -6 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -6$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{6}{2} = 3$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{3} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^3$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^3}{2} + \frac{bx}{2} - \frac{5}{2x} + \frac{b}{a\,x^3} - \frac{b^2}{a^2x^5} - \frac{25}{4a\,x^5} + \frac{b^3}{a^3x^7} + \frac{45b}{4a^2x^7} - \frac{b^4}{a^4x^9} - \frac{69b^2}{4a^3x^9} - \frac{125}{4a^2x^9} + \frac{b^5}{a^5x^{11}} + \frac{97b^3}{4a^4x^{11}} + \frac{100b}{a^3x^{11}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 3$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{3} a_i x^i \\ &= \frac{1}{2}bx + \frac{1}{2}a\,x^3 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^2 = x^2$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2x^2 + \frac{1}{2}ab\,x^4 + \frac{1}{4}a^2x^6$$

This shows that the coefficient of x^2 in the above is $\frac{b^2}{4}$. Now we need to find the coefficient of x^2 in r. How this is done depends on if $v = 0$ or not. Since $v = 3$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^2 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^6 + 2ab\,x^4 + b^2x^2 - 10a\,x^2 - 6b}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{a^2x^6}{4} + \frac{ab\,x^4}{2} + \left(-\frac{5a}{2} + \frac{b^2}{4}\right)x^2 - \frac{3b}{2}\right) + (0) \\
&= \frac{a^2x^6}{4} + \frac{ab\,x^4}{2} + \left(-\frac{5a}{2} + \frac{b^2}{4}\right)x^2 - \frac{3b}{2}
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $-\frac{5a}{2} + \frac{b^2}{4}$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{5a}{2} + \frac{b^2}{4}\right) - \left(\frac{b^2}{4}\right) \\
&= -\frac{5a}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2}bx + \frac{1}{2}a\,x^3 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{5a}{2}}{\frac{a}{2}} - 3\right) &&= -4 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{5a}{2}}{\frac{a}{2}} - 3\right) &&= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{5}{2}a\,x^2 - \frac{3}{2}b + \frac{1}{4}a^2x^6 + \frac{1}{2}ab\,x^4 + \frac{1}{4}b^2x^2$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-6	$\frac{1}{2}bx+\frac{1}{2}a\,x^3$	-4	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^-=1$, and since there are no poles then

$$\begin{aligned}d&=\alpha_\infty^-\\&=1\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}\omega&=(-)[\sqrt{r}]_\infty\\&=0+(-)\left(\frac{1}{2}bx+\frac{1}{2}a\,x^3\right)\\&=-\frac{1}{2}bx-\frac{1}{2}a\,x^3\\&=-\frac{x(a\,x^2+b)}{2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(-\frac{1}{2}bx-\frac{1}{2}a\,x^3\right)(1)+\left(\left(-\frac{b}{2}-\frac{3a\,x^2}{2}\right)+\left(-\frac{1}{2}bx-\frac{1}{2}a\,x^3\right)^2-\left(-\frac{5}{2}a\,x^2-\frac{3}{2}b+\frac{1}{4}a^2x^6+\frac{1}{2}ab\,x\right.\right.$$

$a_0($

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\{a_0 = 0\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= pe^{\int \omega \, dx} \\ &= (x)\,\mathrm{e}^{\int \left(-\frac{1}{2}bx - \frac{1}{2}a\,x^3\right)dx} \\ &= (x)\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{8a}} \\ &= x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{8a}} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{x\left(a\,x^2+b\right)}{1}\,dx} \\ &= z_1 e^{-\frac{\left(a\,x^2+b\right)^2}{8a}} \\ &= z_1\left(\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{8a}}\right) \end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{x\left(a\,x^2+b\right)}{1}dx}}{\left(y_1\right)^2}\, dx$$
$$= y_1 \int \frac{e^{-\frac{\left(a\,x^2+b\right)^2}{4a}}}{\left(y_1\right)^2}\, dx$$
$$= y_1 \left(\int \frac{\mathrm{e}^{\frac{\left(a\,x^2+b\right)^2}{4a}}}{x^2} dx\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}}\right) + c_2 \left(x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}} \left(\int \frac{\mathrm{e}^{\frac{\left(a\,x^2+b\right)^2}{4a}}}{x^2} dx\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}} + c_2 x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}} \left(\int \frac{\mathrm{e}^{\frac{\left(a\,x^2+b\right)^2}{4a}}}{x^2} dx\right) \tag{1}$$

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}} + c_2 x\,\mathrm{e}^{-\frac{\left(a\,x^2+b\right)^2}{4a}} \left(\int \frac{\mathrm{e}^{\frac{\left(a\,x^2+b\right)^2}{4a}}}{x^2} dx\right)$$

Verified OK.

27.32.2 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$y'' + x\left(a\,x^2 + b\right) y' + \left(4a\,x^2 + 2b\right) y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = r(x) \tag{2}$$

Where

$$\begin{aligned} p(x) &= x\left(a\,x^2 + b\right) \\ q(x) &= 4a\,x^2 + 2b \\ r(x) &= 0 \end{aligned}$$

The Lagrange adjoint ode is given by

$$\begin{aligned} \xi'' - (\xi\,p)' + \xi q = 0 \\ \xi'' - \left(x\left(a\,x^2 + b\right)\xi(x)\right)' + \left(\left(4a\,x^2 + 2b\right)\xi(x)\right) = 0 \\ \xi''(x) - x\left(a\,x^2 + b\right)\xi'(x) + \left(a\,x^2 + b\right)\xi(x) = 0 \end{aligned}$$

Which is solved for $\xi(x)$. In normal form the ode

$$\xi''(x) + \left(-a\,x^3 - bx\right)\xi'(x) + \left(a\,x^2 + b\right)\xi(x) = 0 \tag{1}$$

Becomes

$$\xi''(x) + p(x)\,\xi'(x) + q(x)\,\xi(x) = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -a\,x^3 - bx \\ q(x) &= a\,x^2 + b \end{aligned}$$

Applying change of variables on the depndent variable $\xi(x) = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not $\xi(x)$.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(-a\,x^3-bx)}{x}+a\,x^2+b=0 \tag{5}$$

Solving (5) for n gives

$$n=1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned}v''(x)+\left(\frac{2}{x}-a\,x^3-bx\right)v'(x)&=0\\ v''(x)+\left(\frac{2}{x}-a\,x^3-bx\right)v'(x)&=0\end{aligned} \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\left(\frac{2}{x}-a\,x^3-bx\right)u(x)=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\ &=f(x)g(u)\\ &=\frac{u(a\,x^4+b\,x^2-2)}{x}\end{aligned}$$

Where $f(x)=\frac{a\,x^4+b\,x^2-2}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du&=\frac{a\,x^4+b\,x^2-2}{x}\,dx\\ \int\frac{1}{u}\,du&=\int\frac{a\,x^4+b\,x^2-2}{x}\,dx\\ \ln(u)&=\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)+c_1\\ u&=\mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)+c_1}\\ &=c_1\mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)}\end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\, dx + c_2 \\
&= \int c_1 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
\xi(x) &= v(x)\, x^n \\
&= \left(\int c_1 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx + c_2\right) x \\
&= \left(c_1 \left(\int \frac{\mathrm{e}^{\frac{x^2\left(a\,x^2+2b\right)}{4}}}{x^2} dx\right) + c_2\right) x
\end{aligned}
$$

The original ode (2) now reduces to first order ode

$$
\begin{aligned}
\xi(x)\, y' - y\xi'(x) + \xi(x)\, p(x)\, y &= \int \xi(x)\, r(x)\, dx \\
y' + y\left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)\, r(x)\, dx}{\xi\,(x)} \\
y' + y\left(x\left(a\,x^2+b\right) - \frac{c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} x + \int c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx + c_2}{\left(\int c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx + c_2\right) x}\right) &= 0
\end{aligned}
$$

Which is now a first order ode. This is now solved for y. In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= -\frac{y\left(\left(\int c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx\right) a\,x^4 + c_2 a\,x^4 + \left(\int c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx\right) b\,x^2 + c_2 b\,x^2 - c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x}}{\left(\int c_3 \mathrm{e}^{\frac{a\,x^4}{4}+\frac{b\,x^2}{2}-2\ln(x)} dx + c_2\right) x}
\end{aligned}
$$

Where $f(x) = -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} x - \left(\int c_3 e^{\frac{a x^4}{4}+\cdots}\right.}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}$

and $g(y) = y$. Integrating both sides gives

$$\frac{1}{y}\, dy = -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\cdots}}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}$$

$$\int \frac{1}{y}\, dy = \int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}\cdots}}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}$$

$$\ln(y) = \int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}\cdots}}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}$$

$$y = e^{\int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} x - \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln\cdots}\right.}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}}$$

$$= c_3 e^{\int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} x - \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-\cdots}\right.}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}}$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = c_3 e^{\int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} x - \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) - \cdots}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}}$$

Summary

The solution(s) found are the following

$$y = c_3 e^{\int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} x - \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) - \cdots}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}} \tag{1}$$

Verification of solutions

$$y = c_3 e^{\int -\frac{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) a x^4 + c_2 a x^4 + \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) b x^2 + c_2 b x^2 - c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} x - \left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx\right) - \cdots}{\left(\int c_3 e^{\frac{a x^4}{4}+\frac{b x^2}{2}-2\ln(x)} dx + c_2\right) x}}$$

Verified OK.

27.32.3 Maple step by step solution

Let's solve

$y'' + x(a\,x^2 + b)\,y' + (4a\,x^2 + 2b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

- ◦ Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ◦ Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

- ◦ Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k+1-m)\, x^k$

- ◦ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k-1)\, x^{k-2}$

- ◦ Shift index using $k- >k + 2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k+2)\,(k+1)\, x^k$

Rewrite ODE with series expansions

$2a_0 b + 2a_2 + (3a_1 b + 6a_3)\, x + \left(\sum_{k=2}^{\infty} \left(a_{k+2}(k+2)\,(k+1) + a_k b(k+2) + a_{k-2} a(k+2)\right) x^k\right) = 0$

- The coefficients of each power of x must be 0

  $[2a_0 b + 2a_2 = 0, 3a_1 b + 6a_3 = 0]$

- Solve for the dependent coefficient(s)

  $\left\{a_2 = -a_0 b, a_3 = -\frac{a_1 b}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+2)\left(a_{k-2}a + a_k b + k a_{k+2} + a_{k+2}\right) = 0$

- Shift index using $k- >k+2$

  $(k+4)\left(a_k a + a_{k+2} b + (k+2) a_{k+4} + a_{k+4}\right) = 0$

- Recursion relation that defines the series solution to the ODE

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{a_k a + a_{k+2} b}{k+3}, a_2 = -a_0 b, a_3 = -\frac{a_1 b}{2}\right]$

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(ab\,x^3 + b\,x^2 + 2a\right) y' + a^2\left(x^3 b + 1\right) y = 0}$$

27.33.1 Solving using Kovacic algorithm

Writing the ode as

$$y'' + \left(\left(a\,x^3 + x^2\right) b + 2a\right) y' + a^2\left(x^3 b + 1\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= \left(a\,x^3 + x^2\right) b + 2a \\ C &= a^2\left(x^3 b + 1\right) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{bx(a^2b\,x^5 + 2ab\,x^4 + x^3b + 10ax + 4)}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= bx\left(a^2b\,x^5 + 2ab\,x^4 + x^3b + 10ax + 4\right) \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{bx(a^2b\,x^5 + 2ab\,x^4 + x^3b + 10ax + 4)}{4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 72: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 6 \\ &= -6 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -6 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -6$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{6}{2} = 3$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{3} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^3$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ab\,x^3}{2} + \frac{b\,x^2}{2} + \frac{5}{2x} - \frac{3}{2a\,x^2} + \frac{3}{2a^2x^3} - \frac{25}{4ab\,x^5} - \frac{3}{2a^3x^4} + \frac{55}{4a^2b\,x^6} + \frac{3}{2a^4x^5} - \frac{3}{2a^5x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{ab}{2}$$

From Eq. (9) the sum up to $v = 3$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{3} a_i x^i \\ &= \frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^2 = x^2$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2x^4 + \frac{1}{2}a\,b^2x^5 + \frac{1}{4}a^2b^2x^6$$

This shows that the coefficient of x^2 in the above is 0. Now we need to find the coefficient of x^2 in r. How this is done depends on if $v = 0$ or not. Since $v = 3$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x^2 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{bx(a^2b\,x^5 + 2ab\,x^4 + x^3b + 10ax + 4)}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{5}{2}ab\,x^2 + bx + \frac{1}{4}a^2b^2x^6 + \frac{1}{2}a\,b^2x^5 + \frac{1}{4}b^2x^4\right) + (0) \\
&= \frac{5}{2}ab\,x^2 + bx + \frac{1}{4}a^2b^2x^6 + \frac{1}{2}a\,b^2x^5 + \frac{1}{4}b^2x^4
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{5ab}{2}$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{5ab}{2}\right) - (0) \\
&= \frac{5ab}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{5ab}{2}}{\frac{ab}{2}} - 3\right) &&= 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{5ab}{2}}{\frac{ab}{2}} - 3\right) &&= -4
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{bx(a^2b\,x^5 + 2ab\,x^4 + x^3b + 10ax + 4)}{4}$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-6	$\frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3$	1	-4

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3\right) \\ &= \frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3 \\ &= \frac{b\,x^2(ax+1)}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3\right)(1) + \left(\left(\frac{3}{2}ab\,x^2 + bx\right) + \left(\frac{1}{2}b\,x^2 + \frac{1}{2}ab\,x^3\right)^2 - \left(\frac{bx(a^2b\,x^5 + 2ab\,x^4 + x^3b + 10}{4}\right.\right.$$

$$-b\,x^2(a$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{1}{a}\right) e^{\int \left(\frac{1}{2} b x^2 + \frac{1}{2} ab x^3\right) dx} \\
&= \left(x + \frac{1}{a}\right) e^{\frac{b\left(\frac{1}{4} a x^4 + \frac{1}{3} x^3\right)}{2}} \\
&= \frac{(ax+1) e^{\frac{1}{8} ab x^4 + \frac{1}{6} x^3 b}}{a}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{\left(a x^3 + x^2\right) b + 2a}{1} \, dx} \\
&= z_1 e^{-\frac{1}{8} ab x^4 - \frac{1}{6} x^3 b - ax} \\
&= z_1 \left(e^{-\frac{x\left(ab x^3 + \frac{4}{3} b x^2 + 8a\right)}{8}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(ax+1) e^{-ax}}{a}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{(a\,x^3+x^2)b+2a}{1}\,dx}}{(y_1)^2}\,dx$$

$$= y_1 \int \frac{e^{-\frac{x\left(ab\,x^3+\frac{4}{3}b\,x^2+8a\right)}{4}}}{(y_1)^2}\,dx$$

$$= y_1 \left(\int \frac{a^2 \mathrm{e}^{-\frac{x^3\left(ax+\frac{4}{3}\right)b}{4}}}{(ax+1)^2}dx\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a}\right) + c_2 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a}\left(\int \frac{a^2 \mathrm{e}^{-\frac{x^3\left(ax+\frac{4}{3}\right)b}{4}}}{(ax+1)^2}dx\right)\right)$$

Summary

The solution(s) found are the following

$$y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a} + c_2(ax+1)\,\mathrm{e}^{-ax} a \left(\int \frac{\mathrm{e}^{-\frac{x^3\left(ax+\frac{4}{3}\right)b}{4}}}{(ax+1)^2}dx\right) \tag{1}$$

Verification of solutions

$$y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a} + c_2(ax+1)\,\mathrm{e}^{-ax} a \left(\int \frac{\mathrm{e}^{-\frac{x^3\left(ax+\frac{4}{3}\right)b}{4}}}{(ax+1)^2}dx\right)$$

Verified OK.

27.33.2 Maple step by step solution

Let's solve

$y'' + ((a\,x^3 + x^2)\,b + 2a)\,y' + a^2(x^3b + 1)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -(ab\,x^3 + b\,x^2 + 2a)\,y' - a^2(x^3b + 1)\,y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + (ab\,x^3 + b\,x^2 + 2a)\,y' + a^2(x^3b + 1)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^k$

□ Rewrite ODE with series expansions

- ∘ Convert $x^m \cdot y$ to series expansion for $m = 0..3$

  $x^m \cdot y = \sum_{k=\max(0,-m)}^{\infty} a_k x^{k+m}$

  $x^m \cdot y = \sum_{k=\max(0,-m)+m}^{\infty} a_{k-m} x^k$

- ∘ Convert $x^m \cdot y'$ to series expansion for $m = 0..3$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)}^{\infty} a_k k\, x^{k-1+m}$

- ∘ Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=\max(0,1-m)+m-1}^{\infty} a_{k+1-m}(k + 1 - m)\, x^k$

- ∘ Convert y'' to series expansion

  $y'' = \sum_{k=2}^{\infty} a_k k(k - 1)\, x^{k-2}$

- ∘ Shift index using $k- >k + 2$

  $y'' = \sum_{k=0}^{\infty} a_{k+2}(k + 2)\,(k + 1)\, x^k$

Rewrite ODE with series expansions

$$a_0a^2+2a_1a+2a_2+\left(a_1a^2+4aa_2+6a_3\right)x+\left(a_2a^2+6aa_3+a_1b+12a_4\right)x^2+\left(\sum_{k=3}^{\infty}\left(a_{k+2}(k+2)\right.\right.$$

- The coefficients of each power of x must be 0

$$[2a_2+a_0a^2+2a_1a=0, a_1a^2+4aa_2+6a_3=0, a_2a^2+6aa_3+a_1b+12a_4=0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_2=-\frac{1}{2}a_0a^2-a_1a, a_3=\frac{1}{3}a_0a^3+\frac{1}{2}a_1a^2, a_4=-\frac{1}{8}a_0a^4-\frac{1}{6}a_1a^3-\frac{1}{12}a_1b\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$(ba_{k-3}+a_k)a^2+(a_{k-2}(k-2)b+2a_{k+1}(k+1))a+a_{k-1}(k-1)b+a_{k+2}(k+2)(k+1)=0$$

- Shift index using $k->k+3$

$$(ba_k+a_{k+3})a^2+(a_{k+1}(k+1)b+2a_{k+4}(k+4))a+a_{k+2}(k+2)b+a_{k+5}(k+5)(k+4)=0$$

- Recursion relation that defines the series solution to the ODE

$$\left[y=\sum_{k=0}^{\infty}a_kx^k, a_{k+5}=-\frac{a_ka^2b+abka_{k+1}+a^2a_{k+3}+aba_{k+1}+2aka_{k+4}+bka_{k+2}+8aa_{k+4}+2ba_{k+2}}{(k+5)(k+4)}, a_2=-\frac{1}{2}a_0a^2-a_1\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 44.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

```
[[_2nd_order, _missing_y]]
```

$$\boxed{y'' + a\,x^n y' = 0}$$

27.34.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x) = y'$$

Then

$$p'(x) = y''$$

Hence the ode becomes

$$p'(x) + a\,x^n p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= -a\,x^n p \end{aligned}$$

Where $f(x) = -a\,x^n$ and $g(p) = p$. Integrating both sides gives

$$\frac{1}{p}\,dp = -a\,x^n\,dx$$
$$\int \frac{1}{p}\,dp = \int -a\,x^n\,dx$$
$$\ln(p) = -\frac{a\,x^{1+n}}{1+n} + c_1$$
$$p = e^{-\frac{a\,x^{1+n}}{1+n}+c_1}$$
$$= c_1 e^{-\frac{a\,x^{1+n}}{1+n}}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = c_1 e^{-\frac{a\,x^{1+n}}{1+n}}$$

Integrating both sides gives

$$y = \int c_1 e^{-\frac{a\,x^{1+n}}{1+n}}\,dx$$
$$= \frac{c_1\left(\frac{a}{1+n}\right)^{-\frac{1}{1+n}}\left(\frac{(1+n)^2 x^{\frac{1}{1+n}+\frac{n}{1+n}-1-n}\left(\frac{a}{1+n}\right)^{\frac{1}{1+n}}\left(\frac{x^{1+n}a\,n^2}{1+n}+\frac{2x^{1+n}an}{1+n}+n^2+\frac{a\,x^{1+n}}{1+n}+3n+2\right)\left(\frac{a\,x^{1+n}}{1+n}\right)^{-\frac{2+n}{2(1+n)}}e^{-\frac{a\,x^{1+n}}{2(1+n)}}\,\text{Whitta}}{(2+n)(3+2n)a}\right.}{}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\left(\frac{a}{1+n}\right)^{-\frac{1}{1+n}}\left(\frac{(1+n)^2 x^{\frac{1}{1+n}+\frac{n}{1+n}-1-n}\left(\frac{a}{1+n}\right)^{\frac{1}{1+n}}\left(\frac{x^{1+n}a\,n^2}{1+n}+\frac{2x^{1+n}an}{1+n}+n^2+\frac{a\,x^{1+n}}{1+n}+3n+2\right)\left(\frac{a\,x^{1+n}}{1+n}\right)^{-\frac{2+n}{2(1+n)}}e^{-\frac{a\,x^{1+n}}{2(1+n)}}\,\text{Whittaker}}{(2+n)(3+2n)a}\right.}{} + c_2 \tag{1}$$

Verification of solutions

$$y = \frac{c_1\left(\frac{a}{1+n}\right)^{-\frac{1}{1+n}}\left(\frac{(1+n)^2 x^{\frac{1}{1+n}+\frac{n}{1+n}-1-n}\left(\frac{a}{1+n}\right)^{\frac{1}{1+n}}\left(\frac{x^{1+n}a\,n^2}{1+n}+\frac{2x^{1+n}an}{1+n}+n^2+\frac{a\,x^{1+n}}{1+n}+3n+2\right)\left(\frac{a\,x^{1+n}}{1+n}\right)^{-\frac{2+n}{2(1+n)}}e^{-\frac{a\,x^{1+n}}{2(1+n)}}\,\text{Whittaker}}{(2+n)(3+2n)a}\right.}{} + c_2$$

Verified OK.

27.34.2 Maple step by step solution

Let's solve

$y'' + a\,x^n y' = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x) + a\,x^n u(x) = 0$

- Separate variables

  $\frac{u'(x)}{u(x)} = -a\,x^n$

- Integrate both sides with respect to x

  $\int \frac{u'(x)}{u(x)}dx = \int -a\,x^n dx + c_1$

- Evaluate integral

  $\ln\left(u(x)\right) = -\frac{a\,x^{1+n}}{1+n} + c_1$

- Solve for $u(x)$

  $u(x) = \mathrm{e}^{-\frac{-c_1 n + a\,x^{1+n} - c_1}{1+n}}$

- Solve 1st ODE for $u(x)$

  $u(x) = \mathrm{e}^{-\frac{-c_1 n + a\,x^{1+n} - c_1}{1+n}}$

- Make substitution $u = y'$

  $y' = \mathrm{e}^{-\frac{-c_1 n + a\,x^{1+n} - c_1}{1+n}}$

- Integrate both sides to solve for y

  $\int y' dx = \int \mathrm{e}^{-\frac{-c_1 n + a\,x^{1+n} - c_1}{1+n}} dx + c_2$

- Compute integrals

  $$y = \frac{\mathrm{e}^{-\frac{-c_1 n - c_1}{1+n}} \left(\frac{a}{1+n}\right)^{-\frac{1}{1+n}} \left(\frac{(1+n)^2 x^{\frac{1}{1+n}+\frac{n}{1+n}-1-n} \left(\frac{a}{1+n}\right)^{\frac{1}{1+n}} \left(\frac{x^{1+n} a\,n^2}{1+n} + \frac{2x^{1+n} a n}{1+n} + n^2 + \frac{a\,x^{1+n}}{1+n} + 3n + 2\right) \left(\frac{a\,x^{1+n}}{1+n}\right)^{-\frac{2+n}{2(1+n)}} \mathrm{e}^{-\frac{a\,x^{1+n}}{2(1+n)}} \cdots}{(2+n)(3+2n)a} \right.}{\cdots}$$

Internal problem ID [10870]
Internal file name [`OUTPUT/10126_Sunday_December_24_2023_05_13_38_PM_911658/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 46.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_1", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 2a\,x^n y' + a\left(a\,x^{2n} + n\,x^{n-1}\right)y = 0}$$

27.36.1 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right)y}{2} = f(x)$$

Where $p(x) = 2a\,x^n$. Therefore, there is an integrating factor given by

$$\begin{aligned} M(x) &= e^{\frac{1}{2}\int p\,dx} \\ &= e^{\int 2a\,x^n\,dx} \\ &= \mathrm{e}^{\frac{a\,x^{1+n}}{1+n}} \end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$
\begin{aligned}
(M(x)y)'' &= 0 \\
\left(\mathrm{e}^{\frac{a\,x^{1+n}}{1+n}} y\right)'' &= 0
\end{aligned}
$$

Integrating once gives

$$
\left(\mathrm{e}^{\frac{a\,x^{1+n}}{1+n}} y\right)' = c_1
$$

Integrating again gives

$$
\left(\mathrm{e}^{\frac{a\,x^{1+n}}{1+n}} y\right) = c_1 x + c_2
$$

Hence the solution is

$$
y = \frac{c_1 x + c_2}{\mathrm{e}^{\frac{a\,x^{1+n}}{1+n}}}
$$

Or

$$
y = c_1 x\,\mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} + c_2 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\,\mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} + c_2 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \tag{1}
$$

Verification of solutions

$$
y = c_1 x\,\mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} + c_2 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}}
$$

Verified OK.

27.36.2 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$
y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= 2a\,x^n \\
q(x) &= x^{2n}a^2 + \frac{an\,x^n}{x}
\end{aligned}
$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= x^{2n}a^2 + \frac{an\,x^n}{x} - \frac{(2a\,x^n)'}{2} - \frac{(2a\,x^n)^2}{4} \\
&= x^{2n}a^2 + \frac{an\,x^n}{x} - \frac{\left(\frac{2an\,x^n}{x}\right)}{2} - \frac{(4x^{2n}a^2)}{4} \\
&= x^{2n}a^2 + \frac{an\,x^n}{x} - \left(\frac{an\,x^n}{x}\right) - x^{2n}a^2 \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\,z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{2a\,x^n}{2}} \\
&= \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\,\mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v''(x)\,\mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} = 0
$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$
v(x) = c_1 x + c_2
$$

Now that $v(x)$ is known, then

$$
\begin{aligned}
y &= v(x)\,z(x) \\
&= (c_1 x + c_2)\,(z(x))
\end{aligned} \tag{7}
$$

But from (5)

$$z(x) = e^{-\frac{a\,x^{n+1}}{n+1}}$$

Hence (7) becomes

$$y = e^{-\frac{a\,x^{n+1}}{n+1}}(c_1x + c_2)$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{a\,x^{n+1}}{n+1}}(c_1x + c_2) \tag{1}$$

Verification of solutions

$$y = e^{-\frac{a\,x^{n+1}}{n+1}}(c_1x + c_2)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-2 Equation of form $y'' + f(x)y' + g(x)y = 0$
Problem number: 48.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{y'' + a\,x^{n}y' - b\left(a\,x^{m+n} + b\,x^{2m} + m\,x^{m-1}\right)y = 0}$$

Maple trace

```

$$y''+(a\,x^n+b\,x^m)\,y'+\frac{(-a\,x^n-b\,x^m)\,y}{x}=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=a\,x^n+b\,x^m$$
$$q(x)=\frac{-a\,x^n-b\,x^m}{x}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(a\,x^n+b\,x^m)}{x}+\frac{-a\,x^n-b\,x^m}{x}=0 \tag{5}$$

Solving (5) for n gives

$$n=1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x)+\left(\frac{2}{x}+a\,x^n+b\,x^m\right)v'(x)=0$$

$$v''(x)+\left(\frac{2}{x}+a\,x^n+b\,x^m\right)v'(x)=0 \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\left(\frac{2}{x}+a\,x^n+b\,x^m\right)u(x)=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\&=f(x)g(u)\\&=-\frac{u(ax\,x^n+x^m bx+2)}{x}\end{aligned}$$

Where $f(x)=-\frac{ax\,x^n+x^m bx+2}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du&=-\frac{ax\,x^n+x^m bx+2}{x}\,dx\\ \int\frac{1}{u}\,du&=\int-\frac{ax\,x^n+x^m bx+2}{x}\,dx\\ \ln(u)&=-2\ln(x)-\frac{ax\,\mathrm{e}^{n\ln(x)}}{n+1}-\frac{bx\,\mathrm{e}^{m\ln(x)}}{m+1}+c_1\\ u&=\mathrm{e}^{-2\ln(x)-\frac{ax\,\mathrm{e}^{n\ln(x)}}{n+1}-\frac{bx\,\mathrm{e}^{m\ln(x)}}{m+1}+c_1}\\ &=c_1\mathrm{e}^{-2\ln(x)-\frac{ax\,\mathrm{e}^{n\ln(x)}}{n+1}-\frac{bx\,\mathrm{e}^{m\ln(x)}}{m+1}}\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \mathrm{e}^{-\frac{b\,x^{m+1}}{m+1}}}{x^2}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= \int \frac{c_1 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \mathrm{e}^{-\frac{b\,x^{m+1}}{m+1}}}{x^2} dx + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= \left(\int \frac{c_1 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \mathrm{e}^{-\frac{b\,x^{m+1}}{m+1}}}{x^2} dx + c_2\right) x \\ &= \left(c_1 \left(\int \frac{\mathrm{e}^{-\frac{(a\,x^n (m+1)+b\,x^m (n+1))x}{(n+1)(m+1)}}}{x^2} dx\right) + c_2\right) x \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(\int \frac{c_1 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \mathrm{e}^{-\frac{b\,x^{m+1}}{m+1}}}{x^2} dx + c_2\right) x \tag{1}$$

Verification of solutions

$$y = \left(\int \frac{c_1 \mathrm{e}^{-\frac{a\,x^{n+1}}{n+1}} \mathrm{e}^{-\frac{b\,x^{m+1}}{m+1}}}{x^2} dx + c_2\right) x$$

Verified OK.

Problem number: 56.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{y''+(a\,x^n+b\,x^m)\,y'+\left(an\,x^{n-1}+x^{m-1}bm\right)y=0}$$

27.46.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int\left(y''+(a\,x^n+b\,x^m)\,y'+\frac{(x^n na+b\,x^m m)\,y}{x}\right)dx=0$$
$$\frac{(ax\,x^n+x^m bx)\,y}{x}+y'=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$p(x) = a\,x^n + b\,x^m$$
$$q(x) = c_1$$

Hence the ode is

$$y' + (a\,x^n + b\,x^m)\,y = c_1$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int (a\,x^n + b\,x^m)dx}$$
$$= \mathrm{e}^{\frac{a\,x^{n+1}}{n+1} + \frac{b\,x^{m+1}}{m+1}}$$

Which simplifies to

$$\mu = \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\,(c_1)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}} y\right) = \left(\mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}\right)(c_1)$$
$$\mathrm{d}\left(\mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}} y\right) = \left(c_1 \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}\right)\,\mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}} y = \int c_1 \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}\,\mathrm{d}x$$
$$\mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}} y = \int c_1 \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}\,dx + c_2$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}$ results in

$$y = \mathrm{e}^{-\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}} \left(\int c_1 \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}\,dx\right) + c_2 \mathrm{e}^{-\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}$$

which simplifies to

$$y = \mathrm{e}^{-\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}} \left(c_1 \left(\int \mathrm{e}^{\frac{(a\,x^n (m+1) + b\,x^m (n+1))x}{(n+1)(m+1)}}\,dx\right) + c_2\right)$$

Summary
The solution(s) found are the following

$$y = e^{-\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}\left(c_1\left(\int e^{\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}dx\right)+c_2\right) \tag{1}$$

Verification of solutions

$$y = e^{-\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}\left(c_1\left(\int e^{\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}dx\right)+c_2\right)$$

Verified OK.

27.46.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + (a\,x^n + b\,x^m)\,y' + \frac{(x^n na + b\,x^m m)\,y}{x} = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y'' + (a\,x^n + b\,x^m)\,y' + \frac{(x^n na + b\,x^m m)\,y}{x}\right)dx = 0$$
$$\frac{(ax\,x^n + x^m bx)\,y}{x} + y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = a\,x^n + b\,x^m$$
$$q(x) = c_1$$

Hence the ode is

$$y' + (a\,x^n + b\,x^m)\,y = c_1$$

The integrating factor μ is

$$\mu = e^{\int (a\,x^n + b\,x^m)dx}$$
$$= e^{\frac{a\,x^{n+1}}{n+1}+\frac{b\,x^{m+1}}{m+1}}$$

Which simplifies to

$$\mu = \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu) (c_1) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} y\right) &= \left(\mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}}\right) (c_1) \\
\mathrm{d}\left(\mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} y\right) &= \left(c_1 \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}}\right) \mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} y &= \int c_1 \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} \,\mathrm{d}x \\
\mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} y &= \int c_1 \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} dx + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}}$ results in

$$y = \mathrm{e}^{-\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} \left(\int c_1 \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} dx\right) + c_2 \mathrm{e}^{-\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}}$$

which simplifies to

$$y = \mathrm{e}^{-\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} \left(c_1 \left(\int \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} \left(c_1 \left(\int \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} \left(c_1 \left(\int \mathrm{e}^{\frac{\left(a\,x^{n} (m+1)+b\,x^{m} (n+1)\right) x}{(n+1) (m+1)}} dx\right) + c_2\right)$$

Verified OK.

27.46.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned}
p(x) &= 1\\
q(x) &= a\,x^{n}+b\,x^{m}\\
r(x) &= \frac{x^{n} n a+b\,x^{m} m}{x}\\
s(x) &= 0
\end{aligned}$$

Hence

$$\begin{aligned}
p''(x) &= 0\\
q'(x) &= \frac{a n\,x^{n}}{x}+\frac{x^{m} b m}{x}
\end{aligned}$$

Therefore (1) becomes

$$0-\left(\frac{a n\,x^{n}}{x}+\frac{x^{m} b m}{x}\right)+\left(\frac{x^{n} n a+b\,x^{m} m}{x}\right)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+\left(q(x)-p'(x)\right)y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+\left(q(x)-p'(x)\right)y=\int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$y'+\left(a\,x^{n}+b\,x^{m}\right)y=c_1$$

We now have a first order ode to solve which is

$$y'+\left(a\,x^{n}+b\,x^{m}\right)y=c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= a\,x^{n}+b\,x^{m}\\ q(x) &= c_1\end{aligned}$$

Hence the ode is

$$y' + (a\,x^{n}+b\,x^{m})\,y = c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int (a\,x^{n}+b\,x^{m})dx}\\ &= \mathrm{e}^{\frac{a\,x^{n+1}}{n+1}+\frac{b\,x^{m+1}}{m+1}}\end{aligned}$$

Which simplifies to

$$\mu = \mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\,(c_1)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}y\right) &= \left(\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}\right)(c_1)\\ \mathrm{d}\left(\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}y\right) &= \left(c_1\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}y &= \int c_1\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}\,\mathrm{d}x\\ \mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}y &= \int c_1\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}dx + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}$ results in

$$y = \mathrm{e}^{-\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}\left(\int c_1\mathrm{e}^{\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}dx\right) + c_2\mathrm{e}^{-\frac{(a\,x^{n}(m+1)+b\,x^{m}(n+1))x}{(n+1)(m+1)}}$$

which simplifies to

$$y = e^{-\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}\left(c_1\left(\int e^{\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}dx\right)+c_2\right)$$

Summary

The solution(s) found are the following

$$y = e^{-\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}\left(c_1\left(\int e^{\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}dx\right)+c_2\right) \tag{1}$$

Verification of solutions

$$y = e^{-\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}\left(c_1\left(\int e^{\frac{(a\,x^n(m+1)+b\,x^m(n+1))x}{(n+1)(m+1)}}dx\right)+c_2\right)$$

Verified OK.

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + (a\,x^n + b\,x^m)\,y' + \left(a(n+1)\,x^{n-1} + b(m+1)\,x^{m-1}\right)y = 0}$$

27.47.1 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$y'' + (a\,x^n + b\,x^m)\,y' + \frac{(b(m+1)\,x^m + a(n+1)\,x^n)\,y}{x} = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = r(x) \tag{2}$$

Where

$$\begin{aligned} p(x) &= a\,x^n + b\,x^m \\ q(x) &= \frac{b(m+1)\,x^m + a(n+1)\,x^n}{x} \\ r(x) &= 0 \end{aligned}$$

The Lagrange adjoint ode is given by

$$\xi'' - (\xi\, p)' + \xi q = 0$$
$$\xi'' - ((a\,x^n + b\,x^m)\,\xi(x))' + \left(\frac{(b(m+1)\,x^m + a(n+1)\,x^n)\,\xi(x)}{x}\right) = 0$$
$$\xi''(x) + (-a\,x^n - b\,x^m)\,\xi'(x) + \left(\frac{b(m+1)\,x^m + a(n+1)\,x^n}{x} - \frac{an\,x^n}{x} - \frac{x^m bm}{x}\right)\xi(x) = 0$$

Which is solved for $\xi(x)$. In normal form the ode

$$-\xi''(x)\,x + (a\,x^n + b\,x^m)\,\xi'(x)\,x + (-a\,x^n - b\,x^m)\,\xi(x) = 0 \tag{1}$$

Becomes

$$\xi''(x) + p(x)\,\xi'(x) + q(x)\,\xi(x) = 0 \tag{2}$$

Where

$$p(x) = -a\,x^n - b\,x^m$$
$$q(x) = \frac{a\,x^n + b\,x^m}{x}$$

Applying change of variables on the depndent variable $\xi(x) = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not $\xi(x)$.

$$v''(x) + \left(\frac{2n}{x} + p\right)v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(-a\,x^n - b\,x^m)}{x} + \frac{a\,x^n + b\,x^m}{x} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{2}{x} - a\,x^n - b\,x^m\right)v'(x) = 0$$
$$v''(x) + \left(\frac{2}{x} - a\,x^n - b\,x^m\right)v'(x) = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \left(\frac{2}{x} - a\,x^{n} - b\,x^{m}\right) u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= \frac{u(ax\,x^{n} + x^{m}bx - 2)}{x} \end{aligned}$$

Where $f(x) = \frac{ax\,x^{n}+x^{m}bx-2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= \frac{ax\,x^{n} + x^{m}bx - 2}{x}\,dx \\ \int \frac{1}{u}\,du &= \int \frac{ax\,x^{n} + x^{m}bx - 2}{x}\,dx \\ \ln(u) &= -2\ln(x) + \frac{ax\,\mathrm{e}^{n\ln(x)}}{n+1} + \frac{bx\,\mathrm{e}^{m\ln(x)}}{m+1} + c_1 \\ u &= \mathrm{e}^{-2\ln(x)+\frac{ax\,\mathrm{e}^{n\ln(x)}}{n+1}+\frac{bx\,\mathrm{e}^{m\ln(x)}}{m+1}+c_1} \\ &= c_1\mathrm{e}^{-2\ln(x)+\frac{ax\,\mathrm{e}^{n\ln(x)}}{n+1}+\frac{bx\,\mathrm{e}^{m\ln(x)}}{m+1}} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}}{x^{2}}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= \int \frac{c_1\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}}{x^{2}}\,dx + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
\xi(x) &= v(x)\, x^{n} \\
&= \left(\int \frac{c_1 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2}} d x + c_2\right) x \\
&= \left(c_1 \left(\int \frac{\mathrm{e}^{\frac{\left(a\, x^{n} (m+1)+b\, x^{m} (n+1)\right) x}{(n+1)(m+1)}}}{x^{2}} d x\right) + c_2\right) x
\end{aligned}
$$

The original ode (2) now reduces to first order ode

$$
\begin{aligned}
\xi(x)\, y' - y \xi'(x) + \xi(x)\, p(x)\, y &= \int \xi(x)\, r(x)\, d x \\
y' + y \left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)\, r(x)\, d x}{\xi\,(x)}
\end{aligned}
$$

$$
y' + y \left(a\, x^{n} + b\, x^{m} - \frac{\frac{c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x} + \int \frac{c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2}} d x + c_2}{\left(\int \frac{c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2}} d x + c_2\right) x} \right) = 0
$$

Which is now a first order ode. This is now solved for y. In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x) g(y) \\
&= -\frac{y \left(a\, x^{n} x^{2} \left(\int \frac{c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2}} d x\right) + a\, x^{n} x^{2} c_2 + b\, x^{m} x^{2} \left(\int \frac{c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2}} d x\right) + b\, x^{m} x^{2} c_2 - c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2} \left(\int \frac{c_3 \mathrm{e}^{\frac{a x\, x^{n}}{n+1}}\, \mathrm{e}^{\frac{b\, x^{m} x}{m+1}}}{x^{2}} d x + c_2\right)}
\end{aligned}
$$

Where $f(x) = -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}} - \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \cdots}{x^2}\right.}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)}$

and $g(y) = y$. Integrating both sides gives

$$\frac{1}{y}\,dy = -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}} \cdots}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)}$$

$$\int \frac{1}{y}\,dy = \int -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \cdots}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)}$$

$$\ln(y) = \int -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \cdots}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)}$$

$$y = \mathrm{e}^{\int -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}} - \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) \cdots}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)}}$$

$$= c_3 \mathrm{e}^{\int -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}} - \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2} \cdots\right.}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)}}$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = c_3 \mathrm{e}^{\int -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}} - \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) x - c_2 x}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)} dx}$$

Summary

The solution(s) found are the following

$$y = c_3 \mathrm{e}^{\int -\frac{a\,x^n x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + a\,x^n x^2 c_2 + b\,x^m x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) + b\,x^m x^2 c_2 - c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}} - \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx\right) x - c_2 x}{x^2 \left(\int \frac{c_3 \mathrm{e}^{\frac{ax\,x^n}{n+1}} \mathrm{e}^{\frac{b\,x^m x}{m+1}}}{x^2}dx + c_2\right)} dx} \tag{1}$$

Verification of solutions

$$
y = \int -\frac{a\,x^{n}x^{2}\left(\int \frac{c_3\,\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}}{x^{2}}dx\right)+a\,x^{n}x^{2}c_2+b\,x^{m}x^{2}\left(\int \frac{c_3\,\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}}{x^{2}}dx\right)+b\,x^{m}x^{2}c_2-c_3\,\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}-\left(\int \frac{c_3\,\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}}{x^{2}}dx\right)x-c_2x}{x^{2}\left(\int \frac{c_3\,\mathrm{e}^{\frac{ax\,x^{n}}{n+1}}\,\mathrm{e}^{\frac{b\,x^{m}x}{m+1}}}{x^{2}}dx+c_2\right)}\,dx
$$

$$
= c_3\mathrm{e}
$$

Verified OK.

$$\boxed{xy''+\frac{y'}{2}+ay=0}$$

28.1.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$xy''+\frac{y'}{2}+ay=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x) = \frac{1}{2x}$$
$$q(x) = \frac{a}{x}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{1}{2x}dx\right)}dx \\
&= \int e^{-\frac{\ln(x)}{2}}\,dx \\
&= \int \frac{1}{\sqrt{x}}dx \\
&= 2\sqrt{x}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{a}{x}}{\frac{1}{x}} \\
&= a
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + a y(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = a$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + a\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + a = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = a$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(a)} \\ &= \pm\sqrt{-a}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-a} \\ \lambda_2 &= -\sqrt{-a}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-a} \\ \lambda_2 &= -\sqrt{-a}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau} \\ y(\tau) &= c_1 e^{(\sqrt{-a})\tau} + c_2 e^{(-\sqrt{-a})\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{-a}\,\tau} + c_2 e^{-\sqrt{-a}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \mathrm{e}^{2\sqrt{-a}\,\sqrt{x}} + c_2 \mathrm{e}^{-2\sqrt{-a}\,\sqrt{x}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{2\sqrt{-a}\,\sqrt{x}} + c_2 \mathrm{e}^{-2\sqrt{-a}\,\sqrt{x}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{2\sqrt{-a}\,\sqrt{x}} + c_2 \mathrm{e}^{-2\sqrt{-a}\,\sqrt{x}}$$

Verified OK.

28.1.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$xy'' + \frac{y'}{2} + ay = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{1}{2x} \\ q(x) &= \frac{a}{x} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{a}{x}}}{c} \\ \tau'' &= -\frac{a}{2c\sqrt{\frac{a}{x}}\, x^2} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$
\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{a}{2c\sqrt{\frac{a}{x}}\,x^2} + \frac{1}{2x}\frac{\sqrt{\frac{a}{x}}}{c}}{\left(\frac{\sqrt{\frac{a}{x}}}{c}\right)^2} \\
&= 0
\end{aligned}
$$

Therefore ode (3) now becomes

$$
\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}
$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$
y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)
$$

Now from (6)

$$
\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{\frac{a}{x}}dx}{c} \\
&= \frac{2x\sqrt{\frac{a}{x}}}{c}
\end{aligned}
$$

Substituting the above into the solution obtained gives

$$
y = c_1 \cos\left(2\sqrt{a}\,\sqrt{x}\right) + c_2 \sin\left(2\sqrt{a}\,\sqrt{x}\right)
$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos\left(2\sqrt{a}\,\sqrt{x}\right) + c_2 \sin\left(2\sqrt{a}\,\sqrt{x}\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 \cos\left(2\sqrt{a}\,\sqrt{x}\right) + c_2 \sin\left(2\sqrt{a}\,\sqrt{x}\right)
$$

Verified OK.

28.1.3 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{y'x}{2} + yax = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2)\, y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + (\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2)\, y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned} \alpha &= \frac{1}{4} \\ \beta &= 2\sqrt{a} \\ n &= \frac{1}{2} \\ \gamma &= \frac{1}{2} \end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x^{\frac{1}{4}} \sin(2\sqrt{a}\,\sqrt{x})}{\sqrt{\pi}\,\sqrt{\sqrt{a}\,\sqrt{x}}} - \frac{c_2 x^{\frac{1}{4}} \cos(2\sqrt{a}\,\sqrt{x})}{\sqrt{\pi}\,\sqrt{\sqrt{a}\,\sqrt{x}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^{\frac{1}{4}} \sin(2\sqrt{a}\,\sqrt{x})}{\sqrt{\pi}\,\sqrt{\sqrt{a}\,\sqrt{x}}} - \frac{c_2 x^{\frac{1}{4}} \cos(2\sqrt{a}\,\sqrt{x})}{\sqrt{\pi}\,\sqrt{\sqrt{a}\,\sqrt{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^{\frac{1}{4}} \sin(2\sqrt{a}\,\sqrt{x})}{\sqrt{\pi}\,\sqrt{\sqrt{a}\,\sqrt{x}}} - \frac{c_2 x^{\frac{1}{4}} \cos(2\sqrt{a}\,\sqrt{x})}{\sqrt{\pi}\,\sqrt{\sqrt{a}\,\sqrt{x}}}$$

Verified OK.

28.1.4 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + \frac{y'}{2} + ay = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= \frac{1}{2} \\ C &= a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A} \, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-16ax - 3}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -16ax - 3 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-16ax - 3}{16x^2} \right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 75: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 1 \\ &= 1 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [2]$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16x^2} - \frac{a}{x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$
\begin{aligned}
E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\
&= \{1, 2, 3\}
\end{aligned}
$$

Since the order of r at ∞ is $1 < 2$ then

$$
E_\infty = \{1\}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$
e_1 = 1, \; e_\infty = 1
$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$
\begin{aligned}
d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\
&= \frac{1}{2}(1 - (1)) \\
&= 0
\end{aligned}
$$

We now form the following rational function

$$
\begin{aligned}
\theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x - c} \\
&= \frac{1}{2}\left(\frac{1}{(x - (0))}\right) \\
&= \frac{1}{2x}
\end{aligned}
$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$
p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}
$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{2x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{2x} + \frac{16ax + 1}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + 4\sqrt{-ax}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+4\sqrt{-ax}}{4x} dx} \\ &= x^{\frac{1}{4}} \mathrm{e}^{2\sqrt{-ax}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{\frac{1}{2}}{x} \, dx} \\ &= z_1 e^{-\frac{\ln(x)}{4}} \\ &= z_1 \left(\frac{1}{x^{\frac{1}{4}}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{2\sqrt{-ax}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{\frac{1}{2}}{x}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\sqrt{-ax}\left(-1 + \mathrm{e}^{-4\sqrt{-ax}}\right)}{2\sqrt{x}\, a} \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{2\sqrt{-ax}}\right) + c_2 \left(\mathrm{e}^{2\sqrt{-ax}} \left(\frac{\sqrt{-ax}\left(-1 + \mathrm{e}^{-4\sqrt{-ax}}\right)}{2\sqrt{x}\, a} \right) \right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{2\sqrt{-ax}} + \frac{c_2 \sqrt{-ax}\left(-\mathrm{e}^{2\sqrt{-ax}} + \mathrm{e}^{-2\sqrt{-ax}}\right)}{2\sqrt{x}\, a} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{2\sqrt{-ax}} + \frac{c_2 \sqrt{-ax}\left(-\mathrm{e}^{2\sqrt{-ax}} + \mathrm{e}^{-2\sqrt{-ax}}\right)}{2\sqrt{x}\, a}$$

Verified OK.

28.1.5 Maple step by step solution

Let's solve

$y''x + \frac{y'}{2} + ay = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{y'}{2x} - \frac{ay}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{2x} + \frac{ay}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{1}{2x}, P_3(x) = \frac{a}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = \frac{1}{2}$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x + 2ay + y' = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert y' to series expansion

  $y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1}$

  ◦ Shift index using $k- >k+1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+2r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(2k+1+2r) + 2a a_k\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$2(k+1+r)\left(k+\frac{1}{2}+r\right) a_{k+1} + 2a a_k = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{2a a_k}{(k+1+r)(2k+1+2r)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{2a a_k}{(k+1)(2k+1)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{2a a_k}{(k+1)(2k+1)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = -\frac{2a a_k}{\left(k+\frac{3}{2}\right)(2k+2)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+1} = -\frac{2a a_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} b_k x^k\right)+\left(\sum_{k=0}^{\infty} c_k x^{k+\frac{1}{2}}\right), b_{1+k}=-\frac{2ab_k}{(1+k)(2k+1)}, c_{1+k}=-\frac{2ac_k}{\left(k+\frac{3}{2}\right)(2k+2)}\right]$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 62.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{xy''+ay'+yb=0}$$

28.2.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y''+axy'+bxy=0 \tag{1}$$

Bessel ode has the form

$$x^2y''+y'x+\left(-n^2+x^2\right)y=0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y''+(1-2\alpha)\,xy'+\left(\beta^2\gamma^2x^{2\gamma}-n^2\gamma^2+\alpha^2\right)y=0 \tag{3}$$

With the standard solution

$$y=x^{\alpha}(c_1\,\mathrm{BesselJ}\left(n,\beta\,x^{\gamma}\right)+c_2\,\mathrm{BesselY}\left(n,\beta\,x^{\gamma}\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2} - \frac{a}{2}$$
$$\beta = 2\sqrt{b}$$
$$n = -a + 1$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-a+1, 2\sqrt{b}\,\sqrt{x}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-a+1, 2\sqrt{b}\,\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-a+1, 2\sqrt{b}\,\sqrt{x}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-a+1, 2\sqrt{b}\,\sqrt{x}\right) \quad (1)$$

Verification of solutions

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-a+1, 2\sqrt{b}\,\sqrt{x}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-a+1, 2\sqrt{b}\,\sqrt{x}\right)$$

Verified OK.

28.2.2 Maple step by step solution

Let's solve

$y''x + ay' + yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{ay'}{x} - \frac{by}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{ay'}{x} + \frac{by}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{a}{x}, P_3(x) = \frac{b}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$$(x \cdot P_2(x))\Big|_{x=0} = a$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$(x^2 \cdot P_3(x))\Big|_{x=0} = 0$$

- $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$y''x + ay' + yb = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert y' to series expansion

$$y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1}$$

- Shift index using $k- >k + 1$

$$y' = \sum_{k=-1}^{\infty} a_{k+1}(k + 1 + r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r-1}$$

- Shift index using $k- >k + 1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k + 1 + r)\,(k + r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1 + r + a)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k + 1 + r)\,(k + r + a) + a_k b\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-1 + r + a) = 0$

- Values of r that satisfy the indicial equation

$r \in \{0, -a+1\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k+r+a)+a_k b=0$

- Recursion relation that defines series solution to ODE

  $a_{k+1}=-\frac{a_k b}{(k+1+r)(k+r+a)}$

- Recursion relation for $r=0$

  $a_{k+1}=-\frac{a_k b}{(k+1)(k+a)}$

- Solution for $r=0$

  $\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+1}=-\frac{a_k b}{(k+1)(k+a)}\right]$

- Recursion relation for $r=-a+1$

  $a_{k+1}=-\frac{a_k b}{(k+2-a)(k+1)}$

- Solution for $r=-a+1$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-a+1}, a_{k+1}=-\frac{a_k b}{(k+2-a)(k+1)}\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} c_k x^k\right)+\left(\sum_{k=0}^{\infty} d_k x^{k-a+1}\right), c_{1+k}=-\frac{c_k b}{(1+k)(k+a)}, d_{1+k}=-\frac{d_k b}{(k+2-a)(1+k)}\right]$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 65.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler], [_2nd_order, _linear, `_with_symmetry_[0,F(
   x)]`]]
```

$$\boxed{xy''+ny'+b\,x^{1-2n}y=0}$$

28.5.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$xy''+ny'+b\,x^{1-2n}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{n}{x}$$
$$q(x)=b\,x^{-2n}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\ &= \int \mathrm{e}^{-\left(\int \frac{n}{x}dx\right)}dx \\ &= \int e^{-n\ln(x)}\,dx \\ &= \int x^{-n}dx \\ &= -\frac{x^{1-n}}{n-1}\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\ &= \frac{b\,x^{-2n}}{x^{-2n}} \\ &= b\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + b y(\tau) &= 0\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = b$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + b\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + b = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = b$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(b)}\\ &= \pm\sqrt{-b}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-b}\\ \lambda_2 &= -\sqrt{-b}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-b}\\ \lambda_2 &= -\sqrt{-b}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1\tau} + c_2 e^{\lambda_2\tau}\\ y(\tau) &= c_1 e^{(\sqrt{-b})\tau} + c_2 e^{(-\sqrt{-b})\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{-b}\,\tau} + c_2 e^{-\sqrt{-b}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \mathrm{e}^{-\frac{\sqrt{-b}\, x^{1-n}}{n-1}} + c_2 \mathrm{e}^{\frac{\sqrt{-b}\, x^{1-n}}{n-1}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{\sqrt{-b}\, x^{1-n}}{n-1}} + c_2 \mathrm{e}^{\frac{\sqrt{-b}\, x^{1-n}}{n-1}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{\sqrt{-b}\, x^{1-n}}{n-1}} + c_2 \mathrm{e}^{\frac{\sqrt{-b}\, x^{1-n}}{n-1}}$$

Verified OK.

28.5.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$xy'' + ny' + b\, x^{1-2n} y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{n}{x} \\ q(x) &= b\, x^{-2n} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau) \right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{b\, x^{-2n}}}{c} \end{aligned} \tag{6}$$

$$\tau'' = -\frac{b\, x^{-2n} n}{c\sqrt{b\, x^{-2n}}\, x}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{b\,x^{-2n}n}{c\sqrt{b\,x^{-2n}}\,x} + \frac{n}{x}\frac{\sqrt{b\,x^{-2n}}}{c}}{\left(\frac{\sqrt{b\,x^{-2n}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{b\,x^{-2n}}dx}{c} \\ &= -\frac{x\sqrt{b\,x^{-2n}}}{c\,(n-1)} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos\left(\frac{x^{1-n}\sqrt{b}}{n-1}\right) - c_2 \sin\left(\frac{x^{1-n}\sqrt{b}}{n-1}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\frac{x^{1-n}\sqrt{b}}{n-1}\right) - c_2 \sin\left(\frac{x^{1-n}\sqrt{b}}{n-1}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(\frac{x^{1-n}\sqrt{b}}{n-1}\right) - c_2 \sin\left(\frac{x^{1-n}\sqrt{b}}{n-1}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{xy''+ay'+b\,x^n y=0}$$

28.7.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y''+axy'+x^n bxy=0 \tag{1}$$

Bessel ode has the form

$$x^2y''+y'x+\left(-n^2+x^2\right)y=0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y''+(1-2\alpha)\,xy'+\left(\beta^2\gamma^2x^{2\gamma}-n^2\gamma^2+\alpha^2\right)y=0 \tag{3}$$

With the standard solution

$$y=x^\alpha(c_1\,\text{BesselJ}\,(n,\beta\,x^\gamma)+c_2\,\text{BesselY}\,(n,\beta\,x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2} - \frac{a}{2}$$
$$\beta = \frac{2\sqrt{b}}{n+1}$$
$$n = -\frac{a-1}{n+1}$$
$$\gamma = \frac{n}{2} + \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-\frac{a-1}{n+1}, \frac{2\sqrt{b}\, x^{\frac{n}{2}+\frac{1}{2}}}{n+1}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-\frac{a-1}{n+1}, \frac{2\sqrt{b}\, x^{\frac{n}{2}+\frac{1}{2}}}{n+1}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-\frac{a-1}{n+1}, \frac{2\sqrt{b}\, x^{\frac{n}{2}+\frac{1}{2}}}{n+1}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-\frac{a-1}{n+1}, \frac{2\sqrt{b}\, x^{\frac{n}{2}+\frac{1}{2}}}{n+1}\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-\frac{a-1}{n+1}, \frac{2\sqrt{b}\, x^{\frac{n}{2}+\frac{1}{2}}}{n+1}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-\frac{a-1}{n+1}, \frac{2\sqrt{b}\, x^{\frac{n}{2}+\frac{1}{2}}}{n+1}\right)$$

Verified OK.

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 69.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{xy''+axy'+ay=0}$$

28.9.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int (xy''+axy'+ay)\,dx=0$$
$$(ax-1)\,y+y'x=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{-ax+1}{x}\\q(x) &= \frac{c_1}{x}\end{aligned}$$

Hence the ode is

$$y' - \frac{(-ax+1)\,y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-ax+1}{x}dx}\\&= \mathrm{e}^{ax-\ln(x)}\end{aligned}$$

Which simplifies to

$$\mu = \frac{\mathrm{e}^{ax}}{x}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{ax}y}{x}\right) &= \left(\frac{\mathrm{e}^{ax}}{x}\right)\left(\frac{c_1}{x}\right)\\\mathrm{d}\left(\frac{\mathrm{e}^{ax}y}{x}\right) &= \left(\frac{c_1\mathrm{e}^{ax}}{x^2}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{\mathrm{e}^{ax}y}{x} &= \int \frac{c_1\mathrm{e}^{ax}}{x^2}\,\mathrm{d}x\\\frac{\mathrm{e}^{ax}y}{x} &= c_1a\left(-\frac{\mathrm{e}^{ax}}{ax} - \mathrm{expIntegral}_1\left(-ax\right)\right) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{ax}}{x}$ results in

$$y = x\,\mathrm{e}^{-ax}c_1a\left(-\frac{\mathrm{e}^{ax}}{ax} - \mathrm{expIntegral}_1\left(-ax\right)\right) + c_2x\,\mathrm{e}^{-ax}$$

which simplifies to

$$y = -\,\mathrm{expIntegral}_1\left(-ax\right)c_1ax\,\mathrm{e}^{-ax} - c_1 + c_2x\,\mathrm{e}^{-ax}$$

Summary
The solution(s) found are the following

$$y = -\operatorname{expIntegral}_1(-ax)\, c_1 a x\, e^{-ax} - c_1 + c_2 x\, e^{-ax} \tag{1}$$

Verification of solutions

$$y = -\operatorname{expIntegral}_1(-ax)\, c_1 a x\, e^{-ax} - c_1 + c_2 x\, e^{-ax}$$

Verified OK.

28.9.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' + axy' + ay = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int (xy'' + axy' + ay)\, dx = 0$$
$$(ax - 1)\, y + y'x = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-ax + 1}{x}$$
$$q(x) = \frac{c_1}{x}$$

Hence the ode is

$$y' - \frac{(-ax + 1)\, y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-ax+1}{x} dx}$$
$$= e^{ax - \ln(x)}$$

Which simplifies to

$$\mu = \frac{e^{ax}}{x}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{ax} y}{x}\right) &= \left(\frac{\mathrm{e}^{ax}}{x}\right)\left(\frac{c_1}{x}\right)\\ \mathrm{d}\left(\frac{\mathrm{e}^{ax} y}{x}\right) &= \left(\frac{c_1 \mathrm{e}^{ax}}{x^2}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{\mathrm{e}^{ax} y}{x} &= \int \frac{c_1 \mathrm{e}^{ax}}{x^2}\,\mathrm{d}x\\ \frac{\mathrm{e}^{ax} y}{x} &= c_1 a\left(-\frac{\mathrm{e}^{ax}}{ax} - \mathrm{expIntegral}_1(-ax)\right) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{ax}}{x}$ results in

$$y = x\,\mathrm{e}^{-ax} c_1 a\left(-\frac{\mathrm{e}^{ax}}{ax} - \mathrm{expIntegral}_1(-ax)\right) + c_2 x\,\mathrm{e}^{-ax}$$

which simplifies to

$$y = -\mathrm{expIntegral}_1(-ax)\, c_1 a x\,\mathrm{e}^{-ax} - c_1 + c_2 x\,\mathrm{e}^{-ax}$$

Summary

The solution(s) found are the following

$$y = -\mathrm{expIntegral}_1(-ax)\, c_1 a x\,\mathrm{e}^{-ax} - c_1 + c_2 x\,\mathrm{e}^{-ax} \tag{1}$$

Verification of solutions

$$y = -\mathrm{expIntegral}_1(-ax)\, c_1 a x\,\mathrm{e}^{-ax} - c_1 + c_2 x\,\mathrm{e}^{-ax}$$

Verified OK.

28.9.3 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + axy' + ay = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= x\\ B &= ax \\ C &= a\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a(ax - 4)}{4x} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a(ax - 4) \\ t &= 4x \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a(ax - 4)}{4x}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 80: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 1 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}
$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$
\sqrt{r} \approx \frac{a}{2} - \frac{1}{x} - \frac{1}{a\,x^2} - \frac{2}{a^2x^3} - \frac{5}{a^3x^4} - \frac{14}{a^4x^5} - \frac{42}{a^5x^6} - \frac{132}{a^6x^7} + \dots \tag{9}
$$

Comparing Eq. (9) with Eq. (8) shows that

$$
a = \frac{a}{2}
$$

From Eq. (9) the sum up to $v = 0$ gives

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\
&= \frac{a}{2}
\end{aligned} \tag{10}
$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$
\left([\sqrt{r}]_\infty\right)^2 = \frac{a^2}{4}
$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$
r = Q + \frac{R}{t}
$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a(ax-4)}{4x} \\ &= Q + \frac{R}{4x} \\ &= \left(\frac{a^2}{4}\right) + \left(-\frac{a}{x}\right) \\ &= \frac{a^2}{4} - \frac{a}{x} \end{aligned}$$

Since the degree of t is 1, then we see that the coefficient of the term 1 in the remainder R is $-4a$. Dividing this by leading coefficient in t which is 4 gives $-a$. Now b can be found.

$$\begin{aligned} b &= (-a) - (0) \\ &= -a \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_\infty &= \frac{a}{2} \\ \alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{-a}{\frac{a}{2}} - 0\right) &= -1 \\ \alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{-a}{\frac{a}{2}} - 0\right) &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a(ax-4)}{4x}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{a}{2}$	-1	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{1}{x} + (-)\left(\frac{a}{2}\right) \\
&= \frac{1}{x} - \frac{a}{2} \\
&= \frac{1}{x} - \frac{a}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(\frac{1}{x} - \frac{a}{2}\right)(0) + \left(\left(-\frac{1}{x^2}\right) + \left(\frac{1}{x} - \frac{a}{2}\right)^2 - \left(\frac{a(ax-4)}{4x}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{1}{x} - \frac{a}{2}\right) dx} \\
&= x \, e^{-\frac{ax}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{ax}{x}\,dx} \\
&= z_1 e^{-\frac{ax}{2}} \\
&= z_1 \left(\mathrm{e}^{-\frac{ax}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x\,\mathrm{e}^{-ax}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{ax}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-ax}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{-\operatorname{expIntegral}_1(-ax)\,ax - \mathrm{e}^{ax}}{x}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\,\mathrm{e}^{-ax}\right) + c_2 \left(x\,\mathrm{e}^{-ax}\left(\frac{-\operatorname{expIntegral}_1(-ax)\,ax - \mathrm{e}^{ax}}{x}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\,\mathrm{e}^{-ax} + c_2\left(-\operatorname{expIntegral}_1(-ax)\,ax\,\mathrm{e}^{-ax} - 1\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x\,\mathrm{e}^{-ax} + c_2\left(-\operatorname{expIntegral}_1(-ax)\,ax\,\mathrm{e}^{-ax} - 1\right)
$$

Verified OK.

28.9.4 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned}p(x) &= x\\ q(x) &= ax\\ r(x) &= a\\ s(x) &= 0\end{aligned}$$

Hence

$$\begin{aligned}p''(x) &= 0\\ q'(x) &= a\end{aligned}$$

Therefore (1) becomes

$$0 - (a) + (a) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$(ax - 1)\,y + y'x = c_1$$

We now have a first order ode to solve which is

$$(ax - 1)\,y + y'x = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{-ax+1}{x}\\
q(x) &= \frac{c_1}{x}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{(-ax+1)\, y}{x} = \frac{c_1}{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{-ax+1}{x}dx}\\
&= \mathrm{e}^{ax-\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{\mathrm{e}^{ax}}{x}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{ax} y}{x}\right) &= \left(\frac{\mathrm{e}^{ax}}{x}\right)\left(\frac{c_1}{x}\right)\\
\mathrm{d}\left(\frac{\mathrm{e}^{ax} y}{x}\right) &= \left(\frac{c_1 \mathrm{e}^{ax}}{x^2}\right)\, \mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{\mathrm{e}^{ax} y}{x} &= \int \frac{c_1 \mathrm{e}^{ax}}{x^2}\, \mathrm{d}x\\
\frac{\mathrm{e}^{ax} y}{x} &= c_1 a\left(-\frac{\mathrm{e}^{ax}}{ax} - \mathrm{expIntegral}_1\left(-ax\right)\right) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{ax}}{x}$ results in

$$
y = x\,\mathrm{e}^{-ax} c_1 a\left(-\frac{\mathrm{e}^{ax}}{ax} - \mathrm{expIntegral}_1\left(-ax\right)\right) + c_2 x\,\mathrm{e}^{-ax}
$$

which simplifies to

$$
y = -\,\mathrm{expIntegral}_1\left(-ax\right) c_1 a x\,\mathrm{e}^{-ax} - c_1 + c_2 x\,\mathrm{e}^{-ax}
$$

Summary
The solution(s) found are the following

$$y = -\operatorname{expIntegral}_1(-ax)\, c_1 a x\, e^{-ax} - c_1 + c_2 x\, e^{-ax} \tag{1}$$

Verification of solutions

$$y = -\operatorname{expIntegral}_1(-ax)\, c_1 a x\, e^{-ax} - c_1 + c_2 x\, e^{-ax}$$

Verified OK.

28.9.5 Maple step by step solution

Let's solve

$y''x + axy' + ay = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -ay' - \frac{ay}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + ay' + \frac{ay}{x} = 0$

- □ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = a, P_3(x) = \frac{a}{x}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = 0$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + axy' + ay = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$

  - Shift index using $k- >k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-1+r)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(a_{k+1}(k+1+r)\,(k+r) + a a_k(k+1+r)\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 1\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+1+r)\,(a_{k+1}(k+r) + a a_k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a a_k}{k+r}$

- Recursion relation for $r = 0$

  $a_{k+1} = -\frac{a a_k}{k}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+1} = -\frac{a a_k}{k}\right]$

- Recursion relation for $r = 1$

  $a_{k+1} = -\frac{a a_k}{k+1}$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{a a_k}{k+1}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} b_k x^k\right) + \left(\sum_{k=0}^{\infty} c_k x^{1+k}\right), b_{1+k} = -\frac{a b_k}{k}, c_{1+k} = -\frac{a c_k}{1+k}\right]$$

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[_Laguerre]`

Unable to solve or complete the solution.

$$xy''+(-x+b)\,y'-ay=0$$

28.10.1 Maple step by step solution

Let's solve

$y''x+(-x+b)\,y'-ay=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{ay}{x}-\frac{(-x+b)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(-x+b)y'}{x}-\frac{ay}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x)=\frac{-x+b}{x}, P_3(x)=-\frac{a}{x}\right]$

- ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=b$

- ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=0$

- ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $y''x+(-x+b)\,y'-ay=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - ◦ Convert $x^m\cdot y'$ to series expansion for $m=0..1$

    $x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - ◦ Shift index using $k->k+1-m$

    $x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - ◦ Convert $x\cdot y''$ to series expansion

    $x\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

  - ◦ Shift index using $k->k+1$

    $x\cdot y''=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(-1+r+b)\,x^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(k+r+b)-a_k(k+r+a)\right)x^{k+r}\right)=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$r(-1+r+b) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, -b+1\}$

- Each term in the series must be 0, giving the recursion relation

Problem number: 71.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{xy''+(ax+b)\,y'+c((a-c)\,x+b)\,y=0}$$

28.11.1 Maple step by step solution

Let's solve

$y''x+(ax+b)\,y'+c((a-c)\,x+b)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{c(ax-cx+b)y}{x}-\frac{(ax+b)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(ax+b)y'}{x}+\frac{c(ax-cx+b)y}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ○ Define functions

$$\left[P_2(x) = \frac{ax+b}{x}, P_3(x) = \frac{c(ax-cx+b)}{x}\right]$$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = b$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$y''x + (ax+b)\,y' + c(ax-cx+b)\,y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-1}$$

- Shift index using $k- >k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+r+b)\, x^{-1+r} + (a_1(1+r)(r+b) + a_0(ar+bc))\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k+r+b)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+r+b) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, -b+1\}$$

- Each term must be 0

$$a_1(1+r)(r+b) + a_0(ar+bc) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+r+b) + aka_k + ara_k + (ba_k + a_{k-1}(a-c))\, c = 0$$

- Shift index using $k- > k+1$

$$a_{k+2}(k+2+r)(k+1+r+b) + a(k+1)\, a_{k+1} + ara_{k+1} + (ba_{k+1} + a_k(a-c))\, c = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k ac + aka_{k+1} + ara_{k+1} + bca_{k+1} - a_k c^2 + aa_{k+1}}{(k+2+r)(k+1+r+b)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{a_k ac + aka_{k+1} + bca_{k+1} - a_k c^2 + aa_{k+1}}{(k+2)(k+1+b)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k ac + aka_{k+1} + bca_{k+1} - a_k c^2 + aa_{k+1}}{(k+2)(k+1+b)}, a_0 bc + a_1 b = 0\right]$$

- Recursion relation for $r = -b+1$

$$a_{k+2} = -\frac{a_k ac + aka_{k+1} + a(-b+1)a_{k+1} + bca_{k+1} - a_k c^2 + aa_{k+1}}{(k+3-b)(k+2)}$$

- Solution for $r = -b+1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-b+1}, a_{k+2} = -\frac{a_k ac + aka_{k+1} + a(-b+1)a_{k+1} + bca_{k+1} - a_k c^2 + aa_{k+1}}{(k+3-b)(k+2)}, a_1(2-b) + a_0(a(-b+1) +\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} d_k x^k\right) + \left(\sum_{k=0}^{\infty} e_k x^{k-b+1}\right), d_{k+2} = -\frac{acd_k + akd_{1+k} + bcd_{1+k} - c^2 d_k + ad_{1+k}}{(k+2)(k+1+b)}, bcd_0 + bd_1 = 0, e_{k+2} =\right.$$

Problem number: 72.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+(2ax+b)\,y'+a(ax+b)\,y=0}$$

28.12.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+(2ax+b)\,y'+a(ax+b)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= 2ax+b \\ C &= (ax+b)\,a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{b(-2+b)}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= b(-2+b) \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{b(-2+b)}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 84: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{b(-2+b)}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{b(-2+b)}{4}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \left\{2, 2 - 2\sqrt{(b-1)^2}, 2 + 2\sqrt{(b-1)^2}\right\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{b(-2+b)}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{1}{4}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\left\{2, 2-2\sqrt{(b-1)^2}, 2+2\sqrt{(b-1)^2}\right\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = 2, \; e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2-(2)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{2}{(x-(0))}\right) \\ &= \frac{1}{x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{x} - \frac{b(-2+b)}{4x^2} = 0$$

Solving for ω gives

$$\omega = -\frac{-2+b}{2x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx}\\ &= \mathrm{e}^{\int -\frac{-2+b}{2x} dx}\\ &= x^{1-\frac{b}{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{2ax+b}{x} \, dx}\\ &= z_1 e^{-ax-\frac{b\ln(x)}{2}}\\ &= z_1 \left(x^{-\frac{b}{2}}\mathrm{e}^{-ax}\right)\end{aligned}$$

Which simplifies to

$$y_1 = x^{-b+1}\mathrm{e}^{-ax}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2ax+b}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2ax-b\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{x^{b-1}}{b-1}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-b+1} \mathrm{e}^{-ax}\right) + c_2 \left(x^{-b+1} \mathrm{e}^{-ax} \left(\frac{x^{b-1}}{b-1}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
y = c_1 x^{-b+1} \mathrm{e}^{-ax} + \frac{c_2 \mathrm{e}^{-ax}}{b-1} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{-b+1} \mathrm{e}^{-ax} + \frac{c_2 \mathrm{e}^{-ax}}{b-1}
$$

Verified OK.

28.12.2 Maple step by step solution

Let's solve

$y''x + (2ax+b)\,y' + a(ax+b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(ax+b)ay}{x} - \frac{(2ax+b)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(2ax+b)y'}{x} + \frac{(ax+b)ay}{x} = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{2ax+b}{x}, P_3(x) = \frac{(ax+b)a}{x}\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = b$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $y''x + (2ax+b)\,y' + a(ax+b)\,y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$
  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r-1}$$

- Shift index using $k- >k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+r+b) x^{-1+r} + (a_1(1+r)(r+b) + a a_0(2r+b)) x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)(k+r+b)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+r+b) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, -b+1\}$$

- Each term must be 0

$$a_1(1+r)(r+b) + a a_0(2r+b) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+r+b) + a a_k(2k+2r+b) + a_{k-1} a^2 = 0$$

- Shift index using $k- >k+1$

$$a_{k+2}(k+2+r)(k+1+r+b) + a a_{k+1}(2k+2+2r+b) + a_k a^2 = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a(a a_k + b a_{k+1} + 2k a_{k+1} + 2r a_{k+1} + 2a_{k+1})}{(k+2+r)(k+1+r+b)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{a(a a_k + b a_{k+1} + 2k a_{k+1} + 2a_{k+1})}{(k+2)(k+1+b)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a(a a_k + b a_{k+1} + 2k a_{k+1} + 2a_{k+1})}{(k+2)(k+1+b)}, a a_0 b + a_1 b = 0\right]$$

- Recursion relation for $r = -b+1$

$$a_{k+2} = -\frac{a(a a_k + b a_{k+1} + 2k a_{k+1} + 2(-b+1) a_{k+1} + 2a_{k+1})}{(k+3-b)(k+2)}$$

- Solution for $r = -b+1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-b+1}, a_{k+2} = -\frac{a(a a_k + b a_{k+1} + 2k a_{k+1} + 2(-b+1) a_{k+1} + 2a_{k+1})}{(k+3-b)(k+2)}, a_1(2-b) + a a_0(2-b) = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^k\right) + \left(\sum_{k=0}^{\infty} d_k x^{k-b+1}\right), c_{k+2} = -\frac{a(ac_k + bc_{1+k} + 2kc_{1+k} + 2c_{1+k})}{(k+2)(k+1+b)}, abc_0 + bc_1 = 0, d_{k+2} = -\frac{a}{}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 73.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$xy''+((a+b)x+n+m)y'+(abx+an+bm)y=0$$

28.13.1 Maple step by step solution

Let's solve

$y''x+((a+b)x+n+m)y'+((bx+n)a+bm)y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(abx+an+bm)y}{x}-\frac{(ax+bx+m+n)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(ax+bx+m+n)y'}{x}+\frac{(abx+an+bm)y}{x}=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{ax+bx+m+n}{x}, P_3(x) = \frac{abx+an+bm}{x}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$(x \cdot P_2(x))\bigg|_{x=0} = m + n$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$y''x + (ax + bx + m + n)\, y' + (abx + an + bm)\, y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k + 1 - m + r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r-1}$$

- Shift index using $k- >k + 1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+r+m+n)\, x^{-1+r} + (a_1(1+r)(r+m+n) + a_0(an+ar+bm+br))\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}($$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+r+m+n) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, -m-n+1\}$$

- Each term must be 0

$$a_1(1+r)(r+m+n) + a_0(an+ar+bm+br) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+r+m+n) + a_k(a+b)\, k + a_k(a+b)\, r + (an+bm)\, a_k + a_{k-1}ab = 0$$

- Shift index using $k- >k+1$

$$a_{k+2}(k+2+r)(k+1+r+m+n) + a_{k+1}(a+b)(k+1) + a_{k+1}(a+b)\, r + (an+bm)\, a_{k+1} + a$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k ab + aka_{k+1} + ana_{k+1} + ara_{k+1} + bka_{k+1} + bma_{k+1} + bra_{k+1} + aa_{k+1} + ba_{k+1}}{(k+2+r)(k+1+r+m+n)}$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{a_k ab + aka_{k+1} + ana_{k+1} + bka_{k+1} + bma_{k+1} + aa_{k+1} + ba_{k+1}}{(k+2)(k+1+m+n)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a_k ab + aka_{k+1} + ana_{k+1} + bka_{k+1} + bma_{k+1} + aa_{k+1} + ba_{k+1}}{(k+2)(k+1+m+n)}, a_1(m+n) + a_0(an+bm) =\right.$$

- Recursion relation for $r = -m-n+1$

$$a_{k+2} = -\frac{a_k ab + aka_{k+1} + ana_{k+1} + a(-m-n+1)a_{k+1} + bka_{k+1} + bma_{k+1} + b(-m-n+1)a_{k+1} + aa_{k+1} + ba_{k+1}}{(k+3-m-n)(k+2)}$$

- Solution for $r = -m-n+1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-m-n+1}, a_{k+2} = -\frac{a_k ab + aka_{k+1} + ana_{k+1} + a(-m-n+1)a_{k+1} + bka_{k+1} + bma_{k+1} + b(-m-n+1)a_{k+1} + aa_{k+}}{(k+3-m-n)(k+2)}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^k\right) + \left(\sum_{k=0}^{\infty} d_k x^{k-m-n+1}\right), c_{k+2} = -\frac{abc_k + akc_{1+k} + anc_{1+k} + bkc_{1+k} + bmc_{1+k} + ac_{1+k} + bc_{1+k}}{(k+2)(k+1+m+n)}, c_1(r\right.$$

Problem number: 75.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''-(ax+1)\,y'-b\,x^2(bx+a)\,y=0}$$

28.15.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+(-ax-1)\,y'+\left(-b^2x^3-ab\,x^2\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -ax-1 \\ C &= -b^2x^3-ab\,x^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4b^2x^4 + 4ab\,x^3 + a^2x^2 + 2ax + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4b^2x^4 + 4ab\,x^3 + a^2x^2 + 2ax + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4b^2x^4 + 4ab\,x^3 + a^2x^2 + 2ax + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 88: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 4 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = b^2x^2 + abx + \frac{a^2}{4} + \frac{3}{4x^2} + \frac{a}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2} \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx bx+\frac{a}{2}+\frac{a}{4b\,x^2}-\frac{a^2}{8b^2x^3}+\frac{a^3}{16b^3x^4}+\frac{3}{8b\,x^3}-\frac{a^4}{32b^4x^5}-\frac{3a}{16b^2x^4}+\frac{a^5}{64b^5x^6}+\frac{a^2}{16b^3x^5}-\frac{a^6}{128b^6x^7}-\frac{3a^4}{128b^5x^7}-\frac{3a}{32b^3} \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = b$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{a}{2} + bx \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = b^2x^2 + abx + \frac{1}{4}a^2$$

This shows that the coefficient of 1 in the above is $\frac{a^2}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{4b^2x^4 + 4ab\,x^3 + a^2x^2 + 2ax + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(b^2x^2 + abx + \frac{1}{4}a^2\right) + \left(\frac{2ax+3}{4x^2}\right) \\ &= b^2x^2 + abx + \frac{a^2}{4} + \frac{2ax+3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is $\frac{a^2}{4}$. Now b can be found.

$$\begin{aligned} b &= \left(\frac{a^2}{4}\right) - \left(\frac{a^2}{4}\right) \\ &= 0 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{a}{2} + bx \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{b} - 1\right) &&= -\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{b} - 1\right) &&= -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4b^2x^4 + 4ab\,x^3 + a^2x^2 + 2ax + 3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{a}{2} + bx$	$-\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + (-)\left(\frac{a}{2} + bx\right) \\
&= -\frac{1}{2x} - \frac{a}{2} - bx \\
&= -\frac{1}{2x} - \frac{a}{2} - bx
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{2x} - \frac{a}{2} - bx\right)(0) + \left(\left(\frac{1}{2x^2} - b\right) + \left(-\frac{1}{2x} - \frac{a}{2} - bx\right)^2 - \left(\frac{4b^2x^4 + 4ab\, x^3 + a^2x^2 + 2ax + 3}{4x^2}\right.\right.
$$

$$
0 =
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2x} - \frac{a}{2} - bx\right) dx} \\
&= \frac{\mathrm{e}^{-\frac{x(bx+a)}{2}}}{\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-ax-1}{x}\, dx} \\
&= z_1 e^{\frac{ax}{2} + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\, \mathrm{e}^{\frac{ax}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{b\,x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-ax-1}{x}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{ax+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(-\frac{a\sqrt{\pi}\,\mathrm{e}^{-\frac{a^2}{4b}}\,\mathrm{erf}\left(\frac{2bx+a}{2\sqrt{-b}}\right)+2\,\mathrm{e}^{x(bx+a)}\sqrt{-b}}{4\,(-b)^{\frac{3}{2}}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{-\frac{b\,x^2}{2}}\right) + c_2\left(\mathrm{e}^{-\frac{b\,x^2}{2}}\left(-\frac{a\sqrt{\pi}\,\mathrm{e}^{-\frac{a^2}{4b}}\,\mathrm{erf}\left(\frac{2bx+a}{2\sqrt{-b}}\right)+2\,\mathrm{e}^{x(bx+a)}\sqrt{-b}}{4\,(-b)^{\frac{3}{2}}}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{-\frac{b\,x^2}{2}} - \frac{c_2\mathrm{e}^{-\frac{b\,x^2}{2}}\left(a\sqrt{\pi}\,\mathrm{e}^{-\frac{a^2}{4b}}\,\mathrm{erf}\left(\frac{2bx+a}{2\sqrt{-b}}\right)+2\,\mathrm{e}^{x(bx+a)}\sqrt{-b}\right)}{4\,(-b)^{\frac{3}{2}}} \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{-\frac{b\,x^2}{2}} - \frac{c_2\mathrm{e}^{-\frac{b\,x^2}{2}}\left(a\sqrt{\pi}\,\mathrm{e}^{-\frac{a^2}{4b}}\,\mathrm{erf}\left(\frac{2bx+a}{2\sqrt{-b}}\right)+2\,\mathrm{e}^{x(bx+a)}\sqrt{-b}\right)}{4\,(-b)^{\frac{3}{2}}}$$

Verified OK.

28.15.2 Maple step by step solution

Let's solve

$y''x+(-ax-1)\,y'+(-b^2x^3-ab\,x^2)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=bx(bx+a)\,y+\frac{(ax+1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(ax+1)y'}{x}-bx(bx+a)\,y=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=-\frac{ax+1}{x},P_3(x)=-bx(bx+a)\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\Big|_{x=0}=-1$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\Big|_{x=0}=0$

  ◦ $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $y''x+(-ax-1)\,y'-b\,x^2(bx+a)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_kx^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m\cdot y$ to series expansion for $m=2..3$

  $x^m\cdot y=\sum_{k=0}^{\infty}a_kx^{k+r+m}$

  ◦ Shift index using $k->k-m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

  $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-2+r)\, x^{-1+r} + (a_1(1+r)\,(-1+r) - a_0 a r)\, x^r + (a_2(2+r)\, r - a a_1(1+r))\, x^{1+r} + (a_3(3+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r(-2+r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{0, 2\}$$

- The coefficients of each power of x must be 0

  $$[a_1(1+r)\,(-1+r) - a_0 a r = 0, a_2(2+r)\, r - a a_1(1+r) = 0, a_3(3+r)\,(1+r) - a a_2(2+r) - a_0$$

- Solve for the dependent coefficient(s)

  $$\left\{a_1 = \frac{a_0 a r}{r^2-1}, a_2 = \frac{a^2 a_0}{r^2+r-2}, a_3 = \frac{a a_0 (a^2+br-b)}{r^3+3r^2-r-3}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$a_{k+1}(k+1+r)\,(k+r-1) + (-b a_{k-2} - k a_k - r a_k)\, a - a_{k-3} b^2 = 0$$

- Shift index using $k->k+3$

  $$a_{k+4}(k+4+r)\,(k+2+r) + (-b a_{k+1} - (k+3)\, a_{k+3} - r a_{k+3})\, a - a_k b^2 = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+4} = \frac{a b a_{k+1} + a k a_{k+3} + a r a_{k+3} + a_k b^2 + 3 a a_{k+3}}{(k+4+r)(k+2+r)}$$

- Recursion relation for $r = 0$

$$a_{k+4} = \frac{ab a_{k+1} + ak a_{k+3} + a_k b^2 + 3a a_{k+3}}{(k+4)(k+2)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = \frac{ab a_{k+1} + ak a_{k+3} + a_k b^2 + 3a a_{k+3}}{(k+4)(k+2)}, a_1 = 0, a_2 = -\frac{a^2 a_0}{2}, a_3 = -\frac{a a_0 (a^2 - b)}{3}\right]$$

- Recursion relation for $r = 2$

$$a_{k+4} = \frac{ab a_{k+1} + ak a_{k+3} + a_k b^2 + 5a a_{k+3}}{(k+6)(k+4)}$$

- Solution for $r = 2$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+4} = \frac{ab a_{k+1} + ak a_{k+3} + a_k b^2 + 5a a_{k+3}}{(k+6)(k+4)}, a_1 = \frac{2a a_0}{3}, a_2 = \frac{a^2 a_0}{4}, a_3 = \frac{a a_0 (a^2 + b)}{15}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^k\right) + \left(\sum_{k=0}^{\infty} d_k x^{k+2}\right), c_{k+4} = \frac{abc_{1+k} + akc_{k+3} + b^2 c_k + 3ac_{k+3}}{(k+4)(k+2)}, c_1 = 0, c_2 = -\frac{a^2 c_0}{2}, c_3 = -\frac{ac_0(}{}\right.$$

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''-(2ax+1)\,y'+\left(x^3b+a^2x+a\right)y=0}$$

28.16.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+(-2ax-1)\,y'+\left(x^3b+a^2x+a\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= -2ax-1 \\ C &= x^3b+a^2x+a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4b\,x^4 + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4b\,x^4 + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-4b\,x^4 + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 90: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 2 - 4\\ &= -2\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -b\,x^2 + \frac{3}{4x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{3}{2}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = -\frac{1}{2}\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i\\ &= \sum_{i=0}^{1} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx i\sqrt{b}\,x - \frac{3i}{8\sqrt{b}\,x^3} - \frac{9i}{128b^{\frac{3}{2}}x^7} - \frac{27i}{1024b^{\frac{5}{2}}x^{11}} - \frac{405i}{32768b^{\frac{7}{2}}x^{15}} - \frac{1701i}{262144b^{\frac{9}{2}}x^{19}} - \frac{15309i}{4194304b^{\frac{11}{2}}x^{23}} - \frac{72171i}{335554432b^{\frac{13}{2}}x^{27}} \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = i\sqrt{b}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= i\sqrt{b}\,x \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = -b\,x^2$$

This shows that the coefficient of 1 in the above is 0. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{-4b\,x^4 + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(-b\,x^2\right) + \left(\frac{3}{4x^2}\right) \\ &= -b\,x^2 + \frac{3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= i\sqrt{b}\, x \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{i\sqrt{b}} - 1\right) &&= -\frac{1}{2} \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{i\sqrt{b}} - 1\right) &&= -\frac{1}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{-4b\, x^4 + 3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$i\sqrt{b}\, x$	$-\frac{1}{2}$	$-\frac{1}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= -\frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (-)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + (-)\left(i\sqrt{b}\, x\right) \\
&= -\frac{1}{2x} - i\sqrt{b}\, x \\
&= \frac{-2i\sqrt{b}\, x^2 - 1}{2x}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$\begin{aligned}
(0) + 2\left(-\frac{1}{2x} - i\sqrt{b}\, x\right)(0) + \left(\left(\frac{1}{2x^2} - i\sqrt{b}\right) + \left(-\frac{1}{2x} - i\sqrt{b}\, x\right)^2 - \left(\frac{-4b\, x^4 + 3}{4x^2}\right)\right) &= 0 \\
0 &= 0
\end{aligned}$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(-\frac{1}{2x} - i\sqrt{b}\, x\right) dx} \\
&= \frac{\mathrm{e}^{-\frac{i\sqrt{b}\, x^2}{2}}}{\sqrt{x}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2ax-1}{x}\, dx} \\
&= z_1 e^{ax + \frac{\ln(x)}{2}} \\
&= z_1 \left(\sqrt{x}\, \mathrm{e}^{ax}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{ax-\frac{i\sqrt{b}\,x^2}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2ax-1}{x}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2ax+\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(-\frac{i\mathrm{e}^{i\sqrt{b}\,x^2}}{2\sqrt{b}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{ax-\frac{i\sqrt{b}\,x^2}{2}}\right) + c_2 \left(\mathrm{e}^{ax-\frac{i\sqrt{b}\,x^2}{2}} \left(-\frac{i\mathrm{e}^{i\sqrt{b}\,x^2}}{2\sqrt{b}}\right)\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{ax-\frac{i\sqrt{b}\,x^2}{2}} - \frac{ic_2 \mathrm{e}^{\frac{x\left(i\sqrt{b}\,x+2a\right)}{2}}}{2\sqrt{b}} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 \mathrm{e}^{ax-\frac{i\sqrt{b}\,x^2}{2}} - \frac{ic_2 \mathrm{e}^{\frac{x\left(i\sqrt{b}\,x+2a\right)}{2}}}{2\sqrt{b}}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 77.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_missing_y"**

Maple gives the following as the ode type

`[[_2nd_order, _missing_y]]`

$$\boxed{xy''+(ax+b)\,y'=-cx\left(-c\,x^2+ax+b+1\right)}$$

28.17.1 Solving as second order ode missing y ode

This is second order ode with missing dependent variable y. Let

$$p(x)=y'$$

Then

$$p'(x)=y''$$

Hence the ode becomes

$$p'(x)\,x+(ax+b)\,p(x)+cx\left(-c\,x^2+ax+b+1\right)=0$$

Which is now solve for $p(x)$ as first order ode.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$p'(x)+p(x)p(x)=q(x)$$

Where here

$$p(x) = -\frac{-ax-b}{x}$$
$$q(x) = -c(-c\,x^2+ax+b+1)$$

Hence the ode is

$$p'(x) - \frac{(-ax-b)\,p(x)}{x} = -c(-c\,x^2+ax+b+1)$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-ax-b}{x}dx}$$
$$= \mathrm{e}^{ax+b\ln(x)}$$

Which simplifies to

$$\mu = x^b \mathrm{e}^{ax}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu p) = (\mu)\left(-c(-c\,x^2+ax+b+1)\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(x^b\mathrm{e}^{ax}p\right) = \left(x^b\mathrm{e}^{ax}\right)\left(-c(-c\,x^2+ax+b+1)\right)$$
$$\mathrm{d}\left(x^b\mathrm{e}^{ax}p\right) = \left(-c(-c\,x^2+ax+b+1)\,x^b\mathrm{e}^{ax}\right)\,\mathrm{d}x$$

Integrating gives

$$x^b\mathrm{e}^{ax}p = \int -c(-c\,x^2+ax+b+1)\,x^b\mathrm{e}^{ax}\,\mathrm{d}x$$
$$x^b\mathrm{e}^{ax}p = -\frac{(-a)^{-b}\,c^2\left(x^b(-a)^b\,b(b^2+3b+2)\,\Gamma(b)\,(-ax)^{-b} - x^b(-a)^b\,(a^2x^2-abx-2ax+b^2+3b+2)\,\mathrm{e}^{a}}{a^3}$$

Dividing both sides by the integrating factor $\mu = x^b\mathrm{e}^{ax}$ results in

$$p(x) = x^{-b}\mathrm{e}^{-ax}\left(-\frac{(-a)^{-b}\,c^2\left(x^b(-a)^b\,b(b^2+3b+2)\,\Gamma(b)\,(-ax)^{-b} - x^b(-a)^b\,(a^2x^2-abx-2ax+b^2+3b\right.}{a^3}\right.$$

which simplifies to

$$p(x) = \frac{c^2\mathrm{e}^{-ax}((b^3+3b^2+2b)\,\Gamma(b,-ax) - \Gamma(b+3))\,(-ax)^{-b} + x^{-b}c_1a^3\mathrm{e}^{-ax} - c((-a^2x^2+x(2+b)\,a-b^2}{a^3}$$

Since $p = y'$ then the new first order ode to solve is

$$y' = \frac{c^2 e^{-ax}((b^3 + 3b^2 + 2b)\,\Gamma(b, -ax) - \Gamma(b+3))\,(-ax)^{-b} + x^{-b}c_1 a^3 e^{-ax} - c((-a^2x^2 + x(2+b)\,a - b^2 -}{a^3}$$

Integrating both sides gives

$$y = \int \frac{(-ax)^{-b}\, b^3 c^2 \Gamma(b, -ax)\, e^{-ax} + a^2c^2x^2 + 3(-ax)^{-b}\, b^2c^2\Gamma(b, -ax)\, e^{-ax} - a^3cx - a\,c^2bx + x^{-b}c_1a^3e^{-a}}{a^3}$$

$$= \int \frac{(-ax)^{-b}\, b^3 c^2 \Gamma(b, -ax)\, e^{-ax} + a^2c^2x^2 + 3(-ax)^{-b}\, b^2c^2\Gamma(b, -ax)\, e^{-ax} - a^3cx - a\,c^2bx + x^{-b}c_1a^3e^{-a}}{a^3}$$

Summary

The solution(s) found are the following

$$y = \int \frac{(-ax)^{-b}\, b^3 c^2 \Gamma(b, -ax)\, e^{-ax} + a^2c^2x^2 + 3(-ax)^{-b}\, b^2c^2\Gamma(b, -ax)\, e^{-ax} - a^3cx - a\,c^2bx + x^{-b}c_1a^3e^{-ax} -}{a^3} + c_2 \tag{1}$$

Verification of solutions

$$y = \int \frac{(-ax)^{-b}\, b^3 c^2 \Gamma(b, -ax)\, e^{-ax} + a^2c^2x^2 + 3(-ax)^{-b}\, b^2c^2\Gamma(b, -ax)\, e^{-ax} - a^3cx - a\,c^2bx + x^{-b}c_1a^3e^{-ax} -}{a^3} + c_2$$

Verified OK.

28.17.2 Maple step by step solution

Let's solve

$y''x + (ax + b)\, y' = -cx(-c\,x^2 + ax + b + 1)$

- Highest derivative means the order of the ODE is 2

  y''

- Make substitution $u = y'$ to reduce order of ODE

  $u'(x)\, x + (ax + b)\, u(x) = -cx(-c\,x^2 + ax + b + 1)$

- Isolate the derivative

  $u'(x) = -\frac{(ax+b)u(x)}{x} - c(-c\,x^2 + ax + b + 1)$

- Group terms with $u(x)$ on the lhs of the ODE and the rest on the rhs of the ODE

$$u'(x) + \frac{(ax+b)u(x)}{x} = -c(-c\,x^2 + ax + b + 1)$$

- The ODE is linear; multiply by an integrating factor $\mu(x)$

$$\mu(x)\left(u'(x) + \frac{(ax+b)u(x)}{x}\right) = -\mu(x)\,c(-c\,x^2 + ax + b + 1)$$

- Assume the lhs of the ODE is the total derivative $\frac{d}{dx}(\mu(x)\,u(x))$

$$\mu(x)\left(u'(x) + \frac{(ax+b)u(x)}{x}\right) = \mu'(x)\,u(x) + \mu(x)\,u'(x)$$

- Isolate $\mu'(x)$

$$\mu'(x) = \frac{\mu(x)(ax+b)}{x}$$

- Solve to find the integrating factor

$$\mu(x) = x^b \mathrm{e}^{ax}$$

- Integrate both sides with respect to x

$$\int \left(\frac{d}{dx}(\mu(x)\,u(x))\right) dx = \int -\mu(x)\,c(-c\,x^2 + ax + b + 1)\,dx + c_1$$

- Evaluate the integral on the lhs

$$\mu(x)\,u(x) = \int -\mu(x)\,c(-c\,x^2 + ax + b + 1)\,dx + c_1$$

- Solve for $u(x)$

$$u(x) = \frac{\int -\mu(x)c(-c\,x^2+ax+b+1)dx + c_1}{\mu(x)}$$

- Substitute $\mu(x) = x^b \mathrm{e}^{ax}$

$$u(x) = \frac{\int -c(-c\,x^2+ax+b+1)x^b\mathrm{e}^{ax}dx + c_1}{x^b\mathrm{e}^{ax}}$$

- Evaluate the integrals on the rhs

$$u(x) = \frac{-\frac{(-a)^{-b}c^2\left(x^b(-a)^b b\left(b^2+3b+2\right)\Gamma(b)(-ax)^{-b} - x^b(-a)^b\left(a^2x^2 - abx - 2ax + b^2 + 3b + 2\right)\mathrm{e}^{ax} - x^b(-a)^b b\left(b^2+3b+2\right)(-ax)^{-b}\Gamma(b,-ax)\right)}{a^3} - \frac{(-\cdots}{\cdots}}{\cdots}$$

- Simplify

$$u(x) = \frac{c^2\mathrm{e}^{-ax}\left(\left(b^3+3b^2+2b\right)\Gamma(b,-ax) - \Gamma(b+3)\right)(-ax)^{-b} + x^{-b}c_1a^3\mathrm{e}^{-ax} - c\left(\left(-a^2x^2+x(2+b)a-b^2-3b-2\right)c+a^3x\right)}{a^3}$$

- Solve 1st ODE for $u(x)$

$$u(x) = \frac{c^2\mathrm{e}^{-ax}\left(\left(b^3+3b^2+2b\right)\Gamma(b,-ax) - \Gamma(b+3)\right)(-ax)^{-b} + x^{-b}c_1a^3\mathrm{e}^{-ax} - c\left(\left(-a^2x^2+x(2+b)a-b^2-3b-2\right)c+a^3x\right)}{a^3}$$

- Make substitution $u = y'$

$$y' = \frac{c^2\mathrm{e}^{-ax}\left(\left(b^3+3b^2+2b\right)\Gamma(b,-ax) - \Gamma(b+3)\right)(-ax)^{-b} + x^{-b}c_1a^3\mathrm{e}^{-ax} - c\left(\left(-a^2x^2+x(2+b)a-b^2-3b-2\right)c+a^3x\right)}{a^3}$$

- Integrate both sides to solve for y

$$\int y'dx = \int \frac{c^2\mathrm{e}^{-ax}\left(\left(b^3+3b^2+2b\right)\Gamma(b,-ax) - \Gamma(b+3)\right)(-ax)^{-b} + x^{-b}c_1a^3\mathrm{e}^{-ax} - c\left(\left(-a^2x^2+x(2+b)a-b^2-3b-2\right)c+a^3x\right)}{a^3}dx + c_2$$

- Compute integrals

$$y = \int \frac{c^2 \mathrm{e}^{-ax}((b^3+3b^2+2b)\Gamma(b,-ax)-\Gamma(b+3))(-ax)^{-b}+x^{-b}c_1a^3\mathrm{e}^{-ax}-c((-a^2x^2+x(2+b)a-b^2-3b-2)c+a^3x)}{a^3}dx + c_2$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 79.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{xy''+\left(ab\,x^2+b-5\right)y'+2a^2(-2+b)\,x^3y=0}$$

28.19.1 Maple step by step solution

Let's solve

$y''x+\left(ab\,x^2+b-5\right)y'+2a^2(-2+b)\,x^3y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{\left(ab\,x^2+b-5\right)y'}{x}-2x^2a^2(-2+b)\,y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{\left(ab\,x^2+b-5\right)y'}{x}+2x^2a^2(-2+b)\,y=0$

□ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{ab\,x^2+b-5}{x}, P_3(x) = 2a^2x^2(-2+b)\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = b - 5$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (ab\,x^2 + b - 5)\,y' + 2a^2(-2+b)\,x^3y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^3 \cdot y$ to series expansion

  $x^3 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+3}$

- Shift index using $k- >k-3$

  $x^3 \cdot y = \sum_{k=3}^{\infty} a_{k-3} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-1}$

- Shift index using $k- >k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-6+r+b)\, x^{-1+r} + a_1(1+r)(-5+r+b)\, x^r + (a_2(2+r)(-4+r+b) + a_0 abr)\, x^{1+r} + (a_3$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-6+r+b) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, -b+6\}$

- The coefficients of each power of x must be 0

  $[a_1(1+r)(-5+r+b) = 0, a_2(2+r)(-4+r+b) + a_0 abr = 0, a_3(3+r)(-3+r+b) + a_1(1+$

- Solve for the dependent coefficient(s)

  $\left\{a_1 = 0, a_2 = -\frac{a_0 abr}{rb+r^2+2b-2r-8}, a_3 = 0\right\}$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)(k-5+r+b) + a_{k-1}(k+r-1)\, ab + 2a_{k-3}a^2(-2+b) = 0$

- Shift index using $k->k+3$

  $a_{k+4}(k+4+r)(k-2+r+b) + a_{k+2}(k+2+r)\, ab + 2a_k a^2(-2+b) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+4} = -\frac{a(2aba_k+bka_{k+2}+bra_{k+2}-4aa_k+2ba_{k+2})}{(k+4+r)(k-2+r+b)}$

- Recursion relation for $r = 0$

  $a_{k+4} = -\frac{a(2aba_k+bka_{k+2}-4aa_k+2ba_{k+2})}{(k+4)(k-2+b)}$

- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+4} = -\frac{a(2aba_k+bka_{k+2}-4aa_k+2ba_{k+2})}{(k+4)(k-2+b)}, a_1 = 0, a_2 = 0, a_3 = 0\right]$

- Recursion relation for $r = -b+6$

  $a_{k+4} = -\frac{a(2aba_k+bka_{k+2}+b(-b+6)a_{k+2}-4aa_k+2ba_{k+2})}{(k+10-b)(k+4)}$

- Solution for $r = -b+6$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-b+6}, a_{k+4} = -\frac{a(2aba_k+bka_{k+2}+b(-b+6)a_{k+2}-4aa_k+2ba_{k+2})}{(k+10-b)(k+4)}, a_1 = 0, a_2 = -\frac{a_0 ab(-b+6)}{(-b+6)b+(-b+6)^2+}\right.$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^k\right) + \left(\sum_{k=0}^{\infty} d_k x^{k-b+6}\right), c_{k+4} = -\frac{a(2abc_k+bkc_{k+2}-4ac_k+2bc_{k+2})}{(k+4)(k-2+b)}, c_1 = 0, c_2 = 0, c_3 = 0, d_k\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 80.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{xy''+\left(a\,x^2+bx\right)y'-\left(ac\,x^2+\left(bc+c^2+a\right)x+b+2c\right)y=0}$$

28.20.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+x(ax+b)\,y'+\left(-c^2x+\left(-a\,x^2-bx-2\right)c-ax-b\right)y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= (ax+b)\,x \\ C &= -c^2x+\left(-a\,x^2-bx-2\right)c-ax-b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^3 a^2 + 2ab\,x^2 + 4ac\,x^2 + b^2 x + 4bcx + 4c^2 x + 6ax + 4b + 8c}{4x} \tag{6}$$

Comparing the above to (5) shows that

$$s = x^3 a^2 + 2ab\,x^2 + 4ac\,x^2 + b^2 x + 4bcx + 4c^2 x + 6ax + 4b + 8c$$
$$t = 4x$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{x^3 a^2 + 2ab\,x^2 + 4ac\,x^2 + b^2 x + 4bcx + 4c^2 x + 6ax + 4b + 8c}{4x}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 95: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 1 - 3 \\ &= -2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= 1 \\ \alpha_c^- &= 1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{b}{2} + c + \frac{ax}{2} + \frac{3}{2x} + \frac{2bc}{a^2x^3} - \frac{3b^2c}{a^3x^4} - \frac{6b\,c^2}{a^3x^4} + \frac{4b^3c}{a^4x^5} + \frac{12b^2c^2}{a^4x^5} + \frac{16b\,c^3}{a^4x^5} - \frac{22bc}{a^3x^5} - \frac{5b^4c}{a^5x^6} - \frac{20b^3c^2}{a^5x^6} - \frac{40b^2c^3}{a^5x^6} - \frac{40b\,c^4}{a^5x^6} + \cdots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v=1$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\
&= \frac{b}{2} + c + \frac{ax}{2} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2 + bc + \frac{1}{2}abx + c^2 + acx + \frac{1}{4}a^2x^2$$

This shows that the coefficient of 1 in the above is $\frac{1}{4}b^2 + bc + c^2$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v=0$ or not. Since $v=1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^3a^2 + 2ab\,x^2 + 4ac\,x^2 + b^2x + 4bcx + 4c^2x + 6ax + 4b + 8c}{4x} \\
&= Q + \frac{R}{4x} \\
&= \left(\frac{a^2x^2}{4} + \left(\frac{1}{2}ab + ac\right)x + \frac{b^2}{4} + bc + c^2 + \frac{3a}{2}\right) + \left(\frac{4b+8c}{4x}\right) \\
&= \frac{a^2x^2}{4} + \left(\frac{1}{2}ab + ac\right)x + \frac{b^2}{4} + bc + c^2 + \frac{3a}{2} + \frac{4b+8c}{4x}
\end{aligned}$$

We see that the coefficient of the term 1 in the quotient is $\frac{1}{4}b^2 + bc + c^2 + \frac{3}{2}a$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{1}{4}b^2 + bc + c^2 + \frac{3}{2}a\right) - \left(\frac{1}{4}b^2 + bc + c^2\right) \\
&= \frac{3a}{2}
\end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= \frac{b}{2} + c + \frac{ax}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) \quad = \frac{1}{2}\left(\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) \quad = 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) = -2
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{x^3a^2 + 2ab\,x^2 + 4ac\,x^2 + b^2x + 4bcx + 4c^2x + 6ax + 4b + 8c}{4x}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-2	$\frac{b}{2} + c + \frac{ax}{2}$	1	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{+} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{+} - \left(\alpha_{c_1}^{-}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{x} + \left(\frac{b}{2} + c + \frac{ax}{2}\right) \\
&= \frac{1}{x} + \frac{b}{2} + c + \frac{ax}{2} \\
&= \frac{1}{x} + \frac{b}{2} + c + \frac{ax}{2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{1}{x} + \frac{b}{2} + c + \frac{ax}{2}\right)(0) + \left(\left(-\frac{1}{x^2} + \frac{a}{2}\right) + \left(\frac{1}{x} + \frac{b}{2} + c + \frac{ax}{2}\right)^2 - \left(\frac{x^3 a^2 + 2ab\,x^2 + 4ac\,x^2 + b^2 x
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{x} + \frac{b}{2} + c + \frac{ax}{2}\right) dx} \\
&= x\,\mathrm{e}^{\frac{x(ax+2b+4c)}{4}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{(ax+b)x}{x} \, dx} \\
&= z_1 e^{-\frac{1}{4}a\,x^2 - \frac{1}{2}bx} \\
&= z_1 \left(\mathrm{e}^{-\frac{x(ax+2b)}{4}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{cx}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{(ax+b)x}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{1}{2}a\,x^2-bx}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{-\frac{x(ax+2b+4c)}{2}}}{x^2}dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1(x\,\mathrm{e}^{cx}) + c_2\left(x\,\mathrm{e}^{cx}\left(\int \frac{\mathrm{e}^{-\frac{x(ax+2b+4c)}{2}}}{x^2}dx\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x\,\mathrm{e}^{cx} + c_2 x\,\mathrm{e}^{cx}\left(\int \frac{\mathrm{e}^{-\frac{x(ax+2b+4c)}{2}}}{x^2}dx\right) \tag{1}$$

Verification of solutions

$$y = c_1 x\,\mathrm{e}^{cx} + c_2 x\,\mathrm{e}^{cx}\left(\int \frac{\mathrm{e}^{-\frac{x(ax+2b+4c)}{2}}}{x^2}dx\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 81.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(a\,x^{2}+bx+2\right)y'+yb=0}$$

28.21.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+\left(a\,x^{2}+bx+2\right)y'+yb=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= a\,x^{2}+bx+2 \\ C &= b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^2 + 2abx + b^2 + 6a}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^2 + 2abx + b^2 + 6a \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 + \frac{3}{2}a\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 96: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 2 \\ &= -2\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -2 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -2$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{2}{2} = 1$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{1} a_i x^i \qquad (8)\end{aligned}$$

Let a be the coefficient of $x^v = x^1$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ax}{2} + \frac{b}{2} + \frac{3}{2x} - \frac{3b}{2a\,x^2} + \frac{3b^2}{2a^2x^3} - \frac{9}{4a\,x^3} - \frac{3b^3}{2a^3x^4} + \frac{27b}{4a^2x^4} + \frac{3b^4}{2a^4x^5} - \frac{27b^2}{2a^3x^5} - \frac{3b^5}{2a^5x^6} + \frac{27}{4a^2x^5} + \frac{45b^3}{2a^4x^6} - \frac{135b}{4a^3x^6} + \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 1$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{1} a_i x^i \\ &= \frac{ax}{2} + \frac{b}{2} \qquad (10)\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^0 = 1$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2$$

This shows that the coefficient of 1 in the above is $\frac{b^2}{4}$. Now we need to find the coefficient of 1 in r. How this is done depends on if $v = 0$ or not. Since $v = 1$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of 1 in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^2 + 2abx + b^2 + 6a}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 + \frac{3}{2}a\right) + (0) \\
&= \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 + \frac{3}{2}a
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $\frac{3a}{2} + \frac{b^2}{4}$. Now b can be found.

$$\begin{aligned}
b &= \left(\frac{3a}{2} + \frac{b^2}{4}\right) - \left(\frac{b^2}{4}\right) \\
&= \frac{3a}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{ax}{2} + \frac{b}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) &= 1 \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) = \frac{1}{2}\left(-\frac{\frac{3a}{2}}{\frac{a}{2}} - 1\right) = -2
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 + \frac{3}{2}a$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-2	$\frac{ax}{2}+\frac{b}{2}$	1	-2

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = 1$, and since there are no poles, then

$$\begin{aligned} d &= \alpha_\infty^+ \\ &= 1 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned} \omega &= (+)[\sqrt{r}]_\infty \\ &= 0 + \left(\frac{ax}{2} + \frac{b}{2}\right) \\ &= \frac{ax}{2} + \frac{b}{2} \\ &= \frac{ax}{2} + \frac{b}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{ax}{2} + \frac{b}{2}\right)(1) + \left(\left(\frac{a}{2}\right) + \left(\frac{ax}{2} + \frac{b}{2}\right)^2 - \left(\frac{1}{4}a^2x^2 + \frac{1}{2}abx + \frac{1}{4}b^2 + \frac{3}{2}a\right)\right) = 0$$

$$-aa_0 + b = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{b}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{b}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{b}{a}\right) \mathrm{e}^{\int \left(\frac{ax}{2} + \frac{b}{2}\right) dx} \\
&= \left(x + \frac{b}{a}\right) \mathrm{e}^{\frac{1}{4} a\, x^2 + \frac{1}{2} b x} \\
&= \frac{(ax + b)\, \mathrm{e}^{\frac{x(ax+2b)}{4}}}{a}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{a\, x^2 + bx + 2}{x} \, dx} \\
&= z_1 e^{-\frac{a\, x^2}{4} - \frac{bx}{2} - \ln(x)} \\
&= z_1 \left(\frac{\mathrm{e}^{-\frac{x(ax+2b)}{4}}}{x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{ax + b}{xa}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^2+bx+2}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{a\,x^2}{2}-bx-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\left(\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{b^2}{2a}}(ax+b)\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)+2\,\mathrm{e}^{-\frac{x(ax+2b)}{2}}\sqrt{a}\right)\sqrt{a}}{2ax+2b}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{ax+b}{xa}\right) \\
&\quad + c_2\left(\frac{ax+b}{xa}\left(-\frac{\left(\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{b^2}{2a}}(ax+b)\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)+2\,\mathrm{e}^{-\frac{x(ax+2b)}{2}}\sqrt{a}\right)\sqrt{a}}{2ax+2b}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1(ax+b)}{xa} - \frac{c_2\left(\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{b^2}{2a}}(ax+b)\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)+2\,\mathrm{e}^{-\frac{x(ax+2b)}{2}}\sqrt{a}\right)}{2\sqrt{a}\,x} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1(ax+b)}{xa} - \frac{c_2\left(\sqrt{2}\,\sqrt{\pi}\,\mathrm{e}^{\frac{b^2}{2a}}(ax+b)\,\mathrm{erf}\left(\frac{\sqrt{2}\,(ax+b)}{2\sqrt{a}}\right)+2\,\mathrm{e}^{-\frac{x(ax+2b)}{2}}\sqrt{a}\right)}{2\sqrt{a}\,x}
$$

Verified OK.

28.21.2 Maple step by step solution

Let's solve

$y''x + (a\,x^2 + bx + 2)\,y' + yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{by}{x} - \frac{(a\,x^2+bx+2)\,y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a\,x^2+bx+2)\,y'}{x} + \frac{by}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{a\,x^2+bx+2}{x}, P_3(x) = \frac{b}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = 2$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x + (a\,x^2 + bx + 2)\,y' + yb = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $x^{m}\cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x\cdot y''$ to series expansion

  $x\cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$

- Shift index using $k->k+1$

  $x\cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0r(1+r)\, x^{-1+r} + (a_1(1+r)\,(2+r) + a_0b(1+r))\, x^{r} + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)\,(k+2+r) + a_kb($

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 0\}$

- Each term must be 0

  $a_1(1+r)\,(2+r) + a_0b(1+r) = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)\,(k+2+r) + a_kb(k+1+r) + a_{k-1}(k+r-1)\, a = 0$

- Shift index using $k->k+1$

  $a_{k+2}(k+2+r)\,(k+3+r) + a_{k+1}b(k+2+r) + a_k(k+r)\, a = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{aka_k + ara_k + bka_{k+1} + bra_{k+1} + 2ba_{k+1}}{(k+2+r)(k+3+r)}$

- Recursion relation for $r=-1$

  $a_{k+2} = -\frac{aka_k + bka_{k+1} - aa_k + ba_{k+1}}{(k+1)(k+2)}$

- Solution for $r=-1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{aka_k + bka_{k+1} - aa_k + ba_{k+1}}{(k+1)(k+2)}, 0 = 0\right]$

- Recursion relation for $r=0$

  $a_{k+2} = -\frac{aka_k + bka_{k+1} + 2ba_{k+1}}{(k+2)(k+3)}$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{ak a_k+bk a_{k+1}+2b a_{k+1}}{(k+2)(k+3)}, a_0 b+2a_1=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} c_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty} d_k x^k\right), c_{k+2}=-\frac{ak c_k+bk c_{1+k}-a c_k+b c_{1+k}}{(1+k)(k+2)}, 0=0, d_{k+2}=-\frac{ak d_k+bk d_{1+k}+2b d_1}{(k+2)(k+3)}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 82.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{xy''+\left(a\,x^{2}+bx+c\right)y'+\left(2ax+b\right)y=0}$$

28.22.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(xy''+\left(a\,x^{2}+bx+c\right)y'+\left(2ax+b\right)y\right)dx=0$$
$$\left(a\,x^{2}+bx+c-1\right)y+y'x=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{-a\,x^{2}-bx-c+1}{x}\\
q(x) &= \frac{c_1}{x}
\end{aligned}
$$

Hence the ode is

$$
y'-\frac{\left(-a\,x^{2}-bx-c+1\right)y}{x} = \frac{c_1}{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{-a\,x^{2}-bx-c+1}{x}dx}\\
&= \mathrm{e}^{\frac{a\,x^{2}}{2}+bx+(c-1)\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
\mu = x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left(x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y\right) &= \left(x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)\left(\frac{c_1}{x}\right)\\
\mathrm{d}\left(x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y\right) &= \left(c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y &= \int c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}\,\mathrm{d}x\\
x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y &= \int c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}dx + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}$ results in

$$
y = x^{-c+1}\mathrm{e}^{-\frac{x(ax+2b)}{2}}\left(\int c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}dx\right) + c_2x^{-c+1}\mathrm{e}^{-\frac{x(ax+2b)}{2}}
$$

which simplifies to

$$
y = x^{-c+1}\mathrm{e}^{-\frac{x(ax+2b)}{2}}\left(c_1\left(\int x^{c-2}\mathrm{e}^{\frac{1}{2}a\,x^{2}+bx}dx\right)+c_2\right)
$$

Summary
The solution(s) found are the following

$$y = x^{-c+1} \mathrm{e}^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} \mathrm{e}^{\frac{1}{2} a\, x^2 + bx} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = x^{-c+1} \mathrm{e}^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} \mathrm{e}^{\frac{1}{2} a\, x^2 + bx} dx\right) + c_2\right)$$

Verified OK.

28.22.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' + \left(a\, x^2 + bx + c\right) y' + (2ax + b)\, y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(xy'' + \left(a\, x^2 + bx + c\right) y' + (2ax + b)\, y\right) dx = 0$$
$$\left(a\, x^2 + bx + c - 1\right) y + y'x = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-a\, x^2 - bx - c + 1}{x}$$
$$q(x) = \frac{c_1}{x}$$

Hence the ode is

$$y' - \frac{\left(-a\, x^2 - bx - c + 1\right) y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-a\, x^2 - bx - c + 1}{x} dx}$$
$$= \mathrm{e}^{\frac{a\, x^2}{2} + bx + (c-1)\ln(x)}$$

Which simplifies to

$$\mu = x^{c-1} e^{\frac{x(ax+2b)}{2}}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right) \\
\frac{d}{dx}\left(x^{c-1} e^{\frac{x(ax+2b)}{2}} y\right) &= \left(x^{c-1} e^{\frac{x(ax+2b)}{2}}\right)\left(\frac{c_1}{x}\right) \\
d\left(x^{c-1} e^{\frac{x(ax+2b)}{2}} y\right) &= \left(c_1 x^{c-2} e^{\frac{x(ax+2b)}{2}}\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
x^{c-1} e^{\frac{x(ax+2b)}{2}} y &= \int c_1 x^{c-2} e^{\frac{x(ax+2b)}{2}} dx \\
x^{c-1} e^{\frac{x(ax+2b)}{2}} y &= \int c_1 x^{c-2} e^{\frac{x(ax+2b)}{2}} dx + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = x^{c-1} e^{\frac{x(ax+2b)}{2}}$ results in

$$y = x^{-c+1} e^{-\frac{x(ax+2b)}{2}} \left(\int c_1 x^{c-2} e^{\frac{x(ax+2b)}{2}} dx\right) + c_2 x^{-c+1} e^{-\frac{x(ax+2b)}{2}}$$

which simplifies to

$$y = x^{-c+1} e^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} e^{\frac{1}{2} a x^2 + bx} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = x^{-c+1} e^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} e^{\frac{1}{2} a x^2 + bx} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = x^{-c+1} e^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} e^{\frac{1}{2} a x^2 + bx} dx\right) + c_2\right)$$

Verified OK.

28.22.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x \\ q(x) &= a\,x^2 + bx + c \\ r(x) &= 2ax + b \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= 2ax + b \end{aligned}$$

Therefore (1) becomes

$$0 - (2ax + b) + (2ax + b) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$\left(a\,x^2 + bx + c - 1\right) y + y'x = c_1$$

We now have a first order ode to solve which is

$$\left(a\,x^2 + bx + c - 1\right) y + y'x = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{-a\,x^2-bx-c+1}{x}\\
q(x) &= \frac{c_1}{x}
\end{aligned}
$$

Hence the ode is

$$
y'-\frac{(-a\,x^2-bx-c+1)\,y}{x}=\frac{c_1}{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{-a\,x^2-bx-c+1}{x}dx}\\
&= \mathrm{e}^{\frac{a\,x^2}{2}+bx+(c-1)\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
\mu = x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left(x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y\right) &= \left(x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)\left(\frac{c_1}{x}\right)\\
\mathrm{d}\left(x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y\right) &= \left(c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y &= \int c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}\,\mathrm{d}x\\
x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}y &= \int c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}dx + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = x^{c-1}\mathrm{e}^{\frac{x(ax+2b)}{2}}$ results in

$$
y = x^{-c+1}\mathrm{e}^{-\frac{x(ax+2b)}{2}}\left(\int c_1x^{c-2}\mathrm{e}^{\frac{x(ax+2b)}{2}}dx\right)+c_2x^{-c+1}\mathrm{e}^{-\frac{x(ax+2b)}{2}}
$$

which simplifies to

$$
y = x^{-c+1}\mathrm{e}^{-\frac{x(ax+2b)}{2}}\left(c_1\left(\int x^{c-2}\mathrm{e}^{\frac{1}{2}a\,x^2+bx}dx\right)+c_2\right)
$$

Summary
The solution(s) found are the following

$$y = x^{-c+1} e^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} e^{\frac{1}{2} a x^2 + bx} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = x^{-c+1} e^{-\frac{x(ax+2b)}{2}} \left(c_1 \left(\int x^{c-2} e^{\frac{1}{2} a x^2 + bx} dx\right) + c_2\right)$$

Verified OK.

28.22.4 Maple step by step solution

Let's solve

$y'' x + (a x^2 + bx + c) y' + (2ax + b) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(2ax+b)y}{x} - \frac{(a x^2+bx+c)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a x^2+bx+c)y'}{x} + \frac{(2ax+b)y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = \frac{a x^2+bx+c}{x}, P_3(x) = \frac{2ax+b}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = c$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x+(a\,x^{2}+bx+c)\,y'+(2ax+b)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_{k} x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^{m}\cdot y$ to series expansion for $m=0..1$

    $x^{m}\cdot y=\sum_{k=0}^{\infty} a_{k} x^{k+r+m}$

  - Shift index using $k->k-m$

    $x^{m}\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^{m}\cdot y'$ to series expansion for $m=0..2$

    $x^{m}\cdot y'=\sum_{k=0}^{\infty} a_{k}(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^{m}\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x\cdot y''$ to series expansion

    $x\cdot y''=\sum_{k=0}^{\infty} a_{k}(k+r)\,(k+r-1)\,x^{k+r-1}$

  - Shift index using $k->k+1$

    $x\cdot y''=\sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}r(-1+r+c)\,x^{-1+r}+(a_{1}(1+r)\,(r+c)+a_{0}b(1+r))\,x^{r}+\left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)\,(k+r+c)\right.$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $r(-1+r+c)=0$

- Values of r that satisfy the indicial equation

  $r\in\{0,-c+1\}$

- Each term must be 0

  $a_{1}(1+r)\,(r+c)+a_{0}b(1+r)=0$

- Each term in the series must be 0, giving the recursion relation

  $(k+1+r)\left(a_{k+1}(k+r+c)+a_k b+a_{k-1}a\right)=0$
- Shift index using $k->k+1$

  $(k+r+2)\left(a_{k+2}(k+1+r+c)+a_{k+1}b+a_k a\right)=0$
- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a_k a+a_{k+1}b}{k+1+r+c}$
- Recursion relation for $r=0$

  $a_{k+2}=-\frac{a_k a+a_{k+1}b}{k+1+c}$
- Solution for $r=0$

  $\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{a_k a+a_{k+1}b}{k+1+c}, a_0 b+a_1 c=0\right]$
- Recursion relation for $r=-c+1$

  $a_{k+2}=-\frac{a_k a+a_{k+1}b}{k+2}$
- Solution for $r=-c+1$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-c+1}, a_{k+2}=-\frac{a_k a+a_{k+1}b}{k+2}, a_1(-c+2)+a_0 b(-c+2)=0\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} d_k x^k\right)+\left(\sum_{k=0}^{\infty} e_k x^{k-c+1}\right), d_{k+2}=-\frac{a d_k+b d_{1+k}}{k+1+c}, b d_0+c d_1=0, e_{k+2}=-\frac{a e_k+b e_{1+k}}{k+2}, e_1(-c\right.$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 83.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$
\boxed{xy''+\left(a\,x^{2}+bx+c\right)y'+\left(c-1\right)\left(ax+b\right)y=0}
$$

28.23.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$
xy''+\left(a\,x^{2}+bx+c\right)y'+\left(c-1\right)\left(ax+b\right)y=0 \tag{1}
$$

Becomes

$$
y''+p(x)\,y'+q(x)\,y=0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x)&=\frac{a\,x^{2}+bx+c}{x}\\
q(x)&=\frac{\left(c-1\right)\left(ax+b\right)}{x}
\end{aligned}
$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(a\,x^2 + bx + c)}{x^2} + \frac{(c-1)\,(ax+b)}{x} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -c + 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{-2c+2}{x} + \frac{a\,x^2 + bx + c}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(a\,x^2 + bx - c + 2)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(a\,x^2 + bx - c + 2)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(a\,x^2 + bx - c + 2)\, u}{x} \end{aligned}$$

Where $f(x) = -\frac{a\,x^2+bx-c+2}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{a\,x^2+bx-c+2}{x}\,dx\\
\int \frac{1}{u}\,du &= \int -\frac{a\,x^2+bx-c+2}{x}\,dx\\
\ln\left(u\right) &= -\frac{a\,x^2}{2}-bx-\left(-c+2\right)\ln\left(x\right)+c_1\\
u &= \mathrm{e}^{-\frac{a\,x^2}{2}-bx-\left(-c+2\right)\ln\left(x\right)+c_1}\\
&= c_1\mathrm{e}^{-\frac{a\,x^2}{2}-bx-\left(-c+2\right)\ln\left(x\right)}
\end{aligned}
$$

Which simplifies to

$$
u(x) = \frac{c_1\mathrm{e}^{-\frac{a\,x^2}{2}}\mathrm{e}^{-bx}x^c}{x^2}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x)\\
v(x) &= \int u(x)\,dx + c_2\\
&= \int \frac{c_1\mathrm{e}^{-\frac{a\,x^2}{2}}\mathrm{e}^{-bx}x^c}{x^2}dx + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n\\
&= \left(\int \frac{c_1\mathrm{e}^{-\frac{a\,x^2}{2}}\mathrm{e}^{-bx}x^c}{x^2}dx + c_2\right)x^{-c+1}\\
&= x^{-c+1}\left(c_1\left(\int x^{c-2}\mathrm{e}^{-\frac{1}{2}a\,x^2-bx}dx\right)+c_2\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(\int \frac{c_1\mathrm{e}^{-\frac{a\,x^2}{2}}\mathrm{e}^{-bx}x^c}{x^2}dx + c_2\right)x^{-c+1} \tag{1}
$$

Verification of solutions

$$y = \left(\int \frac{c_1 \mathrm{e}^{-\frac{a\,x^2}{2}} \mathrm{e}^{-bx} x^c}{x^2} dx + c_2\right) x^{-c+1}$$

Verified OK.

28.23.2 Maple step by step solution

Let's solve

$y''x + (a\,x^2 + bx + c)\,y' + (c-1)\,(ax+b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(c-1)(ax+b)y}{x} - \frac{(a\,x^2+bx+c)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a\,x^2+bx+c)y'}{x} + \frac{(c-1)(ax+b)y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

- ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = c$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

- ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (a\,x^2 + bx + c)\,y' + (c-1)\,(ax+b)\,y = 0$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

$$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

$$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k- >k + 1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+r+c)\, x^{-1+r} + (a_1(1+r)\,(r+c) + a_0 b(-1+r+c))\, x^r + \left(\sum_{k=1}^{\infty} (a_{k+1}(k+1+r)\,(k+r\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+r+c) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, -c+1\}$$

- Each term must be 0

$$a_1(1+r)\,(r+c) + a_0 b(-1+r+c) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(k+r+c) + a_k b(k+r+c-1) + a_{k-1} a(k-2+r+c) = 0$$

- Shift index using $k- >k + 1$

$$a_{k+2}(k+2+r)(k+1+r+c)+a_{k+1}b(k+r+c)+a_k a(k+r+c-1)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{a_k ac+aka_k+ara_k+bca_{k+1}+bka_{k+1}+bra_{k+1}-a_k a}{(k+2+r)(k+1+r+c)}$$

- Recursion relation for $r=0$

$$a_{k+2}=-\frac{a_k ac+aka_k+bca_{k+1}+bka_{k+1}-a_k a}{(k+2)(k+1+c)}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty}a_k x^k, a_{k+2}=-\frac{a_k ac+aka_k+bca_{k+1}+bka_{k+1}-a_k a}{(k+2)(k+1+c)}, a_1 c+a_0 b(c-1)=0\right]$$

- Recursion relation for $r=-c+1$

$$a_{k+2}=-\frac{a_k ac+aka_k+a(-c+1)a_k+bca_{k+1}+bka_{k+1}+b(-c+1)a_{k+1}-a_k a}{(k+3-c)(k+2)}$$

- Solution for $r=-c+1$

$$\left[y=\sum_{k=0}^{\infty}a_k x^{k-c+1}, a_{k+2}=-\frac{a_k ac+aka_k+a(-c+1)a_k+bca_{k+1}+bka_{k+1}+b(-c+1)a_{k+1}-a_k a}{(k+3-c)(k+2)}, a_1(-c+2)=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}d_k x^k\right)+\left(\sum_{k=0}^{\infty}e_k x^{k-c+1}\right), d_{k+2}=-\frac{acd_k+akd_k+bcd_{1+k}+bkd_{1+k}-ad_k}{(k+2)(k+1+c)}, d_1 c+d_0 b(c-1)=0, e\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 84.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$
\boxed{xy''+\left(a\,x^{2}+bx+c\right)y'+\left(A\,x^{2}+Bx+\mathrm{C0}\right)y=0}
$$

28.24.1 Maple step by step solution

Let's solve

$y''x+\left(a\,x^{2}+bx+c\right)y'+\left(A\,x^{2}+Bx+C0\right)y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{\left(A\,x^{2}+Bx+C0\right)y}{x}-\frac{\left(a\,x^{2}+bx+c\right)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{\left(a\,x^{2}+bx+c\right)y'}{x}+\frac{\left(A\,x^{2}+Bx+C0\right)y}{x}=0$

☐ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{a x^2+bx+c}{x}, P_3(x) = \frac{A x^2+Bx+C0}{x}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = c$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (a x^2 + bx + c) y' + (A x^2 + Bx + C0) y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r) x^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r) x^{k+r}$

- Convert $x \cdot y''$ to series expansion

  $x \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r) (k + r - 1) x^{k+r-1}$

- Shift index using $k- >k + 1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+r+c)\,x^{-1+r} + (a_1(1+r)\,(r+c) + a_0(br+C0))\,x^r + (a_2(2+r)\,(1+r+c) + a_1(br+$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-1+r+c) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, -c+1\}$
- The coefficients of each power of x must be 0

  $[a_1(1+r)\,(r+c) + a_0(br+C0) = 0, a_2(2+r)\,(1+r+c) + a_1(br+C0+b) + a_0(ar+B) = 0]$
- Solve for the dependent coefficient(s)

  $\left\{a_1 = -\frac{a_0(br+C0)}{rc+r^2+c+r}, a_2 = -\frac{a_0(a\,r^2c+a\,r^3-b^2r^2+Brc+B\,r^2-2br\,C0+arc+a\,r^2-b^2r+Bc+Br-C0^2-C0b)}{r^2c^2+2r^3c+r^4+3r\,c^2+7r^2c+4r^3+2c^2+7rc+5r^2+2c+2r}\right\}$
- Each term in the series must be 0, giving the recursion relation

  $a_{k+1}(k+1+r)\,(k+r+c) + a_k((k+r)\,b+C0) + a_{k-1}((k+r-1)\,a+B) + Aa_{k-2} = 0$
- Shift index using $k- >k+2$

  $a_{k+3}(k+3+r)\,(k+2+r+c) + a_{k+2}((k+2+r)\,b+C0) + a_{k+1}((k+1+r)\,a+B) + Aa_k = 0$
- Recursion relation that defines series solution to ODE

  $a_{k+3} = -\frac{aka_{k+1}+ara_{k+1}+bka_{k+2}+bra_{k+2}+Aa_k+Ba_{k+1}+C0a_{k+2}+aa_{k+1}+2ba_{k+2}}{(k+3+r)(k+2+r+c)}$
- Recursion relation for $r = 0$

  $a_{k+3} = -\frac{aka_{k+1}+bka_{k+2}+Aa_k+Ba_{k+1}+C0a_{k+2}+aa_{k+1}+2ba_{k+2}}{(k+3)(k+2+c)}$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{aka_{k+1}+bka_{k+2}+Aa_k+Ba_{k+1}+C0a_{k+2}+aa_{k+1}+2ba_{k+2}}{(k+3)(k+2+c)}, a_1 = -\frac{a_0\,C0}{c}, a_2 = -\frac{a_0\,(Bc-C}{2c^2+}\right.$
- Recursion relation for $r = -c+1$

  $a_{k+3} = -\frac{aka_{k+1}+a(-c+1)a_{k+1}+bka_{k+2}+b(-c+1)a_{k+2}+Aa_k+Ba_{k+1}+C0a_{k+2}+aa_{k+1}+2ba_{k+2}}{(k+4-c)(k+3)}$
- Solution for $r = -c+1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-c+1}, a_{k+3} = -\frac{aka_{k+1}+a(-c+1)a_{k+1}+bka_{k+2}+b(-c+1)a_{k+2}+Aa_k+Ba_{k+1}+C0a_{k+2}+aa_{k+1}+2ba_{k+2}}{(k+4-c)(k+3)}, a\right.$
- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} d_k x^k\right) + \left(\sum_{k=0}^{\infty} e_k x^{k-c+1}\right), d_{k+3} = -\frac{akd_{1+k}+bkd_{k+2}+Ad_k+Bd_{1+k}+C0d_{k+2}+ad_{1+k}+2bd_{k+2}}{(k+3)(k+2+c)}, d_1 = \right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 86.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(a\,x^{3}+b\right)y'+a(b-1)\,x^{2}y=0}$$

28.26.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$xy''+\left(a\,x^{3}+b\right)y'+a(b-1)\,x^{2}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{a\,x^{3}+b}{x} \\ q(x) &= ax(b-1) \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(a\, x^3 + b)}{x^2} + ax(b-1) = 0 \tag{5}$$

Solving (5) for n gives

$$n = -b + 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{-2b+2}{x} + \frac{a\, x^3 + b}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(a\, x^3 - b + 2)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(a\, x^3 - b + 2)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(a\, x^3 - b + 2)\, u}{x} \end{aligned}$$

Where $f(x) = -\frac{a\,x^3-b+2}{x}$ and $g(u) = u$. Integrating both sides gives

$$\frac{1}{u}\,du = -\frac{a\,x^3-b+2}{x}\,dx$$
$$\int \frac{1}{u}\,du = \int -\frac{a\,x^3-b+2}{x}\,dx$$
$$\ln(u) = -\frac{a\,x^3}{3} - (2-b)\ln(x) + c_1$$
$$u = \mathrm{e}^{-\frac{a\,x^3}{3}-(2-b)\ln(x)+c_1}$$
$$= c_1 \mathrm{e}^{-\frac{a\,x^3}{3}-(2-b)\ln(x)}$$

Which simplifies to

$$u(x) = \frac{c_1 \mathrm{e}^{-\frac{a\,x^3}{3}} x^b}{x^2}$$

Now that $u(x)$ is known, then

$$v'(x) = u(x)$$
$$v(x) = \int u(x)\,dx + c_2$$
$$= 3^{-\frac{4}{3}+\frac{b}{3}} a^{-\frac{b}{3}+\frac{1}{3}} c_1 \left(\frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{2+b} a^{\frac{2}{3}+\frac{b}{3}} (a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{1}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right)}{(b-1)(2+b)(5+b)} + \frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{-4+}}{}\right.$$

Hence

$$y = v(x)\,x^n$$
$$= \left(3^{-\frac{4}{3}+\frac{b}{3}} a^{-\frac{b}{3}+\frac{1}{3}} c_1 \left(\frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{2+b} a^{\frac{2}{3}+\frac{b}{3}} (a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{1}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right)}{(b-1)(2+b)(5+b)} + \frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{-4+b} a}{}\right.\right.$$
$$= \frac{3^{\frac{4}{3}+\frac{b}{6}} a c_1 x^3 (a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{1}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right) + (5+b)\left(c_1(a\,x^3+b+2)\,\mathrm{e}^{-\frac{a\,x^3}{3}} + c_2 x^{-}\right.}{(2+b)(5+b)(b-1)}$$

Summary
The solution(s) found are the following

$$y = \left(3^{-\frac{4}{3}+\frac{b}{3}} a^{-\frac{b}{3}+\frac{1}{3}} c_1 \left(\frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{2+b} a^{\frac{2}{3}+\frac{b}{3}} (a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{1}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right)}{(b-1)\,(2+b)\,(5+b)} + \frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{-4+b} a^{-\frac{4}{3}+\frac{b}{3}} (a\,x^3+b+2)\,(a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{4}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right)}{(b-1)\,(2+b)}\right) + c_2\right) x^{-b+1} \tag{1}$$

Verification of solutions

$$y = \left(3^{-\frac{4}{3}+\frac{b}{3}} a^{-\frac{b}{3}+\frac{1}{3}} c_1 \left(\frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{2+b} a^{\frac{2}{3}+\frac{b}{3}} (a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{1}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right)}{(b-1)\,(2+b)\,(5+b)} + \frac{3^{-\frac{b}{6}+\frac{8}{3}} x^{-4+b} a^{-\frac{4}{3}+\frac{b}{3}} (a\,x^3+b+2)\,(a\,x^3)^{-\frac{1}{3}-\frac{b}{6}} \mathrm{e}^{-\frac{a\,x^3}{6}} \operatorname{WhittakerM}\left(\frac{4}{3}+\frac{b}{6}, \frac{b}{6}+\frac{5}{6}, \frac{a\,x^3}{3}\right)}{(b-1)\,(2+b)}\right) + c_2\right) x^{-b+1}$$

Verified OK.

28.26.2 Maple step by step solution

Let's solve

$y''x + (a\,x^3+b)\,y' + a(b-1)\,x^2 y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(a\,x^3+b)\,y'}{x} - ax(b-1)\,y$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a\,x^3+b)\,y'}{x} + ax(b-1)\,y = 0$

- ☐ Check to see if $x_0 = 0$ is a regular singular point
  - Define functions

    $\left[P_2(x) = \frac{a\,x^3+b}{x}, P_3(x) = ax(b-1)\right]$
  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = b$
  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$
  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$
- Multiply by denominators

  $y''x + (a\,x^3 + b)\,y' + a(b-1)\,x^2y = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$
- ☐ Rewrite ODE with series expansions
  - Convert $x^2 \cdot y$ to series expansion

    $x^2 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+2}$
  - Shift index using $k- >k-2$

    $x^2 \cdot y = \sum_{k=2}^{\infty} a_{k-2} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$
  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) x^{k+r-1}$$

- Shift index using $k- >k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)(k+r) x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(-1+r+b) x^{-1+r} + a_1(1+r)(r+b) x^r + a_2(2+r)(1+r+b) x^{1+r} + \left(\sum_{k=2}^{\infty} (a_{k+1}(k+1+r)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(-1+r+b) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{0, -b+1\}$$

- The coefficients of each power of x must be 0

$$[a_1(1+r)(r+b) = 0, a_2(2+r)(1+r+b) = 0]$$

- Solve for the dependent coefficient(s)

$$\{a_1 = 0, a_2 = 0\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)(k+r+b) + a_{k-2} a(k-3+r+b) = 0$$

- Shift index using $k- >k+2$

$$a_{k+3}(k+3+r)(k+2+r+b) + a_k a(k+r+b-1) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+3} = -\frac{a_k a(k+r+b-1)}{(k+3+r)(k+2+r+b)}$$

- Recursion relation for $r = 0$

$$a_{k+3} = -\frac{a_k a(k-1+b)}{(k+3)(k+2+b)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{a_k a(k-1+b)}{(k+3)(k+2+b)}, a_1 = 0, a_2 = 0\right]$$

- Recursion relation for $r = -b+1$

$$a_{k+3} = -\frac{a_k a k}{(k+4-b)(k+3)}$$

- Solution for $r = -b+1$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k-b+1}, a_{k+3}=-\frac{a_k a k}{(k+4-b)(k+3)}, a_1=0, a_2=0\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} c_k x^k\right)+\left(\sum_{k=0}^{\infty} d_k x^{k-b+1}\right), c_{k+3}=-\frac{c_k a(k-1+b)}{(k+3)(k+2+b)}, c_1=0, c_2=0, d_{k+3}=-\frac{d_k a k}{(k+4-b)(k+3)}, d\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 87.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{xy''+x\left(a\,x^2+b\right)y'+\left(3a\,x^2+b\right)y=0}$$

28.27.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(xy''+x\left(a\,x^2+b\right)y'+\left(3a\,x^2+b\right)y\right)dx=0$$
$$\left(a\,x^3+bx-1\right)y+y'x=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{-a\,x^{3}-bx+1}{x}\\
q(x) &= \frac{c_1}{x}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{\left(-a\,x^{3}-bx+1\right)y}{x} = \frac{c_1}{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{-a\,x^{3}-bx+1}{x}dx}\\
&= \mathrm{e}^{\frac{a\,x^{3}}{3}+bx-\ln(x)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}y}{x}\right) &= \left(\frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x}\right)\left(\frac{c_1}{x}\right)\\
\mathrm{d}\left(\frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}y}{x}\right) &= \left(\frac{c_1\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}\right)\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}y}{x} &= \int \frac{c_1\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}\,\mathrm{d}x\\
\frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}y}{x} &= \int \frac{c_1\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x}$ results in

$$
y = x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}}\left(\int \frac{c_1\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx\right) + c_2 x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}}
$$

which simplifies to

$$y = x\,{\mathrm e}^{-\frac{x \left(a\,x^{2}+3 b \right)}{3}} \left(c_{1} \left(\int \frac{{\mathrm e}^{\frac{x \left(a\,x^{2}+3 b \right)}{3}}}{x^{2}}d x \right)+c_{2}\right)$$

Summary
The solution(s) found are the following

$$y = x\,{\mathrm e}^{-\frac{x \left(a\,x^{2}+3 b \right)}{3}} \left(c_{1} \left(\int \frac{{\mathrm e}^{\frac{x \left(a\,x^{2}+3 b \right)}{3}}}{x^{2}}d x \right)+c_{2}\right) \tag{1}$$

Verification of solutions

$$y = x\,{\mathrm e}^{-\frac{x \left(a\,x^{2}+3 b \right)}{3}} \left(c_{1} \left(\int \frac{{\mathrm e}^{\frac{x \left(a\,x^{2}+3 b \right)}{3}}}{x^{2}}d x \right)+c_{2}\right)$$

Verified OK.

28.27.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x y''+x \left(a\,x^{2}+b \right) y'+\left(3 a\,x^{2}+b \right) y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x y''+x \left(a\,x^{2}+b \right) y'+\left(3 a\,x^{2}+b \right) y\right)d x = 0$$
$$\left(a\,x^{3}+b x -1\right) y+y' x = c_{1}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-a\,x^{3}-b x +1}{x}$$
$$q(x) = \frac{c_{1}}{x}$$

Hence the ode is

$$y' - \frac{(-a\,x^3 - bx + 1)\,y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int -\frac{-a\,x^3 - bx + 1}{x}dx}\\ &= e^{\frac{a\,x^3}{3} + bx - \ln(x)}\end{aligned}$$

Which simplifies to

$$\mu = \frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x}$$

The ode becomes

$$\begin{aligned}\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\ \frac{d}{dx}\left(\frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}y}{x}\right) &= \left(\frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x}\right)\left(\frac{c_1}{x}\right)\\ d\left(\frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}y}{x}\right) &= \left(\frac{c_1 e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x^2}\right)dx\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}y}{x} &= \int \frac{c_1 e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x^2}\,dx\\ \frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}y}{x} &= \int \frac{c_1 e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x^2}dx + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x}$ results in

$$y = x\,e^{-\frac{x\left(a\,x^2+3b\right)}{3}}\left(\int \frac{c_1 e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x^2}dx\right) + c_2 x\,e^{-\frac{x\left(a\,x^2+3b\right)}{3}}$$

which simplifies to

$$y = x\,e^{-\frac{x\left(a\,x^2+3b\right)}{3}}\left(c_1\left(\int \frac{e^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x^2}dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}} \left(c_{1} \left(\int \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx\right)+c_{2}\right) \tag{1}$$

Verification of solutions

$$y = x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}} \left(c_{1} \left(\int \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx\right)+c_{2}\right)$$

Verified OK.

28.27.3 Solving using Kovacic algorithm

Writing the ode as

$$xy'' + x\left(a\,x^{2}+b\right)y' + \left(3a\,x^{2}+b\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= x\left(a\,x^{2}+b\right) \\ C &= 3a\,x^{2}+b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^{2} - 4AC}{4A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{x^{5}a^{2} + 2ab\,x^{3} - 8a\,x^{2} + b^{2}x - 4b}{4x} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= x^5 a^2 + 2ab\, x^3 - 8a\, x^2 + b^2 x - 4b \\
t &= 4x
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{x^5 a^2 + 2ab\, x^3 - 8a\, x^2 + b^2 x - 4b}{4x}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 103: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 1 - 5 \\
&= -4
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x$. There is a pole at $x = 0$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = 0$ of order 1 then

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= 1 \\
\alpha_c^{-} &= 1
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{2} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^2}{2} + \frac{b}{2} - \frac{2}{x} + \frac{b}{a\,x^3} - \frac{4}{a\,x^4} - \frac{b^2}{a^2 x^5} + \frac{8b}{a^2 x^6} + \frac{b^3}{a^3 x^7} - \frac{16}{a^2 x^7} + \dots \qquad (9)$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\
&= \frac{a\,x^2}{2} + \frac{b}{2} \qquad (10)
\end{aligned}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2 x^4 + \frac{1}{2}ab\,x^2 + \frac{1}{4}b^2$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{x^5 a^2 + 2ab\,x^3 - 8a\,x^2 + b^2 x - 4b}{4x} \\
&= Q + \frac{R}{4x} \\
&= \left(\frac{1}{4}a^2 x^4 + \frac{1}{2}ab\,x^2 - 2ax + \frac{1}{4}b^2\right) + \left(-\frac{b}{x}\right) \\
&= \frac{a^2 x^4}{4} + \frac{ab\,x^2}{2} - 2ax + \frac{b^2}{4} - \frac{b}{x}
\end{aligned}$$

We see that the coefficient of the term 1 in the quotient is $-2a$. Now b can be found.

$$\begin{aligned}
b &= (-2a) - (0) \\
&= -2a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{a\,x^2}{2} + \frac{b}{2} \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-2a}{\frac{a}{2}} - 2\right) &&= -3 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-2a}{\frac{a}{2}} - 2\right) &&= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{x^5 a^2 + 2ab\,x^3 - 8a\,x^2 + b^2 x - 4b}{4x}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
-4	$\frac{a\,x^2}{2} + \frac{b}{2}$	-3	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$\begin{aligned} d &= \alpha_\infty^{-} - (\alpha_{c_1}^{-}) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{1}{x} + (-)\left(\frac{a\,x^2}{2} + \frac{b}{2} \right) \\ &= \frac{1}{x} - \frac{a\,x^2}{2} - \frac{b}{2} \\ &= \frac{1}{x} - \frac{a\,x^2}{2} - \frac{b}{2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x} - \frac{a\,x^2}{2} - \frac{b}{2}\right)(0) + \left(\left(-\frac{1}{x^2} - ax\right) + \left(\frac{1}{x} - \frac{a\,x^2}{2} - \frac{b}{2}\right)^2 - \left(\frac{x^5a^2 + 2ab\,x^3 - 8a\,x^2 + b^2x - 4b}{4x}\right.\right.$$

$$0 =$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{1}{x} - \frac{a\,x^2}{2} - \frac{b}{2}\right) dx} \\
&= x\,\mathrm{e}^{-\frac{x\left(a\,x^2+3b\right)}{6}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x\left(a\,x^2+b\right)}{x} \, dx} \\
&= z_1 e^{-\frac{1}{2}bx - \frac{1}{6}a\,x^3} \\
&= z_1 \left(\mathrm{e}^{-\frac{x\left(a\,x^2+3b\right)}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x\,\mathrm{e}^{-\frac{x\left(a\,x^2+3b\right)}{3}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x\left(a\,x^2+b\right)}{x} \, dx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \int \frac{e^{-\frac{1}{3}a\,x^3 - bx}}{\left(y_1\right)^2} \, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{x\left(a\,x^2+3b\right)}{3}}}{x^2} \, dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}}\right) + c_2\left(x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}}\left(\int \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}} + c_2 x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}}\left(\int \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}} + c_2 x\,\mathrm{e}^{-\frac{x\left(a\,x^{2}+3b\right)}{3}}\left(\int \frac{\mathrm{e}^{\frac{x\left(a\,x^{2}+3b\right)}{3}}}{x^{2}}dx\right)
$$

Verified OK.

28.27.4 Solving as exact linear second order ode ode

An ode of the form

$$
p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)
$$

is exact if

$$
p''(x) - q'(x) + r(x) = 0 \tag{1}
$$

For the given ode we have

$$
\begin{aligned}
p(x) &= x \\
q(x) &= x\left(a\,x^{2} + b\right) \\
r(x) &= 3a\,x^{2} + b \\
s(x) &= 0
\end{aligned}
$$

Hence

$$
\begin{aligned}
p''(x) &= 0 \\
q'(x) &= 3a\,x^{2} + b
\end{aligned}
$$

Therefore (1) becomes

$$
0 - \left(3a\,x^{2} + b\right) + \left(3a\,x^{2} + b\right) = 0
$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\, y' + (q(x) - p'(x))\, y)' = s(x)$$

Integrating gives

$$p(x)\, y' + (q(x) - p'(x))\, y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$y'x + \left(x\left(a\, x^2 + b\right) - 1\right) y = c_1$$

We now have a first order ode to solve which is

$$y'x + \left(x\left(a\, x^2 + b\right) - 1\right) y = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{-a\, x^3 - bx + 1}{x} \\ q(x) &= \frac{c_1}{x} \end{aligned}$$

Hence the ode is

$$y' - \frac{(-a\, x^3 - bx + 1)\, y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{-a\, x^3 - bx + 1}{x} dx} \\ &= \mathrm{e}^{\frac{a\, x^3}{3} + bx - \ln(x)} \end{aligned}$$

Which simplifies to

$$\mu = \frac{\mathrm{e}^{\frac{x\left(a\, x^2 + 3b\right)}{3}}}{x}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{c_1}{x}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}} y}{x}\right) = \left(\frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x}\right)\left(\frac{c_1}{x}\right)$$
$$\mathrm{d}\left(\frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}} y}{x}\right) = \left(\frac{c_1 \mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2}\right)\mathrm{d}x$$

Integrating gives

$$\frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}} y}{x} = \int \frac{c_1 \mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2}\,\mathrm{d}x$$
$$\frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}} y}{x} = \int \frac{c_1 \mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2} dx + c_2$$

Dividing both sides by the integrating factor $\mu = \frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x}$ results in

$$y = x\,\mathrm{e}^{-\frac{x(a\,x^2+3b)}{3}}\left(\int \frac{c_1 \mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2} dx\right) + c_2 x\,\mathrm{e}^{-\frac{x(a\,x^2+3b)}{3}}$$

which simplifies to

$$y = x\,\mathrm{e}^{-\frac{x(a\,x^2+3b)}{3}}\left(c_1\left(\int \frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = x\,\mathrm{e}^{-\frac{x(a\,x^2+3b)}{3}}\left(c_1\left(\int \frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = x\,\mathrm{e}^{-\frac{x(a\,x^2+3b)}{3}}\left(c_1\left(\int \frac{\mathrm{e}^{\frac{x(a\,x^2+3b)}{3}}}{x^2} dx\right) + c_2\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(a\,x^3+b\,x^2+2\right)y'+bxy=0}$$

28.28.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+\left(a\,x^3+b\,x^2+2\right)y'+bxy=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= a\,x^3+b\,x^2+2 \\ C &= bx \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^4 + 2ab\,x^3 + b^2x^2 + 8ax + 2b}{4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^4 + 2ab\,x^3 + b^2x^2 + 8ax + 2b \\ t &= 4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{1}{4}a^2x^4 + \frac{1}{2}ab\,x^3 + \frac{1}{4}b^2x^2 + 2ax + \frac{1}{2}b\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 104: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 4 \\ &= -4 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{2} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a\,x^2}{2} + \frac{bx}{2} + \frac{2}{x} - \frac{3b}{2a\,x^2} + \frac{3b^2}{2a^2x^3} - \frac{3b^3}{2a^3x^4} - \frac{4}{a\,x^4} + \frac{3b^4}{2a^4x^5} + \frac{10b}{a^2x^5} - \frac{3b^5}{2a^5x^6} - \frac{73b^2}{4a^3x^6} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= \frac{1}{2}bx + \frac{1}{2}a\,x^2 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}b^2x^2 + \frac{1}{2}ab\,x^3 + \frac{1}{4}a^2x^4$$

This shows that the coefficient of x in the above is 0. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{a^2x^4 + 2ab\,x^3 + b^2x^2 + 8ax + 2b}{4} \\
&= Q + \frac{R}{4} \\
&= \left(\frac{1}{4}a^2x^4 + \frac{1}{2}ab\,x^3 + \frac{1}{4}b^2x^2 + 2ax + \frac{1}{2}b\right) + (0) \\
&= \frac{1}{4}a^2x^4 + \frac{1}{2}ab\,x^3 + \frac{1}{4}b^2x^2 + 2ax + \frac{1}{2}b
\end{aligned}$$

We see that the coefficient of the term $\frac{1}{x}$ in the quotient is $2a$. Now b can be found.

$$\begin{aligned}
b &= (2a) - (0) \\
&= 2a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{1}{2}bx + \frac{1}{2}a\,x^2 \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &= \frac{1}{2}\left(\frac{2a}{\frac{a}{2}} - 2\right) &= 1 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &= \frac{1}{2}\left(-\frac{2a}{\frac{a}{2}} - 2\right) &= -3
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{1}{4}a^2x^4 + \frac{1}{2}ab\,x^3 + \frac{1}{4}b^2x^2 + 2ax + \frac{1}{2}b$$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$\frac{1}{2}bx+\frac{1}{2}a\,x^2$	1	-3

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d=\alpha_\infty^{s(\infty)}-\sum_{c\in\Gamma}\alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+=1$, and since there are no poles, then

$$\begin{aligned}d&=\alpha_\infty^+\\&=1\end{aligned}$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$\omega=\sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c+\frac{\alpha_c^{s(c)}}{x-c}\right)+s(\infty)[\sqrt{r}]_\infty$$

Substituting the above values in the above results in

$$\begin{aligned}\omega&=(+)[\sqrt{r}]_\infty\\&=0+\left(\frac{1}{2}bx+\frac{1}{2}a\,x^2\right)\\&=\frac{1}{2}bx+\frac{1}{2}a\,x^2\\&=\frac{(ax+b)\,x}{2}\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p''+2\omega p'+\left(\omega'+\omega^2-r\right)p=0 \tag{1A}$$

Let

$$p(x)=x+a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0)+2\left(\frac{1}{2}bx+\frac{1}{2}a\,x^2\right)(1)+\left(\left(ax+\frac{b}{2}\right)+\left(\frac{1}{2}bx+\frac{1}{2}a\,x^2\right)^2-\left(\frac{1}{4}a^2x^4+\frac{1}{2}ab\,x^3+\frac{1}{4}b^2x^2+2ax+\frac{1}{2}b\right)\right.$$

$$-x(aa_0-b)=$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{b}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{b}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \left(x + \frac{b}{a}\right) e^{\int \left(\frac{1}{2} b x + \frac{1}{2} a\, x^2\right) dx} \\ &= \left(x + \frac{b}{a}\right) e^{\frac{1}{6} a\, x^3 + \frac{1}{4} b\, x^2} \\ &= \frac{(ax + b)\, e^{\frac{1}{6} a\, x^3 + \frac{1}{4} b\, x^2}}{a} \end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2} \frac{a\, x^3 + b\, x^2 + 2}{x} \, dx} \\ &= z_1 e^{-\frac{a\, x^3}{6} - \frac{b\, x^2}{4} - \ln(x)} \\ &= z_1 \left(\frac{e^{-\frac{1}{6} a\, x^3 - \frac{1}{4} b\, x^2}}{x}\right) \end{aligned}$$

Which simplifies to

$$y_1 = \frac{ax + b}{xa}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{a\,x^3+b\,x^2+2}{x}dx}}{(y_1)^2}\,dx$$
$$= y_1 \int \frac{e^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-2\ln(x)}}{(y_1)^2}\,dx$$
$$= y_1 \left(\int \frac{\mathrm{e}^{-\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2}a^2}{(ax+b)^2}dx\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1\left(\frac{ax+b}{xa}\right) + c_2\left(\frac{ax+b}{xa}\left(\int \frac{\mathrm{e}^{-\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2}a^2}{(ax+b)^2}dx\right)\right)$$

Summary

The solution(s) found are the following

$$y = \frac{c_1(ax+b)}{xa} + \frac{c_2(ax+b)\,a\left(\int \frac{\mathrm{e}^{-\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2}}{(ax+b)^2}dx\right)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1(ax+b)}{xa} + \frac{c_2(ax+b)\,a\left(\int \frac{\mathrm{e}^{-\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2}}{(ax+b)^2}dx\right)}{x}$$

Verified OK.

28.28.2 Maple step by step solution

Let's solve

$y''x + (a\,x^3 + b\,x^2 + 2)\,y' + bxy = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(a\,x^3+b\,x^2+2)y'}{x} - yb$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(a\,x^{3}+b\,x^{2}+2)y'}{x}+yb=0$

□ Check to see if $x_{0}=0$ is a regular singular point

  - Define functions

    $\left[P_{2}(x)=\frac{a\,x^{3}+b\,x^{2}+2}{x}, P_{3}(x)=b\right]$

  - $x\cdot P_{2}(x)$ is analytic at $x=0$

    $\left(x\cdot P_{2}(x)\right)\bigg|_{x=0}=2$

  - $x^{2}\cdot P_{3}(x)$ is analytic at $x=0$

    $\left(x^{2}\cdot P_{3}(x)\right)\bigg|_{x=0}=0$

  - $x=0$is a regular singular point

    Check to see if $x_{0}=0$ is a regular singular point

    $x_{0}=0$

- Multiply by denominators

  $y''x+\left(a\,x^{3}+b\,x^{2}+2\right)y'+bxy=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_{k}x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x\cdot y$ to series expansion

    $x\cdot y=\sum_{k=0}^{\infty}a_{k}x^{k+r+1}$

  - Shift index using $k->k-1$

    $x\cdot y=\sum_{k=1}^{\infty}a_{k-1}x^{k+r}$

  - Convert $x^{m}\cdot y'$ to series expansion for $m=0..3$

    $x^{m}\cdot y'=\sum_{k=0}^{\infty}a_{k}(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^{m}\cdot y'=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,x^{k+r}$

- Convert $x \cdot y''$ to series expansion

$$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\,x^{k+r-1}$$

- Shift index using $k->k+1$

$$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+r+1)\,(k+r)\,x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 r(1+r)\,x^{-1+r} + a_1(1+r)\,(2+r)\,x^{r} + (a_2(2+r)\,(3+r) + b a_0(1+r))\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_{k+1}(k+\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(1+r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- The coefficients of each power of x must be 0

$$[a_1(1+r)\,(2+r) = 0, a_2(2+r)\,(3+r) + b a_0(1+r) = 0]$$

- Solve for the dependent coefficient(s)

$$\left\{a_1 = 0, a_2 = -\frac{b a_0(1+r)}{r^2+5r+6}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+r+1)\,(k+2+r) + b a_{k-1}(k+r) + a_{k-2}(k-2+r)\,a = 0$$

- Shift index using $k->k+2$

$$a_{k+3}(k+3+r)\,(k+4+r) + b a_{k+1}(k+2+r) + a_k(k+r)\,a = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+3} = -\frac{aka_k + ara_k + bka_{k+1} + bra_{k+1} + 2ba_{k+1}}{(k+3+r)(k+4+r)}$$

- Recursion relation for $r = -1$

$$a_{k+3} = -\frac{aka_k + bka_{k+1} - aa_k + ba_{k+1}}{(k+2)(k+3)}$$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+3} = -\frac{aka_k + bka_{k+1} - aa_k + ba_{k+1}}{(k+2)(k+3)}, a_1 = 0, a_2 = 0\right]$$

- Recursion relation for $r = 0$

$$a_{k+3} = -\frac{aka_k + bka_{k+1} + 2ba_{k+1}}{(k+3)(k+4)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{a k a_k + b k a_{k+1} + 2 b a_{k+1}}{(k+3)(k+4)}, a_1 = 0, a_2 = -\frac{a_0 b}{6}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} d_k x^k\right), c_{k+3} = -\frac{a k c_k + b k c_{1+k} - a c_k + b c_{1+k}}{(k+2)(k+3)}, c_1 = 0, c_2 = 0, d_{k+3} = -\frac{a k d_k + b k}{(k+}\right.$$

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 89.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(ab\,x^{3}+b\,x^{2}+ax-1\right)y'+a^{2}b\,x^{3}y=0}$$

28.29.1 Solving using Kovacic algorithm

Writing the ode as

$$xy''+\left(ab\,x^{3}+b\,x^{2}+ax-1\right)y'+a^{2}b\,x^{3}y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x \\ B &= ab\,x^{3}+b\,x^{2}+ax-1 \\ C &= a^{2}b\,x^{3} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2b^2x^6 + 2a\,b^2x^5 - 2a^2b\,x^4 + b^2x^4 + 4ab\,x^3 + a^2x^2 - 2ax + 3}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2b^2x^6 + 2a\,b^2x^5 - 2a^2b\,x^4 + b^2x^4 + 4ab\,x^3 + a^2x^2 - 2ax + 3 \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2b^2x^6 + 2a\,b^2x^5 - 2a^2b\,x^4 + b^2x^4 + 4ab\,x^3 + a^2x^2 - 2ax + 3}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 106: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 6 \\
&= -4
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is -4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{a^2 b^2 x^4}{4} + \frac{a\, b^2 x^3}{2} - \frac{a^2 b\, x^2}{2} + \frac{b^2 x^2}{4} + abx + \frac{a^2}{4} + \frac{3}{4x^2} - \frac{a}{2x}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{3}{4}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{3}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1 + 4b} = -\frac{1}{2}
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = -4$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{4}{2} = 2$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{2} a_i x^i \qquad (8)
\end{aligned}$$

Let a be the coefficient of $x^v = x^2$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{ab\,x^2}{2} + \frac{bx}{2} - \frac{a}{2} + \frac{3}{2x} - \frac{3}{2a\,x^2} + \frac{1}{b\,x^3} + \frac{3}{2a^2x^3} - \frac{4}{ab\,x^4} + \frac{1}{b^2x^5} - \frac{3}{2a^3x^4} + \frac{10}{a^2b\,x^5} + \frac{3}{2a^4x^5} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{ab}{2}$$

From Eq. (9) the sum up to $v = 2$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{2} a_i x^i \\ &= -\frac{1}{2}a + \frac{1}{2}bx + \frac{1}{2}ab\,x^2 \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^1 = x$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{1}{4}a^2 - \frac{1}{2}abx - \frac{1}{2}a^2b\,x^2 + \frac{1}{4}b^2x^2 + \frac{1}{2}a\,b^2x^3 + \frac{1}{4}a^2b^2x^4$$

This shows that the coefficient of x in the above is $-\frac{ab}{2}$. Now we need to find the coefficient of x in r. How this is done depends on if $v = 0$ or not. Since $v = 2$ which is not zero, then starting $r = \frac{s}{t}$, we do long division and write this in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of x in r will be the coefficient this term in the quotient. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a^2b^2x^6 + 2a\,b^2x^5 - 2a^2b\,x^4 + b^2x^4 + 4ab\,x^3 + a^2x^2 - 2ax + 3}{4x^2} \\ &= Q + \frac{R}{4x^2} \\ &= \left(\frac{a^2b^2x^4}{4} + \frac{a\,b^2x^3}{2} + \left(-\frac{1}{2}a^2b + \frac{1}{4}b^2\right)x^2 + abx + \frac{a^2}{4}\right) + \left(\frac{-2ax+3}{4x^2}\right) \\ &= \frac{a^2b^2x^4}{4} + \frac{a\,b^2x^3}{2} + \left(-\frac{1}{2}a^2b + \frac{1}{4}b^2\right)x^2 + abx + \frac{a^2}{4} + \frac{-2ax+3}{4x^2} \end{aligned}$$

We see that the coefficient of the term x in the quotient is ab. Now b can be found.

$$\begin{aligned} b &= (ab) - \left(-\frac{ab}{2}\right) \\ &= \frac{3ab}{2} \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= -\frac{1}{2}a + \frac{1}{2}bx + \frac{1}{2}ab\,x^2 \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{\frac{3ab}{2}}{\frac{ab}{2}} - 2\right) &&= \frac{1}{2} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{\frac{3ab}{2}}{\frac{ab}{2}} - 2\right) &&= -\frac{5}{2}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{a^2b^2x^6 + 2a\,b^2x^5 - 2a^2b\,x^4 + b^2x^4 + 4ab\,x^3 + a^2x^2 - 2ax + 3}{4x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{3}{2}$	$-\frac{1}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
-4	$-\frac{1}{2}a + \frac{1}{2}bx + \frac{1}{2}ab\,x^2$	$\frac{1}{2}$	$-\frac{5}{2}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^+ = \frac{1}{2}$ then

$$
\begin{aligned}
d &= \alpha_\infty^+ - \left(\alpha_{c_1}^-\right) \\
&= \frac{1}{2} - \left(-\frac{1}{2}\right) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

Substituting the above values in the above results in

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + (+)[\sqrt{r}]_{\infty} \\
&= -\frac{1}{2x} + \left(-\frac{1}{2}a + \frac{1}{2}bx + \frac{1}{2}ab\,x^2\right) \\
&= -\frac{1}{2x} - \frac{a}{2} + \frac{bx}{2} + \frac{ab\,x^2}{2} \\
&= \frac{(b\,x^2 - 1)\,(ax + 1)}{2x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(-\frac{1}{2x} - \frac{a}{2} + \frac{bx}{2} + \frac{ab\,x^2}{2}\right)(1) + \left(\left(\frac{1}{2x^2} + \frac{b}{2} + abx\right) + \left(-\frac{1}{2x} - \frac{a}{2} + \frac{bx}{2} + \frac{ab\,x^2}{2}\right)^2 - \left(\frac{a^2b^2x^6 +
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = \frac{1}{a}\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + \frac{1}{a}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\,dx} \\
&= \left(x + \frac{1}{a}\right) e^{\int \left(-\frac{1}{2x} - \frac{a}{2} + \frac{bx}{2} + \frac{ab\,x^2}{2}\right) dx} \\
&= \left(x + \frac{1}{a}\right) e^{\frac{b\,x^2}{4} + \frac{ab\,x^3}{6} - \frac{ax}{2} - \frac{\ln(x)}{2}} \\
&= \frac{(ax + 1)\,e^{\frac{1}{4}b\,x^2 + \frac{1}{6}ab\,x^3 - \frac{1}{2}ax}}{a\sqrt{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{ab\,x^3+b\,x^2+ax-1}{x}\,dx} \\
&= z_1 e^{-\frac{ab\,x^3}{6}-\frac{b\,x^2}{4}-\frac{ax}{2}+\frac{\ln(x)}{2}} \\
&= z_1\left(\sqrt{x}\,\mathrm{e}^{-\frac{x\left(ab\,x^2+\frac{3}{2}bx+3a\right)}{6}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(ax+1)\,\mathrm{e}^{-ax}}{a}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{ab\,x^3+b\,x^2+ax-1}{x}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{ab\,x^3}{3}-\frac{b\,x^2}{2}-ax+\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\int \frac{x\,a^2\mathrm{e}^{-\frac{\left(ab\,x^2+\frac{3}{2}bx-3a\right)x}{3}}}{(ax+1)^2}dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a}\right) + c_2\left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a}\left(\int \frac{x\,a^2\mathrm{e}^{-\frac{\left(ab\,x^2+\frac{3}{2}bx-3a\right)x}{3}}}{(ax+1)^2}dx\right)\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a} + c_2(ax+1)\,\mathrm{e}^{-ax}a\left(\int \frac{x\,\mathrm{e}^{-\frac{\left(ab\,x^2+\frac{3}{2}bx-3a\right)x}{3}}}{(ax+1)^2}dx\right) \tag{1}
$$

Verification of solutions

$$y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a} + c_2(ax+1)\,\mathrm{e}^{-ax} a \left(\int \frac{x\,\mathrm{e}^{-\frac{\left(ab\,x^2+\frac{3}{2}bx-3a\right)x}{3}}}{(ax+1)^2} dx\right)$$

Verified OK.

28.29.2 Maple step by step solution

Let's solve

$y''x + (ab\,x^3 + b\,x^2 + ax - 1)\,y' + a^2 b\,x^3 y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -a^2 b\,x^2 y - \frac{(ab\,x^3+b\,x^2+ax-1)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(ab\,x^3+b\,x^2+ax-1)y'}{x} + a^2 b\,x^2 y = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{ab\,x^3+b\,x^2+ax-1}{x}, P_3(x) = a^2 b\,x^2\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = -1$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x + (ab\,x^3 + b\,x^2 + ax - 1)\,y' + a^2 b\,x^3 y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions
  - Convert $x^3 \cdot y$ to series expansion

    $x^3 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+3}$
  - Shift index using $k->k-3$

    $x^3 \cdot y = \sum_{k=3}^{\infty} a_{k-3} x^{k+r}$
  - Convert $x^m \cdot y'$ to series expansion for $m = 0..3$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$
  - Shift index using $k->k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$
  - Convert $x \cdot y''$ to series expansion

    $x \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-1}$
  - Shift index using $k->k+1$

    $x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\,(k+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0 r(-2+r)\, x^{-1+r} + (a_1(1+r)\,(-1+r) + a_0 a r)\, x^r + (a_2(2+r)\, r + a a_1(1+r) + a_0 b r)\, x^{1+r} + ($

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r(-2+r) = 0$
- Values of r that satisfy the indicial equation

  $r \in \{0, 2\}$
- The coefficients of each power of x must be 0

  $[a_1(1+r)\,(-1+r) + a_0 a r = 0, a_2(2+r)\, r + a a_1(1+r) + a_0 b r = 0, a_3(3+r)\,(1+r) + a a_2(2+$
- Solve for the dependent coefficient(s)

  $\left\{a_1 = -\frac{a_0 a r}{r^2-1}, a_2 = \frac{a_0(a^2-br+b)}{r^2+r-2}, a_3 = -\frac{a a_0(b r^2+a^2-3br+b)}{r^3+3r^2-r-3}\right\}$

- Each term in the series must be 0, giving the recursion relation

$$\left(a^2 a_{k-3}+a_{k-2}(k+r-2)\,a+a_{k-1}(k+r-1)\right)b+a a_k(k+r)+a_{k+1}(k+1+r)\,(k+r-1)=0$$

- Shift index using $k->k+3$

$$\left(a^2 a_k+a_{k+1}(k+1+r)\,a+a_{k+2}(k+2+r)\right)b+a a_{k+3}(k+r+3)+a_{k+4}(k+4+r)\,(k+2+r)$$

- Recursion relation that defines series solution to ODE

$$a_{k+4}=-\frac{a^2 b a_k+abk a_{k+1}+abr a_{k+1}+ab a_{k+1}+ak a_{k+3}+ar a_{k+3}+bk a_{k+2}+br a_{k+2}+3a a_{k+3}+2b a_{k+2}}{(k+4+r)(k+2+r)}$$

- Recursion relation for $r=0$

$$a_{k+4}=-\frac{a^2 b a_k+abk a_{k+1}+ab a_{k+1}+ak a_{k+3}+bk a_{k+2}+3a a_{k+3}+2b a_{k+2}}{(k+4)(k+2)}$$

- Solution for $r=0$

$$\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+4}=-\frac{a^2 b a_k+abk a_{k+1}+ab a_{k+1}+ak a_{k+3}+bk a_{k+2}+3a a_{k+3}+2b a_{k+2}}{(k+4)(k+2)}, a_1=0, a_2=-\frac{a_0(a^2+b)}{2}, a_3\right.$$

- Recursion relation for $r=2$

$$a_{k+4}=-\frac{a^2 b a_k+abk a_{k+1}+3ab a_{k+1}+ak a_{k+3}+bk a_{k+2}+5a a_{k+3}+4b a_{k+2}}{(k+6)(k+4)}$$

- Solution for $r=2$

$$\left[y=\sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+4}=-\frac{a^2 b a_k+abk a_{k+1}+3ab a_{k+1}+ak a_{k+3}+bk a_{k+2}+5a a_{k+3}+4b a_{k+2}}{(k+6)(k+4)}, a_1=-\frac{2a a_0}{3}, a_2=\frac{a_0(a^2}{4}\right.$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty} c_k x^k\right)+\left(\sum_{k=0}^{\infty} d_k x^{k+2}\right), c_{k+4}=-\frac{a^2 b c_k+abk c_{1+k}+ab c_{1+k}+ak c_{k+3}+bk c_{k+2}+3a c_{k+3}+2b c_{k+2}}{(k+4)(k+2)}, c_1=0\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 90.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(a\,x^{3}+b\,x^{2}+cx+d\right)y'+(d-1)\left(a\,x^{2}+bx+c\right)y=0}$$

28.30.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$xy''+\left(a\,x^{3}+b\,x^{2}+cx+d\right)y'+(d-1)\left(a\,x^{2}+bx+c\right)y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}
p(x)&=\frac{a\,x^{3}+b\,x^{2}+cx+d}{x}\\
q(x)&=\frac{(d-1)\left(a\,x^{2}+bx+c\right)}{x}
\end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\, x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(a\,x^3 + b\,x^2 + cx + d)}{x^2} + \frac{(d-1)\,(a\,x^2 + bx + c)}{x} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -d + 1 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{-2d+2}{x} + \frac{a\,x^3 + b\,x^2 + cx + d}{x}\right) v'(x) &= 0 \\ v''(x) + \frac{(a\,x^3 + b\,x^2 + cx - d + 2)\, v'(x)}{x} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(a\,x^3 + b\,x^2 + cx - d + 2)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(a\,x^3 + b\,x^2 + cx - d + 2)\, u}{x} \end{aligned}$$

Where $f(x) = -\frac{a\,x^3+b\,x^2+cx-d+2}{x}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{a\,x^3+b\,x^2+cx-d+2}{x}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{a\,x^3+b\,x^2+cx-d+2}{x}\,dx \\
\ln(u) &= -\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)+c_1 \\
u &= \mathrm{e}^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)+c_1} \\
&= c_1\mathrm{e}^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)}
\end{aligned}
$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= \int c_1\mathrm{e}^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)}dx + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(\int c_1\mathrm{e}^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)}dx + c_2\right)x^{-d+1} \\
&= x^{-d+1}\left(c_1\left(\int x^{d-2}\mathrm{e}^{-\frac{1}{3}a\,x^3-\frac{1}{2}b\,x^2-cx}dx\right)+c_2\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(\int c_1\mathrm{e}^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)}dx + c_2\right)x^{-d+1} \tag{1}
$$

Verification of solutions

$$
y = \left(\int c_1\mathrm{e}^{-\frac{a\,x^3}{3}-\frac{b\,x^2}{2}-cx-(2-d)\ln(x)}dx + c_2\right)x^{-d+1}
$$

Verified OK.

28.30.2 Maple step by step solution

Let's solve

$y''x + (a\,x^3 + b\,x^2 + cx + d)\,y' + (d-1)\,(a\,x^2 + bx + c)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(d-1)(a\,x^2+bx+c)y}{x} - \frac{(a\,x^3+b\,x^2+cx+d)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a\,x^3+b\,x^2+cx+d)y'}{x} + \frac{(d-1)(a\,x^2+bx+c)y}{x} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = \frac{a\,x^3+b\,x^2+cx+d}{x}, P_3(x) = \frac{(d-1)(a\,x^2+bx+c)}{x}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left.(x \cdot P_2(x))\right|_{x=0} = d$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left.(x^2 \cdot P_3(x))\right|_{x=0} = 0$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x + (a\,x^3 + b\,x^2 + cx + d)\,y' + (d-1)\,(a\,x^2 + bx + c)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..3$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$$

- Convert $x \cdot y''$ to series expansion

  $$x \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r-1}$$

- Shift index using $k->k+1$

  $$x \cdot y'' = \sum_{k=-1}^{\infty} a_{k+1} (k+1+r)\,(k+r)\, x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0 r(-1+r+d)\, x^{-1+r} + (a_1(1+r)\,(r+d) + a_0 c(-1+r+d))\, x^r + (a_2(2+r)\,(1+r+d) + a_1 c$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$r(-1+r+d) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{0, -d+1\}$$

- The coefficients of each power of x must be 0

  $$[a_1(1+r)\,(r+d) + a_0 c(-1+r+d) = 0, a_2(2+r)\,(1+r+d) + a_1 c(r+d) + b a_0(-1+r+d) =$$

- Solve for the dependent coefficient(s)

  $$\left\{a_1 = -\frac{a_0 c(-1+r+d)}{rd+r^2+d+r}, a_2 = -\frac{a_0 \left(bdr+b\,r^2-c^2 d-c^2 r+bd+c^2-b\right)}{r^2 d+r^3+3rd+4r^2+2d+5r+2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$a_{k+1}(k+1+r)\,(k+r+d) + a_k c(k+r+d-1) + b a_{k-1}(k-2+r+d) + a_{k-2} a(k-3+r+d)$$

- Shift index using $k->k+2$

  $$a_{k+3}(k+3+r)\,(k+2+r+d) + a_{k+2} c(k+1+r+d) + b a_{k+1}(k+r+d) + a_k a(k+r+d-1)$$

- Recursion relation that defines series solution to ODE

$$a_{k+3} = -\frac{a_k a d + a k a_k + a r a_k + b d a_{k+1} + b k a_{k+1} + b r a_{k+1} + c d a_{k+2} + c k a_{k+2} + c r a_{k+2} - a_k a + c a_{k+2}}{(k+3+r)(k+2+r+d)}$$

- Recursion relation for $r = 0$

$$a_{k+3} = -\frac{a_k a d + a k a_k + b d a_{k+1} + b k a_{k+1} + c d a_{k+2} + c k a_{k+2} - a_k a + c a_{k+2}}{(k+3)(k+2+d)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+3} = -\frac{a_k a d + a k a_k + b d a_{k+1} + b k a_{k+1} + c d a_{k+2} + c k a_{k+2} - a_k a + c a_{k+2}}{(k+3)(k+2+d)}, a_1 = -\frac{a_0 c(d-1)}{d}, a_2 = -\frac{a_0 (\right.$$

- Recursion relation for $r = -d + 1$

$$a_{k+3} = -\frac{a_k a d + a k a_k + a(-d+1) a_k + b d a_{k+1} + b k a_{k+1} + b(-d+1) a_{k+1} + c d a_{k+2} + c k a_{k+2} + c(-d+1) a_{k+2} - a_k a + c a_{k+2}}{(k+4-d)(k+3)}$$

- Solution for $r = -d + 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-d+1}, a_{k+3} = -\frac{a_k a d + a k a_k + a(-d+1) a_k + b d a_{k+1} + b k a_{k+1} + b(-d+1) a_{k+1} + c d a_{k+2} + c k a_{k+2} + c(-d+1) a_{k+2}}{(k+4-d)(k+3)}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} e_k x^k\right) + \left(\sum_{k=0}^{\infty} f_k x^{k-d+1}\right), e_{k+3} = -\frac{a d e_k + a k e_k + b d e_{1+k} + b k e_{1+k} + c d e_{k+2} + c k e_{k+2} - a e_k + c e_{k+2}}{(k+3)(k+2+d)}, e_1 =\right.$$

$$\boxed{xy''+(a\,x^n+2)\,y'+x^{n-1}ay=0}$$

28.32.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$xy''+(a\,x^n+2)\,y'+x^{n-1}ay=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{a\,x^n+2}{x}$$
$$q(x)=a\,x^{n-2}$$

Applying change of variables on the depndent variable $y=v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(a\,x^n + 2)}{x^2} + a\,x^{n-2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(-\frac{2}{x} + \frac{a\,x^n + 2}{x}\right) v'(x) = 0$$
$$v''(x) + a\,x^{n-1} v'(x) = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + a\,x^{n-1} u(x) = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x) g(u) \\ &= -a\,x^{n-1} u \end{aligned}$$

Where $f(x) = -a\,x^{n-1}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -a\,x^{n-1}\,dx \\ \int \frac{1}{u}\,du &= \int -a\,x^{n-1}\,dx \\ \ln(u) &= -\frac{a\,x^n}{n} + c_1 \\ u &= e^{-\frac{a\,x^n}{n} + c_1} \\ &= c_1 e^{-\frac{a\,x^n}{n}} \end{aligned}$$

Now that $u(x)$ is known, then

$$v'(x) = u(x)$$

$$v(x) = \int u(x)\, dx + c_2$$

$$= \frac{c_1 \left(\frac{a}{n}\right)^{-\frac{1}{n}} \left(\frac{n^3 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (a\, x^n + n + 1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{WhittakerM}\left(\frac{1}{n} - \frac{n+1}{2n}, \frac{n+1}{2n} + \frac{1}{2}, \frac{a\, x^n}{n}\right)}{(n+1)(2n+1)a} + \frac{n^2 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (n+1) \left(\frac{a\, x^n}{n}\right)}{}\right.}{n}$$

Hence

$$y = v(x)\, x^n$$

$$= \frac{\frac{c_1 \left(\frac{a}{n}\right)^{-\frac{1}{n}} \left(\frac{n^3 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (a\, x^n + n + 1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{WhittakerM}\left(\frac{1}{n} - \frac{n+1}{2n}, \frac{n+1}{2n} + \frac{1}{2}, \frac{a\, x^n}{n}\right)}{(n+1)(2n+1)a} + \frac{n^2 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (n+1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{Wh}}{a(2n+1)}\right.}{n}}{x}$$

$$= \frac{n c_1 x^{1-n} \mathrm{e}^{-\frac{a x^n}{2n}} \left(\frac{a x^n}{n}\right)^{-\frac{n+1}{2n}} (n+1)^2 \operatorname{WhittakerM}\left(\frac{n+1}{2n}, \frac{2n+1}{2n}, \frac{a x^n}{n}\right) + \left((n+1)\, x^{1-n} + ax\right) \left(\frac{a x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a x^n}{2n}}}{(n+1)\,(2n+1)\, ax}$$

Summary

The solution(s) found are the following

$$y = \frac{\frac{c_1 \left(\frac{a}{n}\right)^{-\frac{1}{n}} \left(\frac{n^3 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (a\, x^n + n + 1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{WhittakerM}\left(\frac{1}{n} - \frac{n+1}{2n}, \frac{n+1}{2n} + \frac{1}{2}, \frac{a\, x^n}{n}\right)}{(n+1)(2n+1)a} + \frac{n^2 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (n+1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{Whitta}}{a(2n+1)}\right.}{n}}{x} \tag{1}$$

Verification of solutions

$$y = \frac{\frac{c_1 \left(\frac{a}{n}\right)^{-\frac{1}{n}} \left(\frac{n^3 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (a\, x^n + n + 1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{WhittakerM}\left(\frac{1}{n} - \frac{n+1}{2n}, \frac{n+1}{2n} + \frac{1}{2}, \frac{a\, x^n}{n}\right)}{(n+1)(2n+1)a} + \frac{n^2 x^{1-n} \left(\frac{a}{n}\right)^{\frac{1}{n}} (n+1) \left(\frac{a\, x^n}{n}\right)^{-\frac{n+1}{2n}} \mathrm{e}^{-\frac{a\, x^n}{2n}} \operatorname{Whitta}}{a(2n+1)}\right.}{n}}{x}$$

Verified OK.

Problem number: 94.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{xy''+(a\,x^n+b)\,y'+yx^{n-1}an=0}$$

28.34.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(xy''+(a\,x^n+b)\,y'+yx^{n-1}an\right)dx=0$$
$$(a\,x^n+b-1)\,y+y'x=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{-a\,x^{n}-b+1}{x}\\
q(x) &= \frac{c_1}{x}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{(-a\,x^{n}-b+1)\,y}{x} = \frac{c_1}{x}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{-a\,x^{n}-b+1}{x}dx}\\
&= \mathrm{e}^{\frac{a\,x^{n}+(b-1)\ln(x^{n})}{n}}
\end{aligned}
$$

Which simplifies to

$$
\mu = (x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left((x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}y\right) &= \left((x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}\right)\left(\frac{c_1}{x}\right)\\
\mathrm{d}\left((x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}y\right) &= \left(\frac{c_1(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}}{x}\right)\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}y &= \int \frac{c_1(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}}{x}\,\mathrm{d}x\\
(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}y &= \int \frac{c_1(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}}{x}dx + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = (x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}$ results in

$$
y = \mathrm{e}^{-\frac{a\,x^{n}}{n}}(x^{n})^{\frac{-b+1}{n}}\left(\int \frac{c_1(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}}{x}dx\right) + c_2\mathrm{e}^{-\frac{a\,x^{n}}{n}}(x^{n})^{\frac{-b+1}{n}}
$$

which simplifies to

$$
y = (x^{n})^{\frac{-b+1}{n}}\,\mathrm{e}^{-\frac{a\,x^{n}}{n}}\left(c_1\left(\int \frac{(x^{n})^{\frac{b-1}{n}}\,\mathrm{e}^{\frac{a\,x^{n}}{n}}}{x}dx\right) + c_2\right)
$$

Summary
The solution(s) found are the following

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a\,x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a\,x^n}{n}}}{x} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a\,x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a\,x^n}{n}}}{x} dx\right) + c_2\right)$$

Verified OK.

28.34.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$xy'' + (a\,x^n + b)\,y' + yx^{n-1}an = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(xy'' + (a\,x^n + b)\,y' + yx^{n-1}an\right) dx = 0$$

$$(a\,x^n + b - 1)\,y + y'x = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-a\,x^n - b + 1}{x}$$

$$q(x) = \frac{c_1}{x}$$

Hence the ode is

$$y' - \frac{(-a\,x^n - b + 1)\,y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-a\,x^n - b + 1}{x} dx}$$

$$= \mathrm{e}^{\frac{a\,x^n + (b-1)\ln(x^n)}{n}}$$

Which simplifies to

$$\mu = (x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left((x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}} y\right) &= \left((x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}\right)\left(\frac{c_1}{x}\right) \\
\mathrm{d}\left((x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}} y\right) &= \left(\frac{c_1 (x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x}\right) \mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}} y &= \int \frac{c_1 (x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} \,\mathrm{d}x \\
(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}} y &= \int \frac{c_1 (x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = (x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}$ results in

$$y = \mathrm{e}^{-\frac{a x^n}{n}} (x^n)^{\frac{-b+1}{n}} \left(\int \frac{c_1 (x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2 \mathrm{e}^{-\frac{a x^n}{n}} (x^n)^{\frac{-b+1}{n}}$$

which simplifies to

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2\right)$$

Verified OK.

28.34.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x \\ q(x) &= a\,x^n + b \\ r(x) &= an\,x^{n-1} \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= \frac{an\,x^n}{x} \end{aligned}$$

Therefore (1) becomes

$$0 - \left(\frac{an\,x^n}{x}\right) + \left(an\,x^{n-1}\right) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + \left(q(x) - p'(x)\right)y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + \left(q(x) - p'(x)\right)y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$\left(a\,x^n + b - 1\right)y + y'x = c_1$$

We now have a first order ode to solve which is

$$\left(a\,x^n + b - 1\right)y + y'x = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{-a\,x^n - b + 1}{x} \\ q(x) &= \frac{c_1}{x} \end{aligned}$$

Hence the ode is

$$y' - \frac{(-a\,x^n - b + 1)\,y}{x} = \frac{c_1}{x}$$

The integrating factor μ is

$$\begin{aligned} \mu &= e^{\int -\frac{-a\,x^n - b + 1}{x}dx} \\ &= e^{\frac{a\,x^n + (b-1)\ln(x^n)}{n}} \end{aligned}$$

Which simplifies to

$$\mu = (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}$$

The ode becomes

$$\begin{aligned} \frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x}\right) \\ \frac{d}{dx}\left((x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}\, y\right) &= \left((x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}\right)\left(\frac{c_1}{x}\right) \\ d\left((x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}\, y\right) &= \left(\frac{c_1 (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}}{x}\right) dx \end{aligned}$$

Integrating gives

$$\begin{aligned} (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}\, y &= \int \frac{c_1 (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}}{x}\, dx \\ (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}\, y &= \int \frac{c_1 (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}}{x} dx + c_2 \end{aligned}$$

Dividing both sides by the integrating factor $\mu = (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}$ results in

$$y = e^{-\frac{a\,x^n}{n}} (x^n)^{\frac{-b+1}{n}} \left(\int \frac{c_1 (x^n)^{\frac{b-1}{n}}\, e^{\frac{a\,x^n}{n}}}{x} dx\right) + c_2 e^{-\frac{a\,x^n}{n}} (x^n)^{\frac{-b+1}{n}}$$

which simplifies to

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (x^n)^{\frac{-b+1}{n}} \mathrm{e}^{-\frac{a x^n}{n}} \left(c_1 \left(\int \frac{(x^n)^{\frac{b-1}{n}} \mathrm{e}^{\frac{a x^n}{n}}}{x} dx\right) + c_2\right)$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 95.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(a\,x^{n}+b\right)y'+a(b-1)\,x^{n-1}y=0}$$

28.35.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$xy''+\left(a\,x^{n}+b\right)y'+a(b-1)\,x^{n-1}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{a\,x^{n}+b}{x}\\ q(x)&=a\,x^{n-2}(b-1)\end{aligned}$$

Applying change of variables on the depndent variable $y=v(x)\,x^{n}$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(a\,x^n + b)}{x^2} + a\,x^{n-2}(b-1) = 0 \tag{5}$$

Solving (5) for n gives

$$n = -b + 1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{-2b+2}{x} + \frac{a\,x^n + b}{x}\right) v'(x) = 0$$

$$v''(x) + \frac{(-b + 2 + a\,x^n)\, v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(-b + 2 + a\,x^n)\, u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(-b+2+a\,x^n)\,u}{x} \end{aligned}$$

Where $f(x) = -\frac{-b+2+a\,x^n}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{-b+2+a\,x^n}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{-b+2+a\,x^n}{x}\,dx \\ \ln(u) &= -\frac{a\,x^n + (2-b)\ln(x^n)}{n} + c_1 \\ u &= \mathrm{e}^{-\frac{a\,x^n + (2-b)\ln(x^n)}{n} + c_1} \\ &= c_1 \mathrm{e}^{-\frac{a\,x^n + (2-b)\ln(x^n)}{n}} \end{aligned}$$

Which simplifies to

$$u(x) = c_1 \mathrm{e}^{-\frac{a\,x^n}{n}} \left(x^n\right)^{-\frac{2}{n}} \left(x^n\right)^{\frac{b}{n}}$$

Now that $u(x)$ is known, then

$$v'(x) = u(x)$$

$$v(x) = \int u(x)\, dx + c_2$$

$$= \frac{\left(\frac{a}{n}\right)^{-\frac{b}{n}+\frac{1}{n}} c_1 \left(x^n\right)^{\frac{-2+b}{n}} x^{2-b} \left(\frac{n^3 x^{-n+b-1} \left(\frac{a}{n}\right)^{\frac{b}{n}-\frac{1}{n}} (a\,x^n+b+n-1) \left(\frac{a\,x^n}{n}\right)^{-\frac{b+n-1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \operatorname{WhittakerM}\left(\frac{b-1}{n}-\frac{b+n-1}{2n}, \frac{b+n-1}{2n}+\right.}{(b-1)(b+n-1)(b+2n-1)a}}{n}$$

Hence

$$y = v(x)\, x^n$$

$$= \left(\frac{\left(\frac{a}{n}\right)^{-\frac{b}{n}+\frac{1}{n}} c_1 \left(x^n\right)^{\frac{-2+b}{n}} x^{2-b} \left(\frac{n^3 x^{-n+b-1} \left(\frac{a}{n}\right)^{\frac{b}{n}-\frac{1}{n}} (a\,x^n+b+n-1) \left(\frac{a\,x^n}{n}\right)^{-\frac{b+n-1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \operatorname{WhittakerM}\left(\frac{b-1}{n}-\frac{b+n-1}{2n}, \frac{b+n-1}{2n}+\frac{1}{2}\right.}{(b-1)(b+n-1)(b+2n-1)a}}{n}\right.$$

$$= \frac{x^{-b+1} \left(\left(\frac{a\,x^n}{n}\right)^{-\frac{b+n-1}{2n}} n^2 c_1 \mathrm{e}^{-\frac{a\,x^n}{2n}} \left(x^n\right)^{\frac{-2+b}{n}} \left((b+n-1)\,x^{1-n}+ax\right) \operatorname{WhittakerM}\left(\frac{-n+b-1}{2n}, \frac{b+2n-1}{2n}, \frac{a\,x^n}{n}\right) + \right.}{a\,(b-}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \left(\frac{\left(\frac{a}{n}\right)^{-\frac{b}{n}+\frac{1}{n}} c_1 \left(x^n\right)^{\frac{-2+b}{n}} x^{2-b} \left(\frac{n^3 x^{-n+b-1} \left(\frac{a}{n}\right)^{\frac{b}{n}-\frac{1}{n}} (a\,x^n+b+n-1) \left(\frac{a\,x^n}{n}\right)^{-\frac{b+n-1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \operatorname{WhittakerM}\left(\frac{b-1}{n}-\frac{b+n-1}{2n}, \frac{b+n-1}{2n}+\frac{1}{2}, \right.}{(b-1)(b+n-1)(b+2n-1)a}}{n} + c_2\right) x^{-b+1} \tag{1}$$

Verification of solutions

$$y = \left(\frac{\left(\frac{a}{n}\right)^{-\frac{b}{n}+\frac{1}{n}} c_1 \left(x^n\right)^{\frac{-2+b}{n}} x^{2-b} \left(\frac{n^3 x^{-n+b-1} \left(\frac{a}{n}\right)^{\frac{b}{n}-\frac{1}{n}} (a\,x^n+b+n-1) \left(\frac{a\,x^n}{n}\right)^{-\frac{b+n-1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \operatorname{WhittakerM}\left(\frac{b-1}{n}-\frac{b+n-1}{2n}, \frac{b+n-1}{2n}+\frac{1}{2}, \frac{a\,x^n}{n}\right.}{(b-1)(b+n-1)(b+2n-1)a}}{n} + c_2\right) x^{-b+1}$$

Verified OK.

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 96.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+(a\,x^n+b)\,y'+a(b+n-1)\,x^{n-1}y=0}$$

28.36.1 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$xy''+(a\,x^n+b)\,y'+a(b+n-1)\,x^{n-1}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=r(x) \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{a\,x^n+b}{x} \\
q(x) &= a\,x^{n-2}(b+n-1) \\
r(x) &= 0
\end{aligned}$$

The Lagrange adjoint ode is given by

$$
\begin{aligned}
\xi'' - (\xi\, p)' + \xi q &= 0 \\
\xi'' - \left(\frac{(a\,x^n + b)\,\xi(x)}{x}\right)' + \left(a\,x^{n-2}(b+n-1)\,\xi(x)\right) &= 0 \\
\xi''(x) - \frac{(a\,x^n + b)\,\xi'(x)}{x} + \left(-\frac{an\,x^n}{x^2} + \frac{a\,x^n + b}{x^2} + a\,x^{n-2}(b+n-1)\right)\xi(x) &= 0
\end{aligned}
$$

Which is solved for $\xi(x)$. In normal form the ode

$$
\xi''(x)\,x^2 + (-a\,x^n - b)\,\xi'(x)\,x + b(a\,x^n + 1)\,\xi(x) = 0 \tag{1}
$$

Becomes

$$
\xi''(x) + p(x)\,\xi'(x) + q(x)\,\xi(x) = 0 \tag{2}
$$

Where

$$
\begin{aligned}
p(x) &= \frac{-a\,x^n - b}{x} \\
q(x) &= \frac{b(a\,x^n + 1)}{x^2}
\end{aligned}
$$

Applying change of variables on the depndent variable $\xi(x) = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not $\xi(x)$.

$$
v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}
$$

Let the coefficient of $v(x)$ above be zero. Hence

$$
\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}
$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$
\frac{n(n-1)}{x^2} + \frac{n(-a\,x^n - b)}{x^2} + \frac{b(a\,x^n + 1)}{x^2} = 0 \tag{5}
$$

Solving (5) for n gives

$$
n = b \tag{6}
$$

Substituting this value in (3) gives

$$
\begin{aligned}
v''(x) + \left(\frac{2b}{x} + \frac{-a\,x^n - b}{x}\right) v'(x) &= 0 \\
v''(x) + \frac{(b - a\,x^n)\,v'(x)}{x} &= 0
\end{aligned} \tag{7}
$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(b - a\,x^n)\,u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= \frac{u(-b + a\,x^n)}{x} \end{aligned}$$

Where $f(x) = \frac{-b+a\,x^n}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= \frac{-b + a\,x^n}{x}\,dx \\ \int \frac{1}{u}\,du &= \int \frac{-b + a\,x^n}{x}\,dx \\ \ln(u) &= \frac{a\,x^n}{n} - \frac{b\ln(x^n)}{n} + c_1 \\ u &= \mathrm{e}^{\frac{a\,x^n}{n} - \frac{b\ln(x^n)}{n} + c_1} \\ &= c_1 \mathrm{e}^{\frac{a\,x^n}{n} - \frac{b\ln(x^n)}{n}} \end{aligned}$$

Which simplifies to

$$u(x) = c_1 \mathrm{e}^{\frac{a\,x^n}{n}} (x^n)^{-\frac{b}{n}}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= \int c_1 \mathrm{e}^{\frac{a\,x^n}{n}} (x^n)^{-\frac{b}{n}}\,dx + c_2 \end{aligned}$$

Hence

$$
\begin{aligned}
\xi(x) &= v(x)\, x^{n} \\
&= \left(\int c_1 \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} dx + c_2\right) x^{b} \\
&= \left(c_1 \left(\int \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} dx\right) + c_2\right) x^{b}
\end{aligned}
$$

The original ode (2) now reduces to first order ode

$$
\begin{aligned}
\xi(x)\, y' - y\xi'(x) + \xi(x)\, p(x)\, y &= \int \xi(x)\, r(x)\, dx \\
y' + y\left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)\, r(x)\, dx}{\xi\,(x)}
\end{aligned}
$$

$$
y' + y\left(\frac{a\,x^{n} + b}{x} - \frac{\left(c_3 \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} x^{b} + \frac{\left(\int c_3 \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} dx + c_2\right) x^{b} b}{x}\right) x^{-b}}{\int c_3 \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} dx + c_2}\right) = 0
$$

Which is now a first order ode. This is now solved for y. In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= -\frac{y\left(x^{n}\left(x^{n}\right)^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} dx\right) a + a\,x^{n}\left(x^{n}\right)^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a\,x^{n}}{n}} x\right) \left(x^{n}\right)^{-\frac{b}{n}}}{x\left(\int c_3 \mathrm{e}^{\frac{a\,x^{n}}{n}} \left(x^{n}\right)^{-\frac{b}{n}} dx + c_2\right)}
\end{aligned}
$$

Where $f(x) = -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)}$ and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y}\, dy &= -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx \\
\int \frac{1}{y}\, dy &= \int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx \\
\ln(y) &= \int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx + c_3 \\
y &= \mathrm{e}^{\int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx + c_3} \\
&= c_3 \mathrm{e}^{\int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx}
\end{aligned}
$$

Hence, the solution found using Lagrange adjoint equation method is

$$
y = c_3 \mathrm{e}^{\int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = c_3 \mathrm{e}^{\int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx} \tag{1}
$$

<u>Verification of solutions</u>

$$
y = c_3 \mathrm{e}^{\int -\frac{\left(x^{n} (x^{n})^{\frac{b}{n}} \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx\right) a + a x^{n} (x^{n})^{\frac{b}{n}} c_2 - c_3 \mathrm{e}^{\frac{a x^{n}}{n}} x\right) (x^{n})^{-\frac{b}{n}}}{x \left(\int c_3 \mathrm{e}^{\frac{a x^{n}}{n}} (x^{n})^{-\frac{b}{n}} dx + c_2\right)} dx}
$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y'' + f(x)y' + g(x)y = 0$
Problem number: 97.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{xy'' + (a\,x^n + b)\,y' + c(a\,x^n - cx + b)\,y = 0}$$

Maple trace

```

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 103.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{xy''+\left(a\,x^{n}+b\,x^{m}+c\right)y'+\left(c-1\right)\left(a\,x^{n-1}+b\,x^{m-1}\right)y=0}$$

28.43.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$xy''+\left(a\,x^{n}+b\,x^{m}+c\right)y'+\frac{\left(c-1\right)\left(a\,x^{n}+b\,x^{m}\right)y}{x}=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{a\,x^{n}+b\,x^{m}+c}{x}$$
$$q(x)=\frac{\left(c-1\right)\left(a\,x^{n}+b\,x^{m}\right)}{x^{2}}$$

Applying change of variables on the depndent variable $y=v(x)\,x^{n}$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x)+\left(\frac{2n}{x}+p\right)v'(x)+\left(\frac{n(n-1)}{x^{2}}+\frac{np}{x}+q\right)v(x)=0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(a\,x^n + b\,x^m + c)}{x^2} + \frac{(c-1)\,(a\,x^n + b\,x^m)}{x^2} = 0 \tag{5}$$

Solving (5) for n gives

$$n = -c + 1 \tag{6}$$

Substituting this value in (3) gives

$$v''(x) + \left(\frac{-2c+2}{x} + \frac{a\,x^n + b\,x^m + c}{x}\right) v'(x) = 0$$

$$v''(x) + \frac{(-c + 2 + a\,x^n + b\,x^m)\,v'(x)}{x} = 0 \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{(-c + 2 + a\,x^n + b\,x^m)\,u(x)}{x} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(-c + 2 + a\,x^n + b\,x^m)\,u}{x} \end{aligned}$$

Where $f(x) = -\frac{-c+2+a\,x^n+b\,x^m}{x}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{-c + 2 + a\,x^n + b\,x^m}{x}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{-c + 2 + a\,x^n + b\,x^m}{x}\,dx \\ \ln(u) &= (c-2)\ln(x) - \frac{b\,e^{m\ln(x)}}{m} - \frac{a\,e^{n\ln(x)}}{n} + c_1 \\ u &= e^{(c-2)\ln(x) - \frac{b\,e^{m\ln(x)}}{m} - \frac{a\,e^{n\ln(x)}}{n} + c_1} \\ &= c_1 e^{(c-2)\ln(x) - \frac{b\,e^{m\ln(x)}}{m} - \frac{a\,e^{n\ln(x)}}{n}} \end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^c \mathrm{e}^{-\frac{b\,x^m}{m}} \mathrm{e}^{-\frac{a\,x^n}{n}}}{x^2}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\,dx + c_2 \\ &= \int \frac{c_1 x^c \mathrm{e}^{-\frac{b\,x^m}{m}} \mathrm{e}^{-\frac{a\,x^n}{n}}}{x^2} dx + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\,x^n \\ &= \left(\int \frac{c_1 x^c \mathrm{e}^{-\frac{b\,x^m}{m}} \mathrm{e}^{-\frac{a\,x^n}{n}}}{x^2} dx + c_2\right) x^{-c+1} \\ &= x^{-c+1} \left(c_1 \left(\int x^{c-2} \mathrm{e}^{-\frac{b\,x^m}{m} - \frac{a\,x^n}{n}} dx\right) + c_2\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \left(\int \frac{c_1 x^c \mathrm{e}^{-\frac{b\,x^m}{m}} \mathrm{e}^{-\frac{a\,x^n}{n}}}{x^2} dx + c_2\right) x^{-c+1} \tag{1}$$

<u>Verification of solutions</u>

$$y = \left(\int \frac{c_1 x^c \mathrm{e}^{-\frac{b\,x^m}{m}} \mathrm{e}^{-\frac{a\,x^n}{n}}}{x^2} dx + c_2\right) x^{-c+1}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 105.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x+a)\,y''+(bx+c)\,y'+yb=0}$$

28.45.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int ((x+a)\,y''+(bx+c)\,y'+yb)\,dx=0$$
$$(bx+c-1)\,y+(x+a)\,y'=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$p(x) = -\frac{-bx - c + 1}{x + a}$$
$$q(x) = \frac{c_1}{x + a}$$

Hence the ode is

$$y' - \frac{(-bx - c + 1)\, y}{x + a} = \frac{c_1}{x + a}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-bx-c+1}{x+a}dx}$$
$$= e^{bx + (-ab+c-1)\ln(x+a)}$$

Which simplifies to

$$\mu = (x + a)^{-ab+c-1}\, e^{bx}$$

The ode becomes

$$\frac{d}{dx}(\mu y) = (\mu)\left(\frac{c_1}{x + a}\right)$$
$$\frac{d}{dx}\left((x + a)^{-ab+c-1}\, e^{bx} y\right) = \left((x + a)^{-ab+c-1}\, e^{bx}\right)\left(\frac{c_1}{x + a}\right)$$
$$d\left((x + a)^{-ab+c-1}\, e^{bx} y\right) = \left(c_1 (x + a)^{-ab+c-2}\, e^{bx}\right)\, dx$$

Integrating gives

$$(x + a)^{-ab+c-1}\, e^{bx} y = \int c_1 (x + a)^{-ab+c-2}\, e^{bx}\, dx$$
$$(x + a)^{-ab+c-1}\, e^{bx} y = \int c_1 (x + a)^{-ab+c-2}\, e^{bx} dx + c_2$$

Dividing both sides by the integrating factor $\mu = (x + a)^{-ab+c-1}\, e^{bx}$ results in

$$y = (x + a)^{ab-c+1}\, e^{-bx}\left(\int c_1 (x + a)^{-ab+c-2}\, e^{bx} dx\right) + c_2 (x + a)^{ab-c+1}\, e^{-bx}$$

which simplifies to

$$y = (x + a)^{ab-c+1}\, e^{-bx}\left(c_1\left(\int (x + a)^{-ab+c-2}\, e^{bx} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = (x+a)^{ab-c+1} \mathrm{e}^{-bx} \left(c_1 \left(\int (x+a)^{-ab+c-2} \mathrm{e}^{bx} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (x+a)^{ab-c+1} \mathrm{e}^{-bx} \left(c_1 \left(\int (x+a)^{-ab+c-2} \mathrm{e}^{bx} dx\right) + c_2\right)$$

Verified OK.

28.45.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x+a)\, y'' + (bx+c)\, y' + yb = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int ((x+a)\, y'' + (bx+c)\, y' + yb)\, dx = 0$$
$$(bx+c-1)\, y + (x+a)\, y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-bx-c+1}{x+a}$$
$$q(x) = \frac{c_1}{x+a}$$

Hence the ode is

$$y' - \frac{(-bx-c+1)\, y}{x+a} = \frac{c_1}{x+a}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-bx-c+1}{x+a} dx}$$
$$= \mathrm{e}^{bx+(-ab+c-1)\ln(x+a)}$$

Which simplifies to

$$\mu = (x+a)^{-ab+c-1}\, e^{bx}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x+a}\right) \\
\frac{d}{dx}\left((x+a)^{-ab+c-1}\, e^{bx} y\right) &= \left((x+a)^{-ab+c-1}\, e^{bx}\right)\left(\frac{c_1}{x+a}\right) \\
d\left((x+a)^{-ab+c-1}\, e^{bx} y\right) &= \left(c_1(x+a)^{-ab+c-2}\, e^{bx}\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
(x+a)^{-ab+c-1}\, e^{bx} y &= \int c_1(x+a)^{-ab+c-2}\, e^{bx}\, dx \\
(x+a)^{-ab+c-1}\, e^{bx} y &= \int c_1(x+a)^{-ab+c-2}\, e^{bx} dx + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = (x+a)^{-ab+c-1}\, e^{bx}$ results in

$$y = (x+a)^{ab-c+1}\, e^{-bx}\left(\int c_1(x+a)^{-ab+c-2}\, e^{bx} dx\right) + c_2(x+a)^{ab-c+1}\, e^{-bx}$$

which simplifies to

$$y = (x+a)^{ab-c+1}\, e^{-bx}\left(c_1\left(\int (x+a)^{-ab+c-2}\, e^{bx} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = (x+a)^{ab-c+1}\, e^{-bx}\left(c_1\left(\int (x+a)^{-ab+c-2}\, e^{bx} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (x+a)^{ab-c+1}\, e^{-bx}\left(c_1\left(\int (x+a)^{-ab+c-2}\, e^{bx} dx\right) + c_2\right)$$

Verified OK.

28.45.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x + a \\ q(x) &= bx + c \\ r(x) &= b \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= b \end{aligned}$$

Therefore (1) becomes

$$0 - (b) + (b) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$(bx + c - 1)\,y + (x + a)\,y' = c_1$$

We now have a first order ode to solve which is

$$(bx + c - 1)\,y + (x + a)\,y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-bx - c + 1}{x + a}$$
$$q(x) = \frac{c_1}{x + a}$$

Hence the ode is

$$y' - \frac{(-bx - c + 1)\, y}{x + a} = \frac{c_1}{x + a}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{-bx-c+1}{x+a}dx} \\ &= \mathrm{e}^{bx+(-ab+c-1)\ln(x+a)}\end{aligned}$$

Which simplifies to

$$\mu = (x + a)^{-ab+c-1}\, \mathrm{e}^{bx}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x + a}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left((x + a)^{-ab+c-1}\, \mathrm{e}^{bx} y\right) &= \left((x + a)^{-ab+c-1}\, \mathrm{e}^{bx}\right)\left(\frac{c_1}{x + a}\right) \\ \mathrm{d}\left((x + a)^{-ab+c-1}\, \mathrm{e}^{bx} y\right) &= \left(c_1 (x + a)^{-ab+c-2}\, \mathrm{e}^{bx}\right)\, \mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}(x + a)^{-ab+c-1}\, \mathrm{e}^{bx} y &= \int c_1 (x + a)^{-ab+c-2}\, \mathrm{e}^{bx}\, \mathrm{d}x \\ (x + a)^{-ab+c-1}\, \mathrm{e}^{bx} y &= \int c_1 (x + a)^{-ab+c-2}\, \mathrm{e}^{bx} dx + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = (x + a)^{-ab+c-1}\, \mathrm{e}^{bx}$ results in

$$y = (x + a)^{ab-c+1}\, \mathrm{e}^{-bx}\left(\int c_1 (x + a)^{-ab+c-2}\, \mathrm{e}^{bx} dx\right) + c_2 (x + a)^{ab-c+1}\, \mathrm{e}^{-bx}$$

which simplifies to

$$y = (x + a)^{ab-c+1}\, \mathrm{e}^{-bx}\left(c_1\left(\int (x + a)^{-ab+c-2}\, \mathrm{e}^{bx} dx\right) + c_2\right)$$

Summary
The solution(s) found are the following

$$y = (x+a)^{ab-c+1} \mathrm{e}^{-bx} \left(c_1 \left(\int (x+a)^{-ab+c-2} \mathrm{e}^{bx} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (x+a)^{ab-c+1} \mathrm{e}^{-bx} \left(c_1 \left(\int (x+a)^{-ab+c-2} \mathrm{e}^{bx} dx\right) + c_2\right)$$

Verified OK.

28.45.4 Maple step by step solution

Let's solve

$(x+a)\, y'' + (bx+c)\, y' + yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{by}{x+a} - \frac{(bx+c)y'}{x+a}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(bx+c)y'}{x+a} + \frac{by}{x+a} = 0$

□ Check to see if $x_0 = -a$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{bx+c}{x+a}, P_3(x) = \frac{b}{x+a}\right]$

  - $(x+a) \cdot P_2(x)$ is analytic at $x = -a$

    $\left((x+a) \cdot P_2(x)\right)\Big|_{x=-a} = -ab + c$

  - $(x+a)^2 \cdot P_3(x)$ is analytic at $x = -a$

    $\left((x+a)^2 \cdot P_3(x)\right)\Big|_{x=-a} = 0$

  - $x = -a$is a regular singular point

  Check to see if $x_0 = -a$ is a regular singular point

  $x_0 = -a$

- Multiply by denominators

$(x+a)\,y''+(bx+c)\,y'+yb=0$

- Change variables using $x=u-a$ so that the regular singular point is at $u=0$

$u\left(\frac{d^2}{du^2}y(u)\right)+(-ab+bu+c)\left(\frac{d}{du}y(u)\right)+by(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$

  - Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  - Convert $u\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-1}$

  - Shift index using $k->k+1$

  $u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)\,(k+r)\,u^{k+r}$

Rewrite ODE with series expansions

$-a_0r(ab-c-r+1)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)\,(ab-c-k-r)+ba_k(k+1+r)\right)u^{k+r}\right)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-r(ab-c-r+1)=0$

- Values of r that satisfy the indicial equation

$r\in\{0,ab-c+1\}$

- Each term in the series must be 0, giving the recursion relation

$-(k+1+r)\,(a_{k+1}(ab-c-k-r)-ba_k)=0$

- Recursion relation that defines series solution to ODE

$a_{k+1}=\frac{ba_k}{ab-c-k-r}$

- Recursion relation for $r=0$

$a_{k+1} = \frac{b a_k}{ab-c-k}$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{b a_k}{ab-c-k}\right]$$

- Revert the change of variables $u = x + a$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+a)^k, a_{k+1} = \frac{b a_k}{ab-c-k}\right]$$

- Recursion relation for $r = ab - c + 1$

$a_{k+1} = \frac{b a_k}{-k-1}$

- Solution for $r = ab - c + 1$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{ab-c+k+1}, a_{k+1} = \frac{b a_k}{-k-1}\right]$$

- Revert the change of variables $u = x + a$

$$\left[y = \sum_{k=0}^{\infty} a_k (x+a)^{ab-c+k+1}, a_{k+1} = \frac{b a_k}{-k-1}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} d_k (x+a)^k\right) + \left(\sum_{k=0}^{\infty} e_k (x+a)^{ab-c+k+1}\right), d_{1+k} = \frac{b d_k}{ab-c-k}, e_{1+k} = \frac{b e_k}{-k-1}\right]$$

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$(ax+b)\,y''+s(cx+d)\,y'-s^2((a+c)\,x+b+d)\,y=0$$

28.47.1 Maple step by step solution

Let's solve

$(ax+b)\,y''+s(cx+d)\,y'-s^2((a+c)\,x+b+d)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{s^2(ax+cx+b+d)y}{ax+b}-\frac{s(cx+d)y'}{ax+b}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{s(cx+d)y'}{ax+b}-\frac{s^2(ax+cx+b+d)y}{ax+b}=0$

□ Check to see if $x_0=-\frac{b}{a}$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{s(cx+d)}{ax+b}, P_3(x) = -\frac{s^2(ax+cx+b+d)}{ax+b}\right]$

- $\left(x+\frac{b}{a}\right) \cdot P_2(x)$ is analytic at $x = -\frac{b}{a}$

  $\left(\left(x+\frac{b}{a}\right) \cdot P_2(x)\right)\bigg|_{x=-\frac{b}{a}} = \frac{s\left(-\frac{bc}{a}+d\right)}{a}$

- $\left(x+\frac{b}{a}\right)^2 \cdot P_3(x)$ is analytic at $x = -\frac{b}{a}$

  $\left(\left(x+\frac{b}{a}\right)^2 \cdot P_3(x)\right)\bigg|_{x=-\frac{b}{a}} = 0$

- $x = -\frac{b}{a}$ is a regular singular point

  Check to see if $x_0 = -\frac{b}{a}$ is a regular singular point

  $x_0 = -\frac{b}{a}$

- Multiply by denominators

  $(ax+b)\, y'' + s(cx+d)\, y' - s^2(ax+cx+b+d)\, y = 0$

- Change variables using $x = u - \frac{b}{a}$ so that the regular singular point is at $u = 0$

  $au\left(\frac{d^2}{du^2}y(u)\right) + \left(scu - \frac{csb}{a} + ds\right)\left(\frac{d}{du}y(u)\right) + \left(-s^2au - s^2cu + \frac{s^2bc}{a} - d\,s^2\right) y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k- >k-m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

$$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)(k+r-1)u^{k+r-1}$$

- Shift index using $k->k+1$

$$u\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-1}^{\infty}a_{k+1}(k+1+r)(k+r)u^{k+r}$$

Rewrite ODE with series expansions

$$\frac{a_0 r(a^2r+dsa-bcs-a^2)u^{-1+r}}{a}+\left(\frac{a_1(1+r)(a^2r+dsa-bcs)}{a}+\frac{a_0 s(acr-dsa+bcs)}{a}\right)u^r+\left(\sum_{k=1}^{\infty}\left(\frac{a_{k+1}(k+1+r)(a^2(k+1)+a^2r}{a}\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$\frac{r(a^2r+dsa-bcs-a^2)}{a}=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{-dsa+bcs+a^2}{a^2}\right\}$$

- Each term must be 0

$$\frac{a_1(1+r)(a^2r+dsa-bcs)}{a}+\frac{a_0 s(acr-dsa+bcs)}{a}=0$$

- Each term in the series must be 0, giving the recursion relation

$$\frac{(-s^2a_{k-1}+a_{k+1}(k+1+r)(k+r))a^2+s((-ca_{k-1}-da_k)s+d(k+1+r)a_{k+1}+ca_k(k+r))a-c(-a_ks+a_{k+1}(k+1+r))bs}{a}=0$$

- Shift index using $k->k+1$

$$\frac{(-s^2a_k+a_{k+2}(k+2+r)(k+1+r))a^2+s((-ca_k-da_{k+1})s+d(k+2+r)a_{k+2}+ca_{k+1}(k+1+r))a-c(-a_{k+1}s+a_{k+2}(k+2+r))bs}{a}=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=\frac{s(a^2sa_k-acka_{k+1}-acra_{k+1}+acsa_k+adsa_{k+1}-bcsa_{k+1}-aca_{k+1})}{(k+2+r)(a^2k+a^2r+dsa-bcs+a^2)}$$

- Recursion relation for $r=0$

$$a_{k+2}=\frac{s(a^2sa_k-acka_{k+1}+acsa_k+adsa_{k+1}-bcsa_{k+1}-aca_{k+1})}{(k+2)(a^2k+dsa-bcs+a^2)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^k,a_{k+2}=\frac{s(a^2sa_k-acka_{k+1}+acsa_k+adsa_{k+1}-bcsa_{k+1}-aca_{k+1})}{(k+2)(a^2k+dsa-bcs+a^2)},\frac{a_1(dsa-bcs)}{a}+\frac{a_0s(-dsa+bcs)}{a}=0\right.$$

- Revert the change of variables $u=x+\frac{b}{a}$

$$\left[y=\sum_{k=0}^{\infty}a_k\left(x+\frac{b}{a}\right)^k,a_{k+2}=\frac{s(a^2sa_k-acka_{k+1}+acsa_k+adsa_{k+1}-bcsa_{k+1}-aca_{k+1})}{(k+2)(a^2k+dsa-bcs+a^2)},\frac{a_1(dsa-bcs)}{a}+\frac{a_0s(-dsa+bcs)}{a}\right.$$

- Recursion relation for $r=\frac{-dsa+bcs+a^2}{a^2}$

$$a_{k+2} = \frac{s\left(a^2 s a_k - ack a_{k+1} - \frac{c\left(-dsa+bcs+a^2\right)a_{k+1}}{a} + acsa_k + adsa_{k+1} - bcsa_{k+1} - aca_{k+1}\right)}{\left(k+2+\frac{-dsa+bcs+a^2}{a^2}\right)(a^2k+2a^2)}$$

- Solution for $r = \frac{-dsa+bcs+a^2}{a^2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{-dsa+bcs+a^2}{a^2}}, a_{k+2} = \frac{s\left(a^2 s a_k - ack a_{k+1} - \frac{c\left(-dsa+bcs+a^2\right)a_{k+1}}{a} + acsa_k + adsa_{k+1} - bcsa_{k+1} - aca_{k+1}\right)}{\left(k+2+\frac{-dsa+bcs+a^2}{a^2}\right)(a^2k+2a^2)}\right.$$

- Revert the change of variables $u = x + \frac{b}{a}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x+\frac{b}{a}\right)^{k+\frac{-dsa+bcs+a^2}{a^2}}, a_{k+2} = \frac{s\left(a^2 s a_k - ack a_{k+1} - \frac{c\left(-dsa+bcs+a^2\right)a_{k+1}}{a} + acsa_k + adsa_{k+1} - bcsa_{k+1} - aca\right.}{\left(k+2+\frac{-dsa+bcs+a^2}{a^2}\right)(a^2k+2a^2)}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} e_k \left(x+\frac{b}{a}\right)^{k}\right) + \left(\sum_{k=0}^{\infty} f_k \left(x+\frac{b}{a}\right)^{k+\frac{-dsa+bcs+a^2}{a^2}}\right), e_{k+2} = \frac{s(a^2 se_k - acke_{1+k} + acse_k + adse_{1+k} - bcse_1}{(k+2)(a^2k+dsa-bcs+a^2)}\right.$$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

  $$u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$

- Shift index using $k- >k - m$

  $$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du} y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du} y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r) u^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$u^m \cdot \left(\frac{d}{du} y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r) u^{k+r}$$

- Convert $u \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion

  $$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1) u^{k+r-1}$$

- Shift index using $k- >k+1$

  $$u \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)(k+r) u^{k+r}$$

  Rewrite ODE with series expansions

  $$-\frac{a_0 r(-a_2^2 r+a_1 b_2+a_2^2-a_2 b_1) u^{-1+r}}{a_2} + \left(-\frac{a_1(1+r)(-a_2^2 r+a_1 b_2-a_2 b_1)}{a_2} - \frac{a_0(-a_1 a_2 r+a_0 b_2-a_2 b_0)}{a_2}\right) u^r + \left(\sum_{k=1}^{\infty} \left(-\frac{a_{k+1}(\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-\frac{r(-a_2^2 r+a_1 b_2+a_2^2-a_2 b_1)}{a_2} = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, \frac{a_1 b_2+a_2^2-a_2 b_1}{a_2^2}\right\}$$

- Each term must be 0

  $$-\frac{a_1(1+r)(-a_2^2 r+a_1 b_2-a_2 b_1)}{a_2} - \frac{a_0(-a_1 a_2 r+a_0 b_2-a_2 b_0)}{a_2} = 0$$

- Each term in the series must be 0, giving the recursion relation

  $$\frac{a_{k+1}(k+1+r)(k+r)a_2^2+(b_1(k+1+r)a_{k+1}+k a_1 a_k+r a_1 a_k+a_{k-1}a_0+a_k b_0)a_2-b_2(a_1(k+1+r)a_{k+1}+a_k a_0)}{a_2} = 0$$

- Shift index using $k- >k+1$

  $$\frac{a_{k+2}(k+2+r)(k+1+r)a_2^2+(b_1(k+2+r)a_{k+2}+(k+1)a_1 a_{k+1}+r a_1 a_{k+1}+a_k a_0+a_{k+1}b_0)a_2-b_2(a_1(k+2+r)a_{k+2}+a_{k+1}a_0)}{a_2} = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = \frac{a_1 a_2 k a_{k+1}+a_1 a_2 r a_{k+1}+a_0 a_2 a_k-a_0 b_2 a_{k+1}+a_1 a_2 a_{k+1}+a_2 b_0 a_{k+1}}{(k+2+r)(-a_2^2 k-a_2^2 r+a_1 b_2-a_2^2-a_2 b_1)}$$

- Recursion relation for $r=0$

  $$a_{k+2} = \frac{a_1 a_2 k a_{k+1}+a_0 a_2 a_k-a_0 b_2 a_{k+1}+a_1 a_2 a_{k+1}+a_2 b_0 a_{k+1}}{(k+2)(-a_2^2 k+a_1 b_2-a_2^2-a_2 b_1)}$$

- Solution for $r=0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = \frac{a_1 a_2 k a_{k+1}+a_0 a_2 a_k-a_0 b_2 a_{k+1}+a_1 a_2 a_{k+1}+a_2 b_0 a_{k+1}}{(k+2)(-a_2^2 k+a_1 b_2-a_2^2-a_2 b_1)}, -\frac{a_1(a_1 b_2-a_2 b_1)}{a_2} - \frac{a_0(a_0 b_2-a_2 b_0)}{a_2} =\right.$$

- Revert the change of variables $u = x+\frac{b_2}{a_2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k \left(x+\frac{b_2}{a_2}\right)^k, a_{k+2} = \frac{a_1 a_2 k a_{k+1}+a_0 a_2 a_k-a_0 b_2 a_{k+1}+a_1 a_2 a_{k+1}+a_2 b_0 a_{k+1}}{(k+2)(-a_2^2 k+a_1 b_2-a_2^2-a_2 b_1)}, -\frac{a_1(a_1 b_2-a_2 b_1)}{a_2} - \frac{a_0(a_0 b_2-a\right.}{a_2}$$

- Recursion relation for $r = \frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}$

$$a_{k+2} = \frac{a_1 a_2 k a_{k+1} + \frac{a_1 \left(a_1 b_2 + a_2^2 - a_2 b_1\right) a_{k+1}}{a_2} + a_0 a_2 a_k - a_0 b_2 a_{k+1} + a_1 a_2 a_{k+1} + a_2 b_0 a_{k+1}}{\left(k+2+\frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}\right)\left(-a_2^2 k - 2a_2^2\right)}$$

- Solution for $r = \frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}}, a_{k+2} = \frac{a_1 a_2 k a_{k+1} + \frac{a_1 \left(a_1 b_2 + a_2^2 - a_2 b_1\right) a_{k+1}}{a_2} + a_0 a_2 a_k - a_0 b_2 a_{k+1} + a_1 a_2 a_{k+1} + a_2 b_0 a_{k+1}}{\left(k+2+\frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}\right)\left(-a_2^2 k - 2a_2^2\right)}\right.$$

- Revert the change of variables $u = x + \frac{b_2}{a_2}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x + \frac{b_2}{a_2}\right)^{k+\frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}}, a_{k+2} = \frac{a_1 a_2 k a_{k+1} + \frac{a_1 \left(a_1 b_2 + a_2^2 - a_2 b_1\right) a_{k+1}}{a_2} + a_0 a_2 a_k - a_0 b_2 a_{k+1} + a_1 a_2 a_{k+1} + a_2}{\left(k+2+\frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}\right)\left(-a_2^2 k - 2a_2^2\right)}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k \left(x + \frac{b_2}{a_2}\right)^k\right) + \left(\sum_{k=0}^{\infty} b_k \left(x + \frac{b_2}{a_2}\right)^{k+\frac{a_1 b_2 + a_2^2 - a_2 b_1}{a_2^2}}\right), a_{k+2} = \frac{a_1 a_2 k a_{1+k} + a_0 a_2 a_k - a_0 b_2 a_{1+k} + a_1 a}{(k+2)\left(-a_2^2 k + a_1 b_2 - a_2^2 -\right.}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-3 Equation of form $(ax+b)y''+f(x)y'+g(x)y=0$
Problem number: 109.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{(x+\gamma)\,y''+(a\,x^n+b\,x^m+c)\,y'+\left(an\,x^{n-1}+x^{m-1}bm\right)y=0}$$

28.49.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int\left((x+\gamma)\,y''+(a\,x^n+b\,x^m+c)\,y'+\frac{(x^n na+b\,x^m m)\,y}{x}\right)dx=0$$
$$\frac{(ax\,x^n+x^m bx+cx-x)\,y}{x}+(x+\gamma)\,y'=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$p(x) = -\frac{-a\,x^n - b\,x^m - c + 1}{x+\gamma}$$
$$q(x) = \frac{c_1}{x+\gamma}$$

Hence the ode is

$$y' - \frac{(-a\,x^n - b\,x^m - c + 1)\,y}{x+\gamma} = \frac{c_1}{x+\gamma}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{c_1}{x+\gamma}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx} y\right) = \left(\mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx}\right)\left(\frac{c_1}{x+\gamma}\right)$$
$$\mathrm{d}\left(\mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx} y\right) = \left(\frac{c_1 \mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx}}{x+\gamma}\right)\mathrm{d}x$$

Integrating gives

$$\mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx} y = \int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx}}{x+\gamma}\,\mathrm{d}x$$
$$\mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx} y = \int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx}}{x+\gamma}dx + c_2$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c+1}{x+\gamma}dx}$ results in

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx\right)}\left(\int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2 \mathrm{e}^{-\left(\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx\right)}$$

which simplifies to

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx\right)}\left(c_1\left(\int \frac{\mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx\right)}\left(c_1\left(\int \frac{\mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^n + b\,x^m + c - 1}{x+\gamma} dx\right)} \left(c_1 \left(\int \frac{\mathrm{e}^{\int \frac{a\,x^n + b\,x^m + c - 1}{x+\gamma} dx}}{x+\gamma} dx\right) + c_2\right)$$

Verified OK.

28.49.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(x+\gamma)\,y'' + (a\,x^n + b\,x^m + c)\,y' + \frac{(x^n n a + b\,x^m m)\,y}{x} = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left((x+\gamma)\,y'' + (a\,x^n + b\,x^m + c)\,y' + \frac{(x^n n a + b\,x^m m)\,y}{x}\right) dx = 0$$
$$\frac{(ax\,x^n + x^m bx + cx - x)\,y}{x} + (x+\gamma)\,y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-a\,x^n - b\,x^m - c + 1}{x+\gamma}$$
$$q(x) = \frac{c_1}{x+\gamma}$$

Hence the ode is

$$y' - \frac{(-a\,x^n - b\,x^m - c + 1)\,y}{x+\gamma} = \frac{c_1}{x+\gamma}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-a\,x^n - b\,x^m - c + 1}{x+\gamma} dx}$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x+\gamma}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\int -\frac{-a\,x^n-b\,x^m-c+1}{x+\gamma}dx} y\right) &= \left(\mathrm{e}^{\int -\frac{-a\,x^n-b\,x^m-c+1}{x+\gamma}dx}\right)\left(\frac{c_1}{x+\gamma}\right) \\
\mathrm{d}\left(\mathrm{e}^{\int -\frac{-a\,x^n-b\,x^m-c+1}{x+\gamma}dx} y\right) &= \left(\frac{c_1 \mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}\right)\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{\int -\frac{-a\,x^n-b\,x^m-c+1}{x+\gamma}dx} y &= \int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}\,\mathrm{d}x \\
\mathrm{e}^{\int -\frac{-a\,x^n-b\,x^m-c+1}{x+\gamma}dx} y &= \int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}dx + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-a\,x^n-b\,x^m-c+1}{x+\gamma}dx}$ results in

$$
y = \mathrm{e}^{-\left(\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx\right)}\left(\int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2 \mathrm{e}^{-\left(\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx\right)}
$$

which simplifies to

$$
y = \mathrm{e}^{-\left(\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx\right)}\left(c_1\left(\int \frac{\mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right)
$$

Summary

The solution(s) found are the following

$$
y = \mathrm{e}^{-\left(\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx\right)}\left(c_1\left(\int \frac{\mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right) \tag{1}
$$

Verification of solutions

$$
y = \mathrm{e}^{-\left(\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx\right)}\left(c_1\left(\int \frac{\mathrm{e}^{\int \frac{a\,x^n+b\,x^m+c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right)
$$

Verified OK.

28.49.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\, y'' + q(x)\, y' + r(x)\, y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x + \gamma \\ q(x) &= a\, x^{n} + b\, x^{m} + c \\ r(x) &= \frac{x^{n} n a + b\, x^{m} m}{x} \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= \frac{a n\, x^{n}}{x} + \frac{b\, x^{m} m}{x} \end{aligned}$$

Therefore (1) becomes

$$0 - \left(\frac{a n\, x^{n}}{x} + \frac{b\, x^{m} m}{x}\right) + \left(\frac{x^{n} n a + b\, x^{m} m}{x}\right) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\, y' + \left(q(x) - p'(x)\right) y\right)' = s(x)$$

Integrating gives

$$p(x)\, y' + \left(q(x) - p'(x)\right) y = \int s(x)\, dx$$

Substituting the above values for p, q, r, s gives

$$(x + \gamma)\, y' + \left(a\, x^{n} + b\, x^{m} + c - 1\right) y = c_1$$

We now have a first order ode to solve which is

$$(x + \gamma)\, y' + \left(a\, x^{n} + b\, x^{m} + c - 1\right) y = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}\\ q(x) &= \frac{c_1}{x + \gamma}\end{aligned}$$

Hence the ode is

$$y' - \frac{\left(-a\,x^{n} - b\,x^{m} - c + 1\right) y}{x + \gamma} = \frac{c_1}{x + \gamma}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x + \gamma}\right)\\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx} y\right) &= \left(\mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx}\right)\left(\frac{c_1}{x + \gamma}\right)\\ \mathrm{d}\left(\mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx} y\right) &= \left(\frac{c_1 \mathrm{e}^{\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx}}{x + \gamma}\right)\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx} y &= \int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx}}{x + \gamma}\,\mathrm{d}x\\ \mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx} y &= \int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx}}{x + \gamma}dx + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-a\,x^{n} - b\,x^{m} - c + 1}{x + \gamma}dx}$ results in

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx\right)}\left(\int \frac{c_1 \mathrm{e}^{\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx}}{x + \gamma}dx\right) + c_2 \mathrm{e}^{-\left(\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx\right)}$$

which simplifies to

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx\right)}\left(c_1\left(\int \frac{\mathrm{e}^{\int \frac{a\,x^{n} + b\,x^{m} + c - 1}{x + \gamma}dx}}{x + \gamma}dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^{n}+b\,x^{m}+c-1}{x+\gamma}dx\right)} \left(c_1 \left(\int \frac{\mathrm{e}^{\int \frac{a\,x^{n}+b\,x^{m}+c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-\left(\int \frac{a\,x^{n}+b\,x^{m}+c-1}{x+\gamma}dx\right)} \left(c_1 \left(\int \frac{\mathrm{e}^{\int \frac{a\,x^{n}+b\,x^{m}+c-1}{x+\gamma}dx}}{x+\gamma}dx\right) + c_2\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 110.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + ay = 0}$$

29.1.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + 0rx^{r-1} + a\,x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + 0\,x^r + a\,x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + 0 + a = 0$$

Or

$$r^2 + a - r = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$
\begin{aligned}
r_1 &= \frac{1}{2} - \frac{\sqrt{1-4a}}{2} \\
r_2 &= \frac{1}{2} + \frac{\sqrt{1-4a}}{2}
\end{aligned}
$$

Since the roots are real and distinct, then the general solution is

$$
y = c_1 y_1 + c_2 y_2
$$

Where $y_1 = x^{r_1}$ and $y_2 = x^{r_2}$. Hence

$$
y = c_1 x^{\frac{1}{2} - \frac{\sqrt{1-4a}}{2}} + c_2 x^{\frac{1}{2} + \frac{\sqrt{1-4a}}{2}}
$$

Summary

The solution(s) found are the following

$$
y = c_1 x^{\frac{1}{2} - \frac{\sqrt{1-4a}}{2}} + c_2 x^{\frac{1}{2} + \frac{\sqrt{1-4a}}{2}} \tag{1}
$$

Verification of solutions

$$
y = c_1 x^{\frac{1}{2} - \frac{\sqrt{1-4a}}{2}} + c_2 x^{\frac{1}{2} + \frac{\sqrt{1-4a}}{2}}
$$

Verified OK.

29.1.2 Solving using Kovacic algorithm

Writing the ode as

$$
x^2 y'' + a y = 0 \tag{1}
$$

$$
A y'' + B y' + C y = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 \\
B &= 0 \\
C &= a
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A} \, dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{a}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 113: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{a}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -a$. Hence

$$\begin{aligned}
E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\
&= \left\{2, 2 - 2\sqrt{1 - 4a}, 2 + 2\sqrt{1 - 4a}\right\}
\end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = -\frac{a}{x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -1$. Hence

$$\begin{aligned}
E_\infty &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\
&= \{2\}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{2, 2-2\sqrt{1-4a}, 2+2\sqrt{1-4a}\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2,\; e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2-(2)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{2}{(x-(0))}\right) \\ &= \frac{1}{x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{x} + \frac{a}{x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + \sqrt{1 - 4a}}{2x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{1+\sqrt{1-4a}}{2x} dx} \\ &= x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1 \\ &= x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}}\end{aligned}$$

Which simplifies to

$$y_1 = x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\
&= x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}} \int \frac{1}{x^{1+\sqrt{1-4a}}} \, dx \\
&= x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}} \left(-\frac{x^{-\sqrt{1-4a}}}{\sqrt{1-4a}} \right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}} \right) + c_2 \left(x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}} \left(-\frac{x^{-\sqrt{1-4a}}}{\sqrt{1-4a}} \right) \right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}} - \frac{c_2 x^{\frac{1}{2}-\frac{\sqrt{1-4a}}{2}}}{\sqrt{1-4a}} \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{1}{2}+\frac{\sqrt{1-4a}}{2}} - \frac{c_2 x^{\frac{1}{2}-\frac{\sqrt{1-4a}}{2}}}{\sqrt{1-4a}}$$

Verified OK.

29.1.3 Maple step by step solution

Let's solve

$y''x^2 + ay = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{ay}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{ay}{x^2}=0$

☐ Check to see if $x_0=0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=0, P_3(x)=\frac{a}{x^2}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

    $(x\cdot P_2(x))\bigg|_{x=0}=0$

  ◦ $x^2\cdot P_3(x)$ is analytic at $x=0$

    $(x^2\cdot P_3(x))\bigg|_{x=0}=a$

  ◦ $x=0$is a regular singular point

    Check to see if $x_0=0$ is a regular singular point

    $x_0=0$

- Multiply by denominators

  $y''x^2+ay=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty}a_k x^{k+r}$

☐ Rewrite DE with series expansions

  ◦ Convert $x^2\cdot y''$ to series expansion

    $x^2\cdot y''=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,x^{k+r}$

    Rewrite DE with series expansions

    $\sum_{k=0}^{\infty}a_k(k^2+2kr+r^2+a-k-r)\,x^{k+r}=0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r=0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k^2+a-k)=0$

- Recursion relation that defines series solution to ODE

$a_k = 0$

- Recursion relation for $r = 0$

  $a_k = 0$

- Solution for $r = 0$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_k = 0\right]$$

Problem number: 111.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + (ax + b)\,y = 0}$$

29.2.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + (ax + b)\,y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \,\text{BesselJ}\,(n, \beta\, x^{\gamma}) + c_2 \,\text{BesselY}\,(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2\sqrt{a}$$
$$n = \sqrt{-4b+1}$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\sqrt{-4b+1}, 2\sqrt{a}\,\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\sqrt{-4b+1}, 2\sqrt{a}\,\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\sqrt{-4b+1}, 2\sqrt{a}\,\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\sqrt{-4b+1}, 2\sqrt{a}\,\sqrt{x}\right) \quad (1)$$

Verification of solutions

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\sqrt{-4b+1}, 2\sqrt{a}\,\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\sqrt{-4b+1}, 2\sqrt{a}\,\sqrt{x}\right)$$

Verified OK.

29.2.2 Maple step by step solution

Let's solve

$y''x^2 + (ax+b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(ax+b)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(ax+b)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = 0, P_3(x) = \frac{ax+b}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = 0$$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = b$$

- ◦ $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$$y''x^2 + (ax + b)\, y = 0$$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..1$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- ◦ Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- ◦ Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0 (r^2 + b - r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k (k^2 + 2kr + r^2 + b - k - r) + a_{k-1} a\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r^2 + b - r = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{\frac{1}{2} - \frac{\sqrt{-4b+1}}{2}, \frac{\sqrt{-4b+1}}{2} + \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$\left(k^2 + (2r - 1)\, k + r^2 + b - r\right) a_k + a_{k-1} a = 0$$

- Shift index using $k- > k+1$

$$\left(\left(k+1\right)^{2}+\left(2r-1\right)\left(k+1\right)+r^{2}+b-r\right)a_{k+1}+a_{k}a=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{a_{k}a}{k^{2}+2kr+r^{2}+b+k+r}$$

- Recursion relation for $r=\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}$

$$a_{k+1}=-\frac{a_{k}a}{k^{2}+2k\left(\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}\right)+\left(\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}\right)^{2}+b+k+\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}}$$

- Solution for $r=\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_{k}x^{k+\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}},a_{k+1}=-\frac{a_{k}a}{k^{2}+2k\left(\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}\right)+\left(\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}\right)^{2}+b+k+\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}}\right]$$

- Recursion relation for $r=\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}$

$$a_{k+1}=-\frac{a_{k}a}{k^{2}+2k\left(\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}\right)+\left(\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}\right)^{2}+b+k+\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}}$$

- Solution for $r=\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}$

$$\left[y=\sum_{k=0}^{\infty}a_{k}x^{k+\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}},a_{k+1}=-\frac{a_{k}a}{k^{2}+2k\left(\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}\right)+\left(\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}\right)^{2}+b+k+\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}c_{k}x^{k+\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}}\right)+\left(\sum_{k=0}^{\infty}d_{k}x^{k+\frac{\sqrt{-4b+1}}{2}+\frac{1}{2}}\right),c_{1+k}=-\frac{c_{k}a}{k^{2}+2k\left(\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}\right)+\left(\frac{1}{2}-\frac{\sqrt{-4b+1}}{2}\right)^{2}+b+k+$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 112.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(a^2x^2 - n(n+1)\right) y = 0}$$

29.3.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(a^2x^2 - n^2 - n\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= a \\
n &= -n - \frac{1}{2} \\
\gamma &= 1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\ \mathrm{BesselJ}\left(-n - \frac{1}{2}, ax\right) + c_2\sqrt{x}\ \mathrm{BesselY}\left(-n - \frac{1}{2}, ax\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\ \mathrm{BesselJ}\left(-n - \frac{1}{2}, ax\right) + c_2\sqrt{x}\ \mathrm{BesselY}\left(-n - \frac{1}{2}, ax\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\ \mathrm{BesselJ}\left(-n - \frac{1}{2}, ax\right) + c_2\sqrt{x}\ \mathrm{BesselY}\left(-n - \frac{1}{2}, ax\right)$$

Verified OK.

29.3.2 Maple step by step solution

Let's solve

$y''x^2 + (a^2x^2 - n^2 - n)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(a^2x^2-n^2-n)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a^2x^2-n^2-n)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$\left[P_2(x) = 0, P_3(x) = \frac{a^2x^2-n^2-n}{x^2}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = 0$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = -n^2 - n$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 + (a^2x^2 - n^2 - n)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k - m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(r+n)\,(r-1-n)\,x^r + a_1(r+n+1)\,(r-n)\,x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(r+n+k)\,(r-1-n+k) + a_k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(r+n)\,(r-1-n) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-n, n+1\}$

- Each term must be 0

  $a_1(r+n+1)(r-n)=0$
- Solve for the dependent coefficient(s)

  $a_1=0$
- Each term in the series must be 0, giving the recursion relation

  $a_k(r+n+k)(r-1-n+k)+a_{k-2}a^2=0$
- Shift index using $k->k+2$

  $a_{k+2}(r+n+k+2)(r+1-n+k)+a_k a^2=0$
- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a_k a^2}{(r+n+k+2)(r+1-n+k)}$
- Recursion relation for $r=-n$

  $a_{k+2}=-\frac{a_k a^2}{(k+2)(-2n+1+k)}$
- Solution for $r=-n$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-n}, a_{k+2}=-\frac{a_k a^2}{(k+2)(-2n+1+k)}, a_1=0\right]$
- Recursion relation for $r=n+1$

  $a_{k+2}=-\frac{a_k a^2}{(2n+3+k)(k+2)}$
- Solution for $r=n+1$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+n+1}, a_{k+2}=-\frac{a_k a^2}{(2n+3+k)(k+2)}, a_1=0\right]$
- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} b_k x^{k-n}\right)+\left(\sum_{k=0}^{\infty} c_k x^{k+n+1}\right), b_{k+2}=-\frac{b_k a^2}{(k+2)(-2n+1+k)}, b_1=0, c_{k+2}=-\frac{c_k a^2}{(2n+3+k)(k+2)}, c_1\right.$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 115.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(a\,x^2 + bx + c\right) y = 0}$$

29.6.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(a\,x^2 + bx + c\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = \sqrt{-4c+1}$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\ \mathrm{BesselJ}\left(\sqrt{-4c+1}, 2\sqrt{x}\right) + c_2\sqrt{x}\ \mathrm{BesselY}\left(\sqrt{-4c+1}, 2\sqrt{x}\right)$$

Summary
The solution(s) found are the following

$$y = c_1\sqrt{x}\ \mathrm{BesselJ}\left(\sqrt{-4c+1}, 2\sqrt{x}\right) + c_2\sqrt{x}\ \mathrm{BesselY}\left(\sqrt{-4c+1}, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\ \mathrm{BesselJ}\left(\sqrt{-4c+1}, 2\sqrt{x}\right) + c_2\sqrt{x}\ \mathrm{BesselY}\left(\sqrt{-4c+1}, 2\sqrt{x}\right)$$

Verified OK.

29.6.2 Maple step by step solution

Let's solve

$y''x^2 + (a\,x^2 + bx + c)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(a\,x^2+bx+c)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a\,x^2+bx+c)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = 0, P_3(x) = \frac{a\,x^2+bx+c}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$$\left(x \cdot P_2(x)\right)\Bigg|_{x=0} = 0$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\Bigg|_{x=0} = c$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 + (a\,x^2 + bx + c)\,y = 0$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..2$

    $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

  - Shift index using $k- >k - m$

    $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

  - Convert $x^2 \cdot y''$ to series expansion

    $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(r^2 + c - r)\,x^r + \left((r^2 + c + r)\,a_1 + a_0 b\right)x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k^2 + 2kr + r^2 + c - k - r) + b a_{k-1} +\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r^2 + c - r = 0$

- Values of r that satisfy the indicial equation

  $$r \in \left\{\frac{1}{2} - \frac{\sqrt{-4c+1}}{2}, \frac{\sqrt{-4c+1}}{2} + \frac{1}{2}\right\}$$

- Each term must be 0

  $(r^2 + c + r)\,a_1 + a_0 b = 0$

- Solve for the dependent coefficient(s)

$a_1 = -\frac{a_0 b}{r^2+c+r}$

- Each term in the series must be 0, giving the recursion relation

$(k^2 + (2r-1)k + r^2 + c - r)\, a_k + a_{k-2} a + b a_{k-1} = 0$

- Shift index using $k- > k+2$

$\left((k+2)^2 + (2r-1)(k+2) + r^2 + c - r\right) a_{k+2} + a_k a + b a_{k+1} = 0$

- Recursion relation that defines series solution to ODE

$a_{k+2} = -\frac{a_k a + b a_{k+1}}{k^2+2kr+r^2+c+3k+3r+2}$

- Recursion relation for $r = \frac{1}{2} - \frac{\sqrt{-4c+1}}{2}$

$a_{k+2} = -\frac{a_k a + b a_{k+1}}{k^2+2k\left(\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}\right)+\left(\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}\right)^2+c+3k+\frac{7}{2}-\frac{3\sqrt{-4c+1}}{2}}$

- Solution for $r = \frac{1}{2} - \frac{\sqrt{-4c+1}}{2}$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}}, a_{k+2} = -\frac{a_k a + b a_{k+1}}{k^2+2k\left(\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}\right)+\left(\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}\right)^2+c+3k+\frac{7}{2}-\frac{3\sqrt{-4c+1}}{2}}, a_1 = -\frac{}{\left(\frac{1}{2}-\frac{\sqrt{-4c+}}{2}\right.}\right.$

- Recursion relation for $r = \frac{\sqrt{-4c+1}}{2} + \frac{1}{2}$

$a_{k+2} = -\frac{a_k a + b a_{k+1}}{k^2+2k\left(\frac{\sqrt{-4c+1}}{2}+\frac{1}{2}\right)+\left(\frac{\sqrt{-4c+1}}{2}+\frac{1}{2}\right)^2+c+3k+\frac{3\sqrt{-4c+1}}{2}+\frac{7}{2}}$

- Solution for $r = \frac{\sqrt{-4c+1}}{2} + \frac{1}{2}$

$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{\sqrt{-4c+1}}{2}+\frac{1}{2}}, a_{k+2} = -\frac{a_k a + b a_{k+1}}{k^2+2k\left(\frac{\sqrt{-4c+1}}{2}+\frac{1}{2}\right)+\left(\frac{\sqrt{-4c+1}}{2}+\frac{1}{2}\right)^2+c+3k+\frac{3\sqrt{-4c+1}}{2}+\frac{7}{2}}, a_1 = -\frac{}{\left(\frac{\sqrt{-4c+1}}{2}+\right.}\right.$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} d_k x^{k+\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}}\right) + \left(\sum_{k=0}^{\infty} e_k x^{k+\frac{\sqrt{-4c+1}}{2}+\frac{1}{2}}\right), d_{k+2} = -\frac{a d_k + b d_{1+k}}{k^2+2k\left(\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}\right)+\left(\frac{1}{2}-\frac{\sqrt{-4c+1}}{2}\right)^2+c+3k}\right.$

Problem number: 116.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second__order__bessel__ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - \left(a\,x^3 + \frac{5}{16}\right)y = 0}$$

29.7.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(-a\,x^3 - \frac{5}{16}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\,x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\,x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = \frac{2\sqrt{-a}}{3}$$
$$n = -\frac{1}{2}$$
$$\gamma = \frac{3}{2}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sqrt{6}\,\cos\left(\frac{2\sqrt{-a}\,x^{\frac{3}{2}}}{3}\right)}{2\sqrt{\pi}\,\sqrt{\sqrt{-a}\,x^{\frac{3}{2}}}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sqrt{6}\,\sin\left(\frac{2\sqrt{-a}\,x^{\frac{3}{2}}}{3}\right)}{2\sqrt{\pi}\,\sqrt{\sqrt{-a}\,x^{\frac{3}{2}}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sqrt{6}\,\cos\left(\frac{2\sqrt{-a}\,x^{\frac{3}{2}}}{3}\right)}{2\sqrt{\pi}\,\sqrt{\sqrt{-a}\,x^{\frac{3}{2}}}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sqrt{6}\,\sin\left(\frac{2\sqrt{-a}\,x^{\frac{3}{2}}}{3}\right)}{2\sqrt{\pi}\,\sqrt{\sqrt{-a}\,x^{\frac{3}{2}}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sqrt{6}\,\cos\left(\frac{2\sqrt{-a}\,x^{\frac{3}{2}}}{3}\right)}{2\sqrt{\pi}\,\sqrt{\sqrt{-a}\,x^{\frac{3}{2}}}} + \frac{c_2\sqrt{x}\,\sqrt{2}\,\sqrt{6}\,\sin\left(\frac{2\sqrt{-a}\,x^{\frac{3}{2}}}{3}\right)}{2\sqrt{\pi}\,\sqrt{\sqrt{-a}\,x^{\frac{3}{2}}}}$$

Verified OK.

29.7.2 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + \left(-a\,x^3 - \frac{5}{16}\right)y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= 0 \\ C &= -a\,x^3 - \frac{5}{16} \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{16a\, x^3 + 5}{16x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 16a\, x^3 + 5 \\ t &= 16x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{16a\, x^3 + 5}{16x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 120: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 3 \\
&= -1
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16x^2$. There is a pole at $x = 0$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$
L = [2]
$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = ax + \frac{5}{16x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$
\begin{aligned}
E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\
&= \{-1, 2, 5\}
\end{aligned}
$$

Since the order of r at ∞ is $-1 < 2$ then

$$
E_\infty = \{-1\}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{-1, 2, 5\}$

Order of r at ∞	E_∞
-1	$\{-1\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = -1, \; e_\infty = -1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(-1 - (-1)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{-1}{(x-(0))}\right) \\ &= -\frac{1}{2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= -\frac{1}{2x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 + \frac{w}{2x} + \frac{-16a\,x^3 + 1}{16x^2} = 0$$

Solving for ω gives

$$\omega = \frac{-1 + 4x\sqrt{ax}}{4x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \frac{-1+4x\sqrt{ax}}{4x} dx} \\ &= \frac{\mathrm{e}^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}}\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1 \\ &= \frac{\mathrm{e}^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}}\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\mathrm{e}^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \frac{e^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}} \int \frac{1}{\frac{e^{\frac{4x\sqrt{ax}}{3}}}{\sqrt{x}}}\, dx \\
&= \frac{e^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}} \left(-\frac{\sqrt{x}\left(-1 + e^{-\frac{4x\sqrt{ax}}{3}}\right)}{2\sqrt{ax}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{e^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}}\right) + c_2 \left(\frac{e^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}} \left(-\frac{\sqrt{x}\left(-1 + e^{-\frac{4x\sqrt{ax}}{3}}\right)}{2\sqrt{ax}}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 e^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}} + \frac{c_2 x^{\frac{1}{4}}\left(e^{\frac{2x\sqrt{ax}}{3}} - e^{-\frac{2x\sqrt{ax}}{3}}\right)}{2\sqrt{ax}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 e^{\frac{2x\sqrt{ax}}{3}}}{x^{\frac{1}{4}}} + \frac{c_2 x^{\frac{1}{4}}\left(e^{\frac{2x\sqrt{ax}}{3}} - e^{-\frac{2x\sqrt{ax}}{3}}\right)}{2\sqrt{ax}}$$

Verified OK.

29.7.3 Maple step by step solution

Let's solve

$y''x^2 + \left(-a\,x^3 - \frac{5}{16}\right)y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(16a\,x^3+5)y}{16x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(16a\,x^3+5)y}{16x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

  $\left[P_2(x) = 0, P_3(x) = -\frac{16a\,x^3+5}{16x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\Big|_{x=0} = 0$

  ◦ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = -\frac{5}{16}$

  ◦ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $16y''x^2 + (-16a\,x^3 - 5)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  ◦ Convert $x^m \cdot y$ to series expansion for $m = 0..3$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^{m}\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^{2}\cdot y''$ to series expansion

  $x^{2}\cdot y''=\sum_{k=0}^{\infty} a_{k}(k+r)\left(k+r-1\right) x^{k+r}$

  Rewrite ODE with series expansions

  $a_{0}(1+4r)\left(-5+4r\right) x^{r}+a_{1}(5+4r)\left(-1+4r\right) x^{1+r}+a_{2}(9+4r)\left(3+4r\right) x^{2+r}+\left(\sum_{k=3}^{\infty} (a_{k}(4k+\right.$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $(1+4r)\left(-5+4r\right)=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-\frac{1}{4}, \frac{5}{4}\right\}$

- The coefficients of each power of x must be 0

  $[a_{1}(5+4r)\left(-1+4r\right)=0, a_{2}(9+4r)\left(3+4r\right)=0]$

- Solve for the dependent coefficient(s)

  $\{a_{1}=0, a_{2}=0\}$

- Each term in the series must be 0, giving the recursion relation

  $16\left(k+r-\frac{5}{4}\right)\left(k+r+\frac{1}{4}\right) a_{k}-16a_{k-3}a=0$

- Shift index using $k->k+3$

  $16\left(k+\frac{7}{4}+r\right)\left(k+\frac{13}{4}+r\right) a_{k+3}-16a_{k}a=0$

- Recursion relation that defines series solution to ODE

  $a_{k+3}=\frac{16a_{k}a}{(4k+7+4r)(4k+13+4r)}$

- Recursion relation for $r=-\frac{1}{4}$

  $a_{k+3}=\frac{16a_{k}a}{(4k+6)(4k+12)}$

- Solution for $r=-\frac{1}{4}$

  $\left[y=\sum_{k=0}^{\infty} a_{k} x^{k-\frac{1}{4}}, a_{k+3}=\frac{16a_{k}a}{(4k+6)(4k+12)}, a_{1}=0, a_{2}=0\right]$

- Recursion relation for $r=\frac{5}{4}$

  $a_{k+3}=\frac{16a_{k}a}{(4k+12)(4k+18)}$

- Solution for $r = \frac{5}{4}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{5}{4}}, a_{k+3} = \frac{16 a_k a}{(4k+12)(4k+18)}, a_1 = 0, a_2 = 0\right]$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 117.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' - \left(a^2x^4 + a(-1+2b)\,x^2 + b(1+b)\right)y = 0}$$

29.8.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(-a^2x^4 - 2ab\,x^2 + a\,x^2 - b^2 - b\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1\,\text{BesselJ}\,(n, \beta\,x^{\gamma}) + c_2\,\text{BesselY}\,(n, \beta\,x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = -2b - 1$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\ \text{BesselJ}\left(-2b-1, 2\sqrt{x}\right) + c_2\sqrt{x}\ \text{BesselY}\left(-2b-1, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\ \text{BesselJ}\left(-2b-1, 2\sqrt{x}\right) + c_2\sqrt{x}\ \text{BesselY}\left(-2b-1, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\ \text{BesselJ}\left(-2b-1, 2\sqrt{x}\right) + c_2\sqrt{x}\ \text{BesselY}\left(-2b-1, 2\sqrt{x}\right)$$

Verified OK.

29.8.2 Maple step by step solution

Let's solve

$y''x^2 + \left(-a^2x^4 - 2\left(b - \frac{1}{2}\right)x^2a - b^2 - b\right)y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(a^2x^4 + 2ab\,x^2 - a\,x^2 + b^2 + b)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{(a^2x^4 + 2ab\,x^2 - a\,x^2 + b^2 + b)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

    $\left[P_2(x) = 0, P_3(x) = -\frac{a^2x^4 + 2ab\,x^2 - a\,x^2 + b^2 + b}{x^2}\right]$

  ◦ $x \cdot P_2(x)$ is analytic at $x = 0$

$(x \cdot P_2(x))\Big|_{x=0} = 0$

- ○ $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = -b^2 - b$

- ○ $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 + (-a^2x^4 - 2ab\,x^2 + a\,x^2 - b^2 - b)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- ○ Convert $x^m \cdot y$ to series expansion for $m = 0..4$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- ○ Shift index using $k- > k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- ○ Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0(r+b)\,(-r+1+b)\,x^r - a_1(r+1+b)\,(-r+b)\,x^{1+r} + (-a_2(r+2+b)\,(-r-1+b) - a_0a($

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-(r+b)\,(-r+1+b) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-b, 1+b\}$

- The coefficients of each power of x must be 0

  $[-a_1(r+1+b)\,(-r+b) = 0, -a_2(r+2+b)\,(-r-1+b) - a_0a(-1+2b) = 0, -a_3(r+3+b)\,($

- Solve for the dependent coefficient(s)

  $\left\{a_1 = 0, a_2 = -\frac{a_0 a(-1+2b)}{b^2-r^2+b-3r-2}, a_3 = 0\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-a_k(r+k+b)(-r+1-k+b) - a(a a_{k-4} + 2b a_{k-2} - a_{k-2}) = 0$

- Shift index using $k- >k+4$

  $-a_{k+4}(r+k+4+b)(-r-3-k+b) - a(a_k a + 2b a_{k+2} - a_{k+2}) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+4} = -\frac{a(a_k a+2b a_{k+2}-a_{k+2})}{(r+k+4+b)(-r-3-k+b)}$

- Recursion relation for $r = -b$

  $a_{k+4} = -\frac{a(a_k a+2b a_{k+2}-a_{k+2})}{(k+4)(2b-3-k)}$

- Solution for $r = -b$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-b}, a_{k+4} = -\frac{a(a_k a+2b a_{k+2}-a_{k+2})}{(k+4)(2b-3-k)}, a_1 = 0, a_2 = -\frac{a_0 a(-1+2b)}{-2+4b}, a_3 = 0\right]$

- Recursion relation for $r = 1+b$

  $a_{k+4} = -\frac{a(a_k a+2b a_{k+2}-a_{k+2})}{(5+2b+k)(-k-4)}$

- Solution for $r = 1+b$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1+b}, a_{k+4} = -\frac{a(a_k a+2b a_{k+2}-a_{k+2})}{(5+2b+k)(-k-4)}, a_1 = 0, a_2 = -\frac{a_0 a(-1+2b)}{b^2-(1+b)^2-2b-5}, a_3 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} c_k x^{k-b}\right) + \left(\sum_{k=0}^{\infty} d_k x^{k+1+b}\right), c_{k+4} = -\frac{a(a c_k+2b c_{k+2}-c_{k+2})}{(k+4)(2b-3-k)}, c_1 = 0, c_2 = -\frac{c_0 a(-1+2b)}{-2+4b}, c_3 =\right.$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + (a\,x^n + b)\,y = 0}$$

29.9.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + (a\,x^n + b)\,y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\,x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\,x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = \frac{2\sqrt{a}}{n}$$
$$n = \frac{\sqrt{-4b+1}}{n}$$
$$\gamma = \frac{n}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(\frac{\sqrt{-4b+1}}{n}, \frac{2\sqrt{a}\,x^{\frac{n}{2}}}{n}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(\frac{\sqrt{-4b+1}}{n}, \frac{2\sqrt{a}\,x^{\frac{n}{2}}}{n}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(\frac{\sqrt{-4b+1}}{n}, \frac{2\sqrt{a}\,x^{\frac{n}{2}}}{n}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(\frac{\sqrt{-4b+1}}{n}, \frac{2\sqrt{a}\,x^{\frac{n}{2}}}{n}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(\frac{\sqrt{-4b+1}}{n}, \frac{2\sqrt{a}\,x^{\frac{n}{2}}}{n}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(\frac{\sqrt{-4b+1}}{n}, \frac{2\sqrt{a}\,x^{\frac{n}{2}}}{n}\right)$$

Verified OK.

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 121.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(a\,x^{3n} + b\,x^{2n} + \frac{1}{4} - \frac{n^2}{4}\right)y = 0}$$

29.12.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(a\,x^{3n} + b\,x^{2n} + \frac{1}{4} - \frac{n^2}{4}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\,x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\,x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = n$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\ \text{BesselJ}\left(n, 2\sqrt{x}\right) + c_2\sqrt{x}\ \text{BesselY}\left(n, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\ \text{BesselJ}\left(n, 2\sqrt{x}\right) + c_2\sqrt{x}\ \text{BesselY}\left(n, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\ \text{BesselJ}\left(n, 2\sqrt{x}\right) + c_2\sqrt{x}\ \text{BesselY}\left(n, 2\sqrt{x}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second_order_euler_ode", "second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^2y'' + axy' + yb = 0}$$

29.14.1 Solving as second order euler ode ode

This is Euler second order ODE. Let the solution be $y = x^r$, then $y' = rx^{r-1}$ and $y'' = r(r-1)x^{r-2}$. Substituting these back into the given ODE gives

$$x^2(r(r-1))x^{r-2} + axrx^{r-1} + b\,x^r = 0$$

Simplifying gives

$$r(r-1)\,x^r + ar\,x^r + b\,x^r = 0$$

Since $x^r \neq 0$ then dividing throughout by x^r gives

$$r(r-1) + ar + b = 0$$

Or

$$r^{2}+(a-1)\,r+b=0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$\begin{aligned}
r_1 &= -\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^{2}-2a-4b+1}}{2}\\
r_2 &= -\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^{2}-2a-4b+1}}{2}
\end{aligned}$$

Since the roots are real and distinct, then the general solution is

$$y=c_1y_1+c_2y_2$$

Where $y_1=x^{r_1}$ and $y_2=x^{r_2}$. Hence

$$y=c_1x^{-\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^{2}-2a-4b+1}}{2}}+c_2x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^{2}-2a-4b+1}}{2}}$$

Summary
The solution(s) found are the following

$$y=c_1x^{-\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^{2}-2a-4b+1}}{2}}+c_2x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^{2}-2a-4b+1}}{2}} \tag{1}$$

Verification of solutions

$$y=c_1x^{-\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^{2}-2a-4b+1}}{2}}+c_2x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^{2}-2a-4b+1}}{2}}$$

Verified OK.

29.14.2 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^{2}y''+axy'+yb=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{a}{x}\\
q(x) &= \frac{b}{x^{2}}
\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{a}{x}dx\right)}dx \\
&= \int e^{-a\ln(x)}\,dx \\
&= \int x^{-a}dx \\
&= -\frac{x^{-a+1}}{a-1}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{b}{x^2}}{x^{-2a}} \\
&= b\,x^{-2+2a}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{gathered}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0 \\
\frac{d^2}{d\tau^2}y(\tau) + b\,x^{-2+2a}y(\tau) = 0
\end{gathered}$$

But in terms of τ

$$b\,x^{-2+2a} = \frac{b}{\left(a-1\right)^{2} \tau^{2}}$$

Hence the above ode becomes

$$\frac{d^{2}}{d\tau^{2}}y(\tau) + \frac{b y(\tau)}{\left(a-1\right)^{2} \tau^{2}} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^{2}}{d\tau^{2}}y(\tau)\right) \left(a-1\right)^{2} \tau^{2} + b y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^{r}$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$\left(a-1\right)^{2} \tau^{2}(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + b\,\tau^{r} = 0$$

Simplifying gives

$$\left(a-1\right)^{2} r(r-1)\,\tau^{r} + 0\,\tau^{r} + b\,\tau^{r} = 0$$

Since $\tau^{r} \neq 0$ then dividing throughout by τ^{r} gives

$$\left(a-1\right)^{2} r(r-1) + 0 + b = 0$$

Or

$$\left(a^{2}-2a+1\right) r^{2} + \left(-a^{2}+2a-1\right) r + b = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-a+1+\sqrt{a^{2}-2a-4b+1}}{2\left(a-1\right)}$$
$$r_2 = \frac{a-1+\sqrt{a^{2}-2a-4b+1}}{-2+2a}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{-\frac{-a+1+\sqrt{a^{2}-2a-4b+1}}{2(a-1)}} + c_2 \tau^{\frac{a-1+\sqrt{a^{2}-2a-4b+1}}{-2+2a}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(-\frac{x^{-a+1}}{a-1}\right)^{\frac{a-1-\sqrt{a^2-2a-4b+1}}{-2+2a}} + c_2 \left(-\frac{x^{-a+1}}{a-1}\right)^{\frac{a-1+\sqrt{a^2-2a-4b+1}}{-2+2a}}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(-\frac{x^{-a+1}}{a-1}\right)^{\frac{a-1-\sqrt{a^2-2a-4b+1}}{-2+2a}} + c_2 \left(-\frac{x^{-a+1}}{a-1}\right)^{\frac{a-1+\sqrt{a^2-2a-4b+1}}{-2+2a}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(-\frac{x^{-a+1}}{a-1}\right)^{\frac{a-1-\sqrt{a^2-2a-4b+1}}{-2+2a}} + c_2 \left(-\frac{x^{-a+1}}{a-1}\right)^{\frac{a-1+\sqrt{a^2-2a-4b+1}}{-2+2a}}$$

Verified OK.

29.14.3 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + axy' + yb = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{a}{x}$$
$$q(x) = \frac{b}{x^2}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2} + \frac{np}{x} + q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{na}{x^2}+\frac{b}{x^2}=0 \tag{5}$$

Solving (5) for n gives

$$n=-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2} \tag{6}$$

Substituting this value in (3) gives

$$v''(x)+\left(\frac{-a+1+\sqrt{a^2-2a-4b+1}}{x}+\frac{a}{x}\right)v'(x)=0$$

$$v''(x)+\frac{\left(1+\sqrt{a^2-2a-4b+1}\right)v'(x)}{x}=0 \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\frac{\left(1+\sqrt{a^2-2a-4b+1}\right)u(x)}{x}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned}u'&=F(x,u)\\&=f(x)g(u)\\&=\frac{\left(-1-\sqrt{a^2-2a-4b+1}\right)u}{x}\end{aligned}$$

Where $f(x)=\frac{-1-\sqrt{a^2-2a-4b+1}}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned}\frac{1}{u}\,du&=\frac{-1-\sqrt{a^2-2a-4b+1}}{x}\,dx\\ \int\frac{1}{u}\,du&=\int\frac{-1-\sqrt{a^2-2a-4b+1}}{x}\,dx\\ \ln(u)&=\left(-1-\sqrt{a^2-2a-4b+1}\right)\ln(x)+c_1\\ u&=\mathrm{e}^{\left(-1-\sqrt{a^2-2a-4b+1}\right)\ln(x)+c_1}\\&=c_1\mathrm{e}^{\left(-1-\sqrt{a^2-2a-4b+1}\right)\ln(x)}\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 x^{-\sqrt{a^2-2a-4b+1}}}{x}$$

Now that $u(x)$ is known, then

$$\begin{aligned} v'(x) &= u(x) \\ v(x) &= \int u(x)\, dx + c_2 \\ &= -\frac{c_1 x^{-\sqrt{a^2-2a-4b+1}}}{\sqrt{a^2-2a-4b+1}} + c_2 \end{aligned}$$

Hence

$$\begin{aligned} y &= v(x)\, x^n \\ &= \left(-\frac{c_1 x^{-\sqrt{a^2-2a-4b+1}}}{\sqrt{a^2-2a-4b+1}} + c_2\right) x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}} \\ &= -\frac{x^{-\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^2-2a-4b+1}}{2}} \left(-c_2\sqrt{a^2-2a-4b+1}\, x^{\sqrt{a^2-2a-4b+1}} + c_1\right)}{\sqrt{a^2-2a-4b+1}} \end{aligned}$$

Summary

The solution(s) found are the following

$$y = \left(-\frac{c_1 x^{-\sqrt{a^2-2a-4b+1}}}{\sqrt{a^2-2a-4b+1}} + c_2\right) x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}} \tag{1}$$

Verification of solutions

$$y = \left(-\frac{c_1 x^{-\sqrt{a^2-2a-4b+1}}}{\sqrt{a^2-2a-4b+1}} + c_2\right) x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}}$$

Verified OK.

29.14.4 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + axy' + yb = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= ax \\ C &= b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2 - 2a - 4b}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2 - 2a - 4b \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2 - 2a - 4b}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 123: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{\frac{1}{4}a^2 - \frac{1}{2}a - b}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{1}{4}a^2 - \frac{1}{2}a - b$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \left\{2, 2-2\sqrt{a^2-2a-4b+1}, 2+2\sqrt{a^2-2a-4b+1}\right\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{a^2 - 2a - 4b}{4x^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{1}{4}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\left\{2, 2-2\sqrt{a^2-2a-4b+1}, 2+2\sqrt{a^2-2a-4b+1}\right\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = 2, \; e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (2)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\theta = \frac{1}{2} \sum_{c\in\Gamma} \frac{e_c}{x-c}$$
$$= \frac{1}{2}\left(\frac{2}{(x-(0))}\right)$$
$$= \frac{1}{x}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\phi = \theta + \frac{p'}{p}$$
$$= \frac{1}{x}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{x} + \frac{-a^2 + 2a + 4b}{4x^2} = 0$$

Solving for ω gives

$$\omega = \frac{1 + \sqrt{a^2 - 2a - 4b + 1}}{2x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= e^{\int \omega \,dx} \\
&= \mathrm{e}^{\int \frac{1+\sqrt{a^2-2a-4b+1}}{2x}dx} \\
&= x^{\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{ax}{x^2}\,dx} \\
&= z_1 e^{-\frac{a\ln(x)}{2}} \\
&= z_1\left(x^{-\frac{a}{2}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{ax}{x^2}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-a\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(-\frac{x^{-\sqrt{a^2-2a-4b+1}}}{\sqrt{a^2-2a-4b+1}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}}\right) + c_2\left(x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}}\left(-\frac{x^{-\sqrt{a^2-2a-4b+1}}}{\sqrt{a^2-2a-4b+1}}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}} - \frac{c_2 x^{-\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^2-2a-4b+1}}{2}}}{\sqrt{a^2-2a-4b+1}} \tag{1}$$

Verification of solutions

$$y = c_1 x^{-\frac{a}{2}+\frac{1}{2}+\frac{\sqrt{a^2-2a-4b+1}}{2}} - \frac{c_2 x^{-\frac{a}{2}+\frac{1}{2}-\frac{\sqrt{a^2-2a-4b+1}}{2}}}{\sqrt{a^2-2a-4b+1}}$$

Verified OK.

29.14.5 Maple step by step solution

Let's solve

$y''x^2 + axy' + yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{ay'}{x} - \frac{by}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{ay'}{x} + \frac{by}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{a}{x}, P_3(x) = \frac{b}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\Big|_{x=0} = a$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = b$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x^2 + axy' + yb = 0$
- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite DE with series expansions

  - Convert $x \cdot y'$ to series expansion

    $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$
  - Convert $x^2 \cdot y''$ to series expansion

    $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite DE with series expansions

  $\sum_{k=0}^{\infty} a_k (ak + ar + k^2 + 2kr + r^2 + b - k - r)\, x^{k+r} = 0$
- $a_0$cannot be 0 by assumption, giving the indicial equation

  $r = 0$
- Each term in the series must be 0, giving the recursion relation

  $(k^2 + (a-1)\,k + b)\, a_k = 0$
- Recursion relation that defines series solution to ODE

  $a_k = 0$
- Recursion relation for $r = 0$

  $a_k = 0$
- Solution for $r = 0$

  $\left[y = \sum_{k=0}^{\infty} a_k x^k, a_k = 0\right]$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 124.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + y'x + \left(x^2 - \left(n + \frac{1}{2}\right)^2\right) y = 0}$$

29.15.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + y'x + \left(x^2 - n^2 - n - \frac{1}{4}\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = 0$$
$$\beta = 1$$
$$n = -n - \frac{1}{2}$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = c_1 \operatorname{BesselJ}\left(-n - \frac{1}{2}, x\right) + c_2 \operatorname{BesselY}\left(-n - \frac{1}{2}, x\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \operatorname{BesselJ}\left(-n - \frac{1}{2}, x\right) + c_2 \operatorname{BesselY}\left(-n - \frac{1}{2}, x\right) \tag{1}$$

Verification of solutions

$$y = c_1 \operatorname{BesselJ}\left(-n - \frac{1}{2}, x\right) + c_2 \operatorname{BesselY}\left(-n - \frac{1}{2}, x\right)$$

Verified OK.

29.15.2 Maple step by step solution

Let's solve

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 126.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

`[_Bessel]`

$$\boxed{x^2y'' + y'x + (-\nu^2 + x^2)\, y = 0}$$

29.17.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + y'x + (-\nu^2 + x^2)\, y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2)\, y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + (\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2)\, y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = 0$$
$$\beta = 1$$
$$n = \nu$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = c_1 \operatorname{BesselJ}(\nu, x) + c_2 \operatorname{BesselY}(\nu, x)$$

Summary

The solution(s) found are the following

$$y = c_1 \operatorname{BesselJ}(\nu, x) + c_2 \operatorname{BesselY}(\nu, x) \tag{1}$$

Verification of solutions

$$y = c_1 \operatorname{BesselJ}(\nu, x) + c_2 \operatorname{BesselY}(\nu, x)$$

Verified OK.

29.17.2 Maple step by step solution

Let's solve

$y''x^2 + y'x + (-\nu^2 + x^2)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(\nu^2 - x^2) y}{x^2} - \frac{y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{y'}{x} - \frac{(\nu^2 - x^2) y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{1}{x}, P_3(x) = -\frac{\nu^2 - x^2}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

$$(x \cdot P_2(x))\Big|_{x=0} = 1$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$(x^2 \cdot P_3(x))\Big|_{x=0} = -\nu^2$$

- $x = 0$is a regular singular point

Check to see if $x_0 = 0$ is a regular singular point

$x_0 = 0$

- Multiply by denominators

$$y''x^2 + y'x + (-\nu^2 + x^2)\, y = 0$$

- Assume series solution for y

$$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

$$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

$$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x \cdot y'$ to series expansion

$$x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

$$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

Rewrite ODE with series expansions

$$a_0(\nu + r)\,(-\nu + r)\, x^r + a_1(1 + \nu + r)\,(1 - \nu + r)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(k + \nu + r)\,(k - \nu + r) + a_{k-2}$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(\nu + r)\,(-\nu + r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{\nu, -\nu\}$$

- Each term must be 0

  $a_1(1+\nu+r)(1-\nu+r)=0$

- Solve for the dependent coefficient(s)

  $a_1=0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+\nu+r)(k-\nu+r)+a_{k-2}=0$

- Shift index using $k->k+2$

  $a_{k+2}(k+2+\nu+r)(k+2-\nu+r)+a_k=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a_k}{(k+2+\nu+r)(k+2-\nu+r)}$

- Recursion relation for $r=\nu$

  $a_{k+2}=-\frac{a_k}{(k+2+2\nu)(k+2)}$

- Solution for $r=\nu$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k+\nu}, a_{k+2}=-\frac{a_k}{(k+2+2\nu)(k+2)}, a_1=0\right]$

- Recursion relation for $r=-\nu$

  $a_{k+2}=-\frac{a_k}{(k+2)(k+2-2\nu)}$

- Solution for $r=-\nu$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-\nu}, a_{k+2}=-\frac{a_k}{(k+2)(k+2-2\nu)}, a_1=0\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} a_k x^{k+\nu}\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-\nu}\right), a_{k+2}=-\frac{a_k}{(k+2+2\nu)(k+2)}, a_1=0, b_{k+2}=-\frac{b_k}{(k+2)(k+2-2\nu)}, b_1=0\right.$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 128.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + 2y'x - \left(a^2x^2 + 2\right)y = 0}$$

29.19.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + 2y'x + \left(-a^2x^2 - 2\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= -\frac{1}{2}\\ \beta &= ia\\ n &= -\frac{3}{2}\\ \gamma &= 1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = -\frac{ic_1\sqrt{2}\,(\sinh(ax)\,ax - \cosh(ax))}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{iax}\,a} - \frac{c_2\sqrt{2}\,(-\cosh(ax)\,ax + \sinh(ax))}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{iax}\,a}$$

Summary

The solution(s) found are the following

$$y = -\frac{ic_1\sqrt{2}\,(\sinh(ax)\,ax - \cosh(ax))}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{iax}\,a} - \frac{c_2\sqrt{2}\,(-\cosh(ax)\,ax + \sinh(ax))}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{iax}\,a} \tag{1}$$

Verification of solutions

$$y = -\frac{ic_1\sqrt{2}\,(\sinh(ax)\,ax - \cosh(ax))}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{iax}\,a} - \frac{c_2\sqrt{2}\,(-\cosh(ax)\,ax + \sinh(ax))}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{iax}\,a}$$

Verified OK.

29.19.2 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + 2y'x + \left(-a^2x^2 - 2\right)y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= x^2\\ B &= 2x\\ C &= -a^2x^2 - 2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2x^2 + 2}{x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2x^2 + 2 \\ t &= x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2x^2 + 2}{x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 129: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 2 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$L = [1, 2]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = a^2 + \frac{2}{x^2}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = 2$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = 2 \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = -1 \end{aligned}$$

Since the order of r at ∞ is $O_r(\infty) = 0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \leq i \leq v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned} [\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\ &= \sum_{i=0}^{0} a_i x^i \end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx a + \frac{1}{a\,x^2} - \frac{1}{2a^3x^4} + \frac{1}{2a^5x^6} - \frac{5}{8a^7x^8} + \frac{7}{8a^9x^{10}} - \frac{21}{16a^{11}x^{12}} + \frac{33}{16a^{13}x^{14}} + \dots \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = a$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= a \end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = a^2$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{a^2x^2 + 2}{x^2} \\ &= Q + \frac{R}{x^2} \\ &= (a^2) + \left(\frac{2}{x^2}\right) \\ &= a^2 + \frac{2}{x^2} \end{aligned}$$

Since the degree of t is 2, then we see that the coefficient of the term x in the remainder R is 0. Dividing this by leading coefficient in t which is 1 gives 0. Now b can be found.

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$
\begin{aligned}
[\sqrt{r}]_\infty &= a \\
\alpha_\infty^{+} &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{0}{a} - 0\right) &&= 0 \\
\alpha_\infty^{-} &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{0}{a} - 0\right) &&= 0
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{a^2x^2 + 2}{x^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
0	2	0	2	-1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
0	a	0	0

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 0$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-}\right) \\
&= 0 - (-1) \\
&= 1
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{1}{x} + (-)\,(a) \\
&= -\frac{1}{x} - a \\
&= \frac{-ax-1}{x}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}
$$

Let

$$
p(x) = x + a_0 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{1}{x} - a\right)(1) + \left(\left(\frac{1}{x^2}\right) + \left(-\frac{1}{x} - a\right)^2 - \left(\frac{a^2x^2+2}{x^2}\right)\right) &= 0 \\
\frac{2aa_0 - 2}{x} &= 0
\end{aligned}
$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$
\left\{a_0 = \frac{1}{a}\right\}
$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$
p(x) = x + \frac{1}{a}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{1}{a}\right) e^{\int \left(-\frac{1}{x} - a\right) dx} \\
&= \left(x + \frac{1}{a}\right) e^{-ax - \ln(x)} \\
&= \frac{(ax+1)\, e^{-ax}}{ax}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x}{x^2}\,dx} \\
&= z_1 e^{-\ln(x)} \\
&= z_1 \left(\frac{1}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(ax+1)\,\mathrm{e}^{-ax}}{a\,x^2}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{(ax-1)\,\mathrm{e}^{2ax}}{2\,(ax+1)\,a}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a\,x^2}\right) + c_2 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a\,x^2}\left(\frac{(ax-1)\,\mathrm{e}^{2ax}}{2\,(ax+1)\,a}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a\,x^2} + \frac{c_2(ax-1)\,\mathrm{e}^{ax}}{2a^2x^2} \tag{1}
$$

Verification of solutions

$$y = \frac{c_1(ax+1)\,\mathrm{e}^{-ax}}{a\,x^2} + \frac{c_2(ax-1)\,\mathrm{e}^{ax}}{2a^2x^2}$$

Verified OK.

29.19.3 Maple step by step solution

Let's solve

$y''x^2 + 2y'x + (-a^2x^2 - 2)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(a^2x^2+2)y}{x^2} - \frac{2y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{x} - \frac{(a^2x^2+2)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{2}{x}, P_3(x) = -\frac{a^2x^2+2}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = 2$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = -2$

  - $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y''x^2 + 2y'x + (-a^2x^2 - 2)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\, (k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(2+r)\,(-1+r)\, x^r + a_1(3+r)\, r\, x^{1+r} + \left(\sum_{k=2}^{\infty} \left(a_k(k+r+2)\,(k+r-1) - a_{k-2}a^2\right) x^{k+r}\right) = 0$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(2+r)\,(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{-2, 1\}$

- Each term must be 0

  $a_1(3+r)\, r = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(k+r+2)\,(k+r-1) - a_{k-2}a^2 = 0$

- Shift index using $k- >k + 2$

  $a_{k+2}(k+4+r)\,(k+1+r) - a_k a^2 = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = \frac{a_k a^2}{(k+4+r)(k+1+r)}$

- Recursion relation for $r = -2$

$a_{k+2} = \frac{a_k a^2}{(k+2)(k-1)}$

- Solution for $r = -2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k-2}, a_{k+2} = \frac{a_k a^2}{(k+2)(k-1)}, a_1 = 0\right]$

- Recursion relation for $r = 1$

  $a_{k+2} = \frac{a_k a^2}{(k+5)(k+2)}$

- Solution for $r = 1$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+2} = \frac{a_k a^2}{(k+5)(k+2)}, a_1 = 0\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} b_k x^{k-2}\right) + \left(\sum_{k=0}^{\infty} c_k x^{1+k}\right), b_{k+2} = \frac{b_k a^2}{(k+2)(k-1)}, b_1 = 0, c_{k+2} = \frac{c_k a^2}{(k+5)(k+2)}, c_1 = 0\right]$

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' - 2axy' + \left(b^2x^2 + a(a+1)\right) y = 0}$$

29.20.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2a}{x} \\ q(x) &= \frac{b^2x^2 + a^2 + a}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{b^2x^2 + a^2 + a}{x^2} - \frac{\left(-\frac{2a}{x}\right)'}{2} - \frac{\left(-\frac{2a}{x}\right)^2}{4} \\
&= \frac{b^2x^2 + a^2 + a}{x^2} - \frac{\left(\frac{2a}{x^2}\right)}{2} - \frac{\left(\frac{4a^2}{x^2}\right)}{4} \\
&= \frac{b^2x^2 + a^2 + a}{x^2} - \left(\frac{a}{x^2}\right) - \frac{a^2}{x^2} \\
&= b^2
\end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2a}{x}}{2}} \\
&= x^a
\end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\, x^a \tag{4}$$

Applying this change of variable to the original ode results in

$$x^{a+2}\left(v(x)\, b^2 + v''(x)\right) = 0$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 1, B = 0, C = b^2$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda x} + b^2 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$b^2 + \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = b^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\,(b^2)}\\ &= \pm\sqrt{-b^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-b^2}\\ \lambda_2 &= -\sqrt{-b^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-b^2}\\ \lambda_2 &= -\sqrt{-b^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ v(x) &= c_1 e^{\left(\sqrt{-b^2}\right)x} + c_2 e^{\left(-\sqrt{-b^2}\right)x}\end{aligned}$$

Or

$$v(x) = c_1 \mathrm{e}^{\sqrt{-b^2}\,x} + c_2 \mathrm{e}^{-\sqrt{-b^2}\,x}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\,z(x)\\ &= \left(c_1 \mathrm{e}^{\sqrt{-b^2}\,x} + c_2 \mathrm{e}^{-\sqrt{-b^2}\,x}\right)(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = x^a$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{\sqrt{-b^2}\,x} + c_2 \mathrm{e}^{-\sqrt{-b^2}\,x}\right) x^a$$

Summary
The solution(s) found are the following

$$y = \left(c_1 \mathrm{e}^{\sqrt{-b^2}\, x} + c_2 \mathrm{e}^{-\sqrt{-b^2}\, x}\right) x^a \tag{1}$$

Verification of solutions

$$y = \left(c_1 \mathrm{e}^{\sqrt{-b^2}\, x} + c_2 \mathrm{e}^{-\sqrt{-b^2}\, x}\right) x^a$$

Verified OK.

29.20.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' - 2axy' + \left(b^2 x^2 + a^2 + a\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, xy' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha (c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = a + \frac{1}{2}$$
$$\beta = b$$
$$n = -\frac{1}{2}$$
$$\gamma = 1$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x^{a+\frac{1}{2}} \sqrt{2}\, \cos(bx)}{\sqrt{\pi}\, \sqrt{bx}} + \frac{c_2 x^{a+\frac{1}{2}} \sqrt{2}\, \sin(bx)}{\sqrt{\pi}\, \sqrt{bx}}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 x^{a+\frac{1}{2}} \sqrt{2}\, \cos(bx)}{\sqrt{\pi}\, \sqrt{bx}} + \frac{c_2 x^{a+\frac{1}{2}} \sqrt{2}\, \sin(bx)}{\sqrt{\pi}\, \sqrt{bx}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^{a+\frac{1}{2}} \sqrt{2}\, \cos(bx)}{\sqrt{\pi}\, \sqrt{bx}} + \frac{c_2 x^{a+\frac{1}{2}} \sqrt{2}\, \sin(bx)}{\sqrt{\pi}\, \sqrt{bx}}$$

Verified OK.

29.20.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 2axy' + \left(b^2 x^2 + a^2 + a\right) y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2ax \\ C &= b^2 x^2 + a^2 + a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-b^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -b^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = (-b^2)\, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 131: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - 0 \\ &= 0 \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = -b^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = \mathrm{e}^{\sqrt{-b^2}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned} y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-2ax}{x^2}\,dx} \\ &= z_1 e^{a\ln(x)} \\ &= z_1(x^a) \end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\sqrt{-b^2}\,x} x^a$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-2ax}{x^2}\,dx}}{(y_1)^2}\,dx \\ &= y_1 \int \frac{e^{2a\ln(x)}}{(y_1)^2}\,dx \\ &= y_1 \left(\frac{\sqrt{-b^2}\,\mathrm{e}^{-2\sqrt{-b^2}\,x}}{2b^2}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(\mathrm{e}^{\sqrt{-b^2}\,x} x^a\right) + c_2\left(\mathrm{e}^{\sqrt{-b^2}\,x} x^a \left(\frac{\sqrt{-b^2}\,\mathrm{e}^{-2\sqrt{-b^2}\,x}}{2b^2}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\sqrt{-b^2}\,x} x^a + \frac{c_2 x^a \sqrt{-b^2}\,\mathrm{e}^{-\sqrt{-b^2}\,x}}{2b^2} \tag{1}$$

Verification of solutions

$$y = c_1 e^{\sqrt{-b^2}\, x} x^a + \frac{c_2 x^a \sqrt{-b^2}\, e^{-\sqrt{-b^2}\, x}}{2b^2}$$

Verified OK.

29.20.4 Maple step by step solution

Let's solve

$y''x^2 - 2axy' + (b^2x^2 + a^2 + a)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(b^2x^2+a^2+a)y}{x^2} + \frac{2ay'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2ay'}{x} + \frac{(b^2x^2+a^2+a)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{2a}{x}, P_3(x) = \frac{b^2x^2+a^2+a}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -2a$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $\left.(x^2 \cdot P_3(x))\right|_{x=0} = a^2 + a$

  - $x = 0$is a regular singular point

    Check to see if $x_0 = 0$ is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x^2 - 2axy' + (b^2x^2 + a^2 + a)\, y = 0$

- Assume series solution for y

$y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..2$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k - m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x \cdot y'$ to series expansion

  $x \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-r+1+a)\,(-r+a)\, x^r + a_1(-r+a)\,(-r-1+a)\, x^{1+r} + \left(\sum_{k=2}^{\infty} (a_k(-r+1-k+a)\,(-r-k\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(-r+1+a)\,(-r+a) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{a, a+1\}$

- Each term must be 0

  $a_1(-r+a)\,(-r-1+a) = 0$

- Solve for the dependent coefficient(s)

  $a_1 = 0$

- Each term in the series must be 0, giving the recursion relation

  $a_k(-r+1-k+a)\,(-r-k+a) + a_{k-2}b^2 = 0$

- Shift index using $k- >k+2$

  $a_{k+2}(-r-1-k+a)\,(-r-k-2+a) + a_k b^2 = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+2} = -\frac{a_k b^2}{(-r-1-k+a)(-r-k-2+a)}$

- Recursion relation for $r = a$

  $a_{k+2} = -\frac{a_k b^2}{(-1-k)(-k-2)}$

- Solution for $r = a$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+a}, a_{k+2} = -\frac{a_k b^2}{(-1-k)(-k-2)}, a_1 = 0\right]$

- Recursion relation for $r = a+1$

  $a_{k+2} = -\frac{a_k b^2}{(-k-2)(-3-k)}$

- Solution for $r = a+1$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 130.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' - 2axy' + (-b^2x^2 + a(a+1))\, y = 0}$$

29.21.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -\frac{2a}{x} \\ q(x) &= \frac{-b^2x^2 + a^2 + a}{x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{-b^2x^2 + a^2 + a}{x^2} - \frac{\left(-\frac{2a}{x}\right)'}{2} - \frac{\left(-\frac{2a}{x}\right)^2}{4} \\
&= \frac{-b^2x^2 + a^2 + a}{x^2} - \frac{\left(\frac{2a}{x^2}\right)}{2} - \frac{\left(\frac{4a^2}{x^2}\right)}{4} \\
&= \frac{-b^2x^2 + a^2 + a}{x^2} - \left(\frac{a}{x^2}\right) - \frac{a^2}{x^2} \\
&= -b^2
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{-\frac{2a}{x}}{2}} \\
&= x^a
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$y = v(x)\, x^a \tag{4}$$

Applying this change of variable to the original ode results in

$$-x^{a+2}\left(v(x)\, b^2 - v''(x)\right) = 0$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = -1, B = 0, C = b^2$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$-\lambda^2 \mathrm{e}^{\lambda x} + b^2 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$b^2 - \lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = -1, B = 0, C = b^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(-1)} \pm \frac{1}{(2)(-1)}\sqrt{0^2 - (4)(-1)(b^2)} \\ &= \pm - \sqrt{b^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= + - \sqrt{b^2} \\ \lambda_2 &= - - \sqrt{b^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= -\sqrt{b^2} \\ \lambda_2 &= \sqrt{b^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x} \\ v(x) &= c_1 e^{\left(-\sqrt{b^2}\right)x} + c_2 e^{\left(\sqrt{b^2}\right)x}\end{aligned}$$

Or

$$v(x) = c_1 \mathrm{e}^{-\sqrt{b^2}\, x} + c_2 \mathrm{e}^{\sqrt{b^2}\, x}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\, z(x) \\ &= \left(c_1 \mathrm{e}^{-\sqrt{b^2}\, x} + c_2 \mathrm{e}^{\sqrt{b^2}\, x}\right)(z(x)) \qquad (7)\end{aligned}$$

But from (5)

$$z(x) = x^a$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{-\sqrt{b^2}\, x} + c_2 \mathrm{e}^{\sqrt{b^2}\, x}\right) x^a$$

Summary
The solution(s) found are the following

$$y = \left(c_1 \mathrm{e}^{-\sqrt{b^2}\, x} + c_2 \mathrm{e}^{\sqrt{b^2}\, x}\right) x^a \tag{1}$$

Verification of solutions

$$y = \left(c_1 \mathrm{e}^{-\sqrt{b^2}\, x} + c_2 \mathrm{e}^{\sqrt{b^2}\, x}\right) x^a$$

Verified OK.

29.21.2 Solving as second order bessel ode ode

Writing the ode as

$$x^2 y'' - 2axy' + \left(-b^2 x^2 + a^2 + a\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2 y'' + y' x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2 y'' + (1 - 2\alpha)\, xy' + \left(\beta^2 \gamma^2 x^{2\gamma} - n^2 \gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned} \alpha &= a + \frac{1}{2} \\ \beta &= ib \\ n &= -\frac{1}{2} \\ \gamma &= 1 \end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 x^{a+\frac{1}{2}} \sqrt{2}\, \cosh(bx)}{\sqrt{\pi}\, \sqrt{ibx}} + \frac{i c_2 x^{a+\frac{1}{2}} \sqrt{2}\, \sinh(bx)}{\sqrt{\pi}\, \sqrt{ibx}}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 x^{a+\frac{1}{2}} \sqrt{2}\, \cosh(bx)}{\sqrt{\pi}\, \sqrt{ibx}} + \frac{i c_2 x^{a+\frac{1}{2}} \sqrt{2}\, \sinh(bx)}{\sqrt{\pi}\, \sqrt{ibx}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^{a+\frac{1}{2}} \sqrt{2}\, \cosh(bx)}{\sqrt{\pi}\, \sqrt{ibx}} + \frac{i c_2 x^{a+\frac{1}{2}} \sqrt{2}\, \sinh(bx)}{\sqrt{\pi}\, \sqrt{ibx}}$$

Verified OK.

29.21.3 Solving using Kovacic algorithm

Writing the ode as

$$x^2 y'' - 2axy' + (-b^2x^2 + a^2 + a)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= -2ax \\ C &= -b^2x^2 + a^2 + a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{b^2}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= b^2 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = (b^2)\, z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 133: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - 0 \\
&= 0
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = b^2$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = e^{\sqrt{b^2}\, x}$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2ax}{x^2}\,dx} \\
&= z_1 e^{a\ln(x)} \\
&= z_1 (x^a)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\mathrm{csgn}(b)bx} x^a
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2ax}{x^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{2a\ln(x)}}{(y_1)^2}\,dx \\
&= y_1 \left(-\frac{\mathrm{csgn}(b)\,\mathrm{e}^{-2\,\mathrm{csgn}(b)bx}}{2b}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{\mathrm{csgn}(b)bx} x^a\right) + c_2 \left(\mathrm{e}^{\mathrm{csgn}(b)bx} x^a \left(-\frac{\mathrm{csgn}(b)\,\mathrm{e}^{-2\,\mathrm{csgn}(b)bx}}{2b}\right)\right)
\end{aligned}
$$

Simplifying the solution $y = c_1 \mathrm{e}^{\mathrm{csgn}(b)bx} x^a - \frac{c_2 x^a\,\mathrm{csgn}(b)\mathrm{e}^{-\,\mathrm{csgn}(b)bx}}{2b}$ to $y = c_1 \mathrm{e}^{bx} x^a - \frac{c_2 x^a \mathrm{e}^{-bx}}{2b}$

Summary

The solution(s) found are the following

$$
y = c_1 \mathrm{e}^{bx} x^a - \frac{c_2 x^a \mathrm{e}^{-bx}}{2b} \tag{1}
$$

Verification of solutions

$$y = c_1 e^{bx} x^a - \frac{c_2 x^a e^{-bx}}{2b}$$

Verified OK.

29.21.4 Maple step by step solution

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \lambda xy' + \left(a\,x^2 + bx + c\right) y = 0}$$

29.22.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \lambda xy' + \left(a\,x^2 + bx + c\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}\left(n, \beta\, x^\gamma\right) + c_2 \operatorname{BesselY}\left(n, \beta\, x^\gamma\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= \frac{1}{2}-\frac{\lambda}{2} \\ \beta &= 2 \\ n &= \sqrt{\lambda^{2}-4c-2\lambda+1} \\ \gamma &= \frac{1}{2}\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = c_{1} x^{\frac{1}{2}-\frac{\lambda}{2}} \operatorname{BesselJ}\left(\sqrt{\lambda^{2}-4c-2\lambda+1}, 2\sqrt{x}\right)+c_{2} x^{\frac{1}{2}-\frac{\lambda}{2}} \operatorname{BesselY}\left(\sqrt{\lambda^{2}-4c-2\lambda+1}, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & c_{1} x^{\frac{1}{2}-\frac{\lambda}{2}} \operatorname{BesselJ}\left(\sqrt{\lambda^{2}-4c-2\lambda+1}, 2\sqrt{x}\right) \\ & + c_{2} x^{\frac{1}{2}-\frac{\lambda}{2}} \operatorname{BesselY}\left(\sqrt{\lambda^{2}-4c-2\lambda+1}, 2\sqrt{x}\right)\end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = {} & c_{1} x^{\frac{1}{2}-\frac{\lambda}{2}} \operatorname{BesselJ}\left(\sqrt{\lambda^{2}-4c-2\lambda+1}, 2\sqrt{x}\right) \\ & + c_{2} x^{\frac{1}{2}-\frac{\lambda}{2}} \operatorname{BesselY}\left(\sqrt{\lambda^{2}-4c-2\lambda+1}, 2\sqrt{x}\right)\end{aligned}$$

Verified OK.

29.22.2 Maple step by step solution

Let's solve

$y'' x^{2}+\lambda x y'+\left(a\,x^{2}+b x+c\right) y=0$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 132.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + axy' + (b\,x^n + c)\,y = 0}$$

29.23.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + axy' + (b\,x^n + c)\,y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\,x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\,x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{1}{2}-\frac{a}{2} \\
\beta &= \frac{2\sqrt{b}}{n} \\
n &= \frac{\sqrt{a^{2}-2a-4c+1}}{n} \\
\gamma &= \frac{n}{2}
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(\frac{\sqrt{a^{2}-2a-4c+1}}{n}, \frac{2\sqrt{b}\, x^{\frac{n}{2}}}{n}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(\frac{\sqrt{a^{2}-2a-4c+1}}{n}, \frac{2\sqrt{b}\, x^{\frac{n}{2}}}{n}\right)
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(\frac{\sqrt{a^{2}-2a-4c+1}}{n}, \frac{2\sqrt{b}\, x^{\frac{n}{2}}}{n}\right) \\
& + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(\frac{\sqrt{a^{2}-2a-4c+1}}{n}, \frac{2\sqrt{b}\, x^{\frac{n}{2}}}{n}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(\frac{\sqrt{a^{2}-2a-4c+1}}{n}, \frac{2\sqrt{b}\, x^{\frac{n}{2}}}{n}\right) \\
& + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(\frac{\sqrt{a^{2}-2a-4c+1}}{n}, \frac{2\sqrt{b}\, x^{\frac{n}{2}}}{n}\right)
\end{aligned}
$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + axy' + x^n(b\,x^n + c)\,y = 0}$$

29.24.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + axy' + \left(b\,x^{2n} + x^n c\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1\,\mathrm{BesselJ}\,(n, \beta\,x^{\gamma}) + c_2\,\mathrm{BesselY}\,(n, \beta\,x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{1}{2} - \frac{a}{2} \\
\beta &= 2 \\
n &= -a + 1 \\
\gamma &= \frac{1}{2}
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-a+1, 2\sqrt{x}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-a+1, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-a+1, 2\sqrt{x}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-a+1, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselJ}\left(-a+1, 2\sqrt{x}\right) + c_2 x^{\frac{1}{2}-\frac{a}{2}} \operatorname{BesselY}\left(-a+1, 2\sqrt{x}\right)$$

Verified OK.

Problem number: 135.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{x^2y'' + a\,x^2y' + \left(b\,x^2 + cx + d\right)y = 0}$$

29.26.1 Maple step by step solution

Let's solve

$y''x^2 + a\,x^2y' + (b\,x^2 + cx + d)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -ay' - \frac{(b\,x^2+cx+d)y}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + ay' + \frac{(b\,x^2+cx+d)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$$\left[P_2(x)=a, P_3(x)=\frac{b\,x^2+cx+d}{x^2}\right]$$

- $x \cdot P_2(x)$ is analytic at $x=0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0}=0$$

- $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0}=d$$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $$y''x^2+a\,x^2y'+\left(b\,x^2+cx+d\right)y=0$$

- Assume series solution for y

  $$y=\sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m=0..2$

  $$x^m \cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k->k-m$

  $$x^m \cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^2 \cdot y'$ to series expansion

  $$x^2 \cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r+1}$$

- Shift index using $k->k-1$

  $$x^2 \cdot y'=\sum_{k=1}^{\infty} a_{k-1}(k-1+r)\,x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k-1+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

$$a_0(r^2+d-r)\,x^r+\left(\left(r^2+d+r\right)a_1+a_0(ar+c)\right)x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k\left(k^2+2kr+r^2+d-k-r\right)+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r^2+d-r=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{\frac{1}{2}-\frac{\sqrt{1-4d}}{2},\frac{1}{2}+\frac{\sqrt{1-4d}}{2}\right\}$$

- Each term must be 0

$$\left(r^2+d+r\right)a_1+a_0(ar+c)=0$$

- Solve for the dependent coefficient(s)

$$a_1=-\frac{a_0(ar+c)}{r^2+d+r}$$

- Each term in the series must be 0, giving the recursion relation

$$\left(k^2+(2r-1)\,k+r^2+d-r\right)a_k+(ak+ar-a+c)\,a_{k-1}+a_{k-2}b=0$$

- Shift index using $k->k+2$

$$\left((k+2)^2+(2r-1)\,(k+2)+r^2+d-r\right)a_{k+2}+(a(k+2)+ar-a+c)\,a_{k+1}+a_kb=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{aka_{k+1}+ara_{k+1}+aa_{k+1}+a_kb+ca_{k+1}}{k^2+2kr+r^2+d+3k+3r+2}$$

- Recursion relation for $r=\frac{1}{2}-\frac{\sqrt{1-4d}}{2}$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 137.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(a\,x^2 + bx\right)y' - yb = 0}$$

29.28.1 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$x^2y'' + x(ax + b)\,y' - yb = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = r(x) \tag{2}$$

Where

$$\begin{aligned}
p(x) &= \frac{ax + b}{x} \\
q(x) &= -\frac{b}{x^2} \\
r(x) &= 0
\end{aligned}$$

The Lagrange adjoint ode is given by

$$\begin{aligned}
\xi'' - (\xi\, p)' + \xi q &= 0 \\
\xi'' - \left(\frac{(ax+b)\,\xi(x)}{x}\right)' + \left(-\frac{b\xi(x)}{x^2}\right) &= 0 \\
\xi''(x) - \frac{(ax+b)\,\xi'(x)}{x} + \left(-\frac{a}{x} + \frac{ax+b}{x^2} - \frac{b}{x^2}\right)\xi(x) &= 0
\end{aligned}$$

Which is solved for $\xi(x)$. This is second order ode with missing dependent variable $\xi(x)$. Let

$$p(x) = \xi'(x)$$

Then

$$p'(x) = \xi''(x)$$

Hence the ode becomes

$$p'(x)\,x + (-ax-b)\,p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned}
p' &= F(x,p) \\
&= f(x)g(p) \\
&= \frac{p(ax+b)}{x}
\end{aligned}$$

Where $f(x) = \frac{ax+b}{x}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\,dp &= \frac{ax+b}{x}\,dx \\
\int \frac{1}{p}\,dp &= \int \frac{ax+b}{x}\,dx \\
\ln(p) &= ax + b\ln(x) + c_1 \\
p &= \mathrm{e}^{ax+b\ln(x)+c_1} \\
&= c_1 \mathrm{e}^{ax+b\ln(x)}
\end{aligned}$$

Which simplifies to

$$p(x) = c_1 x^b \mathrm{e}^{ax}$$

Since $p = \xi'(x)$ then the new first order ode to solve is

$$\xi'(x) = c_1 x^b \mathrm{e}^{ax}$$

Integrating both sides gives

$$
\begin{aligned}
\xi(x) &= \int c_1 x^b \mathrm{e}^{ax}\, \mathrm{d}x \\
&= -\frac{c_1(-a)^{-b}\left(x^b(-a)^b b\Gamma(b)\,(-ax)^{-b} - x^b(-a)^b\,\mathrm{e}^{ax} - x^b(-a)^b\, b(-ax)^{-b}\,\Gamma(b,-ax)\right)}{a} + c_2
\end{aligned}
$$

The original ode (2) now reduces to first order ode

$$
\begin{aligned}
\xi(x)\, y' - y\xi'(x) + \xi(x)\, p(x)\, y &= \int \xi(x) \\
y' + y\left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)}{\xi\,(}
\end{aligned}
$$

$$
y' + y\left(\frac{ax+b}{x} + \frac{c_3(-a)^{-b}\left(-\frac{x^b b(-a)^b \mathrm{e}^{ax}}{x} - x^b(-a)^b\, a\,\mathrm{e}^{ax} - x^b(-a)^b\, b(-ax)^{-b}\, a(-ax)^{b-1}\,\mathrm{e}^{ax}\right)}{a\left(-\frac{c_3(-a)^{-b}\left(x^b(-a)^b b\Gamma(b)(-ax)^{-b} - x^b(-a)^b \mathrm{e}^{ax} - x^b(-a)^b b(-ax)^{-b}\Gamma(b,-ax)\right)}{a} + c_2\right)}\right) = 0
$$

Which is now a first order ode. This is now solved for y. In canonical form the ODE is

$$
\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{y\Big(c_3(-a)^{-b}\, a\, x^b(-a)^b\, b(-ax)^{-b}\,(-ax)^{b-1}\,\mathrm{e}^{ax}x + x^b(-a)^{-b}\,(-a)^b\,(-ax)^{-b}\,\Gamma(b)\, c_3abx - x^b(-a)^{-b}\,(-a}{x\,\Big(-c_3\,(-a)^{-b}\,x^b\,(-a)^b\, b\Gamma\,(b)\,(-ax)^{-b} + c_3\,(-}
\end{aligned}
$$

Where $f(x) = \frac{c_3(-a)^{-b} a\, x^b(-a)^b b(-ax)^{-b}(-ax)^{b-1}\mathrm{e}^{ax}x + x^b(-a)^{-b}(-a)^b(-ax)^{-b}\Gamma(b)c_3abx - x^b(-a)^{-b}(-a)^b(-ax)^{-b}\Gamma(b,-ax)c_3abx + x}{\Big(-c_3(-a)^{-b}x^b(-a)^b b\Gamma(b)(-ax)^{-b} + c_3(-a)^{-b}x^b(-a)^b b(-ax)^{-b}\Gamma(b,-a}$
and $g(y) = y$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{y}\, dy &= \frac{c_3(-a)^{-b}\, a\, x^b(-a)^b\, b(-ax)^{-b}\,(-ax)^{b-1}\,\mathrm{e}^{ax}x + x^b(-a)^{-b}\,(-a)^b\,(-ax)^{-b}\,\Gamma(b)\, c_3abx - x^b(-a)^{-b}\,(}{\Big(-c_3\,(-a)^{-b}\,x^b\,(-a)^b\, b\Gamma\,(b)\,(-ax)^{-b} + c_3\,(} \\
\int \frac{1}{y}\, dy &= \int \frac{c_3(-a)^{-b}\, a\, x^b(-a)^b\, b(-ax)^{-b}\,(-ax)^{b-1}\,\mathrm{e}^{ax}x + x^b(-a)^{-b}\,(-a)^b\,(-ax)^{-b}\,\Gamma(b)\, c_3abx - x^b(-a)^{-}}{\Big(-c_3\,(-a)^{-b}\,x^b\,(-a)^b\, b\Gamma\,(b)\,(-ax)^{-b} +} \\
\ln{(y)} &= \int \frac{c_3(-a)^{-b}\, a\, x^b(-a)^b\, b(-ax)^{-b}\,(-ax)^{b-1}\,\mathrm{e}^{ax}x + x^b(-a)^{-b}\,(-a)^b\,(-ax)^{-b}\,\Gamma(b)\, c_3abx - x^b(-a)^{-}}{\Big(-c_3\,(-a)^{-b}\,x^b\,(-a)^b\, b\Gamma\,(b)\,(-ax)^{-b} +} \\
y &= \mathrm{e}^{\int \frac{c_3(-a)^{-b} a\, x^b(-a)^b b(-ax)^{-b}(-ax)^{b-1}\mathrm{e}^{ax}x + x^b(-a)^{-b}(-a)^b(-ax)^{-b}\Gamma(b)c_3abx - x^b(-a)^{-b}(-a)^b(-ax)^{-b}\Gamma(b,-ax)c_3abx + x^b(-a)^{-b}(-a)^b}{\big(-c_3(-a)^{-b}x^b(-a)^b b\Gamma(b)(-ax)^{-b} + c_3(-a)^{-b}x^b(-a)^b b(-ax)^{-b}\Gamma(b,-ax) + c_3(-a)^{-b}x}} \\
&= c_3\mathrm{e}^{\int \frac{c_3(-a)^{-b} a\, x^b(-a)^b b(-ax)^{-b}(-ax)^{b-1}\mathrm{e}^{ax}x + x^b(-a)^{-b}(-a)^b(-ax)^{-b}\Gamma(b)c_3abx - x^b(-a)^{-b}(-a)^b(-ax)^{-b}\Gamma(b,-ax)c_3abx + x^b(-a)^{-b}(-}{\big(-c_3(-a)^{-b}x^b(-a)^b b\Gamma(b)(-ax)^{-b} + c_3(-a)^{-b}x^b(-a)^b b(-ax)^{-b}\Gamma(b,-ax) + c_3(-a)^{-}}}
\end{aligned}
$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = c_3 e^{\int \frac{c_3(-a)^{-b} a x^b (-a)^b b (-ax)^{-b} (-ax)^{b-1} e^{ax} x + x^b (-a)^{-b} (-a)^b (-ax)^{-b} \Gamma(b) c_3 a b x - x^b (-a)^{-b} (-a)^b (-ax)^{-b} \Gamma(b, -ax) c_3 a b x + x^b (-a)^{-b} (-a)^b (-ax)^{-b} \cdots}{\left(-c_3 (-a)^{-b} x^b (-a)^b b \Gamma(b) (-ax)^{-b} + c_3 (-a)^{-b} x^b (-a)^b b (-ax)^{-b} \Gamma(b, -ax) + c_3 (-a)^{-b} x^b (-a)^b e^{a \cdots}\right.}}$$

Summary

The solution(s) found are the following

$$y = c_3 e^{\int \frac{c_3(-a)^{-b} a x^b (-a)^b b (-ax)^{-b} (-ax)^{b-1} e^{ax} x + x^b (-a)^{-b} (-a)^b (-ax)^{-b} \Gamma(b) c_3 a b x - x^b (-a)^{-b} (-a)^b (-ax)^{-b} \Gamma(b, -ax) c_3 a b x + x^b (-a)^{-b} (-a)^b (-ax)^{-b} \cdots}{\left(-c_3 (-a)^{-b} x^b (-a)^b b \Gamma(b) (-ax)^{-b} + c_3 (-a)^{-b} x^b (-a)^b b (-ax)^{-b} \Gamma(b, -ax) + c_3 (-a)^{-b} x^b (-a)^b e^{a \cdots}\right.}} \tag{1}$$

Verification of solutions

$$y = c_3 e^{\int \frac{c_3(-a)^{-b} a x^b (-a)^b b (-ax)^{-b} (-ax)^{b-1} e^{ax} x + x^b (-a)^{-b} (-a)^b (-ax)^{-b} \Gamma(b) c_3 a b x - x^b (-a)^{-b} (-a)^b (-ax)^{-b} \Gamma(b, -ax) c_3 a b x + x^b (-a)^{-b} (-a)^b (-ax)^{-b} \cdots}{\left(-c_3 (-a)^{-b} x^b (-a)^b b \Gamma(b) (-ax)^{-b} + c_3 (-a)^{-b} x^b (-a)^b b (-ax)^{-b} \Gamma(b, -ax) + c_3 (-a)^{-b} x^b (-a)^b e^{a \cdots}\right.}}$$

Verified OK.

29.28.2 Maple step by step solution

Let's solve

$y'' x^2 + x(ax + b) y' - yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(ax+b)y'}{x} + \frac{by}{x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(ax+b)y'}{x} - \frac{by}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{ax+b}{x}, P_3(x) = -\frac{b}{x^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left(x \cdot P_2(x)\right)\bigg|_{x=0} = b$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = -b$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $y'' x^2 + x(ax+b)\, y' - yb = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k- > k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^2 \cdot y''$ to series expansion

  $x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r}$

  Rewrite ODE with series expansions

  $$a_0(r-1)\,(b+r)\, x^r + \left(\sum_{k=1}^{\infty} \left(a_k(k+r-1)\,(k+b+r) + a a_{k-1}(k+r-1)\right) x^{k+r}\right) = 0$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $(r-1)\,(b+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{1, -b\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-1)\,(a_k(k+b+r) + a a_{k-1}) = 0$

- Shift index using $k- > k+1$

  $(k+r)\,(a_{k+1}(k+1+b+r) + a a_k) = 0$

- Recursion relation that defines series solution to ODE

$a_{k+1} = -\frac{a a_k}{k+1+b+r}$

- Recursion relation for $r = 1$

$a_{k+1} = -\frac{a a_k}{k+2+b}$

- Solution for $r = 1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+1}, a_{k+1} = -\frac{a a_k}{k+2+b}\right]$$

- Recursion relation for $r = -b$

$a_{k+1} = -\frac{a a_k}{k+1}$

- Solution for $r = -b$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-b}, a_{k+1} = -\frac{a a_k}{k+1}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^{1+k}\right) + \left(\sum_{k=0}^{\infty} d_k x^{k-b}\right), c_{1+k} = -\frac{a c_k}{k+2+b}, d_{1+k} = -\frac{a d_k}{1+k}\right]$$

$$x^2y'' + \left(a\,x^2 + bx\right) y' + \left(k(a-k)\,x^2 + (an + bk - 2kn)\,x + n(-n + b - 1)\right) y = 0$$

29.29.1 Maple step by step solution

Let's solve

$y''x^2 + x(ax+b)\,y' + \left(-n^2 + ((a-2k)\,x + b - 1)\,n + kx((a-k)\,x + b)\right) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(ak\,x^2 - k^2x^2 + anx + kxb - 2knx + nb - n^2 - n)y}{x^2} - \frac{(ax+b)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(ax+b)y'}{x} + \frac{(ak\,x^2 - k^2x^2 + anx + kxb - 2knx + nb - n^2 - n)y}{x^2} = 0$

□ Check to see if $x_0 = 0$ is a regular singular point

  ◦ Define functions

$$\left[P_2(x)=\frac{ax+b}{x}, P_3(x)=\frac{ak\,x^2-k^2x^2+anx+kxb-2knx+nb-n^2-n}{x^2}\right]$$

- $x \cdot P_2(x)$ is analytic at $x=0$

  $$\left(x\cdot P_2(x)\right)\bigg|_{x=0}=b$$

- $x^2 \cdot P_3(x)$ is analytic at $x=0$

  $$\left(x^2\cdot P_3(x)\right)\bigg|_{x=0}=nb-n^2-n$$

- $x=0$is a regular singular point

  Check to see if $x_0=0$ is a regular singular point

  $x_0=0$

- Multiply by denominators

  $$y''x^2+x(ax+b)\,y'+\left(ak\,x^2-k^2x^2+anx+kxb-2knx+nb-n^2-n\right)y=0$$

- Assume series solution for y

  $$y=\sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m=0..2$

  $$x^m\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k->k-m$

  $$x^m\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m=1..2$

  $$x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r}$$

  Rewrite ODE with series expansions

$$a_0(n+r)(b+r-1-n)x^r + (a_1(1+n+r)(b+r-n) + a_0(an+ar+bk-2kn))x^{1+r} + \left(\sum_{k=2}^{\infty}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$(n+r)(b+r-1-n) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-n, n-b+1\}$$

- Each term must be 0

$$a_1(1+n+r)(b+r-n) + a_0(an+ar+bk-2kn) = 0$$

- Solve for the dependent coefficient(s)

$$a_1 = -\frac{a_0(an+ar+bk-2kn)}{nb+br-n^2+r^2+b-n+r}$$

- Each term in the series must be 0, giving the recursion relation

$$a_k(k+n+r)(k+b+r-1-n) + ((k+n+r-1)a + k(-2n+b))a_{k-1} + ka_{k-2}(a-k) = 0$$

- Shift index using $k- >k+2$

$$a_{k+2}(k+2+n+r)(k+1+b+r-n) + ((k+1+n+r)a + k(-2n+b))a_{k+1} + ka_k(a-k) =$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a_k ak + ak a_{k+1} + an a_{k+1} + ar a_{k+1} + bk a_{k+1} - a_k k^2 - 2kn a_{k+1} + a a_{k+1}}{(k+2+n+r)(k+1+b+r-n)}$$

- Recursion relation for $r = -n$

$$a_{k+2} = -\frac{a_k ak + ak a_{k+1} + bk a_{k+1} - a_k k^2 - 2kn a_{k+1} + a a_{k+1}}{(k+2)(k+1+b-2n)}$$

- Solution for $r = -n$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-n}, a_{k+2} = -\frac{a_k ak + ak a_{k+1} + bk a_{k+1} - a_k k^2 - 2kn a_{k+1} + a a_{k+1}}{(k+2)(k+1+b-2n)}, a_1 = -\frac{a_0(bk-2kn)}{-2n+b}\right]$$

- Recursion relation for $r = n-b+1$

$$a_{k+2} = -\frac{a_k ak + ak a_{k+1} + an a_{k+1} + a(n-b+1)a_{k+1} + bk a_{k+1} - a_k k^2 - 2kn a_{k+1} + a a_{k+1}}{(k+3+2n-b)(k+2)}$$

- Solution for $r = n-b+1$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 140.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2y'' + \left(a\,x^2 + (ab-1)\,x + b\right)y' + a^2bxy = 0}$$

29.31.1 Solving using Kovacic algorithm

Writing the ode as

$$x^2y'' + \left(abx + a\,x^2 + b - x\right)y' + a^2bxy = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2 \\ B &= abx + a\,x^2 + b - x \\ C &= a^2bx \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{a^2b^2x^2 - 2a^2b\,x^3 + a^2x^4 + 2a\,b^2x - 2ab\,x^2 - 2a\,x^3 + b^2 - 6bx + 3x^2}{4x^4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= a^2b^2x^2 - 2a^2b\,x^3 + a^2x^4 + 2a\,b^2x - 2ab\,x^2 - 2a\,x^3 + b^2 - 6bx + 3x^2 \\
t &= 4x^4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{a^2b^2x^2 - 2a^2b\,x^3 + a^2x^4 + 2a\,b^2x - 2ab\,x^2 - 2a\,x^3 + b^2 - 6bx + 3x^2}{4x^4}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\,dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 140: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 4 \\ &= 0 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 0 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = \frac{a^2}{4} + \frac{b^2}{4x^4} + \frac{\frac{1}{2}a\,b^2 - \frac{3}{2}b}{x^3} + \frac{\frac{1}{4}a^2b^2 - \frac{1}{2}ab + \frac{3}{4}}{x^2} + \frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{x}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{b}{2x^2} + \frac{2a\,b^2 - 6b}{4bx} + \frac{b\left(\frac{a^2b^2-2ab+3}{2b^2} - \frac{(2a\,b^2-6b)^2}{8b^4}\right)}{2} + \frac{b\left(\frac{-2a^2b-2a}{2b^2} - \frac{(2a\,b^2-6b)\,(a^2b^2-2ab+3)}{4b^4} + \frac{(2a\,b^2-6b)^3}{16b^6}\right)x}{2} + \tag{2B}$$

Using eq. (1B), taking the sum up to $v=2$ the above becomes

$$[\sqrt{r}]_c = \frac{b}{2x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = \frac{b}{2}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c=0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be $\frac{1}{2}a\,b^2 - \frac{3}{2}b$. Therefore

$$\begin{aligned}
b &= \left(\frac{1}{2}a\,b^2 - \frac{3}{2}b\right) - (0) \\
&= \frac{1}{2}a\,b^2 - \frac{3}{2}b
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_c &= \frac{b}{2x^2} \\
\alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a}+v\right) &&= \frac{1}{2}\left(\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{\frac{b}{2}}+2\right) &&= \frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1 \\
\alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a}+v\right) &&= \frac{1}{2}\left(-\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{\frac{b}{2}}+2\right) &&= -\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1
\end{aligned}$$

Since the order of r at ∞ is $O_r(\infty)=0$ then

$$v = \frac{-O_r(\infty)}{2} = \frac{0}{2} = 0$$

$[\sqrt{r}]_\infty$ is the sum of terms involving x^i for $0 \le i \le v$ in the Laurent series for $\sqrt{r}$ at ∞. Therefore

$$\begin{aligned}
[\sqrt{r}]_\infty &= \sum_{i=0}^{v} a_i x^i \\
&= \sum_{i=0}^{0} a_i x^i
\end{aligned} \tag{8}$$

Let a be the coefficient of $x^v = x^0$ in the above sum. The Laurent series of $\sqrt{r}$ at ∞ is

$$\sqrt{r} \approx \frac{a}{2} - \frac{1}{2x} - \frac{ab}{2x} - \frac{13b^2}{4a\,x^4} - \frac{163b^4}{4a^2x^7} - \frac{20b^3}{a^2x^6} - \frac{23b^2}{4a^3x^6} + \frac{11b}{4a^3x^5} + \frac{14b^2}{a^4x^7} + \frac{11b}{2a^4x^6} + \frac{3b}{a^5x^7} - \frac{3}{4a^6x^7} - \frac{b^6}{2x^7} - \frac{b^5}{2x^6} - \frac{b^4}{2x^5} - \tag{9}$$

Comparing Eq. (9) with Eq. (8) shows that

$$a = \frac{a}{2}$$

From Eq. (9) the sum up to $v = 0$ gives

$$\begin{aligned}[\sqrt{r}]_\infty &= \sum_{i=0}^{0} a_i x^i \\ &= \frac{a}{2}\end{aligned} \tag{10}$$

Now we need to find b, where b be the coefficient of $x^{v-1} = x^{-1} = \frac{1}{x}$ in r minus the coefficient of same term but in $\left([\sqrt{r}]_\infty\right)^2$ where $[\sqrt{r}]_\infty$ was found above in Eq (10). Hence

$$\left([\sqrt{r}]_\infty\right)^2 = \frac{a^2}{4}$$

This shows that the coefficient of $\frac{1}{x}$ in the above is 0. Now we need to find the coefficient of $\frac{1}{x}$ in r. How this is done depends on if $v = 0$ or not. Since $v = 0$ then starting from $r = \frac{s}{t}$ and doing long division in the form

$$r = Q + \frac{R}{t}$$

Where Q is the quotient and R is the remainder. Then the coefficient of $\frac{1}{x}$ in r will be the coefficient in R of the term in x of degree of t minus one, divided by the leading coefficient in t. Doing long division gives

$$\begin{aligned}r &= \frac{s}{t} \\ &= \frac{a^2b^2x^2 - 2a^2b\,x^3 + a^2x^4 + 2a\,b^2x - 2ab\,x^2 - 2a\,x^3 + b^2 - 6bx + 3x^2}{4x^4} \\ &= Q + \frac{R}{4x^4} \\ &= \left(\frac{a^2}{4}\right) + \left(\frac{(-2a^2b - 2a)\,x^3 + (a^2b^2 - 2ab + 3)\,x^2 + (2a\,b^2 - 6b)\,x + b^2}{4x^4}\right) \\ &= \frac{a^2}{4} + \frac{(-2a^2b - 2a)\,x^3 + (a^2b^2 - 2ab + 3)\,x^2 + (2a\,b^2 - 6b)\,x + b^2}{4x^4}\end{aligned}$$

Since the degree of t is 4, then we see that the coefficient of the term x^3 in the remainder R is $-2a^2b - 2a$. Dividing this by leading coefficient in t which is 4 gives $-\frac{1}{2}a^2b - \frac{1}{2}a$. Now b can be found.

$$\begin{aligned}
b &= \left(-\frac{1}{2}a^2b - \frac{1}{2}a\right) - (0) \\
&= -\frac{1}{2}a^2b - \frac{1}{2}a
\end{aligned}$$

Hence

$$\begin{aligned}
[\sqrt{r}]_\infty &= \frac{a}{2} \\
\alpha_\infty^+ &= \frac{1}{2}\left(\frac{b}{a} - v\right) &&= \frac{1}{2}\left(\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{\frac{a}{2}} - 0\right) &&= \frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a} \\
\alpha_\infty^- &= \frac{1}{2}\left(-\frac{b}{a} - v\right) &&= \frac{1}{2}\left(-\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{\frac{a}{2}} - 0\right) &&= -\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a}
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a^2b^2x^2 - 2a^2b\,x^3 + a^2x^4 + 2a\,b^2x - 2ab\,x^2 - 2a\,x^3 + b^2 - 6bx + 3x^2}{4x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{b}{2x^2}$	$\frac{\frac{1}{2}a\,b^2 - \frac{3}{2}b}{b} + 1$	$-\frac{\frac{1}{2}a\,b^2 - \frac{3}{2}b}{b} + 1$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
0	$\frac{a}{2}$	$\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a}$	$-\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a}$

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = -\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a}$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^+\right) \\
&= -\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a} - \left(-\frac{-\frac{1}{2}a^2b - \frac{1}{2}a}{a} - 1\right) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((+)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{+}}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{b}{2x^2} + \frac{\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1}{x} + (-)\left(\frac{a}{2}\right) \\
&= \frac{b}{2x^2} + \frac{\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1}{x} - \frac{a}{2} \\
&= \frac{(-x+b)(ax+1)}{2x^2}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\,p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{b}{2x^2} + \frac{\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1}{x} - \frac{a}{2}\right)(1) + \left(\left(-\frac{b}{x^3} - \frac{\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1}{x^2}\right) + \left(\frac{b}{2x^2} + \frac{\frac{\frac{1}{2}a\,b^2-\frac{3}{2}b}{b}+1}{x} - \frac{a}{2}\right)^2 - \left(\frac{a^2 b}{\cdots}\right.\right.$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{1}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{1}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x+\frac{1}{a}\right) \mathrm{e}^{\int \left(\frac{b}{2x^2}+\frac{\frac{\frac{1}{2} a\, b^2-\frac{3}{2} b}{b}+1}{x}-\frac{a}{2}\right) dx} \\
&= \left(x+\frac{1}{a}\right) \mathrm{e}^{-\frac{b}{2x}-\frac{ax}{2}+\frac{\ln(x)ab}{2}-\frac{\ln(x)}{2}} \\
&= \frac{x^{\frac{ab}{2}-\frac{1}{2}} (ax+1)\, \mathrm{e}^{-\frac{a\,x^2+b}{2x}}}{a}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{abx+a\,x^2+b-x}{x^2} \, dx} \\
&= z_1 e^{-\frac{ax}{2}+\frac{b}{2x}-\frac{(ab-1)\ln(x)}{2}} \\
&= z_1 \left(x^{-\frac{ab}{2}+\frac{1}{2}} \mathrm{e}^{\frac{-a\,x^2+b}{2x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{(ax+1)\, \mathrm{e}^{-ax}}{a}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{abx+a\,x^2+b-x}{x^2} \, dx}}{(y_1)^2} \, dx \\
&= y_1 \int \frac{e^{-ax+\frac{b}{x}-\ln(x)ab+\ln(x)}}{(y_1)^2} \, dx \\
&= y_1 \left(\int \frac{x^{-ab+1} a^2 \mathrm{e}^{\frac{a\,x^2+b}{x}}}{(ax+1)^2} dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a}\right) + c_2 \left(\frac{(ax+1)\,\mathrm{e}^{-ax}}{a} \left(\int \frac{x^{-ab+1} a^2 \mathrm{e}^{\frac{a\,x^2+b}{x}}}{(ax+1)^2} dx\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 (ax+1)\,\mathrm{e}^{-ax}}{a} + c_2 a (ax+1)\,\mathrm{e}^{-ax} \left(\int \frac{x^{-ab+1} \mathrm{e}^{\frac{a\,x^2+b}{x}}}{(ax+1)^2} dx\right) \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 (ax+1)\,\mathrm{e}^{-ax}}{a} + c_2 a (ax+1)\,\mathrm{e}^{-ax} \left(\int \frac{x^{-ab+1} \mathrm{e}^{\frac{a\,x^2+b}{x}}}{(ax+1)^2} dx\right)
$$

Verified OK.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$x^2y'' + x(a\,x^2 + bx + c)\,y' + (A\,x^3 + B\,x^2 + Cx + d)\,y = 0$$

29.33.1 Maple step by step solution

Let's solve

$y''x^2 + x(a\,x^2 + bx + c)\,y' + (A\,x^3 + B\,x^2 + Cx + d)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(A\,x^3+B\,x^2+Cx+d)y}{x^2} - \frac{(a\,x^2+bx+c)y'}{x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(a\,x^2+bx+c)y'}{x} + \frac{(A\,x^3+B\,x^2+Cx+d)y}{x^2} = 0$

☐ Check to see if $x_0 = 0$ is a regular singular point

  - Define functions

$$\left[P_2(x) = \frac{a\,x^2+bx+c}{x}, P_3(x) = \frac{A\,x^3+B\,x^2+Cx+d}{x^2}\right]$$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $$\left(x \cdot P_2(x)\right)\bigg|_{x=0} = c$$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $$\left(x^2 \cdot P_3(x)\right)\bigg|_{x=0} = d$$

- $x = 0$is a regular singular point

  Check to see if $x_0 = 0$ is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $$y''x^2 + x(a\,x^2 + bx + c)\,y' + (A\,x^3 + B\,x^2 + Cx + d)\,y = 0$$

- Assume series solution for y

  $$y = \sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..3$

  $$x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$$

- Shift index using $k- >k - m$

  $$x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..3$

  $$x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$$

- Shift index using $k- >k + 1 - m$

  $$x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$$

- Convert $x^2 \cdot y''$ to series expansion

  $$x^2 \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)\,(k+r-1)\, x^{k+r}$$

  Rewrite ODE with series expansions

$$a_0(cr + r^2 + d - r)\, x^r + ((cr + r^2 + c + d + r)\, a_1 + a_0(br + C))\, x^{1+r} + ((cr + r^2 + 2c + d + 3r +$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$cr + r^2 + d - r = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}, -\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}\right\}$$

- The coefficients of each power of x must be 0

  $$[(cr + r^2 + c + d + r)\, a_1 + a_0(br + C) = 0, (cr + r^2 + 2c + d + 3r + 2)\, a_2 + a_1(br + C + b) + a_0($$

- Solve for the dependent coefficient(s)

  $$\left\{a_1 = -\frac{a_0(br+C)}{cr+r^2+c+d+r}, a_2 = -\frac{a_0\left(a\, r^2 c + a\, r^3 - b^2 r^2 + Bcr + B\, r^2 - 2brC + arc + ard + a\, r^2 - b^2 r + Bc + Bd + Br - C^2 - Cb\right)}{c^2r^2 + 2c\, r^3 + r^4 + 3c^2 r + 2crd + 7c\, r^2 + 2r^2 d + 4r^3 + 2c^2 + 3cd + 7cr + d^2 + 4dr + 5r^2 + 2c + 2d + 2r}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$(k^2 + (c + 2r - 1)\, k + r^2 + (c - 1)\, r + d)\, a_k + (a a_{k-2} + b a_{k-1})\, k + (a a_{k-2} + b a_{k-1})\, r + (B - 2a)$$

- Shift index using $k- >k + 3$

  $$\left((k + 3)^2 + (c + 2r - 1)\, (k + 3) + r^2 + (c - 1)\, r + d\right) a_{k+3} + (a a_{k+1} + b a_{k+2})\, (k + 3) + (a a_{k+1} +$$

- Recursion relation that defines series solution to ODE

  $$a_{k+3} = -\frac{aka_{k+1} + ara_{k+1} + bka_{k+2} + bra_{k+2} + Aa_k + Ba_{k+1} + Ca_{k+2} + aa_{k+1} + 2ba_{k+2}}{ck + cr + k^2 + 2kr + r^2 + 3c + d + 5k + 5r + 6}$$

- Recursion relation for $r = -\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}$

  $$a_{k+3} = -\frac{aka_{k+1} + a\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) a_{k+1} + bka_{k+2} + b\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) a_{k+2} + Aa_k + Ba_{k+1} + Ca_{k+2} + aa_{k+1} -}{ck + c\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) + k^2 + 2k\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) + \left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right)^2 + \frac{c}{2} + d + 5k + \frac{17}{2} + \frac{5\sqrt{c^2-}}{}}$$

- Solution for $r = -\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}$

  $$\left[y = \sum_{k=0}^{\infty} a_k x^{k - \frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}}, a_{k+3} = -\frac{aka_{k+1} + a\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) a_{k+1} + bka_{k+2} + b\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-}}{2}\right.}{ck + c\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) + k^2 + 2k\left(-\frac{c}{2} + \frac{1}{2} + \frac{\sqrt{c^2-2c-4d+1}}{2}\right) + \left(-\frac{c}{2} +\right.}\right.$$

- Recursion relation for $r = -\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}$

  $$a_{k+3} = -\frac{aka_{k+1} + a\left(-\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}\right) a_{k+1} + bka_{k+2} + b\left(-\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}\right) a_{k+2} + Aa_k + Ba_{k+1} + Ca_{k+2} + aa_{k+1} -}{ck + c\left(-\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}\right) + k^2 + 2k\left(-\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}\right) + \left(-\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}\right)^2 + \frac{c}{2} + d + 5k - \frac{5\sqrt{c^2-2c-}}{2}}$$

- Solution for $r = -\frac{c}{2} - \frac{\sqrt{c^2-2c-4d+1}}{2} + \frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-\frac{c}{2}-\frac{\sqrt{c^2-2c-4d+1}}{2}+\frac{1}{2}}, a_{k+3} = -\frac{aka_{k+1}+a\left(-\frac{c}{2}-\frac{\sqrt{c^2-2c-4d+1}}{2}+\frac{1}{2}\right)a_{k+1}+bka_{k+2}+b\left(-\frac{c}{2}-\frac{\sqrt{c^2-2c-4d+1}}{2}\right.}{ck+c\left(-\frac{c}{2}-\frac{\sqrt{c^2-2c-4d+1}}{2}+\frac{1}{2}\right)+k^2+2k\left(-\frac{c}{2}-\frac{\sqrt{c^2-2c-4d+1}}{2}+\frac{1}{2}\right)+\left(-\frac{c}{2}-\right.}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} e_k x^{k-\frac{c}{2}+\frac{1}{2}+\frac{\sqrt{c^2-2c-4d+1}}{2}}\right) + \left(\sum_{k=0}^{\infty} f_k x^{k-\frac{c}{2}-\frac{\sqrt{c^2-2c-4d+1}}{2}+\frac{1}{2}}\right), e_{k+3} = -\frac{ake_{1+k}+a\left(-\frac{c}{2}+\frac{1}{2}+\frac{\sqrt{c^2}}{}\right.}{ck+c\left(-\frac{c}{2}+\frac{1}{2}+\frac{\sqrt{c^2-2c-4d}}{2}\right.}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-4 Equation of form $x^2y'' + f(x)y' + g(x)y = 0$
Problem number: 145.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2y'' + x(a\,x^n + b)\,y' + b(a\,x^n - 1)\,y = 0}$$

29.36.1 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2y'' + x(a\,x^n + b)\,y' + b(a\,x^n - 1)\,y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{a\,x^n + b}{x} \\ q(x) &= \frac{b(a\,x^n - 1)}{x^2} \end{aligned}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x} + p\right) v'(x) + \left(\frac{n(n-1)}{x^2} + \frac{np}{x} + q\right) v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q=0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2}+\frac{n(a\,x^n+b)}{x^2}+\frac{b(a\,x^n-1)}{x^2}=0 \tag{5}$$

Solving (5) for n gives

$$n=-b \tag{6}$$

Substituting this value in (3) gives

$$v''(x)+\left(-\frac{2b}{x}+\frac{a\,x^n+b}{x}\right)v'(x)=0$$

$$v''(x)+\frac{(-b+a\,x^n)\,v'(x)}{x}=0 \tag{7}$$

Using the substitution

$$u(x)=v'(x)$$

Then (7) becomes

$$u'(x)+\frac{(-b+a\,x^n)\,u(x)}{x}=0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{(-b+a\,x^n)\,u}{x} \end{aligned}$$

Where $f(x)=-\frac{-b+a\,x^n}{x}$ and $g(u)=u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{-b+a\,x^n}{x}\,dx \\ \int\frac{1}{u}\,du &= \int-\frac{-b+a\,x^n}{x}\,dx \\ \ln(u) &= -\frac{a\,x^n}{n}+\frac{b\ln(x^n)}{n}+c_1 \\ u &= \mathrm{e}^{-\frac{a\,x^n}{n}+\frac{b\ln(x^n)}{n}+c_1} \\ &= c_1\mathrm{e}^{-\frac{a\,x^n}{n}+\frac{b\ln(x^n)}{n}} \end{aligned}$$

Which simplifies to

$$u(x) = c_1 \mathrm{e}^{-\frac{a\,x^n}{n}} \left(x^n\right)^{\frac{b}{n}}$$

Now that $u(x)$ is known, then

$$v'(x) = u(x)$$

$$v(x) = \int u(x)\,dx + c_2$$

$$= \frac{c_1 \left(x^n\right)^{\frac{b}{n}} x^{-b} \left(\frac{a}{n}\right)^{-\frac{b}{n}-\frac{1}{n}} \left(\frac{n^3 x^{b-n+1} \left(\frac{a}{n}\right)^{\frac{b}{n}+\frac{1}{n}} (a\,x^n+b+n+1) \left(\frac{a\,x^n}{n}\right)^{-\frac{n+b+1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \mathrm{WhittakerM}\left(\frac{1+b}{n}-\frac{n+b+1}{2n}, \frac{n+b+1}{2n}+\frac{1}{2}, \frac{a\,x^n}{n}\right)}{(1+b)(n+b+1)(2n+b+1)a}\right.}{n}$$

Hence

$$y = v(x)\,x^n$$

$$= \left(\frac{c_1 \left(x^n\right)^{\frac{b}{n}} x^{-b} \left(\frac{a}{n}\right)^{-\frac{b}{n}-\frac{1}{n}} \left(\frac{n^3 x^{b-n+1} \left(\frac{a}{n}\right)^{\frac{b}{n}+\frac{1}{n}} (a\,x^n+b+n+1) \left(\frac{a\,x^n}{n}\right)^{-\frac{n+b+1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \mathrm{WhittakerM}\left(\frac{1+b}{n}-\frac{n+b+1}{2n}, \frac{n+b+1}{2n}+\frac{1}{2}, \frac{a\,x^n}{n}\right)}{(1+b)(n+b+1)(2n+b+1)a}\right.}{n}\right.$$

$$= \frac{x^{-b}\left(\left(\frac{a\,x^n}{n}\right)^{-\frac{n+b+1}{2n}} \left((n+b+1)\,x^{1-n} + ax\right) n^2 c_1 \mathrm{e}^{-\frac{a\,x^n}{2n}} \left(x^n\right)^{\frac{b}{n}} \mathrm{WhittakerM}\left(\frac{b-n+1}{2n}, \frac{2n+b+1}{2n}, \frac{a\,x^n}{n}\right) + (n+b\right.}{(1+b)\,(n}$$

Summary

The solution(s) found are the following

$$y = \left(\frac{c_1 \left(x^n\right)^{\frac{b}{n}} x^{-b} \left(\frac{a}{n}\right)^{-\frac{b}{n}-\frac{1}{n}} \left(\frac{n^3 x^{b-n+1} \left(\frac{a}{n}\right)^{\frac{b}{n}+\frac{1}{n}} (a\,x^n+b+n+1) \left(\frac{a\,x^n}{n}\right)^{-\frac{n+b+1}{2n}} \mathrm{e}^{-\frac{a\,x^n}{2n}} \mathrm{WhittakerM}\left(\frac{1+b}{n}-\frac{n+b+1}{2n}, \frac{n+b+1}{2n}+\frac{1}{2}, \frac{a\,x^n}{n}\right)}{(1+b)(n+b+1)(2n+b+1)a} + \right.}{n} + c_2\right) x^{-b} \tag{1}$$

Verification of solutions

$$y = \left(\frac{c_1 (x^n)^{\frac{b}{n}} x^{-b} \left(\frac{a}{n}\right)^{-\frac{b}{n}-\frac{1}{n}} \left(\frac{n^3 x^{b-n+1} \left(\frac{a}{n}\right)^{\frac{b}{n}+\frac{1}{n}} (a x^n+b+n+1) \left(\frac{a x^n}{n}\right)^{-\frac{n+b+1}{2n}} e^{-\frac{a x^n}{2n}} \operatorname{WhittakerM}\left(\frac{1+b}{n}-\frac{n+b+1}{2n}, \frac{n+b+1}{2n}+\frac{1}{2}, \frac{a x^n}{n}\right)}{(1+b)(n+b+1)(2n+b+1)a} + \right.}{n} + c_2\right) x^{-b}$$

Verified OK.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[_Gegenbauer]
```

Unable to solve or complete the solution.

$$\boxed{(-x^2 + 1)\, y'' + n(n-1)\, y = 0}$$

30.1.1 Maple step by step solution

Let's solve

$(-x^2 + 1)\, y'' + (n^2 - n)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{n(n-1)y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{n(n-1)y}{x^2-1} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = 0, P_3(x) = -\frac{(n-1)n}{x^2-1}\right]$

- $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1} = 0$

- $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $y''(x^2-1) - n(n-1)\,y = 0$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (-n^2+n)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-2a_0r(-1+r)\,u^{-1+r} + \left(\sum_{k=0}^{\infty}\left(-2a_{k+1}(k+1+r)\,(k+r) + a_k(r-1+n+k)\,(r-n+k)\right)u^{k+r}\right)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(-1+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, 1\}$

- Each term in the series must be 0, giving the recursion relation

  $$-2a_{k+1}(k+1+r)(k+r)+a_k(r-1+n+k)(r-n+k)=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1}=\frac{a_k(r-1+n+k)(r-n+k)}{2(k+1+r)(k+r)}$$

- Recursion relation for $r=0$

  $$a_{k+1}=\frac{a_k(-1+n+k)(-n+k)}{2(k+1)k}$$

- Solution for $r=0$

  $$\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{a_k(-1+n+k)(-n+k)}{2(k+1)k}\right]$$

- Revert the change of variables $u=1+x$

  $$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^k, a_{k+1}=\frac{a_k(-1+n+k)(-n+k)}{2(k+1)k}\right]$$

- Recursion relation for $r=1$

  $$a_{k+1}=\frac{a_k(n+k)(1-n+k)}{2(k+2)(k+1)}$$

- Solution for $r=1$

  $$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k+1}, a_{k+1}=\frac{a_k(n+k)(1-n+k)}{2(k+2)(k+1)}\right]$$

- Revert the change of variables $u=1+x$

  $$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k+1}, a_{k+1}=\frac{a_k(n+k)(1-n+k)}{2(k+2)(k+1)}\right]$$

- Combine solutions and rename parameters

  $$\left[y=\left(\sum_{k=0}^{\infty}a_k(1+x)^k\right)+\left(\sum_{k=0}^{\infty}b_k(1+x)^{1+k}\right), a_{1+k}=\frac{a_k(k+n-1)(-n+k)}{2(1+k)k}, b_{1+k}=\frac{b_k(k+n)(1-n+k)}{2(k+2)(1+k)}\right]$$

Problem number: 150.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{(-a^2 + x^2)\, y'' + y'b - 6y = 0}$$

30.2.1 Maple step by step solution

Let's solve

$(-a^2 + x^2)\, y'' + y'b - 6y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{6y}{a^2-x^2} + \frac{by'}{a^2-x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{by'}{a^2-x^2} + \frac{6y}{a^2-x^2} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{b}{a^2-x^2}, P_3(x) = \frac{6}{a^2-x^2}\right]$

- $(x-a) \cdot P_2(x)$ is analytic at $x = a$

  $\left((x-a) \cdot P_2(x)\right)\Big|_{x=a} = \frac{b}{2a}$

- $(x-a)^2 \cdot P_3(x)$ is analytic at $x = a$

  $\left((x-a)^2 \cdot P_3(x)\right)\Big|_{x=a} = 0$

- $x = a$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = a$

- Multiply by denominators

  $y''(a^2 - x^2) - y'b + 6y = 0$

- Change variables using $x = u + a$ so that the regular singular point is at $u = 0$

  $(-2ua - u^2)\left(\frac{d^2}{du^2}y(u)\right) - b\left(\frac{d}{du}y(u)\right) + 6y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $\frac{d}{du}y(u)$ to series expansion

  $\frac{d}{du}y(u) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1}$

- Shift index using $k- >k+1$

  $\frac{d}{du}y(u) = \sum_{k=-1}^{\infty} a_{k+1}(k+1+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

$$-a_0 r(2ar-2a+b)\,u^{r-1}+\left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)\left(2a(k+1)+2ar-2a+b\right)-a_k(k+r+2)\left(\right.\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(2ar-2a+b)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{2a-b}{2a}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2(k+1+r)\left(ak+ar+\frac{1}{2}b\right)a_{k+1}-a_k(k+r+2)\left(k+r-3\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{a_k(k+r+2)(k+r-3)}{(k+1+r)(2ak+2ar+b)}$$

- Recursion relation for $r=0$; series terminates at $k=3$

$$a_{k+1}=-\frac{a_k(k+2)(k-3)}{(k+1)(2ak+b)}$$

Problem number: 151.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[_Gegenbauer, [_2nd_order, _linear, `_with_symmetry_[0,F(x)]`]]
```

$$\boxed{(x^2-1)\,y''+y'x+ay=0}$$

30.3.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$(x^2-1)\,y''+y'x+ay=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{x}{x^2-1}\\ q(x)&=\frac{a}{x^2-1}\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int \frac{x}{x^2-1}dx\right)}dx \\
&= \int e^{-\frac{\ln(x-1)}{2}-\frac{\ln(1+x)}{2}}\,dx \\
&= \int \frac{1}{\sqrt{x-1}\,\sqrt{1+x}}dx \\
&= \frac{\sqrt{(x-1)(1+x)}\,\ln\left(x+\sqrt{x^2-1}\right)}{\sqrt{x-1}\,\sqrt{1+x}}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{a}{x^2-1}}{\frac{1}{(x-1)(1+x)}} \\
&= a
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + a y(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = a$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + a\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + a = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = a$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(a)} \\ &= \pm\sqrt{-a}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-a} \\ \lambda_2 &= -\sqrt{-a}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-a} \\ \lambda_2 &= -\sqrt{-a}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau} \\ y(\tau) &= c_1 e^{(\sqrt{-a})\tau} + c_2 e^{(-\sqrt{-a})\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{-a}\,\tau} + c_2 e^{-\sqrt{-a}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(x + \sqrt{x^2 - 1}\right)^{\frac{\sqrt{-a}\,\sqrt{x^2-1}}{\sqrt{x-1}\,\sqrt{1+x}}} + c_2 \left(x + \sqrt{x^2 - 1}\right)^{-\frac{\sqrt{-a}\,\sqrt{x^2-1}}{\sqrt{x-1}\,\sqrt{1+x}}}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(x + \sqrt{x^2 - 1}\right)^{\frac{\sqrt{-a}\,\sqrt{x^2-1}}{\sqrt{x-1}\,\sqrt{1+x}}} + c_2 \left(x + \sqrt{x^2 - 1}\right)^{-\frac{\sqrt{-a}\,\sqrt{x^2-1}}{\sqrt{x-1}\,\sqrt{1+x}}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(x + \sqrt{x^2 - 1}\right)^{\frac{\sqrt{-a}\,\sqrt{x^2-1}}{\sqrt{x-1}\,\sqrt{1+x}}} + c_2 \left(x + \sqrt{x^2 - 1}\right)^{-\frac{\sqrt{-a}\,\sqrt{x^2-1}}{\sqrt{x-1}\,\sqrt{1+x}}}$$

Verified OK.

30.3.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(x^2 - 1\right) y'' + y'x + ay = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{x}{x^2 - 1} \\ q(x) &= \frac{a}{x^2 - 1} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{a}{x^2-1}}}{c} \\ \tau'' &= -\frac{ax}{c\sqrt{\frac{a}{x^2-1}}\,(x^2-1)^2} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{ax}{c\sqrt{\frac{a}{x^2-1}}\,(x^2-1)^2} + \frac{x}{x^2-1}\frac{\sqrt{\frac{a}{x^2-1}}}{c}}{\left(\frac{\sqrt{\frac{a}{x^2-1}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{\frac{a}{x^2-1}}dx}{c} \\ &= \frac{\sqrt{\frac{a}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)}{c} \end{aligned}$$

Substituting the above into the solution obtained gives

$$\begin{aligned} y = {} & c_1 \cos\left(\sqrt{a}\sqrt{\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \\ & + c_2 \sin\left(\sqrt{a}\sqrt{\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \end{aligned}$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 \cos\left(\sqrt{a}\,\sqrt{\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \\
& + c_2 \sin\left(\sqrt{a}\,\sqrt{\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 \cos\left(\sqrt{a}\,\sqrt{\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \\
& + c_2 \sin\left(\sqrt{a}\,\sqrt{\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right)
\end{aligned}
$$

Verified OK.

30.3.3 Solving using Kovacic algorithm

Writing the ode as

$$
\left(x^2-1\right) y'' + y'x + ay = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2 - 1 \\
B &= x \\
C &= a
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$
z''(x) = r z(x) \tag{4}
$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-4a\,x^2 - x^2 + 4a - 2}{4\,(x^2-1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -4a\,x^2 - x^2 + 4a - 2 \\ t &= 4(x^2-1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-4a\,x^2 - x^2 + 4a - 2}{4\,(x^2-1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 144: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16(x-1)^2} + \frac{\frac{1}{16}-\frac{a}{2}}{x-1} - \frac{3}{16(1+x)^2} + \frac{-\frac{1}{16}+\frac{a}{2}}{1+x}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-4a\,x^2 - x^2 + 4a - 2}{4(x^2-1)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -1$. Hence

$$\begin{aligned} E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
1	2	$\{1,2,3\}$
-1	2	$\{1,2,3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (1 + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{(x-(1))} + \frac{1}{(x-(-1))}\right) \\ &= \frac{1}{2x-2} + \frac{1}{2+2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$
\begin{aligned}
\phi &= \theta + \frac{p'}{p} \\
&= \frac{1}{2x-2} + \frac{1}{2+2x}
\end{aligned}
$$

Let ω be the solution of

$$
\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0
$$

Substituting the values for ϕ and r into the above equation gives

$$
w^2 - \left(\frac{1}{2x-2} + \frac{1}{2+2x}\right) w + \frac{4a\,x^2 + x^2 - 4a}{4\left(x^2-1\right)^2} = 0
$$

Solving for ω gives

$$
\omega = \frac{x + 2\sqrt{-a\left(x^2-1\right)}}{2\left(x-1\right)\left(1+x\right)}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \frac{x+2\sqrt{-a\left(x^2-1\right)}}{2(x-1)(1+x)} dx} \\
&= \left(x^2-1\right)^{\frac{1}{4}} \mathrm{e}^{-\sqrt{a}\,\arctan\left(\frac{\sqrt{a}\,x}{\sqrt{\left(-x^2+1\right)a}}\right)}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x}{x^2-1}\, dx} \\
&= z_1 e^{-\frac{\ln(x-1)}{4} - \frac{\ln(1+x)}{4}} \\
&= z_1 \left(\frac{1}{\left(x-1\right)^{\frac{1}{4}}\left(1+x\right)^{\frac{1}{4}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \frac{\left(x^2-1\right)^{\frac{1}{4}} \mathrm{e}^{-\sqrt{a}\,\arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{\left(x-1\right)^{\frac{1}{4}}\left(1+x\right)^{\frac{1}{4}}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x}{x^2-1}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-\frac{\ln(x-1)}{2}-\frac{\ln(1+x)}{2}}}{(y_1)^2}\, dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{2\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{\sqrt{x^2-1}} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{(x^2-1)^{\frac{1}{4}}\, \mathrm{e}^{-\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{(x-1)^{\frac{1}{4}}\, (1+x)^{\frac{1}{4}}}\right) \\
&\quad + c_2 \left(\frac{(x^2-1)^{\frac{1}{4}}\, \mathrm{e}^{-\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{(x-1)^{\frac{1}{4}}\, (1+x)^{\frac{1}{4}}} \left(\int \frac{\mathrm{e}^{2\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{\sqrt{x^2-1}} dx\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned}
y &= \frac{c_1 (x^2-1)^{\frac{1}{4}}\, \mathrm{e}^{-\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{(x-1)^{\frac{1}{4}}\, (1+x)^{\frac{1}{4}}} \\
&\quad + \frac{c_2 (x^2-1)^{\frac{1}{4}}\, \mathrm{e}^{-\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)} \left(\int \frac{\mathrm{e}^{2\sqrt{a}\, \arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{\sqrt{x^2-1}} dx\right)}{(x-1)^{\frac{1}{4}}\, (1+x)^{\frac{1}{4}}}
\end{aligned} \tag{1}$$

Verification of solutions

$$y = \frac{c_1(x^2-1)^{\frac{1}{4}} \mathrm{e}^{-\sqrt{a}\,\arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{(x-1)^{\frac{1}{4}}(1+x)^{\frac{1}{4}}} + \frac{c_2(x^2-1)^{\frac{1}{4}} \mathrm{e}^{-\sqrt{a}\,\arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)} \left(\int \frac{\mathrm{e}^{2\sqrt{a}\,\arctan\left(x\sqrt{-\frac{1}{x^2-1}}\right)}}{\sqrt{x^2-1}}dx\right)}{(x-1)^{\frac{1}{4}}(1+x)^{\frac{1}{4}}}$$

Verified OK.

30.3.4 Maple step by step solution

Let's solve

$y''(x^2-1)+y'x+ay=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{xy'}{x^2-1}-\frac{ay}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{xy'}{x^2-1}+\frac{ay}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

    $\left[P_2(x)=\frac{x}{x^2-1}, P_3(x)=\frac{a}{x^2-1}\right]$

  ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

    $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1}=\frac{1}{2}$

  ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

    $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

$y''(x^2-1)+y'x+ay=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(u-1)\left(\frac{d}{du}y(u)\right)+ay(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  ○ Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ○ Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ○ Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

  ○ Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $-a_0r(-1+2r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-a_{k+1}(k+1+r)\,(2k+1+2r)+a_k(k^2+2kr+r^2+a)\right)u^{k+r}\right)=$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-r(-1+2r)=0$

- Values of r that satisfy the indicial equation

$r\in\left\{0,\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

$-2\left(k+\frac{1}{2}+r\right)(k+1+r)\,a_{k+1}+a_k\left(k^2+2kr+r^2+a\right)=0$

- Recursion relation that defines series solution to ODE

$a_{k+1}=\frac{a_k\,(k^2+2kr+r^2+a)}{(2k+1+2r)(k+1+r)}$

- Recursion relation for $r=0$

$a_{k+1} = \frac{a_k(k^2+a)}{(2k+1)(k+1)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k^2+a)}{(2k+1)(k+1)}\right]$

- Revert the change of variables $u = 1 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k (1+x)^k, a_{k+1} = \frac{a_k(k^2+a)}{(2k+1)(k+1)}\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{a_k(k^2+a+k+\frac{1}{4})}{(2k+2)(k+\frac{3}{2})}$

- Solution for $r = \frac{1}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k(k^2+a+k+\frac{1}{4})}{(2k+2)(k+\frac{3}{2})}\right]$

- Revert the change of variables $u = 1 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k(k^2+a+k+\frac{1}{4})}{(2k+2)(k+\frac{3}{2})}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} b_k (1+x)^k\right) + \left(\sum_{k=0}^{\infty} c_k (1+x)^{k+\frac{1}{2}}\right), b_{1+k} = \frac{b_k(k^2+a)}{(2k+1)(1+k)}, c_{1+k} = \frac{c_k(k^2+a+k+\frac{1}{4})}{(2k+2)(k+\frac{3}{2})}\right]$

Maple gives the following as the ode type

```
[_Gegenbauer, [_2nd_order, _linear, `_with_symmetry_[0,F(x)]`]]
```

$$\boxed{\left(-x^2+1\right)y''-y'x+yn^2=0}$$

30.4.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(-x^2+1\right)y''-y'x+yn^2=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{x}{x^2-1} \\ q(x) &= \frac{n^2}{-x^2+1} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int \frac{x}{x^2-1} dx\right)} dx \\
&= \int e^{-\frac{\ln(x-1)}{2} - \frac{\ln(1+x)}{2}} dx \\
&= \int \frac{1}{\sqrt{x-1}\,\sqrt{1+x}} dx \\
&= \frac{\sqrt{(x-1)(1+x)}\,\ln\left(x + \sqrt{x^2-1}\right)}{\sqrt{x-1}\,\sqrt{1+x}}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{n^2}{-x^2+1}}{\frac{1}{(x-1)(1+x)}} \\
&= -n^2
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) - n^2 y(\tau) &= 0
\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -n^2$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} - n^2 e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - n^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -n^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-n^2)} \\ &= \pm\sqrt{n^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{n^2} \\ \lambda_2 &= -\sqrt{n^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{n^2} \\ \lambda_2 &= -\sqrt{n^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1\tau} + c_2 e^{\lambda_2\tau} \\ y(\tau) &= c_1 e^{\left(\sqrt{n^2}\right)\tau} + c_2 e^{\left(-\sqrt{n^2}\right)\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{n^2}\,\tau} + c_2 e^{-\sqrt{n^2}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(x + \sqrt{x^2 - 1}\right)^n + c_2 \left(x + \sqrt{x^2 - 1}\right)^{-n}$$

Summary
The solution(s) found are the following

$$y = c_1 \left(x + \sqrt{x^2 - 1}\right)^n + c_2 \left(x + \sqrt{x^2 - 1}\right)^{-n} \tag{1}$$

Verification of solutions

$$y = c_1 \left(x + \sqrt{x^2 - 1}\right)^n + c_2 \left(x + \sqrt{x^2 - 1}\right)^{-n}$$

Verified OK.

30.4.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(-x^2 + 1\right) y'' - y'x + yn^2 = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{x}{x^2 - 1} \\ q(x) &= -\frac{n^2}{x^2 - 1} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{-\frac{n^2}{x^2-1}}}{c} \\ \tau'' &= \frac{n^2 x}{c\sqrt{-\frac{n^2}{x^2-1}}\,(x^2-1)^2}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{\frac{n^2 x}{c\sqrt{-\frac{n^2}{x^2-1}}\,(x^2-1)^2} + \frac{x}{x^2-1}\frac{\sqrt{-\frac{n^2}{x^2-1}}}{c}}{\left(\frac{\sqrt{-\frac{n^2}{x^2-1}}}{c}\right)^2} \\ &= 0\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{-\frac{n^2}{x^2-1}}dx}{c} \\ &= \frac{\sqrt{-\frac{n^2}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$
\begin{aligned}
y = {} & c_1 \cos\left(n\sqrt{-\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \\
& + c_2 \sin\left(n\sqrt{-\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = {} & c_1 \cos\left(n\sqrt{-\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \\
& + c_2 \sin\left(n\sqrt{-\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 \cos\left(n\sqrt{-\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right) \\
& + c_2 \sin\left(n\sqrt{-\frac{1}{x^2-1}}\,\sqrt{x^2-1}\,\ln\left(x+\sqrt{x^2-1}\right)\right)
\end{aligned}
$$

Verified OK.

30.4.3 Solving using Kovacic algorithm

Writing the ode as

$$
\left(-x^2+1\right) y'' - y'x + yn^2 = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= -x^2+1 \\
B &= -x \\
C &= n^2
\end{aligned}
\tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4n^2x^2 - 4n^2 - x^2 - 2}{4\left(x^2 - 1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4n^2x^2 - 4n^2 - x^2 - 2 \\ t &= 4\left(x^2 - 1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4n^2x^2 - 4n^2 - x^2 - 2}{4\left(x^2 - 1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 146: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16(x-1)^2} + \frac{\frac{1}{16} + \frac{n^2}{2}}{x-1} - \frac{3}{16(1+x)^2} + \frac{-\frac{n^2}{2} - \frac{1}{16}}{1+x}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{4n^2x^2 - 4n^2 - x^2 - 2}{4(x^2-1)^2}$$

Since the gcd$(s,t)=1$. This gives $b=1$. Hence

$$\begin{aligned}E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\}\\ &= \{2\}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
1	2	$\{1,2,3\}$
-1	2	$\{1,2,3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned}d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right)\\ &= \frac{1}{2}(2-(1+(1)))\\ &= 0\end{aligned}$$

We now form the following rational function

$$\begin{aligned}\theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c}\\ &= \frac{1}{2}\left(\frac{1}{(x-(1))}+\frac{1}{(x-(-1))}\right)\\ &= \frac{1}{2x-2}+\frac{1}{2+2x}\end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d=0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{2x-2} + \frac{1}{2+2x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{2x-2} + \frac{1}{2+2x}\right)w + \frac{-4n^2x^2 + 4n^2 + x^2}{4\left(x^2-1\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{x + 2n\sqrt{x^2-1}}{2\left(x-1\right)\left(1+x\right)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx}\\ &= \mathrm{e}^{\int \frac{x+2n\sqrt{x^2-1}}{2(x-1)(1+x)}dx}\\ &= \left(x^2-1\right)^{\frac{1}{4}}\left(x+\sqrt{x^2-1}\right)^n\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{-x}{-x^2+1}\, dx}\\ &= z_1 e^{-\frac{\ln(x-1)}{4} - \frac{\ln(1+x)}{4}}\\ &= z_1\left(\frac{1}{\left(x-1\right)^{\frac{1}{4}}\left(1+x\right)^{\frac{1}{4}}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^n}{(x-1)^{\frac{1}{4}} (1+x)^{\frac{1}{4}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-x}{-x^2+1}\, dx}}{(y_1)^2}\, dx \\ &= y_1 \int \frac{e^{-\frac{\ln(x-1)}{2}-\frac{\ln(1+x)}{2}}}{(y_1)^2}\, dx \\ &= y_1 \left(-\frac{\left(x+\sqrt{x^2-1}\right)^{-2n}}{2n}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^n}{(x-1)^{\frac{1}{4}} (1+x)^{\frac{1}{4}}}\right) \\ &\quad + c_2 \left(\frac{(x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^n}{(x-1)^{\frac{1}{4}} (1+x)^{\frac{1}{4}}} \left(-\frac{\left(x+\sqrt{x^2-1}\right)^{-2n}}{2n}\right)\right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{c_1 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^n}{(x-1)^{\frac{1}{4}} (1+x)^{\frac{1}{4}}} - \frac{c_2 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{-n}}{2n (1+x)^{\frac{1}{4}} (x-1)^{\frac{1}{4}}} \tag{1}$$

<u>Verification of solutions</u>

$$y = \frac{c_1 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^n}{(x-1)^{\frac{1}{4}} (1+x)^{\frac{1}{4}}} - \frac{c_2 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{-n}}{2n (1+x)^{\frac{1}{4}} (x-1)^{\frac{1}{4}}}$$

Verified OK.

30.4.4 Maple step by step solution

Let's solve

$(-x^2+1)\,y''-y'x+yn^2=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{xy'}{x^2-1}+\frac{n^2y}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{xy'}{x^2-1}-\frac{n^2y}{x^2-1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{x}{x^2-1}, P_3(x)=-\frac{n^2}{x^2-1}\right]$

  ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\bigg|_{x=-1}=\frac{1}{2}$

  ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\bigg|_{x=-1}=0$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $y''(x^2-1)+y'x-yn^2=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(u-1)\left(\frac{d}{du}y(u)\right)-n^2y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0 r(-1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(2k+1+2r) + a_k(k+n+r)\,(k-n+r)\right) u^{k+r}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$-2\left(k+\frac{1}{2}+r\right)(k+1+r)\, a_{k+1} + a_k(k+n+r)\,(k-n+r) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = \frac{a_k(k+n+r)(k-n+r)}{(2k+1+2r)(k+1+r)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = \frac{a_k(k+n)(k-n)}{(2k+1)(k+1)}$$

- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k+n)(k-n)}{(2k+1)(k+1)}\right]$$

- Revert the change of variables $u = 1+x$

  $$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+1} = \frac{a_k(k+n)(k-n)}{(2k+1)(k+1)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{a_k \left(k+n+\frac{1}{2}\right) \left(k-n+\frac{1}{2}\right)}{(2k+2) \left(k+\frac{3}{2}\right)}$

- Solution for $r = \frac{1}{2}$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k \left(k+n+\frac{1}{2}\right) \left(k-n+\frac{1}{2}\right)}{(2k+2) \left(k+\frac{3}{2}\right)}\right]$$

- Revert the change of variables $u = 1 + x$

  $$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k \left(k+n+\frac{1}{2}\right) \left(k-n+\frac{1}{2}\right)}{(2k+2) \left(k+\frac{3}{2}\right)}\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k (1+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k (1+x)^{k+\frac{1}{2}}\right), a_{1+k} = \frac{a_k (k+n) (k-n)}{(2k+1) (1+k)}, b_{1+k} = \frac{b_k \left(k+n+\frac{1}{2}\right) \left(k-n+\frac{1}{2}\right)}{(2k+2) \left(k+\frac{3}{2}\right)}\right]$$

30.7 problem 155

Internal problem ID [10979]
Internal file name [`OUTPUT/10235_Sunday_December_31_2023_11_10_35_AM_79879110/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2+bx+c)y''+f(x)y'+g(x)y=0$
Problem number: 155.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

`[_Gegenbauer]`

$$\boxed{(-x^2+1)\,y''-3y'x+ny(2+n)=0}$$

30.7.1 Solving using Kovacic algorithm

Writing the ode as

$$(-x^2+1)\,y''-3y'x+(n^2+2n)\,y=0 \tag{1}$$
$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=-x^2+1\\ B&=-3x\\ C&=n^2+2n\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4n^2x^2 + 8n\,x^2 - 4n^2 + 3x^2 - 8n - 6}{4\left(x^2-1\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4n^2x^2 + 8n\,x^2 - 4n^2 + 3x^2 - 8n - 6 \\ t &= 4\left(x^2-1\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4n^2x^2 + 8n\,x^2 - 4n^2 + 3x^2 - 8n - 6}{4\left(x^2-1\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 150: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2-1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16(x-1)^2} + \frac{\frac{9}{16} + \frac{1}{2}n^2 + n}{x-1} - \frac{3}{16(1+x)^2} + \frac{-\frac{9}{16} - \frac{1}{2}n^2 - n}{1+x}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{4n^2x^2 + 8n\,x^2 - 4n^2 + 3x^2 - 8n - 6}{4(x^2-1)^2}$$

Since the gcd$(s,t) = 1$. This gives $b = 1$. Hence

$$\begin{aligned} E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
1	2	$\{1,2,3\}$
-1	2	$\{1,2,3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1, \;\; e_2 = 1, \;\; e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2-(1+(1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{(x-(1))} + \frac{1}{(x-(-1))}\right) \\ &= \frac{1}{2x-2} + \frac{1}{2+2x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}
\phi &= \theta + \frac{p'}{p} \\
&= \frac{1}{2x-2} + \frac{1}{2+2x}
\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{2x-2} + \frac{1}{2+2x}\right) w + \frac{-4n^2x^2 - 8n\,x^2 + 4n^2 - 3x^2 + 8n + 4}{4\left(x^2-1\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{2n\sqrt{x^2-1} + 2\sqrt{x^2-1} + x}{2\left(x-1\right)\left(1+x\right)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= e^{\int \frac{2n\sqrt{x^2-1}+2\sqrt{x^2-1}+x}{2(x-1)(1+x)} dx} \\
&= \left(x^2-1\right)^{\frac{1}{4}} \left(x + \sqrt{x^2-1}\right)^{n+1}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-3x}{-x^2+1} \, dx} \\
&= z_1 e^{-\frac{3\ln(x-1)}{4} - \frac{3\ln(1+x)}{4}} \\
&= z_1 \left(\frac{1}{\left(x-1\right)^{\frac{3}{4}}\left(1+x\right)^{\frac{3}{4}}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{(x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{n+1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} dx}}{y_1^2} dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{-3x}{-x^2+1} dx}}{(y_1)^2} dx \\ &= y_1 \int \frac{e^{-\frac{3\ln(x-1)}{2} - \frac{3\ln(1+x)}{2}}}{(y_1)^2} dx \\ &= y_1 \left(-\frac{\left(x+\sqrt{x^2-1}\right)^{-2n-2}}{2+2n} \right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\frac{(x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{n+1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}}} \right) \\ &\quad + c_2 \left(\frac{(x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{n+1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}}} \left(-\frac{\left(x+\sqrt{x^2-1}\right)^{-2n-2}}{2+2n} \right) \right) \end{aligned}$$

<u>Summary</u>

The solution(s) found are the following

$$y = \frac{c_1 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{n+1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}}} - \frac{c_2 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{-n-1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}} (2+2n)} \tag{1}$$

<u>Verification of solutions</u>

$$y = \frac{c_1 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{n+1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}}} - \frac{c_2 (x^2-1)^{\frac{1}{4}} \left(x+\sqrt{x^2-1}\right)^{-n-1}}{(x-1)^{\frac{3}{4}} (1+x)^{\frac{3}{4}} (2+2n)}$$

Verified OK.

30.7.2 Maple step by step solution

Let's solve

$(-x^2+1)\,y''-3y'x+(n^2+2n)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{n(2+n)y}{x^2-1}-\frac{3xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{3xy'}{x^2-1}-\frac{n(2+n)y}{x^2-1}=0$

☐ Check to see if x_0 is a regular singular point

- ∘ Define functions

  $\left[P_2(x)=\frac{3x}{x^2-1},P_3(x)=-\frac{n(2+n)}{x^2-1}\right]$

- ∘ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1}=\frac{3}{2}$

- ∘ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1}=0$

- ∘ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $y''(x^2-1)+3y'x-ny(2+n)=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right)+(3u-3)\left(\frac{d}{du}y(u)\right)+(-n^2-2n)\,y(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

  Rewrite ODE with series expansions

  $$-a_0 r(1+2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)(2k+3+2r) + a_k(r+2+n+k)(r-n+k)\right) u^{k}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-r(1+2r) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, -\frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$a_k(r+2+n+k)(r-n+k) - 2\left(k+\frac{3}{2}+r\right)(k+1+r)\, a_{k+1} = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = \frac{a_k(r+2+n+k)(r-n+k)}{(2k+3+2r)(k+1+r)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = \frac{a_k(2+n+k)(-n+k)}{(2k+3)(k+1)}$$

- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(2+n+k)(-n+k)}{(2k+3)(k+1)}\right]$$

- Revert the change of variables $u = 1+x$

  $$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+1} = \frac{a_k(2+n+k)(-n+k)}{(2k+3)(k+1)}\right]$$

- Recursion relation for $r = -\frac{1}{2}$

  $$a_{k+1} = \frac{a_k\left(\frac{3}{2}+n+k\right)\left(-\frac{1}{2}-n+k\right)}{(2k+2)\left(k+\frac{1}{2}\right)}$$

- Solution for $r = -\frac{1}{2}$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k\left(\frac{3}{2}+n+k\right)\left(-\frac{1}{2}-n+k\right)}{(2k+2)\left(k+\frac{1}{2}\right)}\right]$$

- Revert the change of variables $u = 1 + x$

  $$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^{k-\frac{1}{2}}, a_{k+1} = \frac{a_k\left(\frac{3}{2}+n+k\right)\left(-\frac{1}{2}-n+k\right)}{(2k+2)\left(k+\frac{1}{2}\right)}\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k(1+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k(1+x)^{k-\frac{1}{2}}\right), a_{1+k} = \frac{a_k(2+n+k)(-n+k)}{(2k+3)(1+k)}, b_{1+k} = \frac{b_k\left(\frac{3}{2}+n+k\right)\left(-\frac{1}{2}-n+k\right)}{(2k+2)\left(k+\frac{1}{2}\right)}\right]$$

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[_Gegenbauer]`

Unable to solve or complete the solution.

$$\boxed{(x^2-1)\,y''-2(n-1)\,xy'-(\nu-n+1)\,(\nu+n)\,y=0}$$

30.9.1 Maple step by step solution

Let's solve

$y''(x^2-1)+(-2xn+2x)\,y'+(n^2-\nu^2-n-\nu)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(n^2-\nu^2-n-\nu)y}{x^2-1}+\frac{2(n-1)xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{2(n-1)xy'}{x^2-1}+\frac{(n^2-\nu^2-n-\nu)y}{x^2-1}=0$

☐ Check to see if x_0 is a regular singular point

  ○ Define functions

$$\left[P_2(x) = -\frac{2x(n-1)}{x^2-1}, P_3(x) = \frac{n^2-\nu^2-n-\nu}{x^2-1}\right]$$

- $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $$\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1} = 1-n$$

- $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $$\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1} = 0$$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $$y''(x^2-1) - 2(n-1)\,xy' + (n^2-\nu^2-n-\nu)\,y = 0$$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $$(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (-2un+2n+2u-2)\left(\frac{d}{du}y(u)\right) + (n^2-\nu^2-n-\nu)\,y(u) = 0$$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

$$-2a_0 r(r-n)\,u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)\,(k+1+r-n) + a_k(k-n+\nu+r+1)\,(r-\nu-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-2r(r-n) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{0, n\}$

- Each term in the series must be 0, giving the recursion relation

  $-2a_{k+1}(k+1+r)\,(k+1+r-n) + a_k(k-n+\nu+r+1)\,(r-\nu-n+k) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k(k-n+\nu+r+1)(r-\nu-n+k)}{2(k+1+r)(k+1+r-n)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(k-n+\nu+1)(-\nu-n+k)}{2(k+1)(k+1-n)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k-n+\nu+1)(-\nu-n+k)}{2(k+1)(k+1-n)}\right]$

- Revert the change of variables $u = 1 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+1} = \frac{a_k(k-n+\nu+1)(-\nu-n+k)}{2(k+1)(k+1-n)}\right]$

- Recursion relation for $r = n$

  $a_{k+1} = \frac{a_k(k+\nu+1)(-\nu+k)}{2(k+1+n)(k+1)}$

- Solution for $r = n$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+n}, a_{k+1} = \frac{a_k(k+\nu+1)(-\nu+k)}{2(k+1+n)(k+1)}\right]$

- Revert the change of variables $u = 1 + x$

  $\left[y = \sum_{k=0}^{\infty} a_k(1+x)^{k+n}, a_{k+1} = \frac{a_k(k+\nu+1)(-\nu+k)}{2(k+1+n)(k+1)}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} a_k(1+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k(1+x)^{k+n}\right), a_{1+k} = \frac{a_k(k-n+\nu+1)(-\nu-n+k)}{2(1+k)(k+1-n)}, b_{1+k} = \frac{b_k(k+\nu+1)(-\nu+k}{2(k+1+n)(1+k)}\right.$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2 + bx + c)y'' + f(x)y' + g(x)y = 0$
Problem number: 160.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$(-x^2 + 1) y'' + (\beta - \alpha - (\alpha + \beta + 2) x) y' + n(n + \alpha + \beta + 1) y = 0$$

30.12.1 Maple step by step solution

Let's solve

$(-x^2 + 1) y'' + ((-\beta - \alpha - 2) x + \beta - \alpha) y' + n(n + \alpha + \beta + 1) y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{n(n+\alpha+\beta+1)y}{x^2-1} - \frac{(x\alpha+\beta x+\alpha-\beta+2x)y'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x\alpha+\beta x+\alpha-\beta+2x)y'}{x^2-1} - \frac{n(n+\alpha+\beta+1)y}{x^2-1} = 0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{x\alpha+\beta x+\alpha-\beta+2x}{x^2-1}, P_3(x) = -\frac{n(n+\alpha+\beta+1)}{x^2-1}\right]$

- $(1+x) \cdot P_2(x)$ is analytic at $x=-1$

  $((1+x) \cdot P_2(x))\bigg|_{x=-1} = \beta + 1$

- $(1+x)^2 \cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $y''(x^2-1) + (x\alpha + \beta x + \alpha - \beta + 2x)\, y' - n(n+\alpha+\beta+1)\, y = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u=0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (\alpha u + \beta u - 2\beta + 2u - 2)\left(\frac{d}{du}y(u)\right) + (-\alpha n - \beta n - n^2 - n)\, y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

$$-2a_0 r(r+\beta)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-2a_{k+1}(k+1+r)\,(k+1+r+\beta) + a_k(k-n+r)\,(k+\alpha+\beta+r+\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$-2r(r+\beta) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \{0, -\beta\}$$

- Each term in the series must be 0, giving the recursion relation

  $$-2a_{k+1}(k+1+r)\,(k+1+r+\beta) + a_k(k-n+r)\,(k+\alpha+\beta+r+1+n) = 0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1} = \frac{a_k(k-n+r)(k+\alpha+\beta+r+1+n)}{2(k+1+r)(k+1+r+\beta)}$$

- Recursion relation for $r = 0$

  $$a_{k+1} = \frac{a_k(k-n)(k+\alpha+\beta+1+n)}{2(k+1)(k+1+\beta)}$$

- Solution for $r = 0$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k-n)(k+\alpha+\beta+1+n)}{2(k+1)(k+1+\beta)}\right]$$

- Revert the change of variables $u = 1 + x$

  $$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k, a_{k+1} = \frac{a_k(k-n)(k+\alpha+\beta+1+n)}{2(k+1)(k+1+\beta)}\right]$$

- Recursion relation for $r = -\beta$

  $$a_{k+1} = \frac{a_k(k-n-\beta)(k+\alpha+1+n)}{2(k+1-\beta)(k+1)}$$

- Solution for $r = -\beta$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\beta}, a_{k+1} = \frac{a_k(k-n-\beta)(k+\alpha+1+n)}{2(k+1-\beta)(k+1)}\right]$$

- Revert the change of variables $u = 1 + x$

  $$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^{k-\beta}, a_{k+1} = \frac{a_k(k-n-\beta)(k+\alpha+1+n)}{2(k+1-\beta)(k+1)}\right]$$

- Combine solutions and rename parameters

  $$\left[y = \left(\sum_{k=0}^{\infty} a_k(1+x)^k\right) + \left(\sum_{k=0}^{\infty} b_k(1+x)^{k-\beta}\right), a_{1+k} = \frac{a_k(k-n)(k+\alpha+\beta+1+n)}{2(1+k)(k+1+\beta)}, b_{1+k} = \frac{b_k(k-n-\beta)(k+\alpha+1}{2(k+1-\beta)(1+k)}\right.$$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{\left(a\,x^2+b\right)y''+axy'+yc=0}$$

30.14.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(a\,x^2+b\right)y''+axy'+yc=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{ax}{a\,x^2+b}$$
$$q(x)=\frac{c}{a\,x^2+b}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int \frac{ax}{a\,x^2+b}dx\right)}dx \\
&= \int e^{-\frac{\ln\left(a\,x^2+b\right)}{2}}dx \\
&= \int \frac{1}{\sqrt{a\,x^2+b}}dx \\
&= \frac{\ln\left(\sqrt{a}\,x + \sqrt{a\,x^2+b}\right)}{\sqrt{a}}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{c}{a\,x^2+b}}{\frac{1}{a\,x^2+b}} \\
&= c
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + cy(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = c$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + c\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + c = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = c$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(c)}\\ &= \pm\sqrt{-c}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-c}\\ \lambda_2 &= -\sqrt{-c}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-c}\\ \lambda_2 &= -\sqrt{-c}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1\tau} + c_2 e^{\lambda_2\tau}\\ y(\tau) &= c_1 e^{(\sqrt{-c})\tau} + c_2 e^{(-\sqrt{-c})\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{-c}\,\tau} + c_2 e^{-\sqrt{-c}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(\sqrt{a}\, x + \sqrt{a\, x^2 + b}\right)^{\frac{\sqrt{-c}}{\sqrt{a}}} + c_2 \left(\sqrt{a}\, x + \sqrt{a\, x^2 + b}\right)^{-\frac{\sqrt{-c}}{\sqrt{a}}}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(\sqrt{a}\, x + \sqrt{a\, x^2 + b}\right)^{\frac{\sqrt{-c}}{\sqrt{a}}} + c_2 \left(\sqrt{a}\, x + \sqrt{a\, x^2 + b}\right)^{-\frac{\sqrt{-c}}{\sqrt{a}}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(\sqrt{a}\, x + \sqrt{a\, x^2 + b}\right)^{\frac{\sqrt{-c}}{\sqrt{a}}} + c_2 \left(\sqrt{a}\, x + \sqrt{a\, x^2 + b}\right)^{-\frac{\sqrt{-c}}{\sqrt{a}}}$$

Verified OK.

30.14.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(a\, x^2 + b\right) y'' + axy' + yc = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{ax}{a\, x^2 + b} \\ q(x) &= \frac{c}{a\, x^2 + b} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\, \tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{c}{a\,x^2+b}}}{c} \\ \tau'' &= -\frac{cax}{c\sqrt{\frac{c}{a\,x^2+b}}\,(a\,x^2+b)^2} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{cax}{c\sqrt{\frac{c}{a\,x^2+b}}\,(a\,x^2+b)^2} + \frac{ax}{a\,x^2+b}\frac{\sqrt{\frac{c}{a\,x^2+b}}}{c}}{\left(\frac{\sqrt{\frac{c}{a\,x^2+b}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{\frac{c}{a\,x^2+b}}dx}{c} \\ &= \frac{\sqrt{\frac{c}{a\,x^2+b}}\,\sqrt{a\,x^2+b}\,\ln\left(\sqrt{a}\,x + \sqrt{a\,x^2+b}\right)}{c\sqrt{a}} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos\left(\frac{\sqrt{c}\,\ln\left(\sqrt{a}\,x + \sqrt{a\,x^2+b}\right)}{\sqrt{a}}\right) + c_2 \sin\left(\frac{\sqrt{c}\,\ln\left(\sqrt{a}\,x + \sqrt{a\,x^2+b}\right)}{\sqrt{a}}\right)$$

Summary
The solution(s) found are the following

$$y = c_1 \cos\left(\frac{\sqrt{c}\, \ln\left(\sqrt{a}\, x+\sqrt{a\, x^2+b}\right)}{\sqrt{a}}\right)+c_2 \sin\left(\frac{\sqrt{c}\, \ln\left(\sqrt{a}\, x+\sqrt{a\, x^2+b}\right)}{\sqrt{a}}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(\frac{\sqrt{c}\, \ln\left(\sqrt{a}\, x+\sqrt{a\, x^2+b}\right)}{\sqrt{a}}\right)+c_2 \sin\left(\frac{\sqrt{c}\, \ln\left(\sqrt{a}\, x+\sqrt{a\, x^2+b}\right)}{\sqrt{a}}\right)$$

Verified OK.

30.14.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(a\, x^2+b\right) y''+a x y'+y c = 0 \tag{1}$$
$$A y''+B y'+C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= a\, x^2+b \\ B &= a x \\ C &= c \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB'-2BA'+B^2-4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a^2 x^2-4 a c\, x^2+2 a b-4 b c}{4\left(a\, x^2+b\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= -a^2x^2 - 4ac\,x^2 + 2ab - 4bc \\
t &= 4\left(a\,x^2 + b\right)^2
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{-a^2x^2 - 4ac\,x^2 + 2ab - 4bc}{4\left(a\,x^2 + b\right)^2}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 158: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 2 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4\left(a\,x^2 + b\right)^2$. There is a pole at $x = \frac{\sqrt{-ab}}{a}$ of order 2. There is a pole at

$x = -\frac{\sqrt{-ab}}{a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Unable to find solution using case two.

Attempting to find a solution using $n = 4$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16\left(x-\sqrt{-\frac{b}{a}}\right)^2} - \frac{3}{16\left(x+\sqrt{-\frac{b}{a}}\right)^2} + \frac{-ab+8bc}{16\left(-\frac{b}{a}\right)^{\frac{3}{2}} a^2 \left(x-\sqrt{-\frac{b}{a}}\right)} - \frac{-ab+8bc}{16\left(-\frac{b}{a}\right)^{\frac{3}{2}} a^2 \left(x+\sqrt{-\frac{b}{a}}\right)}$$

For the pole at $x = \frac{\sqrt{-ab}}{a}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{-ab}}{a}\right)^2}$ in the partial fractions decomposition of r given above. This shows that $b = 0$. Hence

$$E_c = \left\{6 + \frac{12k}{n}\sqrt{1+4b} | k = 0, \pm 1, \pm 2, \dots, \pm \frac{n}{2}\right\} \cap \mathbb{Z}$$

Where n for case 3 is $4, 6$ or 12. For the current case $n = 4$. Hence the above becomes

$$E_c = \{0, 3, 6, 9, 12\}$$

For the pole at $x = -\frac{\sqrt{-ab}}{a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{-ab}}{a}\right)^2}$ in the partial fractions decomposition of r given above. This shows that $b = 0$. Hence

$$E_c = \left\{6 + \frac{12k}{n}\sqrt{1+4b} | k = 0, \pm 1, \pm 2, \dots, \pm \frac{n}{2}\right\} \cap \mathbb{Z}$$

Where n for case 3 is $4, 6$ or 12. For the current case $n = 4$. Hence the above becomes

$$E_c = \{0, 3, 6, 9, 12\}$$

Let

$$E_\infty = \left\{6 + \frac{12k}{n}\sqrt{1+4b} | k = 0, \pm 1, \pm 2, \dots, \pm \frac{n}{2}\right\} \cap \mathbb{Z} \tag{B1}$$

Where b is the coefficient of $\frac{1}{x^2}$ in the Laurent series for r at ∞ given by

$$r \approx \frac{-a^2 - 4ac}{4a^2 x^2} + \frac{-\frac{(-a^2-4ac)b}{2a^3} + \frac{2ab-4bc}{4a^2}}{x^4} + \frac{\frac{3(-a^2-4ac)b^2}{4a^4} - \frac{(2ab-4bc)b}{2a^3}}{x^6} + \frac{-\frac{(-a^2-4ac)b^3}{a^5} + \frac{3(2ab-4bc)b^2}{4a^4}}{x^8} + \frac{\frac{5(-a^2-4ac)b^4}{4a^6}}{x}$$

The above shows that

$$b = -\frac{1}{4}$$

The value of n in eq. (B1) for case 3 is $4, 6$ or 2.For the current case $n = 4$. eq. (B1) simplifies to the following, after removing any duplicate and non integer entries in the set.

$$E_\infty = \{6\}$$

The following table summarizes the results found so far for poles and for the order of r at ∞ for case 3 of Kovacic algorithm using $n = 4$.

pole c location	pole order	set $\{E_c\}$
$\frac{\sqrt{-ab}}{a}$	2	$\{0, 3, 6, 9, 12\}$
$-\frac{\sqrt{-ab}}{a}$	2	$\{0, 3, 6, 9, 12\}$

Order of r at ∞	set $\{E_\infty\}$
2	$\{6\}$

Now that E_c sets for all poles are found and E_∞ set is found, the next step is to determine a non negative integer d using the following

$$d = \frac{n}{12}\left(e_\infty - \sum_{c \in \Gamma} e_c\right)$$

Where in the above e_c is a distinct element from each corresponding E_c. This means all possible tuples $\{e_{c_1}, e_{c_2}, \dots, e_{c_n}\}$ are tried in the sum above, where e_{c_i} is one element of each E_c found earlier. Using the following family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 3, \ e_2 = 3, \ e_\infty = 6$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$
\begin{aligned}
d &= \frac{n}{12}\left(e_\infty - \sum_{c\in\Gamma} e_c\right)\\
&= \frac{4}{12}(6-(3+(3)))\\
&= 0
\end{aligned}
$$

The following rational function is

$$
\begin{aligned}
\theta &= \frac{n}{12}\sum_{c\in\Gamma}\frac{e_c}{x-c}\\
&= \frac{4}{12}\left(\frac{3}{\left(x-\left(\frac{\sqrt{-ab}}{a}\right)\right)}+\frac{3}{\left(x-\left(-\frac{\sqrt{-ab}}{a}\right)\right)}\right)\\
&= \frac{2ax}{a\,x^2+b}
\end{aligned}
$$

And

$$
\begin{aligned}
S &= \prod_{c\in\Gamma}(x-c)\\
&= \left(x-\frac{\sqrt{-ab}}{a}\right)\left(x+\frac{\sqrt{-ab}}{a}\right)
\end{aligned}
$$

The polynomial $p(x)$ is now determined. Since the degree of the polynomial is $d=0$, then let

$$
p(x) = 1
$$

The following set of equations are set up in order to determine the coefficients a_i (if any) of the above polynomial

$$
\begin{aligned}
P_n &= -p(x)\\
&= -1\\
P_{i-1} &= -Sp_i' + ((n-i)S' - S\theta)P_i - (n-1)(i+1)S^2rP_{i+1} \qquad i = n, n-1, \ldots, 0
\end{aligned} \tag{1A}
$$

The coefficients a_i are solved for from

$$
P_{-1} = 0 \tag{2A}
$$

By using method of undetermined coefficients. Carrying the above computation in eq. (1A) gives the following sequence of polynomials P_i (noting that $n = 4$ and $r = \frac{-a^2x^2-4ac\,x^2+2ab-4bc}{4(a\,x^2+b)^2}$).

$$
\begin{aligned}
P_4 &= -p\\
&= -1\\
P_3 &= 2x\\
P_2 &= \frac{-3a^2x^2-4ac\,x^2-4bc}{a^2}\\
P_1 &= \frac{3x(a\,x^2(a+4c)+4bc)}{a^2}\\
P_0 &= -\frac{3(a^2x^2+4ac\,x^2+4bc)^2}{2a^4}\\
P_{-1} &= 0
\end{aligned}
$$

Because $P_{-1} = 0$ then $z = e^{\int \omega}$ is a solution. ω is found by finding a solution to the equation generated by the following sum

$$
\begin{aligned}
\sum_{i=0}^{n} S^i \frac{P_i}{(n-i)!}\omega^i &= 0\\
\sum_{i=0}^{4} S^i \frac{P_i}{(4-i)!}\omega^i &= 0
\end{aligned}
$$

Where the P_i are the polynomials found earlier. Computing the above sum gives

$$
\frac{1}{16a^4}\left(-\left(4a^2x^4\omega^2-4a^2x^3\omega+8ab\,\omega^2x^2+a^2x^2-4ab\omega x+4ac\,x^2+4b^2\omega^2+4bc\right)^2\right) = 0 \tag{3A}
$$

The solution ω of eq. 3A is found as

$$
\omega = \frac{1}{2a\,x^2+2b}\left(ax-2\sqrt{-\left(a\,x^2+b\right)c}\right)
$$

This ω is used to find a solution to $z'' = rz$.

$$
z_1(x) = e^{\int \omega\,dx} \tag{5A}
$$

Doing the integration gives in eq. (4A) gives

$$
\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{ax-2\sqrt{-\left(a\,x^2+b\right)c}}{2a\,x^2+2b}dx} \\
&= \left(a\,x^2+b\right)^{\frac{1}{4}} \mathrm{e}^{\frac{c \arctan\left(\frac{\sqrt{ac}\,x}{\sqrt{-\left(a\,x^2+b\right)c}}\right)}{\sqrt{ac}}}
\end{aligned}
$$

Which simplifies to

$$
z_1(x) = \left(a\,x^2+b\right)^{\frac{1}{4}} \mathrm{e}^{\frac{c \arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{ax}{a\,x^2+b}\, dx} \\
&= z_1 e^{-\frac{\ln\left(a\,x^2+b\right)}{4}} \\
&= z_1 \left(\frac{1}{\left(a\,x^2+b\right)^{\frac{1}{4}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{c \arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{ax}{a\,x^2+b}\,dx}}{(y_1)^2}\,dx$$

$$= y_1 \int \frac{e^{-\frac{\ln\left(a\,x^2+b\right)}{2}}}{(y_1)^2}\,dx$$

$$= y_1 \left(\int \frac{\mathrm{e}^{-\frac{2c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}}{\sqrt{a\,x^2+b}}dx\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(\mathrm{e}^{\frac{c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}\right) + c_2 \left(\mathrm{e}^{\frac{c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}\left(\int \frac{\mathrm{e}^{-\frac{2c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}}{\sqrt{a\,x^2+b}}dx\right)\right)$$

Summary

The solution(s) found are the following

$$y = c_1\mathrm{e}^{\frac{c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}} + c_2\mathrm{e}^{\frac{c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}\left(\int \frac{\mathrm{e}^{-\frac{2c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}}{\sqrt{a\,x^2+b}}dx\right) \tag{1}$$

Verification of solutions

$$y = c_1\mathrm{e}^{\frac{c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}} + c_2\mathrm{e}^{\frac{c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}\left(\int \frac{\mathrm{e}^{-\frac{2c\arctan\left(x\sqrt{-\frac{a}{a\,x^2+b}}\right)}{\sqrt{ac}}}}{\sqrt{a\,x^2+b}}dx\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2 + bx + c)y'' + f(x)y' + g(x)y = 0$
Problem number: 163.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{(x^2 + a)\, y'' + 2bxy' + 2(b-1)\, y = 0}$$

30.15.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left((x^2 + a)\, y'' + 2bxy' + (2b-2)\, y\right) dx = 0$$
$$(2bx - 2x)\, y + (x^2 + a)\, y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2x(b-1)}{x^2+a}$$
$$q(x) = \frac{c_1}{x^2+a}$$

Hence the ode is

$$y' + \frac{2x(b-1)\,y}{x^2+a} = \frac{c_1}{x^2+a}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int \frac{2x(b-1)}{x^2+a}dx}$$
$$= \mathrm{e}^{\frac{(2b-2)\ln\left(x^2+a\right)}{2}}$$

Which simplifies to

$$\mu = \left(x^2+a\right)^{b-1}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{c_1}{x^2+a}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\left(x^2+a\right)^{b-1} y\right) = \left(\left(x^2+a\right)^{b-1}\right)\left(\frac{c_1}{x^2+a}\right)$$
$$\mathrm{d}\left(\left(x^2+a\right)^{b-1} y\right) = \left(c_1\left(x^2+a\right)^{-2+b}\right)\,\mathrm{d}x$$

Integrating gives

$$\left(x^2+a\right)^{b-1} y = \int c_1\left(x^2+a\right)^{-2+b}\,\mathrm{d}x$$
$$\left(x^2+a\right)^{b-1} y = \int c_1\left(x^2+a\right)^{-2+b} dx + c_2$$

Dividing both sides by the integrating factor $\mu = \left(x^2+a\right)^{b-1}$ results in

$$y = \left(x^2+a\right)^{-b+1}\left(\int c_1\left(x^2+a\right)^{-2+b} dx\right) + c_2\left(x^2+a\right)^{-b+1}$$

which simplifies to

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right)\left(x^2+a\right)^{-b+1}$$

Summary
The solution(s) found are the following

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right)+c_2\right)\left(x^2+a\right)^{-b+1} \tag{1}$$

Verification of solutions

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right)+c_2\right)\left(x^2+a\right)^{-b+1}$$

Verified OK.

30.15.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$\left(x^2+a\right)y''+2bxy'+(2b-2)\,y=0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(\left(x^2+a\right)y''+2bxy'+(2b-2)\,y\right)dx = 0$$
$$(2bx-2x)\,y+\left(x^2+a\right)y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y = q(x)$$

Where here

$$p(x) = \frac{2x(b-1)}{x^2+a}$$
$$q(x) = \frac{c_1}{x^2+a}$$

Hence the ode is

$$y'+\frac{2x(b-1)\,y}{x^2+a} = \frac{c_1}{x^2+a}$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int \frac{2x(b-1)}{x^2+a}dx}$$
$$= \mathrm{e}^{\frac{(2b-2)\ln\left(x^2+a\right)}{2}}$$

Which simplifies to

$$\mu = \left(x^2+a\right)^{b-1}$$

The ode becomes

$$\begin{aligned}
\frac{d}{dx}(\mu y) &= (\mu)\left(\frac{c_1}{x^2+a}\right) \\
\frac{d}{dx}\left(\left(x^2+a\right)^{b-1} y\right) &= \left(\left(x^2+a\right)^{b-1}\right)\left(\frac{c_1}{x^2+a}\right) \\
d\left(\left(x^2+a\right)^{b-1} y\right) &= \left(c_1\left(x^2+a\right)^{-2+b}\right) dx
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\left(x^2+a\right)^{b-1} y &= \int c_1\left(x^2+a\right)^{-2+b} dx \\
\left(x^2+a\right)^{b-1} y &= \int c_1\left(x^2+a\right)^{-2+b} dx + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \left(x^2+a\right)^{b-1}$ results in

$$y = \left(x^2+a\right)^{-b+1}\left(\int c_1\left(x^2+a\right)^{-2+b} dx\right) + c_2\left(x^2+a\right)^{-b+1}$$

which simplifies to

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right)\left(x^2+a\right)^{-b+1}$$

<u>Summary</u>
The solution(s) found are the following

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right)\left(x^2+a\right)^{-b+1} \tag{1}$$

<u>Verification of solutions</u>

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right)\left(x^2+a\right)^{-b+1}$$

Verified OK.

30.15.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x^2 + a \\ q(x) &= 2bx \\ r(x) &= 2b - 2 \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 2 \\ q'(x) &= 2b \end{aligned}$$

Therefore (1) becomes

$$2 - (2b) + (2b - 2) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p, q, r, s gives

$$(2bx - 2x)\,y + \left(x^2 + a\right)y' = c_1$$

We now have a first order ode to solve which is

$$(2bx - 2x)\,y + \left(x^2 + a\right)y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = \frac{2x(b-1)}{x^2+a}$$
$$q(x) = \frac{c_1}{x^2+a}$$

Hence the ode is

$$y' + \frac{2x(b-1)\,y}{x^2+a} = \frac{c_1}{x^2+a}$$

The integrating factor μ is

$$\mu = e^{\int \frac{2x(b-1)}{x^2+a}dx}$$
$$= e^{\frac{(2b-2)\ln\left(x^2+a\right)}{2}}$$

Which simplifies to

$$\mu = \left(x^2+a\right)^{b-1}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{c_1}{x^2+a}\right)$$
$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\left(x^2+a\right)^{b-1} y\right) = \left(\left(x^2+a\right)^{b-1}\right)\left(\frac{c_1}{x^2+a}\right)$$
$$\mathrm{d}\left(\left(x^2+a\right)^{b-1} y\right) = \left(c_1\left(x^2+a\right)^{-2+b}\right)\,\mathrm{d}x$$

Integrating gives

$$\left(x^2+a\right)^{b-1} y = \int c_1\left(x^2+a\right)^{-2+b}\,\mathrm{d}x$$
$$\left(x^2+a\right)^{b-1} y = \int c_1\left(x^2+a\right)^{-2+b} dx + c_2$$

Dividing both sides by the integrating factor $\mu = \left(x^2+a\right)^{b-1}$ results in

$$y = \left(x^2+a\right)^{-b+1}\left(\int c_1\left(x^2+a\right)^{-2+b} dx\right) + c_2\left(x^2+a\right)^{-b+1}$$

which simplifies to

$$y = \left(c_1\left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right)\left(x^2+a\right)^{-b+1}$$

Summary
The solution(s) found are the following

$$y = \left(c_1 \left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right) \left(x^2+a\right)^{-b+1} \tag{1}$$

Verification of solutions

$$y = \left(c_1 \left(\int \left(x^2+a\right)^{-2+b} dx\right) + c_2\right) \left(x^2+a\right)^{-b+1}$$

Verified OK.

Problem number: 164.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{(-a^2+x^2)\,y''+2bxy'+b(b-1)\,y=0}$$

30.16.1 Maple step by step solution

Let's solve

$(-a^2+x^2)\,y''+2bxy'+(b^2-b)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{b(b-1)y}{a^2-x^2}+\frac{2bxy'}{a^2-x^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{2bxy'}{a^2-x^2}-\frac{b(b-1)y}{a^2-x^2}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = -\frac{2bx}{a^2-x^2}, P_3(x) = -\frac{b(b-1)}{a^2-x^2}\right]$

- $(x-a)\cdot P_2(x)$ is analytic at $x=a$

  $$\left((x-a)\cdot P_2(x)\right)\Big|_{x=a} = b$$

- $(x-a)^2\cdot P_3(x)$ is analytic at $x=a$

  $$\left((x-a)^2\cdot P_3(x)\right)\Big|_{x=a} = 0$$

- $x=a$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = a$

- Multiply by denominators

  $$y''(a^2-x^2) - 2bxy' - b(b-1)\,y = 0$$

- Change variables using $x = u+a$ so that the regular singular point is at $u=0$

  $$(-2ua-u^2)\left(\frac{d^2}{du^2}y(u)\right) + (-2ab-2bu)\left(\frac{d}{du}y(u)\right) + (-b^2+b)\,y(u) = 0$$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

□ Rewrite ODE with series expansions

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^m\cdot\left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

$$-2aa_0r(r-1+b)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(-2aa_{k+1}(k+1+r)\,(r+k+b)-a_k(r+k+b)\,(r-1+k+b\right)\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2ar(r-1+b)=0$$

- Values of r that satisfy the indicial equation

$$r\in\{0,-b+1\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2(r+k+b)\left(\frac{a_k(r-1+k+b)}{2}+aa_{k+1}(k+1+r)\right)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=-\frac{a_k(r-1+k+b)}{2a(k+1+r)}$$

- Recursion relation for $r=0$

$$a_{k+1}=-\frac{a_k(-1+k+b)}{2a(k+1)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=-\frac{a_k(-1+k+b)}{2a(k+1)}\right]$$

- Revert the change of variables $u=x-a$

$$\left[y=\sum_{k=0}^{\infty}a_k(x-a)^k, a_{k+1}=-\frac{a_k(-1+k+b)}{2a(k+1)}\right]$$

- Recursion relation for $r=-b+1$

$$a_{k+1}=-\frac{a_k k}{2a(k+2-b)}$$

- Solution for $r=-b+1$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k-b+1}, a_{k+1}=-\frac{a_k k}{2a(k+2-b)}\right]$$

- Revert the change of variables $u=x-a$

$$\left[y=\sum_{k=0}^{\infty}a_k(x-a)^{k-b+1}, a_{k+1}=-\frac{a_k k}{2a(k+2-b)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}c_k(x-a)^k\right)+\left(\sum_{k=0}^{\infty}d_k(x-a)^{k-b+1}\right), c_{1+k}=-\frac{c_k(-1+k+b)}{2a(1+k)}, d_{1+k}=-\frac{d_k k}{2a(k+2-b)}\right]$$

Problem number: 165.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(a^2 + x^2)\, y'' + 2bxy' + b(b-1)\, y = 0}$$

30.17.1 Solving using Kovacic algorithm

Writing the ode as

$$(a^2 + x^2)\, y'' + 2bxy' + (b^2 - b)\, y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= a^2 + x^2 \\ B &= 2bx \\ C &= b^2 - b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$r = \frac{s}{t} \tag{5}$$
$$= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-b\,a^2(-2+b)}{(a^2+x^2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -b\,a^2(-2+b)$$
$$t = (a^2+x^2)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{b\,a^2(-2+b)}{(a^2+x^2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 160: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (a^2 + x^2)^2$. There is a pole at $x = ia$ of order 2. There is a pole at $x = -ia$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{b(-2+b)}{4\left(x - \sqrt{-a^2}\right)^2} + \frac{b(-2+b)}{4\left(x + \sqrt{-a^2}\right)^2} + \frac{b\,a^2(-2+b)}{4\left(-a^2\right)^{\frac{3}{2}}\left(x - \sqrt{-a^2}\right)} - \frac{b\,a^2(-2+b)}{4\left(-a^2\right)^{\frac{3}{2}}\left(x + \sqrt{-a^2}\right)}$$

For the pole at $x = ia$ let b be the coefficient of $\frac{1}{(-ia+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

For the pole at $x = -ia$ let b be the coefficient of $\frac{1}{(ia+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

Now since the order of r at ∞ is $4 > 2$ then

$$E_\infty = \{0, 2, 4\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
ia	2	$\{0,2,4\}$
$-ia$	2	$\{0,2,4\}$

Order of r at ∞	E_∞
4	$\{0,2,4\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2,\ e_2 = 2,\ e_\infty = 4$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(4 - (2 + (2))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{2}{(x-(ia))} + \frac{2}{(x-(-ia))}\right) \\ &= \frac{1}{-ia+x} + \frac{1}{ia+x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{-ia+x} + \frac{1}{ia+x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{-ia+x} + \frac{1}{ia+x}\right) w + \frac{(b-1)^2 a^2 + x^2}{(a^2+x^2)^2} = 0$$

Solving for ω gives

$$\omega = \frac{iab - ia + x}{a^2 + x^2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx}\\ &= \mathrm{e}^{\int \frac{iab-ia+x}{a^2+x^2} dx}\\ &= \sqrt{a^2+x^2}\, \mathrm{e}^{i(b-1)\arctan\left(\frac{x}{a}\right)}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}\\ &= z_1 e^{-\int \frac{1}{2}\frac{2bx}{a^2+x^2}\, dx}\\ &= z_1 e^{-\frac{b\ln\left(a^2+x^2\right)}{2}}\\ &= z_1\left(\left(a^2+x^2\right)^{-\frac{b}{2}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \left(a^2+x^2\right)^{-\frac{b}{2}+\frac{1}{2}} \mathrm{e}^{i(b-1)\arctan\left(\frac{x}{a}\right)}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2bx}{a^2+x^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{-b\ln(a^2+x^2)}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{-2i(b-1)\arctan\left(\frac{x}{a}\right)}(ia+x)(ix+a)}{2a(b-1)(a^2+x^2)}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(a^2+x^2\right)^{-\frac{b}{2}+\frac{1}{2}} \mathrm{e}^{i(b-1)\arctan\left(\frac{x}{a}\right)}\right) \\
&\quad + c_2\left(\left(a^2+x^2\right)^{-\frac{b}{2}+\frac{1}{2}} \mathrm{e}^{i(b-1)\arctan\left(\frac{x}{a}\right)}\left(\frac{\mathrm{e}^{-2i(b-1)\arctan\left(\frac{x}{a}\right)}(ia+x)(ix+a)}{2a(b-1)(a^2+x^2)}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\left(a^2+x^2\right)^{-\frac{b}{2}+\frac{1}{2}} \mathrm{e}^{i(b-1)\arctan\left(\frac{x}{a}\right)} + \frac{c_2(ia+x)(ix+a)\left(a^2+x^2\right)^{-\frac{1}{2}-\frac{b}{2}} \mathrm{e}^{-i(b-1)\arctan\left(\frac{x}{a}\right)}}{2a(b-1)} \tag{1}$$

Verification of solutions

$$y = c_1\left(a^2+x^2\right)^{-\frac{b}{2}+\frac{1}{2}} \mathrm{e}^{i(b-1)\arctan\left(\frac{x}{a}\right)} + \frac{c_2(ia+x)(ix+a)\left(a^2+x^2\right)^{-\frac{1}{2}-\frac{b}{2}} \mathrm{e}^{-i(b-1)\arctan\left(\frac{x}{a}\right)}}{2a(b-1)}$$

Verified OK.

Problem number: 167.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$\boxed{\left(-x^{2}+1\right) y''-y' x+\left(2 a \,x^{2}+b \right) y=0}$$

30.19.1 Maple step by step solution

Let's solve

$\left(-x^{2}+1\right) y''-y' x+\left(2 a \,x^{2}+b \right) y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{\left(2 a \,x^{2}+b \right) y}{x^{2}-1}-\frac{x y'}{x^{2}-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{x y'}{x^{2}-1}-\frac{\left(2 a \,x^{2}+b \right) y}{x^{2}-1}=0$

□ Check to see if x_0 is a regular singular point

  ○ Define functions

$\left[P_2(x) = \frac{x}{x^2-1}, P_3(x) = -\frac{2a\,x^2+b}{x^2-1}\right]$

- $(1+x) \cdot P_2(x)$ is analytic at $x = -1$

  $\left((1+x) \cdot P_2(x)\right)\bigg|_{x=-1} = \frac{1}{2}$

- $(1+x)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $\left((1+x)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $y''(x^2-1) + y'x + (-2a\,x^2 - b)\,y = 0$

- Change variables using $x = u - 1$ so that the regular singular point is at $u = 0$

  $(u^2 - 2u)\left(\frac{d^2}{du^2}y(u)\right) + (u-1)\left(\frac{d}{du}y(u)\right) + (-2a\,u^2 + 4au - 2a - b)\,y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..2$

  $u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k- >k - m$

  $u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k+r)\,u^{k+r-1+m}$

- Shift index using $k- >k + 1 - m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0r(-1+2r)\,u^{-1+r} + (-a_1(1+r)\,(1+2r) - a_0(-r^2+2a+b))\,u^r + (-a_2(2+r)\,(3+2r) - a$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- The coefficients of each power of u must be 0

$$[-a_1(1+r)\,(1+2r) - a_0(-r^2+2a+b) = 0, -a_2(2+r)\,(3+2r) - a_1(-r^2+2a+b-2r-1) +$$

- Solve for the dependent coefficient(s)

$$\left\{a_1 = -\frac{a_0(-r^2+2a+b)}{2r^2+3r+1}, a_2 = \frac{a_0(r^4+4r^2a-2r^2b+2r^3+4a^2+4ab+8ar+b^2-2br+r^2+2a-b)}{4r^4+20r^3+35r^2+25r+6}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$-2\left(k+\frac{1}{2}+r\right)(k+1+r)\,a_{k+1} + (k^2+2kr+r^2-2a-b)\,a_k - 2a(a_{k-2}-2a_{k-1}) = 0$$

- Shift index using $k->k+2$

$$-2\left(k+\frac{5}{2}+r\right)(k+3+r)\,a_{k+3} + \left((k+2)^2+2(k+2)\,r+r^2-2a-b\right)a_{k+2} - 2a(a_k-2a_{k+1}) =$$

- Recursion relation that defines series solution to ODE

$$a_{k+3} = -\frac{-k^2a_{k+2}-2kra_{k+2}-r^2a_{k+2}+2a_ka-4aa_{k+1}+2aa_{k+2}+ba_{k+2}-4ka_{k+2}-4ra_{k+2}-4a_{k+2}}{(2k+5+2r)(k+3+r)}$$

- Recursion relation for $r=0$

$$a_{k+3} = -\frac{-k^2a_{k+2}+2a_ka-4aa_{k+1}+2aa_{k+2}+ba_{k+2}-4ka_{k+2}-4a_{k+2}}{(2k+5)(k+3)}$$

- Solution for $r=0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_ku^k, a_{k+3} = -\frac{-k^2a_{k+2}+2a_ka-4aa_{k+1}+2aa_{k+2}+ba_{k+2}-4ka_{k+2}-4a_{k+2}}{(2k+5)(k+3)}, a_1 = -a_0(2a+b)\,, a_2 =\right.$$

- Revert the change of variables $u = 1+x$

$$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^k\,, a_{k+3} = -\frac{-k^2a_{k+2}+2a_ka-4aa_{k+1}+2aa_{k+2}+ba_{k+2}-4ka_{k+2}-4a_{k+2}}{(2k+5)(k+3)}, a_1 = -a_0(2a+b)\,, a_2\right.$$

- Recursion relation for $r = \frac{1}{2}$

$a_{k+3} = -\frac{-k^2 a_{k+2}+2a_k a-4a a_{k+1}+2a a_{k+2}+b a_{k+2}-5k a_{k+2}-\frac{25}{4}a_{k+2}}{(2k+6)\left(k+\frac{7}{2}\right)}$

- Solution for $r = \frac{1}{2}$

$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+3} = -\frac{-k^2 a_{k+2}+2a_k a-4a a_{k+1}+2a a_{k+2}+b a_{k+2}-5k a_{k+2}-\frac{25}{4}a_{k+2}}{(2k+6)\left(k+\frac{7}{2}\right)}, a_1 = -\frac{a_0\left(-\frac{1}{4}+2a+b\right)}{3}, a\right.$

- Revert the change of variables $u = 1 + x$

$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{1}{2}}, a_{k+3} = -\frac{-k^2 a_{k+2}+2a_k a-4a a_{k+1}+2a a_{k+2}+b a_{k+2}-5k a_{k+2}-\frac{25}{4}a_{k+2}}{(2k+6)\left(k+\frac{7}{2}\right)}, a_1 = -\frac{a_0\left(-\frac{1}{4}+2a+b\right.}{3}\right.$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} c_k (1+x)^k\right) + \left(\sum_{k=0}^{\infty} d_k (1+x)^{k+\frac{1}{2}}\right), c_{k+3} = -\frac{-k^2 c_{k+2}+2a c_k-4a c_{1+k}+2a c_{k+2}+b c_{k+2}-4k c_{k+2}-4c}{(2k+5)(k+3)}\right.$

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$(-x^2+1)\,y''+(ax+b)\,y'+yc=0$$

30.20.1 Maple step by step solution

Let's solve

$(-x^2+1)\,y''+(ax+b)\,y'+yc=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{cy}{x^2-1}+\frac{(ax+b)y'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''-\frac{(ax+b)y'}{x^2-1}-\frac{cy}{x^2-1}=0$

- □ Check to see if x_0 is a regular singular point
  - Define functions

$\left[P_2(x) = -\frac{ax+b}{x^2-1}, P_3(x) = -\frac{c}{x^2-1}\right]$

- $(1+x) \cdot P_2(x)$ is analytic at $x = -1$

  $\left((1+x) \cdot P_2(x)\right)\bigg|_{x=-1} = -\frac{a}{2} + \frac{b}{2}$

- $(1+x)^2 \cdot P_3(x)$ is analytic at $x = -1$

  $\left((1+x)^2 \cdot P_3(x)\right)\bigg|_{x=-1} = 0$

- $x = -1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $y''(x^2-1) + (-ax-b)\, y' - yc = 0$

- Change variables using $x = u-1$ so that the regular singular point is at $u = 0$

  $(u^2-2u)\left(\frac{d^2}{du^2}y(u)\right) + (-au+a-b)\left(\frac{d}{du}y(u)\right) - cy(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$

  Rewrite ODE with series expansions

$$a_0 r(2-2r+a-b)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(a_{k+1}(k+1+r)\,(-2k-2r+a-b)-a_k(ak+ar-k^2-2kr\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$r(2-2r+a-b)=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{0,\frac{a}{2}-\frac{b}{2}+1\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)\,(-2k-2r+a-b)-a_k(-k^2+(a-2r+1)\,k-r^2+(a+1)\,r+c)=0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1}=\frac{a_k(ak+ar-k^2-2kr-r^2+c+k+r)}{(k+1+r)(-2k-2r+a-b)}$$

- Recursion relation for $r=0$

$$a_{k+1}=\frac{a_k(ak-k^2+c+k)}{(k+1)(-2k+a-b)}$$

- Solution for $r=0$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^k, a_{k+1}=\frac{a_k(ak-k^2+c+k)}{(k+1)(-2k+a-b)}\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^k, a_{k+1}=\frac{a_k(ak-k^2+c+k)}{(k+1)(-2k+a-b)}\right]$$

- Recursion relation for $r=\frac{a}{2}-\frac{b}{2}+1$

$$a_{k+1}=\frac{a_k\left(ak+a\left(\frac{a}{2}-\frac{b}{2}+1\right)-k^2-2k\left(\frac{a}{2}-\frac{b}{2}+1\right)-\left(\frac{a}{2}-\frac{b}{2}+1\right)^2+c+k+\frac{a}{2}-\frac{b}{2}+1\right)}{\left(k+2+\frac{a}{2}-\frac{b}{2}\right)(-2k-2)}$$

- Solution for $r=\frac{a}{2}-\frac{b}{2}+1$

$$\left[y(u)=\sum_{k=0}^{\infty}a_k u^{k+\frac{a}{2}-\frac{b}{2}+1}, a_{k+1}=\frac{a_k\left(ak+a\left(\frac{a}{2}-\frac{b}{2}+1\right)-k^2-2k\left(\frac{a}{2}-\frac{b}{2}+1\right)-\left(\frac{a}{2}-\frac{b}{2}+1\right)^2+c+k+\frac{a}{2}-\frac{b}{2}+1\right)}{\left(k+2+\frac{a}{2}-\frac{b}{2}\right)(-2k-2)}\right]$$

- Revert the change of variables $u=1+x$

$$\left[y=\sum_{k=0}^{\infty}a_k(1+x)^{k+\frac{a}{2}-\frac{b}{2}+1}, a_{k+1}=\frac{a_k\left(ak+a\left(\frac{a}{2}-\frac{b}{2}+1\right)-k^2-2k\left(\frac{a}{2}-\frac{b}{2}+1\right)-\left(\frac{a}{2}-\frac{b}{2}+1\right)^2+c+k+\frac{a}{2}-\frac{b}{2}+1\right)}{\left(k+2+\frac{a}{2}-\frac{b}{2}\right)(-2k-2)}\right]$$

- Combine solutions and rename parameters

$$\left[y=\left(\sum_{k=0}^{\infty}d_k(1+x)^k\right)+\left(\sum_{k=0}^{\infty}e_k(1+x)^{k+\frac{a}{2}-\frac{b}{2}+1}\right), d_{1+k}=\frac{d_k(ak-k^2+c+k)}{(1+k)(-2k+a-b)}, e_{1+k}=\frac{e_k\left(ak+a\left(\frac{a}{2}-\frac{b}{2}+1\right.\right.}{}\right.$$

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

[_Jacobi]

Unable to solve or complete the solution.

$$x(x-1)\,y'' + ((\alpha+\beta+1)\,x-\gamma)\,y' + \alpha\beta y = 0$$

30.23.1 Maple step by step solution

Let's solve

$(x^2-x)\,y'' + ((\alpha+\beta+1)\,x-\gamma)\,y' + \alpha\beta y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{\alpha\beta y}{x(x-1)} - \frac{(x\alpha+\beta x-\gamma+x)y'}{x(x-1)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x\alpha+\beta x-\gamma+x)y'}{x(x-1)} + \frac{\alpha\beta y}{x(x-1)} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$\left[P_2(x) = \frac{x\alpha+\beta x-\gamma+x}{x(x-1)}, P_3(x) = \frac{\alpha\beta}{x(x-1)}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $\left(x \cdot P_2(x)\right)\Big|_{x=0} = \gamma$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $\left(x^2 \cdot P_3(x)\right)\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x(x-1)\, y'' + (x\alpha + \beta x - \gamma + x)\, y' + \alpha\beta y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y'$ to series expansion for $m = 0..1$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot y''$ to series expansion for $m = 1..2$

  $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k- >k+2-m$

  $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, x^{k+r}$

  Rewrite ODE with series expansions

  $-a_0 r(-1+r+\gamma)\, x^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-a_{k+1}(k+1+r)\,(k+r+\gamma) + a_k(\beta+k+r)\,(\alpha+k+r)\right) x^{k+}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$-r(-1+r+\gamma)=0$

- Values of r that satisfy the indicial equation

$r \in \{0, -\gamma+1\}$

- Each term in the series must be 0, giving the recursion relation

$-a_{k+1}(k+1+r)\,(k+r+\gamma)+a_k(\beta+k+r)\,(\alpha+k+r)=0$

- Recursion relation that defines series solution to ODE

$a_{k+1}=\frac{a_k(\beta+k+r)(\alpha+k+r)}{(k+1+r)(k+r+\gamma)}$

- Recursion relation for $r=0$

$a_{k+1}=\frac{a_k(\beta+k)(\alpha+k)}{(k+1)(k+\gamma)}$

- Solution for $r=0$

$\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+1}=\frac{a_k(\beta+k)(\alpha+k)}{(k+1)(k+\gamma)}\right]$

- Recursion relation for $r=-\gamma+1$

$a_{k+1}=\frac{a_k(\beta+k-\gamma+1)(\alpha+k-\gamma+1)}{(k+2-\gamma)(k+1)}$

- Solution for $r=-\gamma+1$

$\left[y=\sum_{k=0}^{\infty} a_k x^{k-\gamma+1}, a_{k+1}=\frac{a_k(\beta+k-\gamma+1)(\alpha+k-\gamma+1)}{(k+2-\gamma)(k+1)}\right]$

- Combine solutions and rename parameters

$\left[y=\left(\sum_{k=0}^{\infty} a_k x^k\right)+\left(\sum_{k=0}^{\infty} b_k x^{k-\gamma+1}\right), a_{1+k}=\frac{a_k(\beta+k)(\alpha+k)}{(1+k)(k+\gamma)}, b_{1+k}=\frac{b_k(\beta+k-\gamma+1)(\alpha+k-\gamma+1)}{(k+2-\gamma)(1+k)}\right]$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$-a_0 r(-1+2r)\, x^{-1+r} + (-a_1(1+r)(1+2r) + a_0(2r^2+b))\, x^r + \left(\sum_{k=1}^{\infty} (-a_{k+1}(k+1+r)(2k+1\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-r(-1+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{1}{2}\right\}$$

- Each term must be 0

$$-a_1(1+r)(1+2r) + a_0(2r^2+b) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$-2(k+1+r)\left(k+\frac{1}{2}+r\right)a_{k+1} + 2k^2 a_k + 4kra_k + 2r^2 a_k + a_{k-1}a + a_k b = 0$$

- Shift index using $k->k+1$

$$-2(k+2+r)\left(k+\frac{3}{2}+r\right)a_{k+2} + 2(k+1)^2 a_{k+1} + 4(k+1)\, ra_{k+1} + 2r^2 a_{k+1} + a_k a + a_{k+1} b = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{2k^2 a_{k+1} + 4kra_{k+1} + 2r^2 a_{k+1} + a_k a + a_{k+1} b + 4ka_{k+1} + 4ra_{k+1} + 2a_{k+1}}{(k+2+r)(2k+3+2r)}$$

- Recursion relation for $r=0$

$$a_{k+2} = \frac{2k^2 a_{k+1} + a_k a + a_{k+1} b + 4ka_{k+1} + 2a_{k+1}}{(k+2)(2k+3)}$$

- Solution for $r=0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = \frac{2k^2 a_{k+1} + a_k a + a_{k+1} b + 4ka_{k+1} + 2a_{k+1}}{(k+2)(2k+3)}, a_0 b - a_1 = 0\right]$$

- Recursion relation for $r=\frac{1}{2}$

$$a_{k+2} = \frac{2k^2 a_{k+1} + a_k a + a_{k+1} b + 6ka_{k+1} + \frac{9}{2}a_{k+1}}{\left(k+\frac{5}{2}\right)(2k+4)}$$

- Solution for $r=\frac{1}{2}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{1}{2}}, a_{k+2} = \frac{2k^2 a_{k+1} + a_k a + a_{k+1} b + 6ka_{k+1} + \frac{9}{2}a_{k+1}}{\left(k+\frac{5}{2}\right)(2k+4)}, -3a_1 + a_0\left(b+\frac{1}{2}\right) = 0\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^k\right) + \left(\sum_{k=0}^{\infty} d_k x^{k+\frac{1}{2}}\right), c_{k+2} = \frac{2k^2 c_{1+k} + ac_k + bc_{1+k} + 4kc_{1+k} + 2c_{1+k}}{(k+2)(2k+3)}, bc_0 - c_1 = 0, d_{k+2} = \frac{2k^2 c\right.$$

$$\boxed{\left(2ax + x^2 + b\right) y'' + (x + a) y' - y m^2 = 0}$$

30.26.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(2ax + x^2 + b\right) y'' + (x + a) y' - y m^2 = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{x + a}{2ax + x^2 + b} \\ q(x) &= -\frac{m^2}{2ax + x^2 + b} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{x+a}{2ax+x^2+b} dx\right)} dx \\
&= \int e^{-\frac{\ln\left(2ax+x^2+b\right)}{2}} dx \\
&= \int \frac{1}{\sqrt{2ax+x^2+b}} dx \\
&= \ln\left(x+a+\sqrt{2ax+x^2+b}\right)
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{-\frac{m^2}{2ax+x^2+b}}{\frac{1}{2ax+x^2+b}} \\
&= -m^2
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) - m^2 y(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = -m^2$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau} - m^2 \mathrm{e}^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 - m^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = -m^2$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(-m^2)} \\ &= \pm\sqrt{m^2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{m^2} \\ \lambda_2 &= -\sqrt{m^2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{m^2} \\ \lambda_2 &= -\sqrt{m^2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau} \\ y(\tau) &= c_1 e^{\left(\sqrt{m^2}\right)\tau} + c_2 e^{\left(-\sqrt{m^2}\right)\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 \mathrm{e}^{\sqrt{m^2}\,\tau} + c_2 \mathrm{e}^{-\sqrt{m^2}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(x + a + \sqrt{2ax + x^2 + b}\right)^m + c_2 \left(x + a + \sqrt{2ax + x^2 + b}\right)^{-m}$$

Summary
The solution(s) found are the following

$$y = c_1 \left(x + a + \sqrt{2ax + x^2 + b}\right)^m + c_2 \left(x + a + \sqrt{2ax + x^2 + b}\right)^{-m} \tag{1}$$

Verification of solutions

$$y = c_1 \left(x + a + \sqrt{2ax + x^2 + b}\right)^m + c_2 \left(x + a + \sqrt{2ax + x^2 + b}\right)^{-m}$$

Verified OK.

30.26.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(2ax + x^2 + b\right) y'' + (x + a) y' - y m^2 = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$p(x) = \frac{x + a}{2ax + x^2 + b}$$
$$q(x) = -\frac{m^2}{2ax + x^2 + b}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$
$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}\tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{-\frac{m^2}{2ax+x^2+b}}}{c} \\ \tau'' &= \frac{m^2(2a+2x)}{2c\sqrt{-\frac{m^2}{2ax+x^2+b}}\,(2ax+x^2+b)^2}\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}p_1(\tau) &= \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{\frac{m^2(2a+2x)}{2c\sqrt{-\frac{m^2}{2ax+x^2+b}}\,(2ax+x^2+b)^2} + \frac{x+a}{2ax+x^2+b}\frac{\sqrt{-\frac{m^2}{2ax+x^2+b}}}{c}}{\left(\frac{\sqrt{-\frac{m^2}{2ax+x^2+b}}}{c}\right)^2} \\ &= 0\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1\cos(c\tau) + c_2\sin(c\tau)$$

Now from (6)

$$\begin{aligned}\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{-\frac{m^2}{2ax+x^2+b}}dx}{c} \\ &= \frac{\sqrt{-\frac{m^2}{2ax+x^2+b}}\,\sqrt{2ax+x^2+b}\,\ln\left(x+a+\sqrt{2ax+x^2+b}\right)}{c}\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cosh\left(m \ln\left(x + a + \sqrt{2ax + x^2 + b}\right)\right) + i c_2 \sinh\left(m \ln\left(x + a + \sqrt{2ax + x^2 + b}\right)\right)$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & c_1 \cosh\left(m \ln\left(x + a + \sqrt{2ax + x^2 + b}\right)\right) \\ & + i c_2 \sinh\left(m \ln\left(x + a + \sqrt{2ax + x^2 + b}\right)\right) \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 \cosh\left(m \ln\left(x + a + \sqrt{2ax + x^2 + b}\right)\right) + i c_2 \sinh\left(m \ln\left(x + a + \sqrt{2ax + x^2 + b}\right)\right)$$

Verified OK.

30.26.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(2ax + x^2 + b\right) y'' + (x + a)\, y' - y m^2 = 0 \tag{1}$$

$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 2ax + x^2 + b \\ B &= x + a \\ C &= -m^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{8m^2ax + 4m^2x^2 + 4b\,m^2 - 3a^2 - 2ax - x^2 + 2b}{4\left(2ax + x^2 + b\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 8m^2ax + 4m^2x^2 + 4b\,m^2 - 3a^2 - 2ax - x^2 + 2b \\ t &= 4\left(2ax + x^2 + b\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{8m^2ax + 4m^2x^2 + 4b\,m^2 - 3a^2 - 2ax - x^2 + 2b}{4\left(2ax + x^2 + b\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 166: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(2ax + x^2 + b)^2$. There is a pole at $x = -a + \sqrt{a^2 - b}$ of order 2. There is a pole at $x = -a - \sqrt{a^2 - b}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r &= \frac{4\left(-a+\sqrt{a^2-b}\right)^2 m^2 + 8\left(-a+\sqrt{a^2-b}\right) a\, m^2 + 4b\, m^2 - \left(-a+\sqrt{a^2-b}\right)^2 - 2\left(-a+\sqrt{a^2-b}\right) a - 3a}{16\left(a^2-b\right)\left(x+a-\sqrt{a^2-b}\right)^2} \\ &+ \frac{4\left(-a-\sqrt{a^2-b}\right)^2 m^2 + 8\left(-a-\sqrt{a^2-b}\right) a\, m^2 + 4b\, m^2 - \left(-a-\sqrt{a^2-b}\right)^2 - 2\left(-a-\sqrt{a^2-b}\right) a -}{16\left(a^2-b\right)\left(x+a+\sqrt{a^2-b}\right)^2} \\ &+ \frac{4\left(-a+\sqrt{a^2-b}\right)^2 m^2 + 8\left(-a+\sqrt{a^2-b}\right) a\, m^2 + 8a^2m^2 - 4b\, m^2 - \left(-a+\sqrt{a^2-b}\right)^2 - 2\left(-a+\sqrt{a^2}\right.}{16\left(a^2-b\right)^{\frac{3}{2}}\left(x+a-\sqrt{a^2-b}\right)} \\ &- \frac{4\left(-a-\sqrt{a^2-b}\right)^2 m^2 + 8\left(-a-\sqrt{a^2-b}\right) a\, m^2 + 8a^2m^2 - 4b\, m^2 - \left(-a-\sqrt{a^2-b}\right)^2 - 2\left(-a-\sqrt{a^2}\right.}{16\left(a^2-b\right)^{\frac{3}{2}}\left(x+a+\sqrt{a^2-b}\right)} \end{aligned}$$

For the pole at $x = -a + \sqrt{a^2 - b}$ let b be the coefficient of $\frac{1}{\left(x+a-\sqrt{a^2-b}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -a - \sqrt{a^2 - b}$ let b be the coefficient of $\frac{1}{\left(x+a+\sqrt{a^2-b}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{8m^2ax + 4m^2x^2 + 4b\,m^2 - 3a^2 - 2ax - x^2 + 2b}{4\left(2ax + x^2 + b\right)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
$-a + \sqrt{a^2 - b}$	2	$\{1, 2, 3\}$
$-a - \sqrt{a^2 - b}$	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
2	$\{1, 2, 3\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (1 + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{1}{\left(x - \left(-a + \sqrt{a^2-b}\right)\right)} + \frac{1}{\left(x - \left(-a - \sqrt{a^2-b}\right)\right)}\right) \\ &= \frac{1}{2x + 2a - 2\sqrt{a^2-b}} + \frac{1}{2x + 2a + 2\sqrt{a^2-b}} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d=0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p}\\ &= \frac{1}{2x + 2a - 2\sqrt{a^2 - b}} + \frac{1}{2x + 2a + 2\sqrt{a^2 - b}}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{2x + 2a - 2\sqrt{a^2 - b}} + \frac{1}{2x + 2a + 2\sqrt{a^2 - b}}\right) w + \frac{\left(-4m^2 + 1\right) x^2 + \left(-8m^2 + 2\right) a x - 4b\, m^2 + a^2}{4 \left(x + a - \sqrt{a^2 - b}\right)^2 \left(x + a + \sqrt{a^2 - b}\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{2m\sqrt{2ax + x^2 + b} + a + x}{4ax + 2x^2 + 2b}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx}\\ &= \mathrm{e}^{\int \frac{2m\sqrt{2ax + x^2 + b} + a + x}{4ax + 2x^2 + 2b} dx}\\ &= \left(2ax + x^2 + b\right)^{\frac{1}{4}} \left(x + a + \sqrt{2ax + x^2 + b}\right)^m\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{x+a}{2ax+x^2+b}\,dx} \\
&= z_1 e^{-\frac{\ln\left(2ax+x^2+b\right)}{4}} \\
&= z_1\left(\frac{1}{\left(2ax+x^2+b\right)^{\frac{1}{4}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \left(x+a+\sqrt{2ax+x^2+b}\right)^m
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{x+a}{2ax+x^2+b}\,dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln\left(2ax+x^2+b\right)}{2}}}{\left(y_1\right)^2}\,dx \\
&= y_1\left(-\frac{\left(x+a+\sqrt{2ax+x^2+b}\right)^{-2m}}{2m}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x+a+\sqrt{2ax+x^2+b}\right)^m\right) \\
&\quad + c_2\left(\left(x+a+\sqrt{2ax+x^2+b}\right)^m\left(-\frac{\left(x+a+\sqrt{2ax+x^2+b}\right)^{-2m}}{2m}\right)\right)
\end{aligned}
$$

Summary
The solution(s) found are the following

$$y = c_1 \left(x + a + \sqrt{2ax + x^2 + b}\right)^m - \frac{c_2 \left(x + a + \sqrt{2ax + x^2 + b}\right)^{-m}}{2m} \tag{1}$$

Verification of solutions

$$y = c_1 \left(x + a + \sqrt{2ax + x^2 + b}\right)^m - \frac{c_2 \left(x + a + \sqrt{2ax + x^2 + b}\right)^{-m}}{2m}$$

Verified OK.

30.26.4 Maple step by step solution

Let's solve

$(2ax + x^2 + b)\, y'' + (x + a)\, y' - y m^2 = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{m^2 y}{2ax+x^2+b} - \frac{(x+a)y'}{2ax+x^2+b}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(x+a)y'}{2ax+x^2+b} - \frac{m^2 y}{2ax+x^2+b} = 0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{x+a}{2ax+x^2+b}, P_3(x) = -\frac{m^2}{2ax+x^2+b}\right]$

- ◦ $\left(x + a + \sqrt{a^2 - b}\right) \cdot P_2(x)$ is analytic at $x = -a - \sqrt{a^2 - b}$

  $\left(\left(x + a + \sqrt{a^2 - b}\right) \cdot P_2(x)\right)\Big|_{x=-a-\sqrt{a^2-b}} = 0$

- ◦ $\left(x + a + \sqrt{a^2 - b}\right)^2 \cdot P_3(x)$ is analytic at $x = -a - \sqrt{a^2 - b}$

  $\left(\left(x + a + \sqrt{a^2 - b}\right)^2 \cdot P_3(x)\right)\Big|_{x=-a-\sqrt{a^2-b}} = 0$

- ◦ $x = -a - \sqrt{a^2 - b}$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -a - \sqrt{a^2 - b}$

- Multiply by denominators

  $(2ax + x^2 + b)\, y'' + (x + a)\, y' - y m^2 = 0$

- Change variables using $x = u - a - \sqrt{a^2 - b}$ so that the regular singular point is at $u = 0$

  $\left(u^2 - 2u\sqrt{a^2 - b}\right)\left(\frac{d^2}{du^2}y(u)\right) + \left(u - \sqrt{a^2 - b}\right)\left(\frac{d}{du}y(u)\right) - m^2 y(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k (k + r)\, u^{k+r-1+m}$

  - Shift index using $k- > k + 1 - m$

    $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k + 1 - m + r)\, u^{k+r}$

  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k (k + r)\,(k + r - 1)\, u^{k+r-2+m}$

  - Shift index using $k- > k + 2 - m$

    $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m} (k + 2 - m + r)\,(k + 1 - m + r)\, u^{k+r}$

  Rewrite ODE with series expansions

  $-\sqrt{a^2 - b}\, a_0 r(-1 + 2r)\, u^{-1+r} + \left(\sum_{k=0}^{\infty} \left(-\sqrt{a^2 - b}\, a_{k+1}(k + 1 + r)\,(2k + 1 + 2r) + a_k(k + m + r)\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-\sqrt{a^2 - b}\, r(-1 + 2r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \left\{0, \frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

  $-2a_{k+1}\left(k + r + \frac{1}{2}\right)(k + 1 + r)\sqrt{a^2 - b} + a_k(k + m + r)\,(k - m + r) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = \frac{a_k (k^2 + 2kr - m^2 + r^2)}{\sqrt{a^2 - b}\,(2k^2 + 4kr + 2r^2 + 3k + 3r + 1)}$

- Recursion relation for $r = 0$

  $a_{k+1} = \frac{a_k(k^2-m^2)}{\sqrt{a^2-b}\,(2k^2+3k+1)}$

- Solution for $r = 0$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = \frac{a_k(k^2-m^2)}{\sqrt{a^2-b}\,(2k^2+3k+1)}\right]$

- Revert the change of variables $u = x + a + \sqrt{a^2-b}$

  $\left[y = \sum_{k=0}^{\infty} a_k \left(x+a+\sqrt{a^2-b}\right)^k, a_{k+1} = \frac{a_k(k^2-m^2)}{\sqrt{a^2-b}\,(2k^2+3k+1)}\right]$

- Recursion relation for $r = \frac{1}{2}$

  $a_{k+1} = \frac{a_k(k^2-m^2+k+\frac{1}{4})}{\sqrt{a^2-b}\,(2k^2+5k+3)}$

- Solution for $r = \frac{1}{2}$

  $\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k(k^2-m^2+k+\frac{1}{4})}{\sqrt{a^2-b}\,(2k^2+5k+3)}\right]$

- Revert the change of variables $u = x + a + \sqrt{a^2-b}$

  $\left[y = \sum_{k=0}^{\infty} a_k \left(x+a+\sqrt{a^2-b}\right)^{k+\frac{1}{2}}, a_{k+1} = \frac{a_k(k^2-m^2+k+\frac{1}{4})}{\sqrt{a^2-b}\,(2k^2+5k+3)}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} c_k \left(x+a+\sqrt{a^2-b}\right)^k\right) + \left(\sum_{k=0}^{\infty} d_k \left(x+a+\sqrt{a^2-b}\right)^{k+\frac{1}{2}}\right), c_{1+k} = \frac{c_k(k^2-m^2)}{\sqrt{a^2-b}\,(2k^2+3k+1)}, d_{1-}\right.$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2+bx+c)y''+f(x)y'+g(x)y=0$
Problem number: 175.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{\left(a\,x^{2}+bx+c\right)y''+\left(dx+k\right)y'+\left(-2a+d\right)y=0}$$

30.27.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(\left(a\,x^{2}+bx+c\right)y''+\left(dx+k\right)y'+\left(-2a+d\right)y\right)dx=0$$
$$\left(-2ax+dx-b+k\right)y+\left(a\,x^{2}+bx+c\right)y'=c_{1}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{(2a-d)\,x+b-k}{a\,x^2+bx+c}\\
q(x) &= \frac{c_1}{a\,x^2+bx+c}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{((2a-d)\,x+b-k)\,y}{a\,x^2+bx+c} = \frac{c_1}{a\,x^2+bx+c}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{(2a-d)x+b-k}{a\,x^2+bx+c}dx}\\
&= \mathrm{e}^{-\frac{(2a-d)\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(b-k-\frac{(2a-d)b}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}
\end{aligned}
$$

Which simplifies to

$$
\mu = \left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{a\,x^2+bx+c}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}y\right) &= \left(\left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\right)\left(\frac{}{a\,x^2}\right.\\
\mathrm{d}\left(\left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}y\right) &= \left(c_1\left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\right)\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}y &= \int c_1\left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\,\mathrm{d}x\\
\left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}y &= \int c_1\left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}}\,\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}dx+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \left(a\,x^2+bx+c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}$ results in

$$y = \left(a\,x^2+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}} \left(\int c_1 \left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} dx\right) + c_2$$

which simplifies to

$$y = \left(a\,x^2+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}} \left(c_1 \left(\int \left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = \left(a\,x^2+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}} \left(c_1 \left(\int \left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \left(a\,x^2+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}} \left(c_1 \left(\int \left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} dx\right) + c_2\right)$$

Verified OK.

30.27.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$\left(a\,x^{2}+b x +c \right) y''+\left(d x +k \right) y'+\left(-2 a +d \right) y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(\left(a\,x^{2}+b x +c \right) y''+\left(d x +k \right) y'+\left(-2 a +d \right) y\right)d x = 0$$
$$\left(-2 a x +d x -b +k \right) y+\left(a\,x^{2}+b x +c \right) y' = c_{1}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{\left(2 a -d \right) x +b -k}{a\,x^{2}+b x +c}$$
$$q(x) = \frac{c_{1}}{a\,x^{2}+b x +c}$$

Hence the ode is

$$y'-\frac{\left(\left(2 a -d \right) x +b -k \right) y}{a\,x^{2}+b x +c} = \frac{c_{1}}{a\,x^{2}+b x +c}$$

The integrating factor μ is

$$\mu = {\mathrm e}^{\int -\frac{\left(2 a -d \right) x +b -k}{a\,x^{2}+b x +c}d x}$$
$$= {\mathrm e}^{-\frac{\left(2 a -d \right) \ln\left(a\,x^{2}+b x +c \right)}{2 a}-\frac{2 \left(b -k -\frac{\left(2 a -d \right) b}{2 a}\right) \arctan\left(\frac{2 a x +b}{\sqrt{4 a c -b^{2}}}\right)}{\sqrt{4 a c -b^{2}}}}$$

Which simplifies to

$$\mu = \left(a\,x^{2}+b x +c \right)^{\frac{-2 a +d}{2 a}} {\mathrm e}^{\frac{\left(2 a k -b d \right) \arctan\left(\frac{2 a x +b}{\sqrt{4 a c -b^{2}}}\right)}{a \sqrt{4 a c -b^{2}}}}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) = (\mu)\left(\frac{c_1}{a\,x^2 + bx + c}\right)$$

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\left(a\,x^2 + bx + c\right)^{\frac{-2a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} y\right) = \left(\left(a\,x^2 + bx + c\right)^{\frac{-2a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\right)\left(\frac{}{a\,x^2}\right.$$

$$\mathrm{d}\left(\left(a\,x^2 + bx + c\right)^{\frac{-2a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} y\right) = \left(c_1\left(a\,x^2 + bx + c\right)^{\frac{-4a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\right)\mathrm{d}x$$

Integrating gives

$$\left(a\,x^2 + bx + c\right)^{\frac{-2a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} y = \int c_1\left(a\,x^2 + bx + c\right)^{\frac{-4a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\mathrm{d}x$$

$$\left(a\,x^2 + bx + c\right)^{\frac{-2a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} y = \int c_1\left(a\,x^2 + bx + c\right)^{\frac{-4a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}dx + c_2$$

Dividing both sides by the integrating factor $\mu = \left(a\,x^2 + bx + c\right)^{\frac{-2a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}$ results in

$$y = \left(a\,x^2 + bx + c\right)^{\frac{2a-d}{2a}}\mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}}\left(\int c_1\left(a\,x^2 + bx + c\right)^{\frac{-4a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}dx\right) + c_2$$

which simplifies to

$$y = \left(a\,x^2 + bx + c\right)^{\frac{2a-d}{2a}}\mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}}\left(c_1\left(\int\left(a\,x^2 + bx + c\right)^{\frac{-4a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}dx\right) + \right.$$

<u>Summary</u>

The solution(s) found are the following

$$y = \left(a\,x^2 + bx + c\right)^{\frac{2a-d}{2a}}\mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}}\left(c_1\left(\int\left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}}\mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \left(a\,x^2+bx+c\right)^{\frac{2a-d}{2a}} e^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^2}\,a}} \left(c_1\left(\int \left(a\,x^2+bx+c\right)^{\frac{-4a+d}{2a}} e^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} dx\right) + c_2\right)$$

Verified OK.

30.27.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y''+q(x)\,y'+r(x)\,y=s(x)$$

is exact if

$$p''(x)-q'(x)+r(x)=0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x)&=a\,x^2+bx+c\\ q(x)&=dx+k\\ r(x)&=-2a+d\\ s(x)&=0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x)&=2a\\ q'(x)&=d \end{aligned}$$

Therefore (1) becomes

$$2a-(d)+(-2a+d)=0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y'+(q(x)-p'(x))\,y\right)'=s(x)$$

Integrating gives

$$p(x)\,y'+(q(x)-p'(x))\,y=\int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$(-2ax + dx - b + k)\, y + \left(a\, x^2 + bx + c\right) y' = c_1$$

We now have a first order ode to solve which is

$$(-2ax + dx - b + k)\, y + \left(a\, x^2 + bx + c\right) y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned} p(x) &= -\frac{(2a-d)\, x + b - k}{a\, x^2 + bx + c} \\ q(x) &= \frac{c_1}{a\, x^2 + bx + c} \end{aligned}$$

Hence the ode is

$$y' - \frac{((2a-d)\, x + b - k)\, y}{a\, x^2 + bx + c} = \frac{c_1}{a\, x^2 + bx + c}$$

The integrating factor μ is

$$\begin{aligned} \mu &= \mathrm{e}^{\int -\frac{(2a-d)x+b-k}{a\, x^2+bx+c}dx} \\ &= \mathrm{e}^{-\frac{(2a-d)\ln\left(a\, x^2+bx+c\right)}{2a} - \frac{2\left(b-k-\frac{(2a-d)b}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}} \end{aligned}$$

Which simplifies to

$$\mu = \left(a\, x^2 + bx + c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}$$

The ode becomes

$$\begin{aligned} \frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{a\, x^2 + bx + c}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\left(a\, x^2 + bx + c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} y\right) &= \left(\left(a\, x^2 + bx + c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\right)\left(\frac{}{a\, x^2}\right. \\ \mathrm{d}\left(\left(a\, x^2 + bx + c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}} y\right) &= \left(c_1\left(a\, x^2 + bx + c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{a\sqrt{4ac-b^2}}}\right) \mathrm{d}x \end{aligned}$$

Integrating gives

$$\left(a\,x^{2}+bx+c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} y = \int c_{1}\left(a\,x^{2}+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} \mathrm{d}x$$

$$\left(a\,x^{2}+bx+c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} y = \int c_{1}\left(a\,x^{2}+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} dx + c_{2}$$

Dividing both sides by the integrating factor $\mu = \left(a\,x^{2}+bx+c\right)^{\frac{-2a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}}$ results in

$$y = \left(a\,x^{2}+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^{2}}\,a}} \left(\int c_{1}\left(a\,x^{2}+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} dx\right) + c_{2}$$

which simplifies to

$$y = \left(a\,x^{2}+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^{2}}\,a}} \left(c_{1}\left(\int \left(a\,x^{2}+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} dx\right) + \cdots$$

Summary

The solution(s) found are the following

$$y = \left(a\,x^{2}+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^{2}}\,a}} \left(c_{1}\left(\int \left(a\,x^{2}+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} dx\right) + c_{2}\right) \tag{1}$$

Verification of solutions

$$y = \left(a\,x^{2}+bx+c\right)^{\frac{2a-d}{2a}} \mathrm{e}^{-\frac{2\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)\left(ak-\frac{bd}{2}\right)}{\sqrt{4ac-b^{2}}\,a}} \left(c_{1}\left(\int \left(a\,x^{2}+bx+c\right)^{\frac{-4a+d}{2a}} \mathrm{e}^{\frac{(2ak-bd)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^{2}}}\right)}{a\sqrt{4ac-b^{2}}}} dx\right) + c_{2}\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2 + bx + c)y'' + f(x)y' + g(x)y = 0$
Problem number: 176.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(a\,x^2+bx+c\right)y''+\left(kx+d\right)y'-yk=0}$$

30.28.1 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay''+By'+Cy=F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y=Bv$$

This results in

$$\begin{aligned} y' &= B'v+v'B \\ y'' &= B''v+B'v'+v''B+v'B' \\ &= v''B+2v'+B'+B''v \end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\
ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0 \qquad (1)
\end{aligned}
$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$
ABv'' + \left(2AB' + B^2\right) v' = 0
$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu' + \left(2AB' + B^2\right) u = 0
$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A &= a\,x^2 + bx + c \\
B &= kx + d \\
C &= -k \\
F &= 0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB'' + BB' + CB &= \left(a\,x^2 + bx + c\right)(0) + (kx + d)(k) + (-k)(kx + d) \\
&= 0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
\left(a\,x^2 + bx + c\right)(kx + d)\, v'' + \left(2k\left(a\,x^2 + bx + c\right) + (kx + d)^2\right) v' = 0
$$

Now by applying $v' = u$ the above becomes

$$
\left(a\,x^2 + bx + c\right)(kx + d)\, u'(x) + 2\left(k\left(a + \frac{k}{2}\right) x^2 + k(b + d)\, x + ck + \frac{d^2}{2}\right) u(x) = 0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u' &= F(x, u) \\
&= f(x)g(u) \\
&= -\frac{u(2ak\,x^2 + k^2x^2 + 2kxb + 2dkx + 2ck + d^2)}{\left(a\,x^2 + bx + c\right)(kx + d)}
\end{aligned}
$$

Where $f(x) = -\frac{2ak\,x^2+k^2x^2+2kxb+2dkx+2ck+d^2}{(a\,x^2+bx+c)(kx+d)}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= -\frac{2ak\,x^2+k^2x^2+2kxb+2dkx+2ck+d^2}{(a\,x^2+bx+c)\,(kx+d)}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{2ak\,x^2+k^2x^2+2kxb+2dkx+2ck+d^2}{(a\,x^2+bx+c)\,(kx+d)}\,dx \\
\ln(u) &= -\frac{k\ln(a\,x^2+bx+c)}{2a} - \frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}} - 2\ln(kx+d) + c_1 \\
u &= \mathrm{e}^{-\frac{k\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}-2\ln(kx+d)+c_1} \\
&= c_1\mathrm{e}^{-\frac{k\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}-2\ln(kx+d)}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u \\
&= c_1\mathrm{e}^{-\frac{k\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}-2\ln(kx+d)}
\end{aligned}
$$

Which is now solved for v. Integrating both sides gives

$$
\begin{aligned}
v(x) &= \int c_1\mathrm{e}^{-\frac{k\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}-2\ln(kx+d)}\,\mathrm{d}x \\
&= \int c_1\mathrm{e}^{-\frac{k\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}-2\ln(kx+d)}dx + c_2
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y(x) &= Bv \\
&= (kx+d)\left(\int c_1\mathrm{e}^{-\frac{k\ln\left(a\,x^2+bx+c\right)}{2a}-\frac{2\left(d-\frac{kb}{2a}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}-2\ln(kx+d)}dx + c_2\right) \\
&= (kx+d)\left(c_1\left(\int \frac{(a\,x^2+bx+c)^{-\frac{k}{2a}}\,\mathrm{e}^{-\frac{2\left(ad-\frac{bk}{2}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}\,a}}}{(kx+d)^2}dx\right) + c_2\right)
\end{aligned}
$$

<u>Summary</u>

The solution(s) found are the following

$$
y = (kx+d)\left(c_1\left(\int \frac{(a\,x^2+bx+c)^{-\frac{k}{2a}}\,\mathrm{e}^{-\frac{2\left(ad-\frac{bk}{2}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}\,a}}}{(kx+d)^2}dx\right) + c_2\right) \tag{1}
$$

Verification of solutions

$$y = (kx+d)\left(c_1\left(\int \frac{(a\,x^2+bx+c)^{-\frac{k}{2a}}\,\mathrm{e}^{-\frac{2\left(ad-\frac{bk}{2}\right)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}\,a}}}{(kx+d)^2}dx\right)+c_2\right)$$

Verified OK.

  $(a\,x^2+bx+c)\,y''+(kx+d)\,y'-yk=0$

- Change variables using $x = u + \frac{-b+\sqrt{-4ac+b^2}}{2a}$ so that the regular singular point is at $u = 0$

$$\left(a\,u^2 + u\sqrt{-4ac+b^2}\right)\left(\frac{d^2}{du^2}y(u)\right) + \left(ku - \frac{kb}{2a} + \frac{k\sqrt{-4ac+b^2}}{2a} + d\right)\left(\frac{d}{du}y(u)\right) - ky(u) = 0$$

- Assume series solution for $y(u)$

$$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

  - Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

  - Shift index using $k- > k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

  - Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

  - Shift index using $k- > k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$\frac{a_0 r\left(2\sqrt{-4ac+b^2}\,ar - 2\sqrt{-4ac+b^2}\,a + k\sqrt{-4ac+b^2} + 2ad - bk\right)u^{r-1}}{2a} + \left(\sum_{k=0}^{\infty}\left(\frac{a_{k+1}(k+1+r)\left(2\sqrt{-4ac+b^2}\,a(k+1) + 2\sqrt{-4ac+b^2}\,ar\right.}{2a}\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$\frac{r\left(2\sqrt{-4ac+b^2}\,ar - 2\sqrt{-4ac+b^2}\,a + k\sqrt{-4ac+b^2} + 2ad - bk\right)}{2a} = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk}{2\sqrt{-4ac+b^2}\,a}\right\}$$

- Each term in the series must be 0, giving the recursion relation

$$\frac{2a_{k+1}\left((k+r)a + \frac{k}{2}\right)(k+1+r)\sqrt{-4ac+b^2} + 2a_k(k+r)(k+r-1)a^2 + (2d(k+1+r)a_{k+1} + 2ka_k(k+r-1))a - a_{k+1}bk(k+1+r)}{2a} = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{2aa_k\left(a\,k^2 + 2akr + a\,r^2 - ak - ar + kk + kr - k\right)}{2\sqrt{-4ac+b^2}\,a\,k^2 + 4\sqrt{-4ac+b^2}\,akr + 2\sqrt{-4ac+b^2}\,a\,r^2 + 2\sqrt{-4ac+b^2}\,ak + 2\sqrt{-4ac+b^2}\,ar + \sqrt{-4ac+b^2}\,kk + \sqrt{-4ac+b^2}\,kr}$$

- Recursion relation for $r = 0$; series terminates at $k = 1$

$$a_{k+1} = -\frac{2 a a_k \left(a\,k^2 - ak + kk - k\right)}{2\sqrt{-4ac+b^2}\,a\,k^2 + 2\sqrt{-4ac+b^2}\,ak + \sqrt{-4ac+b^2}\,kk + 2adk - bkk + k\sqrt{-4ac+b^2} + 2ad - bk}$$

- Apply recursion relation for $k = 0$

$$a_1 = \frac{2 a a_0 k}{k\sqrt{-4ac+b^2} + 2ad - bk}$$

- Terminating series solution of the ODE for $r = 0$. Use reduction of order to find the second li

$$y(u) = a_0 \cdot \left(1 + \frac{2aku}{k\sqrt{-4ac+b^2} + 2ad - bk}\right)$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left[y = \frac{2 a_0 a (kx+d)}{k\sqrt{-4ac+b^2} + 2ad - bk}\right]$$

- Recursion relation for $r = \frac{2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk}{2\sqrt{-4ac+b^2}\,a}$

$$a_{k+1} = -\frac{2 a a_k \left(a\,k^2 + \frac{k\left(2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk\right)}{\sqrt{-4ac+b^2}} + \frac{\left(2\sqrt{-4ac+b^2}\,a - \cdots\right.}{4a\left(\cdots\right.}\right.}{2\sqrt{-4ac+b^2}\,a\,k^2 + 2k\left(2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk\right) + \frac{\left(2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk\right)^2}{2\sqrt{-4ac+b^2}\,a} + 2\sqrt{-4ac+b^2}\,ak + \cdots}$$

- Solution for $r = \frac{2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk}{2\sqrt{-4ac+b^2}\,a}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k + \frac{2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk}{2\sqrt{-4ac+b^2}\,a}}, a_{k+1} = -\frac{2 a a_k \left(\cdots\right.}{2\sqrt{-4ac+b^2}\,a\,k^2 + 2k\left(2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + \cdots\right.}\right.$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^{k + \frac{2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk}{2\sqrt{-4ac+b^2}\,a}}, a_{k+1} = -\frac{\cdots}{2\sqrt{-4ac+b^2}\,a\,k^2 + 2k\left(2\sqrt{-4ac+b^2}\,a - \cdots\right.}\right.$$

- Combine solutions and rename parameters

$$\left[y = \frac{2 e_0 a (kx+d)}{k\sqrt{-4ac+b^2} + 2ad - bk} + \left(\sum_{m=0}^{\infty} f_m \left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^{m + \frac{2\sqrt{-4ac+b^2}\,a - k\sqrt{-4ac+b^2} - 2ad + bk}{2\sqrt{-4ac+b^2}\,a}}\right), f_{m+1} = -\frac{\cdots}{2\sqrt{\cdots}}\right.$$

$$\boxed{\left(a\,x^{2}+2bx+c\right)y''+\left(ax+b\right)y'+yd=0}$$

30.29.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(a\,x^{2}+2bx+c\right)y''+\left(ax+b\right)y'+yd=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{ax+b}{a\,x^{2}+2bx+c} \\ q(x) &= \frac{d}{a\,x^{2}+2bx+c} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{ax+b}{a\,x^2+2bx+c}dx\right)}dx \\
&= \int e^{-\frac{\ln\left(a\,x^2+2bx+c\right)}{2}}dx \\
&= \int \frac{1}{\sqrt{a\,x^2+2bx+c}}dx \\
&= \frac{\ln\left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)}{\sqrt{a}}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{d}{a\,x^2+2bx+c}}{\frac{1}{a\,x^2+2bx+c}} \\
&= d
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + d y(\tau) &= 0
\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = d$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + d\, e^{\lambda\tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + d = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = d$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(d)}\\ &= \pm\sqrt{-d}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-d}\\ \lambda_2 &= -\sqrt{-d}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-d}\\ \lambda_2 &= -\sqrt{-d}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1\tau} + c_2 e^{\lambda_2\tau}\\ y(\tau) &= c_1 e^{(\sqrt{-d})\tau} + c_2 e^{(-\sqrt{-d})\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{-d}\,\tau} + c_2 e^{-\sqrt{-d}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)^{\frac{\sqrt{-d}}{\sqrt{a}}} + c_2 \left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)^{-\frac{\sqrt{-d}}{\sqrt{a}}}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)^{\frac{\sqrt{-d}}{\sqrt{a}}} + c_2 \left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)^{-\frac{\sqrt{-d}}{\sqrt{a}}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)^{\frac{\sqrt{-d}}{\sqrt{a}}} + c_2 \left(\frac{ax+b}{\sqrt{a}} + \sqrt{a\,x^2+2bx+c}\right)^{-\frac{\sqrt{-d}}{\sqrt{a}}}$$

Verified OK.

30.29.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(a\,x^2+2bx+c\right) y'' + (ax+b)\, y' + yd = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{ax+b}{a\,x^2+2bx+c}$$
$$q(x) = \frac{d}{a\,x^2+2bx+c}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{\frac{d}{a\,x^2+2bx+c}}}{c} \\ \tau'' &= -\frac{d(2ax+2b)}{2c\sqrt{\frac{d}{a\,x^2+2bx+c}}\,(a\,x^2+2bx+c)^2} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{d(2ax+2b)}{2c\sqrt{\frac{d}{a\,x^2+2bx+c}}\,(a\,x^2+2bx+c)^2}+\frac{ax+b}{a\,x^2+2bx+c}\frac{\sqrt{\frac{d}{a\,x^2+2bx+c}}}{c}}{\left(\frac{\sqrt{\frac{d}{a\,x^2+2bx+c}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)''+p_1 y(\tau)'+q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2}y(\tau)+c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1\cos(c\tau)+c_2\sin(c\tau)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{\frac{d}{a\,x^2+2bx+c}}dx}{c} \\ &= \frac{\sqrt{\frac{d}{a\,x^2+2bx+c}}\,\sqrt{a\,x^2+2bx+c}\,\ln\left(\frac{\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b}{\sqrt{a}}\right)}{c\sqrt{a}} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos\left(\frac{\sqrt{d}\left(2\ln\left(\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b\right)-\ln\left(a\right)\right)}{2\sqrt{a}}\right) + c_2 \sin\left(\frac{\sqrt{d}\left(2\ln\left(\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b\right)-\ln\left(a\right)\right)}{2\sqrt{a}}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\frac{\sqrt{d}\left(2\ln\left(\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b\right)-\ln\left(a\right)\right)}{2\sqrt{a}}\right) + c_2 \sin\left(\frac{\sqrt{d}\left(2\ln\left(\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b\right)-\ln\left(a\right)\right)}{2\sqrt{a}}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(\frac{\sqrt{d}\left(2\ln\left(\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b\right)-\ln\left(a\right)\right)}{2\sqrt{a}}\right) + c_2 \sin\left(\frac{\sqrt{d}\left(2\ln\left(\sqrt{a\,x^2+2bx+c}\,\sqrt{a}+ax+b\right)-\ln\left(a\right)\right)}{2\sqrt{a}}\right)$$

Verified OK.

30.29.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(a\,x^2+2bx+c\right)y''+\left(ax+b\right)y'+yd=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= a\,x^2+2bx+c \\ B &= ax+b \\ C &= d \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a^2x^2 - 4ad\,x^2 - 2abx - 8bdx + 2ac - 3b^2 - 4cd}{4\left(a\,x^2 + 2bx + c\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a^2x^2 - 4ad\,x^2 - 2abx - 8bdx + 2ac - 3b^2 - 4cd \\ t &= 4\left(a\,x^2 + 2bx + c\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-a^2x^2 - 4ad\,x^2 - 2abx - 8bdx + 2ac - 3b^2 - 4cd}{4\left(a\,x^2 + 2bx + c\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 170: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(a\,x^2 + 2bx + c)^2$. There is a pole at $x = -\frac{b-\sqrt{-ac+b^2}}{a}$ of order 2. There is a pole at $x = -\frac{b+\sqrt{-ac+b^2}}{a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r &= \frac{-\left(-b+\sqrt{-ac+b^2}\right)^2 - \frac{4\left(-b+\sqrt{-ac+b^2}\right)^2 d}{a} - 2\left(-b+\sqrt{-ac+b^2}\right) b - \frac{8\left(-b+\sqrt{-ac+b^2}\right) bd}{a} + 2ac - 3b^2 - 4cd}{16\left(-ac+b^2\right)\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^2} \\ &+ \frac{-\left(b+\sqrt{-ac+b^2}\right)^2 - \frac{4\left(b+\sqrt{-ac+b^2}\right)^2 d}{a} + 2\left(b+\sqrt{-ac+b^2}\right) b + \frac{8\left(b+\sqrt{-ac+b^2}\right) bd}{a} + 2ac - 3b^2 - 4cd}{16\left(-ac+b^2\right)\left(x + \frac{b+\sqrt{-ac+b^2}}{a}\right)^2} \\ &+ \frac{-\left(-b+\sqrt{-ac+b^2}\right)^2 a - 4\left(-b+\sqrt{-ac+b^2}\right)^2 d - 2\left(-b+\sqrt{-ac+b^2}\right) ab - 8\left(-b+\sqrt{-ac+b^2}\right) bd}{16\left(-ac+b^2\right)^{\frac{3}{2}}\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)} \\ &- \frac{-\left(b+\sqrt{-ac+b^2}\right)^2 a - 4\left(b+\sqrt{-ac+b^2}\right)^2 d + 2\left(b+\sqrt{-ac+b^2}\right) ab + 8\left(b+\sqrt{-ac+b^2}\right) bd - 2a^2c}{16\left(-ac+b^2\right)^{\frac{3}{2}}\left(x + \frac{b+\sqrt{-ac+b^2}}{a}\right)} \end{aligned}$$

For the pole at $x = -\frac{b-\sqrt{-ac+b^2}}{a}$ let b be the coefficient of $\frac{1}{\left(x + \frac{b-\sqrt{-ac+b^2}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -\frac{b+\sqrt{-ac+b^2}}{a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b+\sqrt{-ac+b^2}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-a^2x^2 - 4ad\,x^2 - 2abx - 8bdx + 2ac - 3b^2 - 4cd}{4\left(a\,x^2 + 2bx + c\right)^2}$$

Since the $\gcd(s, t) = 1$. This gives $b = -\frac{1}{4}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{2\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
$-\frac{b-\sqrt{-ac+b^2}}{a}$	2	$\{1, 2, 3\}$
$-\frac{b+\sqrt{-ac+b^2}}{a}$	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (1 + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned}\theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c}\\ &= \frac{1}{2}\left(\frac{1}{\left(x-\left(-\frac{b-\sqrt{-ac+b^2}}{a}\right)\right)}+\frac{1}{\left(x-\left(-\frac{b+\sqrt{-ac+b^2}}{a}\right)\right)}\right)\\ &= \frac{1}{2x+\frac{2\left(b-\sqrt{-ac+b^2}\right)}{a}}+\frac{1}{2x+\frac{2\left(b+\sqrt{-ac+b^2}\right)}{a}}\end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$p'''+3\theta p''+\left(3\theta^2+3\theta'-4r\right)p'+\left(\theta''+3\theta\theta'+\theta^3-4r\theta-2r'\right)p=0 \tag{1A}$$

Since $d=0$, then letting

$$p=1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0=0$$

And solving for p gives

$$p=1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta+\frac{p'}{p}\\ &= \frac{1}{2x+\frac{2\left(b-\sqrt{-ac+b^2}\right)}{a}}+\frac{1}{2x+\frac{2\left(b+\sqrt{-ac+b^2}\right)}{a}}\end{aligned}$$

Let ω be the solution of

$$\omega^2-\phi\omega+\left(\frac{1}{2}\phi'+\frac{1}{2}\phi^2-r\right)=0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2-\left(\frac{1}{2x+\frac{2\left(b-\sqrt{-ac+b^2}\right)}{a}}+\frac{1}{2x+\frac{2\left(b+\sqrt{-ac+b^2}\right)}{a}}\right)w+\frac{\left(a^2x^2+\left(4d\,x^2+2bx\right)a+8bdx+b^2+4cd\right)a^2}{4\left(ax+b-\sqrt{-ac+b^2}\right)^2\left(ax+\sqrt{-ac+b^2}+b\right)^2}=0$$

Solving for ω gives

$$\omega = \frac{ax + 2\sqrt{-d\left(a\,x^{2}+2bx+c\right)} + b}{2a\,x^{2}+4bx+2c}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{ax+2\sqrt{-d\left(a\,x^{2}+2bx+c\right)}+b}{2a\,x^{2}+4bx+2c}dx} \\
&= \left(a\,x^{2}+2bx+c\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{d \arctan\left(\frac{\sqrt{ad}\,(ax+b)}{a\sqrt{-\frac{d\left(ax+b-\sqrt{-ac+b^{2}}\right)\left(ax+\sqrt{-ac+b^{2}}+b\right)}{a}}}\right)}{\sqrt{ad}}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{ax+b}{a\,x^{2}+2bx+c}\,dx} \\
&= z_1 e^{-\frac{\ln\left(a\,x^{2}+2bx+c\right)}{4}} \\
&= z_1\left(\frac{1}{\left(a\,x^{2}+2bx+c\right)^{\frac{1}{4}}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{d \arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^{2}}\right)\left(ax+\sqrt{-ac+b^{2}}+b\right)}}\right)}{\sqrt{ad}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^{2}}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{ax+b}{a\,x^2+2bx+c}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{\ln\left(a\,x^2+2bx+c\right)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\mathrm{e}^{\frac{2d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}}}{\sqrt{a\,x^2+2bx+c}}\,dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}} \right) \\
&\quad + c_2 \left(\mathrm{e}^{-\frac{d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}} \right) \left(\int \frac{\mathrm{e}^{\frac{2d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}}}{\sqrt{a\,x^2+2bx+c}}\,dx \right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 \mathrm{e}^{-\frac{d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}} \\
&\quad + c_2 \mathrm{e}^{-\frac{d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}} \left(\int \frac{\mathrm{e}^{\frac{2d\arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}}}{\sqrt{a\,x^2+2bx+c}}\,dx \right)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$y = c_1 e^{-\frac{d \arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}} + c_2 e^{-\frac{d \arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}} \left(\int \frac{e^{\frac{2d \arctan\left((ax+b)\sqrt{-\frac{1}{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}}\right)}{\sqrt{ad}}}}{\sqrt{a\,x^2+2bx+c}}dx\right)$$

Verified OK.

30.29.4 Maple step by step solution

Let's solve

$(a\,x^2+2bx+c)\,y''+(ax+b)\,y'+yd=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{dy}{a\,x^2+2bx+c}-\frac{(ax+b)y'}{a\,x^2+2bx+c}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(ax+b)y'}{a\,x^2+2bx+c}+\frac{dy}{a\,x^2+2bx+c}=0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x)=\frac{ax+b}{a\,x^2+2bx+c}, P_3(x)=\frac{d}{a\,x^2+2bx+c}\right]$

  - $\left(x-\frac{-b+\sqrt{-ac+b^2}}{a}\right)\cdot P_2(x)$ is analytic at $x=\frac{-b+\sqrt{-ac+b^2}}{a}$

    $\left(\left(x-\frac{-b+\sqrt{-ac+b^2}}{a}\right)\cdot P_2(x)\right)\bigg|_{x=\frac{-b+\sqrt{-ac+b^2}}{a}}=0$

  - $\left(x-\frac{-b+\sqrt{-ac+b^2}}{a}\right)^2\cdot P_3(x)$ is analytic at $x=\frac{-b+\sqrt{-ac+b^2}}{a}$

    $\left(\left(x-\frac{-b+\sqrt{-ac+b^2}}{a}\right)^2\cdot P_3(x)\right)\bigg|_{x=\frac{-b+\sqrt{-ac+b^2}}{a}}=0$

  - $x=\frac{-b+\sqrt{-ac+b^2}}{a}$ is a regular singular point

    Check to see if x_0 is a regular singular point

$x_0 = \frac{-b+\sqrt{-ac+b^2}}{a}$

- Multiply by denominators

$(a\,x^2+2bx+c)\,y''+(ax+b)\,y'+yd=0$

- Change variables using $x=u+\frac{-b+\sqrt{-ac+b^2}}{a}$ so that the regular singular point is at $u=0$

$\left(a\,u^2+2u\sqrt{-ac+b^2}\right)\left(\frac{d^2}{du^2}y(u)\right)+\left(au+\sqrt{-ac+b^2}\right)\left(\frac{d}{du}y(u)\right)+dy(u)=0$

- Assume series solution for $y(u)$

$y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

  ○ Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..1$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

  ○ Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

  ○ Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=1..2$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

  ○ Shift index using $k->k+2-m$

  $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $\sqrt{-ac+b^2}\,a_0r(-1+2r)\,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(\sqrt{-ac+b^2}\,a_{k+1}(k+1+r)\,(2k+1+2r)+a_k(a\,k^2+2a\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$\sqrt{-ac+b^2}\,r(-1+2r)=0$

- Values of r that satisfy the indicial equation

$r\in\left\{0,\frac{1}{2}\right\}$

- Each term in the series must be 0, giving the recursion relation

$2a_{k+1}(k+1+r)\left(k+r+\frac{1}{2}\right)\sqrt{-ac+b^2}+a_k(a\,k^2+2akr+a\,r^2+d)=0$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a_k (a\,k^2+2akr+a\,r^2+d)}{\sqrt{-ac+b^2}\,(2k^2+4kr+2r^2+3k+3r+1)}$$

- Recursion relation for $r = 0$

$$a_{k+1} = -\frac{a_k (a\,k^2+d)}{\sqrt{-ac+b^2}\,(2k^2+3k+1)}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+1} = -\frac{a_k (a\,k^2+d)}{\sqrt{-ac+b^2}\,(2k^2+3k+1)}\right]$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-ac+b^2}}{a}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^k, a_{k+1} = -\frac{a_k (a\,k^2+d)}{\sqrt{-ac+b^2}\,(2k^2+3k+1)}\right]$$

- Recursion relation for $r = \frac{1}{2}$

$$a_{k+1} = -\frac{a_k (a\,k^2+ak+\frac{1}{4}a+d)}{\sqrt{-ac+b^2}\,(2k^2+5k+3)}$$

- Solution for $r = \frac{1}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k (a\,k^2+ak+\frac{1}{4}a+d)}{\sqrt{-ac+b^2}\,(2k^2+5k+3)}\right]$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-ac+b^2}}{a}$

$$\left[y = \sum_{k=0}^{\infty} a_k \left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^{k+\frac{1}{2}}, a_{k+1} = -\frac{a_k (a\,k^2+ak+\frac{1}{4}a+d)}{\sqrt{-ac+b^2}\,(2k^2+5k+3)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} e_k \left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^k\right) + \left(\sum_{k=0}^{\infty} f_k \left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^{k+\frac{1}{2}}\right), e_{1+k} = -\frac{e_k (a\,k^2+d)}{\sqrt{-ac+b^2}\,(2k^2+3k+1)},\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2 + bx + c)y'' + f(x)y' + g(x)y = 0$
Problem number: 178.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(a\,x^2 + 2bx + c)\,y'' + 3(ax + b)\,y' + yd = 0}$$

30.30.1 Solving using Kovacic algorithm

Writing the ode as

$$(a\,x^2 + 2bx + c)\,y'' + (3ax + 3b)\,y' + yd = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= a\,x^2 + 2bx + c \\ B &= 3ax + 3b \\ C &= d \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{3a^2x^2 - 4ad\,x^2 + 6abx - 8bdx + 6ac - 3b^2 - 4cd}{4\,(a\,x^2 + 2bx + c)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 3a^2x^2 - 4ad\,x^2 + 6abx - 8bdx + 6ac - 3b^2 - 4cd \\ t &= 4\left(a\,x^2 + 2bx + c\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{3a^2x^2 - 4ad\,x^2 + 6abx - 8bdx + 6ac - 3b^2 - 4cd}{4\,(a\,x^2 + 2bx + c)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 172: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(a\,x^2 + 2bx + c)^2$. There is a pole at $x = -\frac{b-\sqrt{-ac+b^2}}{a}$ of order 2. There is a pole at $x = -\frac{b+\sqrt{-ac+b^2}}{a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r &= \frac{3\left(-b+\sqrt{-ac+b^2}\right)^2 - \frac{4\left(-b+\sqrt{-ac+b^2}\right)^2 d}{a} + 6\left(-b+\sqrt{-ac+b^2}\right) b - \frac{8\left(-b+\sqrt{-ac+b^2}\right) bd}{a} + 6ac - 3b^2 - 4cd}{16\left(-ac+b^2\right)\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^2} \\ &+ \frac{3\left(b+\sqrt{-ac+b^2}\right)^2 - \frac{4\left(b+\sqrt{-ac+b^2}\right)^2 d}{a} - 6\left(b+\sqrt{-ac+b^2}\right) b + \frac{8\left(b+\sqrt{-ac+b^2}\right) bd}{a} + 6ac - 3b^2 - 4cd}{16\left(-ac+b^2\right)\left(x + \frac{b+\sqrt{-ac+b^2}}{a}\right)^2} \\ &+ \frac{3\left(-b+\sqrt{-ac+b^2}\right)^2 a - 4\left(-b+\sqrt{-ac+b^2}\right)^2 d + 6\left(-b+\sqrt{-ac+b^2}\right) ab - 8\left(-b+\sqrt{-ac+b^2}\right) bd -}{16\left(-ac+b^2\right)^{\frac{3}{2}}\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)} \\ &- \frac{3\left(b+\sqrt{-ac+b^2}\right)^2 a - 4\left(b+\sqrt{-ac+b^2}\right)^2 d - 6\left(b+\sqrt{-ac+b^2}\right) ab + 8\left(b+\sqrt{-ac+b^2}\right) bd - 6a^2c -}{16\left(-ac+b^2\right)^{\frac{3}{2}}\left(x + \frac{b+\sqrt{-ac+b^2}}{a}\right)} \end{aligned}$$

For the pole at $x = -\frac{b-\sqrt{-ac+b^2}}{a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b-\sqrt{-ac+b^2}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -\frac{b+\sqrt{-ac+b^2}}{a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b+\sqrt{-ac+b^2}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{3a^2x^2 - 4ad\,x^2 + 6abx - 8bdx + 6ac - 3b^2 - 4cd}{4\,(a\,x^2 + 2bx + c)^2}$$

Since the $\gcd(s,t) = 1$. This gives $b = \frac{3}{4}$. Hence

$$\begin{aligned} E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{-2, 2, 6\} \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
$-\frac{b-\sqrt{-ac+b^2}}{a}$	2	$\{1, 2, 3\}$
$-\frac{b+\sqrt{-ac+b^2}}{a}$	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
2	$\{-2, 2, 6\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2 - (1 + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned}\theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c}\\ &= \frac{1}{2}\left(\frac{1}{\left(x-\left(-\frac{b-\sqrt{-ac+b^2}}{a}\right)\right)}+\frac{1}{\left(x-\left(-\frac{b+\sqrt{-ac+b^2}}{a}\right)\right)}\right)\\ &= \frac{1}{2x+\frac{2\left(b-\sqrt{-ac+b^2}\right)}{a}}+\frac{1}{2x+\frac{2\left(b+\sqrt{-ac+b^2}\right)}{a}}\end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$p'''+3\theta p''+\left(3\theta^2+3\theta'-4r\right)p'+\left(\theta''+3\theta\theta'+\theta^3-4r\theta-2r'\right)p=0 \tag{1A}$$

Since $d=0$, then letting

$$p=1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0=0$$

And solving for p gives

$$p=1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta+\frac{p'}{p}\\ &= \frac{1}{2x+\frac{2\left(b-\sqrt{-ac+b^2}\right)}{a}}+\frac{1}{2x+\frac{2\left(b+\sqrt{-ac+b^2}\right)}{a}}\end{aligned}$$

Let ω be the solution of

$$\omega^2-\phi\omega+\left(\frac{1}{2}\phi'+\frac{1}{2}\phi^2-r\right)=0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2-\left(\frac{1}{2x+\frac{2\left(b-\sqrt{-ac+b^2}\right)}{a}}+\frac{1}{2x+\frac{2\left(b+\sqrt{-ac+b^2}\right)}{a}}\right)w\\ -\frac{3a^2\left(a^2x^2+\left(-\frac{4}{3}d\,x^2+2bx+\frac{4}{3}c\right)a-\frac{8bdx}{3}-\frac{b^2}{3}-\frac{4cd}{3}\right)}{4\left(ax+b-\sqrt{-ac+b^2}\right)^2\left(ax+\sqrt{-ac+b^2}+b\right)^2}=0$$

Solving for ω gives

$$\omega = \frac{ax + 2\sqrt{a^2x^2 - ad\,x^2 + 2abx - 2bdx + ac - cd} + b}{2a\,x^2 + 4bx + 2c}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= e^{\int \omega \,dx} \\
&= \mathrm{e}^{\int \frac{ax+2\sqrt{a^2x^2-ad\,x^2+2abx-2bdx+ac-cd}+b}{2a\,x^2+4bx+2c}dx} \\
&= \left(a\,x^2 + 2bx + c\right)^{\frac{1}{4}} \left(\frac{\sqrt{\frac{(a-d)\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}{a}}\,\sqrt{a\,(a-d)} + (a-d)\,(ax+b)}{\sqrt{a\,(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{3ax+3b}{a\,x^2+2bx+c}\,dx} \\
&= z_1 e^{-\frac{3\ln\left(a\,x^2+2bx+c\right)}{4}} \\
&= z_1 \left(\frac{1}{\left(a\,x^2+2bx+c\right)^{\frac{3}{4}}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}}}{\sqrt{a\,x^2+2bx+c}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{3ax+3b}{a\,x^2+2bx+c}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{3\ln\left(a\,x^2+2bx+c\right)}{2}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{-\frac{2(a-d)}{\sqrt{a(a-d)}}}}{\sqrt{a\,x^2+2bx+c}}\,dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}}}{\sqrt{a\,x^2+2bx+c}} \right) \\
&\quad + c_2 \left(\frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}}}{\sqrt{a\,x^2+2bx+c}} \right) \left(\int \frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac\right.}\right.}{\sqrt{a(a-d)}}\right.}{\sqrt{a\,x^2+2bx+c}} \right.
\end{aligned}
$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}}}{\sqrt{a\,x^2+2bx+c}} + \frac{c_2 \left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}} \left(\int \frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right. \cdots}{\sqrt{a\,x^2+2bx+c}} \cdots\right.}{\sqrt{a\,x^2+2bx+c}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}}}{\sqrt{a\,x^2+2bx+c}} + \frac{c_2 \left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right)^{\frac{a-d}{\sqrt{a(a-d)}}} \left(\int \frac{\left(\frac{(a-d)\left(ax+\sqrt{\left(ax+b-\sqrt{-ac+b^2}\right)\left(ax+\sqrt{-ac+b^2}+b\right)}+b\right)}{\sqrt{a(a-d)}}\right. \cdots}{\sqrt{a\,x^2+2bx+c}} \cdots\right.}{\sqrt{a\,x^2+2bx+c}}$$

Verified OK.

30.30.2 Maple step by step solution

Let's solve

$(a\,x^2+2bx+c)\,y''+(3ax+3b)\,y'+yd=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{dy}{a\,x^2+2bx+c}-\frac{3(ax+b)y'}{a\,x^2+2bx+c}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{3(ax+b)y'}{a\,x^2+2bx+c}+\frac{dy}{a\,x^2+2bx+c}=0$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x) = \frac{3(ax+b)}{a\,x^2+2bx+c}, P_3(x) = \frac{d}{a\,x^2+2bx+c}\right]$

- $\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right) \cdot P_2(x)$ is analytic at $x = \frac{-b+\sqrt{-ac+b^2}}{a}$

  $\left(\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right) \cdot P_2(x)\right)\bigg|_{x=\frac{-b+\sqrt{-ac+b^2}}{a}} = 0$

- $\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^2 \cdot P_3(x)$ is analytic at $x = \frac{-b+\sqrt{-ac+b^2}}{a}$

  $\left(\left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^2 \cdot P_3(x)\right)\bigg|_{x=\frac{-b+\sqrt{-ac+b^2}}{a}} = 0$

- $x = \frac{-b+\sqrt{-ac+b^2}}{a}$ is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = \frac{-b+\sqrt{-ac+b^2}}{a}$

- Multiply by denominators

  $(a\,x^2 + 2bx + c)\,y'' + (3ax + 3b)\,y' + yd = 0$

- Change variables using $x = u + \frac{-b+\sqrt{-ac+b^2}}{a}$ so that the regular singular point is at $u = 0$

  $\left(a\,u^2 + 2u\sqrt{-ac+b^2}\right)\left(\frac{d^2}{du^2}y(u)\right) + \left(3au + 3\sqrt{-ac+b^2}\right)\left(\frac{d}{du}y(u)\right) + dy(u) = 0$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..1$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $$u^{m}\cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m} \left(k+2-m+r \right) \left(k+1-m+r \right) u^{k+r}$$

  Rewrite ODE with series expansions

  $$\sqrt{-a c+b^{2}}\, a_{0} \left(1+2 r \right) r \,u^{-1+r}+\left(\sum_{k=0}^{\infty}\left(\sqrt{-a c+b^{2}}\, a_{k+1} \left(2 k+3+2 r \right) \left(k+1+r \right)+a_{k} \left(a \,k^{2}+2 a k\right.\right.\right.$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $$\sqrt{-a c+b^{2}}\, \left(1+2 r \right) r =0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{0, -\frac{1}{2}\right\}$$

- Each term in the series must be 0, giving the recursion relation

  $$2 a_{k+1} \left(k+1+r \right) \left(k+r+\frac{3}{2}\right) \sqrt{-a c+b^{2}}+\left(a \,k^{2}+2 a \left(r+1\right) k+a \,r^{2}+2 a r+d \right) a_{k}=0$$

- Recursion relation that defines series solution to ODE

  $$a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+2 a k r+a \,r^{2}+2 a k+2 a r+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+4 k r+2 r^{2}+5 k+5 r+3\right)}$$

- Recursion relation for $r =0$

  $$a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+2 a k+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+5 k+3\right)}$$

- Solution for $r =0$

  $$\left[y \left(u \right)=\sum_{k=0}^{\infty}a_{k} u^{k}, a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+2 a k+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+5 k+3\right)}\right]$$

- Revert the change of variables $u =x -\frac{-b+\sqrt{-a c+b^{2}}}{a}$

  $$\left[y=\sum_{k=0}^{\infty}a_{k} \left(x -\frac{-b+\sqrt{-a c+b^{2}}}{a}\right)^{k}, a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+2 a k+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+5 k+3\right)}\right]$$

- Recursion relation for $r =-\frac{1}{2}$

  $$a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+a k-\frac{3}{4} a+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+3 k+1\right)}$$

- Solution for $r =-\frac{1}{2}$

  $$\left[y \left(u \right)=\sum_{k=0}^{\infty}a_{k} u^{k -\frac{1}{2}}, a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+a k-\frac{3}{4} a+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+3 k+1\right)}\right]$$

- Revert the change of variables $u =x -\frac{-b+\sqrt{-a c+b^{2}}}{a}$

  $$\left[y=\sum_{k=0}^{\infty}a_{k} \left(x -\frac{-b+\sqrt{-a c+b^{2}}}{a}\right)^{k -\frac{1}{2}}, a_{k+1}=-\frac{a_{k} \left(a \,k^{2}+a k-\frac{3}{4} a+d \right)}{\sqrt{-a c+b^{2}}\, \left(2 k^{2}+3 k+1\right)}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} e_k \left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^k\right) + \left(\sum_{k=0}^{\infty} f_k \left(x - \frac{-b+\sqrt{-ac+b^2}}{a}\right)^{k-\frac{1}{2}}\right), e_{1+k} = -\frac{e_k\left(a\,k^2+2ak+d\right)}{\sqrt{-ac+b^2}\,(2k^2+5k+3)},\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-5 Equation of form $(ax^2+bx+c)y''+f(x)y'+g(x)y=0$
Problem number: 180.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\left(a\,x^2+bx+c\right)y''-\left(-k^2+x^2\right)y'+(x+k)\,y=0$$

30.32.1 Maple step by step solution

Let's solve

$\left(a\,x^2+bx+c\right)y''+\left(k^2-x^2\right)y'+(x+k)\,y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{(x+k)y}{a\,x^2+bx+c}-\frac{(k^2-x^2)y'}{a\,x^2+bx+c}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(k^2-x^2)y'}{a\,x^2+bx+c}+\frac{(x+k)y}{a\,x^2+bx+c}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$$\left[P_2(x)=\frac{k^2-x^2}{a\,x^2+bx+c}, P_3(x)=\frac{x+k}{a\,x^2+bx+c}\right]$$

- $\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)\cdot P_2(x)$ is analytic at $x=\frac{-b+\sqrt{-4ac+b^2}}{2a}$

  $$\left(\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)\cdot P_2(x)\right)\bigg|_{x=\frac{-b+\sqrt{-4ac+b^2}}{2a}}=0$$

- $\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2\cdot P_3(x)$ is analytic at $x=\frac{-b+\sqrt{-4ac+b^2}}{2a}$

  $$\left(\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2\cdot P_3(x)\right)\bigg|_{x=\frac{-b+\sqrt{-4ac+b^2}}{2a}}=0$$

- $x=\frac{-b+\sqrt{-4ac+b^2}}{2a}$ is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=\frac{-b+\sqrt{-4ac+b^2}}{2a}$

- Multiply by denominators

  $$(a\,x^2+bx+c)\,y''+(k^2-x^2)\,y'+(x+k)\,y=0$$

- Change variables using $x=u+\frac{-b+\sqrt{-4ac+b^2}}{2a}$ so that the regular singular point is at $u=0$

  $$\left(a\,u^2+u\sqrt{-4ac+b^2}\right)\left(\frac{d^2}{du^2}y(u)\right)+\left(k^2-u^2+\frac{ub}{a}-\frac{u\sqrt{-4ac+b^2}}{a}-\frac{b^2}{2a^2}+\frac{b\sqrt{-4ac+b^2}}{2a^2}+\frac{c}{a}\right)\left(\frac{d}{du}y(u)\right)$$

- Assume series solution for $y(u)$

  $$y(u)=\sum_{k=0}^{\infty}a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot y(u)$ to series expansion for $m=0..1$

  $$u^m\cdot y(u)=\sum_{k=0}^{\infty}a_k u^{k+r+m}$$

- Shift index using $k->k-m$

  $$u^m\cdot y(u)=\sum_{k=m}^{\infty}a_{k-m}u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=0..2$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 1..2$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$\frac{a_0 r\left(2a^2\sqrt{-4ac+b^2}\,r+2a^2k^2-2a^2\sqrt{-4ac+b^2}+b\sqrt{-4ac+b^2}+2ac-b^2\right)u^{-1+r}}{2a^2} + \left(\frac{a_1(1+r)\left(2a^2\sqrt{-4ac+b^2}\,r+2a^2k^2+b\sqrt{-4ac+b^2}+\right.}{2a^2}\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$\frac{r\left(2a^2\sqrt{-4ac+b^2}\,r+2a^2k^2-2a^2\sqrt{-4ac+b^2}+b\sqrt{-4ac+b^2}+2ac-b^2\right)}{2a^2} = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{0, \frac{-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2}{2a^2\sqrt{-4ac+b^2}}\right\}$$

- Each term must be 0

$$\frac{a_1(1+r)\left(2a^2\sqrt{-4ac+b^2}\,r+2a^2k^2+b\sqrt{-4ac+b^2}+2ac-b^2\right)}{2a^2} - \frac{a_0\left(-2a^2r^2+2a^2r+2\sqrt{-4ac+b^2}\,r-2ak-2br-\sqrt{-4ac+b^2}+b\right)}{2a} = 0$$

- Each term in the series must be 0, giving the recursion relation

$$\frac{\left(2a_{k+1}(k+1+r)(k+r)a^2-2\left(k+r-\frac{1}{2}\right)a_k a+b a_{k+1}(k+1+r)\right)\sqrt{-4ac+b^2}+2a_k(k+r)(k+r-1)a^3+\left(2k^2(k+1+r)a_{k+1}+2a_k k-2k a_{k-1}-\right.}{2a^2}$$

- Shift index using $k->k+1$

$$\frac{\left(2a_{k+2}(k+2+r)(k+1+r)a^2-2\left(k+\frac{1}{2}+r\right)a_{k+1}a+b a_{k+2}(k+2+r)\right)\sqrt{-4ac+b^2}+2a_{k+1}(k+1+r)(k+r)a^3+\left(2k^2(k+2+r)a_{k+2}+2a_{k+1}k-\right.}{2a^2}$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-4a^2kra_{k+1}-2a^2r^2a_{k+1}-2a^2ka_{k+1}-2a^2ra_{k+1}+2\sqrt{-4ac+b^2}\,ka_{k+1}+2\sqrt{-4ac+b^2}\,ra_{k+1}-\right.}{4\sqrt{-4ac+b^2}\,a^2kr-2b^2-b^2k-b^2r+4a^2k^2+4ac+4a^2\sqrt{-4ac+b^2}+2b\sqrt{-4ac+b^2}+2a^2k^2k+2a^2k^2r+2ack+2acr+2\sqrt{-4ac+b^2}}$$

- Recursion relation for $r = 0$

$$a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-2a^2ka_{k+1}+2\sqrt{-4ac+b^2}\,ka_{k+1}-2aka_{k+1}+2aka_k-2bka_{k+1}+\sqrt{-4ac+b^2}\,a_{k+1}-2a_ka-ba_{k+1}\right)}{-2b^2-b^2k+4a^2k^2+4ac+4a^2\sqrt{-4ac+b^2}+2b\sqrt{-4ac+b^2}+2a^2k^2k+2ack+2\sqrt{-4ac+b^2}\,a^2k^2+6a^2\sqrt{-4ac+b^2}\,k+\sqrt{-4ac+b^2}}$$

- Solution for $r = 0$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^k, a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-2a^2ka_{k+1}+2\sqrt{-4ac+b^2}\,ka_{k+1}-2aka_{k+1}+2aka_k-2bka_{k+1}+\sqrt{-4ac+b^2}\right.}{-2b^2-b^2k+4a^2k^2+4ac+4a^2\sqrt{-4ac+b^2}+2b\sqrt{-4ac+b^2}+2a^2k^2k+2ack+2\sqrt{-4ac+b^2}\,a^2k^2+6a^2\sqrt{}}\right.$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left[y = \sum_{k=0}^{\infty} a_k\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^k, a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-2a^2ka_{k+1}+2\sqrt{-4ac+b^2}\,ka_{k+1}-2aka_{k+1}+2aka_k-2b\right.}{-2b^2-b^2k+4a^2k^2+4ac+4a^2\sqrt{-4ac+b^2}+2b\sqrt{-4ac+b^2}+2a^2k^2k+2ack+2\sqrt{-}}\right.$$

- Recursion relation for $r = \frac{-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2}{2a^2\sqrt{-4ac+b^2}}$

$$a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-\frac{2k\left(-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2\right)a_{k+1}}{\sqrt{-4ac+b^2}}-\frac{\left(-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2\right)^2a_{k-}}{2a^2\left(-4ac+b^2\right)}\right.}{2k\left(-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2\right)+b^2-b^2k-\frac{b^2\left(-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2\right)}{2a^2\sqrt{-4ac+b^2}}-2a^2k}$$

- Solution for $r = \frac{-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2}{2a^2\sqrt{-4ac+b^2}}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2}{2a^2\sqrt{-4ac+b^2}}}, a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-\frac{2k\left(-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4a}\right.}{\sqrt{-4ac+b^2}}\right.}{2k\left(-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac\right.}\right.$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left[y = \sum_{k=0}^{\infty} a_k\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^{k+\frac{-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-2ac+b^2}{2a^2\sqrt{-4ac+b^2}}}, a_{k+2} = \frac{a\left(-2a^2k^2a_{k+1}-\frac{2k\left(-2a^2k^2+2\right.}{}\right.}{2k\left(-2a^2k^2+2a^2\sqrt{-4ac+b}\right.}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{m=0}^{\infty} d_m\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^m\right) + \left(\sum_{m=0}^{\infty} e_m\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^{m+\frac{-2a^2k^2+2a^2\sqrt{-4ac+b^2}-b\sqrt{-4ac+b^2}-}{2a^2\sqrt{-4ac+b^2}}}\right.\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-6 Equation of form $(a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 182.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^3y'' + (ax + b)\,y = 0}$$

31.1.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(a + \frac{b}{x}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= 2\sqrt{b} \\
n &= \sqrt{1-4a} \\
\gamma &= -\frac{1}{2}
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(\sqrt{1-4a}, \frac{2\sqrt{b}}{\sqrt{x}}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(\sqrt{1-4a}, \frac{2\sqrt{b}}{\sqrt{x}}\right)
$$

Summary

The solution(s) found are the following

$$
y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(\sqrt{1-4a}, \frac{2\sqrt{b}}{\sqrt{x}}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(\sqrt{1-4a}, \frac{2\sqrt{b}}{\sqrt{x}}\right) \tag{1}
$$

Verification of solutions

$$
y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(\sqrt{1-4a}, \frac{2\sqrt{b}}{\sqrt{x}}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(\sqrt{1-4a}, \frac{2\sqrt{b}}{\sqrt{x}}\right)
$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-6 Equation of form $(a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 189.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{x\left(a\,x^2+b\right)y''+2\left(a\,x^2+b\right)y'-2yax=0}$$

31.8.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x\left(a\,x^2+b\right)y''+\left(2a\,x^2+2b\right)y'-2yax\right)dx=0$$
$$\left(-a\,x^2+b\right)y+\left(a\,x^3+bx\right)y'=c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{a\,x^2 - b}{x\,(a\,x^2 + b)} \\
q(x) &= \frac{c_1}{x\,(a\,x^2 + b)}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{(a\,x^2 - b)\,y}{x\,(a\,x^2 + b)} = \frac{c_1}{x\,(a\,x^2 + b)}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{a\,x^2 - b}{x\left(a\,x^2 + b\right)}dx} \\
&= \mathrm{e}^{\ln(x) - \ln\left(a\,x^2 + b\right)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{x}{a\,x^2 + b}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x\,(a\,x^2 + b)}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{xy}{a\,x^2 + b}\right) &= \left(\frac{x}{a\,x^2 + b}\right)\left(\frac{c_1}{x\,(a\,x^2 + b)}\right) \\
\mathrm{d}\left(\frac{xy}{a\,x^2 + b}\right) &= \left(\frac{c_1}{(a\,x^2 + b)^2}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{xy}{a\,x^2 + b} &= \int \frac{c_1}{(a\,x^2 + b)^2}\,\mathrm{d}x \\
\frac{xy}{a\,x^2 + b} &= c_1\left(\frac{x}{2b\,(a\,x^2 + b)} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2b\sqrt{ab}}\right) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{x}{a\,x^2 + b}$ results in

$$
y = \frac{(a\,x^2 + b)\,c_1\left(\frac{x}{2b(a\,x^2 + b)} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2b\sqrt{ab}}\right)}{x} + \frac{c_2(a\,x^2 + b)}{x}
$$

which simplifies to

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2+b)}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2+b)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2+b)}{x}$$

Verified OK.

31.8.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$x\left(a\,x^2+b\right)y'' + \left(2a\,x^2+2b\right)y' - 2yax = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left(x\left(a\,x^2+b\right)y'' + \left(2a\,x^2+2b\right)y' - 2yax\right)dx = 0$$
$$\left(-a\,x^2+b\right)y + \left(a\,x^3+bx\right)y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{a\,x^2-b}{x\,(a\,x^2+b)}$$
$$q(x) = \frac{c_1}{x\,(a\,x^2+b)}$$

Hence the ode is

$$y' - \frac{(a\,x^2 - b)\,y}{x\,(a\,x^2 + b)} = \frac{c_1}{x\,(a\,x^2 + b)}$$

The integrating factor μ is

$$\begin{aligned}\mu &= \mathrm{e}^{\int -\frac{a\,x^2 - b}{x\left(a\,x^2 + b\right)} dx} \\ &= \mathrm{e}^{\ln(x) - \ln\left(a\,x^2 + b\right)}\end{aligned}$$

Which simplifies to

$$\mu = \frac{x}{a\,x^2 + b}$$

The ode becomes

$$\begin{aligned}\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x\,(a\,x^2 + b)}\right) \\ \frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{xy}{a\,x^2 + b}\right) &= \left(\frac{x}{a\,x^2 + b}\right)\left(\frac{c_1}{x\,(a\,x^2 + b)}\right) \\ \mathrm{d}\!\left(\frac{xy}{a\,x^2 + b}\right) &= \left(\frac{c_1}{(a\,x^2 + b)^2}\right)\,\mathrm{d}x\end{aligned}$$

Integrating gives

$$\begin{aligned}\frac{xy}{a\,x^2 + b} &= \int \frac{c_1}{(a\,x^2 + b)^2}\,\mathrm{d}x \\ \frac{xy}{a\,x^2 + b} &= c_1\left(\frac{x}{2b\,(a\,x^2 + b)} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2b\sqrt{ab}}\right) + c_2\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \frac{x}{a\,x^2 + b}$ results in

$$y = \frac{(a\,x^2 + b)\,c_1\left(\frac{x}{2b(a\,x^2 + b)} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2b\sqrt{ab}}\right)}{x} + \frac{c_2(a\,x^2 + b)}{x}$$

which simplifies to

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2 + b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2 + b)}{x}$$

Summary
The solution(s) found are the following

$$
y=\frac{c_{1}}{2b}+\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(a\,x^{2}+b\right)c_{1}}{2b\sqrt{ab}\,x}+\frac{c_{2}\left(a\,x^{2}+b\right)}{x} \tag{1}
$$

Verification of solutions

$$
y=\frac{c_{1}}{2b}+\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(a\,x^{2}+b\right)c_{1}}{2b\sqrt{ab}\,x}+\frac{c_{2}\left(a\,x^{2}+b\right)}{x}
$$

Verified OK.

31.8.3 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
x\left(a\,x^{2}+b\right)y''+\left(2a\,x^{2}+2b\right)y'-2yax&=0 \tag{1}\\
Ay''+By'+Cy&=0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A&=x\left(a\,x^{2}+b\right)\\
B&=2a\,x^{2}+2b \tag{3}\\
C&=-2ax
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x)=ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x)=rz(x) \tag{4}
$$

Where r is given by

$$
\begin{align*}
r&=\frac{s}{t} \tag{5}\\
&=\frac{2AB'-2BA'+B^{2}-4AC}{4A^{2}}
\end{align*}
$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$
r=\frac{2a}{a\,x^{2}+b} \tag{6}
$$

Comparing the above to (5) shows that

$$s = 2a$$
$$t = a\,x^2 + b$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{2a}{a\,x^2 + b}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 176: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 2 - 0 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = a\,x^2 + b$. There is a pole at $x = \frac{\sqrt{-ab}}{a}$ of order 1. There is a pole at

$x = -\frac{\sqrt{-ab}}{a}$ of order 1. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 1. For the pole at $x = \frac{\sqrt{-ab}}{a}$ of order 1 then

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= 1\\ \alpha_c^- &= 1\end{aligned}$$

Since the order of r at ∞ is 2 then $[\sqrt{r}]_\infty = 0$. Let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{2a}{a\,x^2 + b}$$

Since the $\gcd(s, t) = 1$. This gives $b = 2$. Hence

$$\begin{aligned}[\sqrt{r}]_\infty &= 0\\ \alpha_\infty^+ &= \frac{1}{2} + \sqrt{1+4b} = 2\\ \alpha_\infty^- &= \frac{1}{2} - \sqrt{1+4b} = -1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{2a}{a\,x^2 + b}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$\frac{\sqrt{-ab}}{a}$	1	0	0	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
2	0	2	-1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_{\infty}^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_{\infty}^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_{\infty}^{+} = 2$ then

$$\begin{aligned}
d &= \alpha_{\infty}^{+} - \left(\alpha_{c_1}^{-}\right) \\
&= 2 - (1) \\
&= 1
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_{\infty}$$

Substituting the above values in the above results in

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1} \right) + (+)[\sqrt{r}]_{\infty} \\
&= \frac{1}{x - \frac{\sqrt{-ab}}{a}} + (0) \\
&= \frac{1}{x - \frac{\sqrt{-ab}}{a}} \\
&= -\frac{a}{-ax + \sqrt{-ab}}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 1$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = x + a_0 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{1}{x - \frac{\sqrt{-ab}}{a}}\right)(1) + \left(\left(-\frac{1}{\left(x - \frac{\sqrt{-ab}}{a}\right)^2}\right) + \left(\frac{1}{x - \frac{\sqrt{-ab}}{a}}\right)^2 - \left(\frac{2a}{a\,x^2 + b}\right)\right) = 0$$

$$-\frac{2a\left((-x - a_0)\sqrt{-ab} + axa_0 - b\right)}{\left(ax - \sqrt{-ab}\right)\left(a\,x^2 + b\right)} = 0$$

Solving for the coefficients a_i in the above using method of undetermined coefficients gives

$$\left\{a_0 = \frac{\sqrt{-ab}}{a}\right\}$$

Substituting these coefficients in $p(x)$ in eq. (2A) results in

$$p(x) = x + \frac{\sqrt{-ab}}{a}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \left(x + \frac{\sqrt{-ab}}{a}\right) \mathrm{e}^{\int \frac{1}{x - \frac{\sqrt{-ab}}{a}} dx} \\
&= \left(x + \frac{\sqrt{-ab}}{a}\right) x - \frac{\sqrt{-ab}}{a} \\
&= \frac{a\,x^2 + b}{a}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{2a\,x^2+2b}{x\left(a\,x^2+b\right)} \, dx} \\
&= z_1 e^{-\ln(x)} \\
&= z_1 \left(\frac{1}{x}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{a\,x^2 + b}{ax}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2a\,x^2+2b}{x\left(a\,x^2+b\right)}dx}}{\left(y_1\right)^2}\,dx \\
&= y_1 \int \frac{e^{-2\ln(x)}}{\left(y_1\right)^2}\,dx \\
&= y_1 \left(\frac{a^2\left(\frac{x}{a\,x^2+b}+\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}\right)}{2b}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{a\,x^2+b}{ax}\right) + c_2\left(\frac{a\,x^2+b}{ax}\left(\frac{a^2\left(\frac{x}{a\,x^2+b}+\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}\right)}{2b}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1(a\,x^2+b)}{ax} + \frac{c_2 a\left(\sqrt{ab}\,x + \arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\right)}{2xb\sqrt{ab}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1(a\,x^2+b)}{ax} + \frac{c_2 a\left(\sqrt{ab}\,x + \arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\right)}{2xb\sqrt{ab}}
$$

Verified OK.

31.8.4 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= x\left(a\,x^2 + b\right) \\ q(x) &= 2a\,x^2 + 2b \\ r(x) &= -2ax \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 6ax \\ q'(x) &= 4ax \end{aligned}$$

Therefore (1) becomes

$$6ax - (4ax) + (-2ax) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$x\left(a\,x^2 + b\right)y' + \left(-a\,x^2 + b\right)y = c_1$$

We now have a first order ode to solve which is

$$x\left(a\,x^2 + b\right)y' + \left(-a\,x^2 + b\right)y = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{a\,x^2-b}{x\,(a\,x^2+b)} \\
q(x) &= \frac{c_1}{x\,(a\,x^2+b)}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{(a\,x^2-b)\,y}{x\,(a\,x^2+b)} = \frac{c_1}{x\,(a\,x^2+b)}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{a\,x^2-b}{x\left(a\,x^2+b\right)}dx} \\
&= \mathrm{e}^{\ln(x)-\ln\left(a\,x^2+b\right)}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{x}{a\,x^2+b}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{x\,(a\,x^2+b)}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{xy}{a\,x^2+b}\right) &= \left(\frac{x}{a\,x^2+b}\right)\left(\frac{c_1}{x\,(a\,x^2+b)}\right) \\
\mathrm{d}\left(\frac{xy}{a\,x^2+b}\right) &= \left(\frac{c_1}{(a\,x^2+b)^2}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{xy}{a\,x^2+b} &= \int \frac{c_1}{(a\,x^2+b)^2}\,\mathrm{d}x \\
\frac{xy}{a\,x^2+b} &= c_1\left(\frac{x}{2b\,(a\,x^2+b)} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2b\sqrt{ab}}\right) + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{x}{a\,x^2+b}$ results in

$$
y = \frac{(a\,x^2+b)\,c_1\left(\frac{x}{2b(a\,x^2+b)} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2b\sqrt{ab}}\right)}{x} + \frac{c_2(a\,x^2+b)}{x}
$$

which simplifies to

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2+b)}{x}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2+b)}{x} \tag{1}$$

Verification of solutions

$$y = \frac{c_1}{2b} + \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)(a\,x^2+b)\,c_1}{2b\sqrt{ab}\,x} + \frac{c_2(a\,x^2+b)}{x}$$

Verified OK.

31.8.5 Maple step by step solution

Let's solve

$x(a\,x^2+b)\,y'' + (2a\,x^2+2b)\,y' - 2yax = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2y'}{x} + \frac{2ay}{a\,x^2+b}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2y'}{x} - \frac{2ay}{a\,x^2+b} = 0$

☐ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x) = \frac{2}{x}, P_3(x) = -\frac{2a}{a\,x^2+b}\right]$

- ◦ $x \cdot P_2(x)$ is analytic at $x=0$

  $(x \cdot P_2(x))\Big|_{x=0} = 2$

- ◦ $x^2 \cdot P_3(x)$ is analytic at $x=0$

$$(x^2 \cdot P_3(x))\bigg|_{x=0} = 0$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x(a\,x^2+b)\,y''+(2a\,x^2+2b)\,y'-2yax=0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- □ Rewrite ODE with series expansions

  - Convert $x \cdot y$ to series expansion

    $x \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+1}$

  - Shift index using $k->k-1$

    $x \cdot y = \sum_{k=1}^{\infty} a_{k-1} x^{k+r}$

  - Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k->k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m \cdot y''$ to series expansion for $m = 1..3$

    $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $ba_0r(1+r)\,x^{-1+r}+ba_1(1+r)\,(2+r)\,x^r+\left(\sum_{k=1}^{\infty}(ba_{k+1}(k+r+1)\,(k+r+2)+aa_{k-1}(k+r+1\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$br(1+r)=0$

- Values of r that satisfy the indicial equation

  $r \in \{-1, 0\}$

- Each term must be 0

  $ba_1(1+r)(2+r)=0$

- Each term in the series must be 0, giving the recursion relation

  $(k+r+1)(ba_{k+1}(k+r+2)+aa_{k-1}(k-2+r))=0$

- Shift index using $k->k+1$

  $(k+r+2)(ba_{k+2}(k+3+r)+aa_k(k+r-1))=0$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{aa_k(k+r-1)}{b(k+3+r)}$

- Recursion relation for $r=-1$; series terminates at $k=2$

  $a_{k+2}=-\frac{aa_k(k-2)}{b(k+2)}$

- Solution for $r=-1$

  $\left[y=\sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2}=-\frac{aa_k(k-2)}{b(k+2)}, 0=0\right]$

- Recursion relation for $r=0$

  $a_{k+2}=-\frac{aa_k(k-1)}{b(k+3)}$

- Solution for $r=0$

  $\left[y=\sum_{k=0}^{\infty} a_k x^k, a_{k+2}=-\frac{aa_k(k-1)}{b(k+3)}, 2ba_1=0\right]$

- Combine solutions and rename parameters

  $\left[y=\left(\sum_{k=0}^{\infty} c_k x^{k-1}\right)+\left(\sum_{k=0}^{\infty} d_k x^k\right), c_{k+2}=-\frac{ac_k(k-2)}{b(k+2)}, 0=0, d_{k+2}=-\frac{ad_k(k-1)}{b(k+3)}, 2bd_1=0\right]$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-6 Equation of form $(a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 192.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_y_method_1", "second_order_change_of_variable_on_y_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^2(ax+b)\,y'' - 2x(ax+2b)\,y' + 2(ax+3b)\,y = 0}$$

31.11.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{-2a\,x^2 - 4bx}{a\,x^3 + b\,x^2} \\ q(x) &= \frac{2ax + 6b}{a\,x^3 + b\,x^2} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= \frac{2ax+6b}{a\,x^3+b\,x^2} - \frac{\left(\frac{-2a\,x^2-4bx}{a\,x^3+b\,x^2}\right)'}{2} - \frac{\left(\frac{-2a\,x^2-4bx}{a\,x^3+b\,x^2}\right)^2}{4} \\
&= \frac{2ax+6b}{a\,x^3+b\,x^2} - \frac{\left(\frac{-4ax-4b}{a\,x^3+b\,x^2} - \frac{(-2a\,x^2-4bx)\,(3a\,x^2+2bx)}{(a\,x^3+b\,x^2)^2}\right)}{2} - \frac{\left(\frac{(-2a\,x^2-4bx)^2}{(a\,x^3+b\,x^2)^2}\right)}{4} \\
&= \frac{2ax+6b}{a\,x^3+b\,x^2} - \left(\frac{-4ax-4b}{2a\,x^3+2b\,x^2} - \frac{(-2a\,x^2-4bx)\,(3a\,x^2+2bx)}{2\,(a\,x^3+b\,x^2)^2}\right) - \frac{(-2a\,x^2-4bx)^2}{4\,(a\,x^3+b\,x^2)^2} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\,z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2}dx\right)} \\
&= e^{-\int \frac{\frac{-2a\,x^2-4bx}{a\,x^3+b\,x^2}}{2}} \\
&= \frac{x^2}{ax+b}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = \frac{v(x)\,x^2}{ax+b} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
x^4 v''(x) = 0
$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$
v(x) = c_1 x + c_2
$$

Now that $v(x)$ is known, then

$$
\begin{aligned}
y &= v(x)\,z(x) \\
&= (c_1 x + c_2)\,(z(x))
\end{aligned} \tag{7}
$$

But from (5)

$$z(x) = \frac{x^2}{ax+b}$$

Hence (7) becomes

$$y = \frac{(c_1x+c_2)\,x^2}{ax+b}$$

Summary

The solution(s) found are the following

$$y = \frac{(c_1x+c_2)\,x^2}{ax+b} \tag{1}$$

Verification of solutions

$$y = \frac{(c_1x+c_2)\,x^2}{ax+b}$$

Verified OK.

31.11.2 Solving as second order change of variable on y method 2 ode

In normal form the ode

$$x^2(ax+b)\,y'' + \left(-2a\,x^2-4bx\right)y' + (2ax+6b)\,y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{-2ax-4b}{(ax+b)\,x}$$
$$q(x) = \frac{2ax+6b}{x^2\,(ax+b)}$$

Applying change of variables on the depndent variable $y = v(x)\,x^n$ to (2) gives the following ode where the dependent variables is $v(x)$ and not y.

$$v''(x) + \left(\frac{2n}{x}+p\right)v'(x) + \left(\frac{n(n-1)}{x^2}+\frac{np}{x}+q\right)v(x) = 0 \tag{3}$$

Let the coefficient of $v(x)$ above be zero. Hence

$$\frac{n(n-1)}{x^2}+\frac{np}{x}+q = 0 \tag{4}$$

Substituting the earlier values found for $p(x)$ and $q(x)$ into (4) gives

$$\frac{n(n-1)}{x^2} + \frac{n(-2ax-4b)}{(ax+b)\,x^2} + \frac{2ax+6b}{x^2\,(ax+b)} = 0 \tag{5}$$

Solving (5) for n gives

$$n = 2 \tag{6}$$

Substituting this value in (3) gives

$$\begin{aligned} v''(x) + \left(\frac{4}{x} + \frac{-2ax-4b}{(ax+b)\,x}\right) v'(x) &= 0 \\ v''(x) + \frac{2av'(x)}{ax+b} &= 0 \end{aligned} \tag{7}$$

Using the substitution

$$u(x) = v'(x)$$

Then (7) becomes

$$u'(x) + \frac{2au(x)}{ax+b} = 0 \tag{8}$$

The above is now solved for $u(x)$. In canonical form the ODE is

$$\begin{aligned} u' &= F(x,u) \\ &= f(x)g(u) \\ &= -\frac{2au}{ax+b} \end{aligned}$$

Where $f(x) = -\frac{2a}{ax+b}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned} \frac{1}{u}\,du &= -\frac{2a}{ax+b}\,dx \\ \int \frac{1}{u}\,du &= \int -\frac{2a}{ax+b}\,dx \\ \ln(u) &= -2\ln(ax+b) + c_1 \\ u &= \mathrm{e}^{-2\ln(ax+b)+c_1} \\ &= \frac{c_1}{(ax+b)^2} \end{aligned}$$

Now that $u(x)$ is known, then

$$
\begin{aligned}
v'(x) &= u(x) \\
v(x) &= \int u(x)\,dx + c_2 \\
&= -\frac{c_1}{(ax+b)\,a} + c_2
\end{aligned}
$$

Hence

$$
\begin{aligned}
y &= v(x)\,x^n \\
&= \left(-\frac{c_1}{(ax+b)\,a} + c_2\right)x^2 \\
&= \left(-\frac{c_1}{(ax+b)\,a} + c_2\right)x^2
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \left(-\frac{c_1}{(ax+b)\,a} + c_2\right)x^2 \tag{1}
$$

Verification of solutions

$$
y = \left(-\frac{c_1}{(ax+b)\,a} + c_2\right)x^2
$$

Verified OK.

31.11.3 Solving using Kovacic algorithm

Writing the ode as

$$
x^2(ax+b)\,y'' + \left(-2a\,x^2 - 4bx\right)y' + (2ax+6b)\,y = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^2(ax+b) \\
B &= -2a\,x^2 - 4bx \\
C &= 2ax+6b
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 0 \\ t &= 1 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 180: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 0 - -\infty \\
&= \infty
\end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-2a\,x^2-4bx}{x^2(ax+b)}\,dx} \\
&= z_1 e^{2\ln(x)-\ln(ax+b)} \\
&= z_1\left(\frac{x^2}{ax+b}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^2}{ax+b}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-2a\,x^2-4bx}{x^2(ax+b)}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{4\ln(x)-2\ln(ax+b)}}{(y_1)^2}\,dx \\
&= y_1(x)
\end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\frac{x^2}{ax+b}\right) + c_2\left(\frac{x^2}{ax+b}(x)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 x^2}{ax+b} + \frac{c_2 x^3}{ax+b} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 x^2}{ax+b} + \frac{c_2 x^3}{ax+b}
$$

Verified OK.

31.11.4 Maple step by step solution

Let's solve

$x^2(ax+b)\,y'' + (-2a\,x^2 - 4bx)\,y' + (2ax+6b)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{2(ax+3b)y}{x^2(ax+b)} + \frac{2(ax+2b)y'}{x(ax+b)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{2(ax+2b)y'}{x(ax+b)} + \frac{2(ax+3b)y}{x^2(ax+b)} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = -\frac{2(ax+2b)}{(ax+b)x}, P_3(x) = \frac{2(ax+3b)}{x^2(ax+b)}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $\left.(x \cdot P_2(x))\right|_{x=0} = -4$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

$$\left(x^{2} \cdot P_{3}(x)\right)\bigg|_{x=0} = 6$$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^{2}(ax+b)\,y'' - 2x(ax+2b)\,y' + (2ax+6b)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $x^m \cdot y$ to series expansion for $m = 0..1$

    $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

  - Shift index using $k- >k-m$

    $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

  - Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

    $x^m \cdot y' = \sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$

  - Shift index using $k- >k+1-m$

    $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$

  - Convert $x^m \cdot y''$ to series expansion for $m = 2..3$

    $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

  - Shift index using $k- >k+2-m$

    $x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $b a_0(-2+r)\,(-3+r)\,x^r + \left(\sum_{k=1}^{\infty} \left(b a_k(k+r-2)\,(k+r-3) + a a_{k-1}(k+r-2)\,(k+r-3)\right) x^{k+r}\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$b(-2+r)(-3+r) = 0$

- Values of r that satisfy the indicial equation

  $r \in \{2, 3\}$

- Each term in the series must be 0, giving the recursion relation

  $(k+r-2)(k+r-3)(a a_{k-1} + a_k b) = 0$

- Shift index using $k- > k+1$

  $(k+r-1)(k+r-2)(a_k a + b a_{k+1}) = 0$

- Recursion relation that defines series solution to ODE

  $a_{k+1} = -\frac{a a_k}{b}$

- Recursion relation for $r = 2$

  $a_{k+1} = -\frac{a a_k}{b}$

- Solution for $r = 2$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+2}, a_{k+1} = -\frac{a a_k}{b}\right]$

- Recursion relation for $r = 3$

  $a_{k+1} = -\frac{a a_k}{b}$

- Solution for $r = 3$

  $\left[y = \sum_{k=0}^{\infty} a_k x^{k+3}, a_{k+1} = -\frac{a a_k}{b}\right]$

- Combine solutions and rename parameters

  $\left[y = \left(\sum_{k=0}^{\infty} c_k x^{k+2}\right) + \left(\sum_{k=0}^{\infty} d_k x^{k+3}\right), c_{1+k} = -\frac{a c_k}{b}, d_{1+k} = -\frac{a d_k}{b}\right]$

Problem number: 193.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$x^2(ax+b)\,y'' + \left(a(2-m-n)\,x^2 - b(m+n)\,x\right)y' + \left(am(n-1)\,x + bn(m+1)\right)y = 0$$

31.12.1 Solving using Kovacic algorithm

Writing the ode as

$$x^2(ax+b)\,y'' - x(a(m+n-2)\,x + (m+n)\,b)\,y' + (((ax+b)\,n - ax)\,m + nb)\,y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^2(ax+b) \\ B &= -x(a(m+n-2)\,x + (m+n)\,b) \\ C &= ((ax+b)\,n - ax)\,m + nb \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{m^2 - 2nm + n^2 + 2m - 2n}{4x^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= m^2 - 2nm + n^2 + 2m - 2n \\ t &= 4x^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{m^2 - 2nm + n^2 + 2m - 2n}{4x^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 182: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 2 - 0 \\
&= 2
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^2$. There is a pole at $x = 0$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = \frac{\frac{1}{4}m^2 - \frac{1}{2}nm + \frac{1}{4}n^2 + \frac{1}{2}m - \frac{1}{2}n}{x^2}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{(m-n+2)(m-n)}{4}$. Hence

$$
\begin{aligned}
E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\
&= \left\{2, 2 - 2\sqrt{(-m - 1 + n)^2}, 2 + 2\sqrt{(-m - 1 + n)^2}\right\}
\end{aligned}
$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$
r = \frac{s}{t} = \frac{m^2 - 2nm + n^2 + 2m - 2n}{4x^2}
$$

Since the $\gcd(s, t) = 1$. This gives $b = \frac{1}{4}$. Hence

$$
\begin{aligned}
E_\infty &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\
&= \{2\}
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\left\{2, 2-2\sqrt{(-m-1+n)^2}, 2+2\sqrt{(-m-1+n)^2}\right\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(2-(2)) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{2}{(x-(0))}\right) \\ &= \frac{1}{x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \frac{w}{x} - \frac{(m-n+2)(m-n)}{4x^2} = 0$$

Solving for ω gives

$$\omega = -\frac{m-n}{2x}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= e^{\int -\frac{m-n}{2x} dx} \\ &= x^{-\frac{m}{2}+\frac{n}{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{-x(a(m+n-2)x+(m+n)b)}{x^2(ax+b)} \, dx} \\ &= z_1 e^{\frac{(m+n)\ln(x)}{2} - \ln(ax+b)} \\ &= z_1 \left(\frac{x^{\frac{m}{2}+\frac{n}{2}}}{ax+b}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \frac{x^n}{ax+b}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$y_2 = y_1 \int \frac{e^{\int -\frac{-x(a(m+n-2)x+(m+n)b)}{x^2(ax+b)}dx}}{(y_1)^2} dx$$

$$= y_1 \int \frac{e^{-2\ln(ax+b)+(m+n)\ln(x)}}{(y_1)^2} dx$$

$$= y_1 \left(\frac{x^{m+1-n}}{m+1-n}\right)$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$
$$= c_1 \left(\frac{x^n}{ax+b}\right) + c_2 \left(\frac{x^n}{ax+b}\left(\frac{x^{m+1-n}}{m+1-n}\right)\right)$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 x^n}{ax+b} + \frac{c_2 x^{m+1}}{(m+1-n)(ax+b)} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 x^n}{ax+b} + \frac{c_2 x^{m+1}}{(m+1-n)(ax+b)}$$

Verified OK.

31.12.2 Maple step by step solution

Let's solve

$x^2(ax+b)y'' - x(a(m+n-2)x+(m+n)b)y' + (((ax+b)n-ax)m+nb)y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(axmn-axm+nbm+nb)y}{x^2(ax+b)} + \frac{(axm+anx-2ax+bm+nb)y'}{(ax+b)x}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

$y'' - \frac{(axm+anx-2ax+bm+nb)y'}{(ax+b)x} + \frac{(axmn-axm+nbm+nb)y}{x^2(ax+b)} = 0$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x) = -\frac{axm+anx-2ax+bm+nb}{(ax+b)x}, P_3(x) = \frac{axmn-axm+nbm+nb}{x^2(ax+b)}\right]$

- $x \cdot P_2(x)$ is analytic at $x = 0$

  $(x \cdot P_2(x))\bigg|_{x=0} = -\frac{bm+nb}{b}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{nbm+nb}{b}$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $x^2(ax+b)\,y'' - (axm+anx-2ax+bm+nb)\,y'x + (axmn-axm+nbm+nb)\,y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m \cdot y$ to series expansion for $m = 0..1$

  $x^m \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k- >k-m$

  $x^m \cdot y = \sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 1..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k+r)\, x^{k+r-1+m}$

- Shift index using $k- >k+1-m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m} (k+1-m+r)\, x^{k+r}$

- Convert $x^m \cdot y''$ to series expansion for $m = 2..3$

$$x^m \cdot y'' = \sum_{k=0}^{\infty} a_k (k+r)(k+r-1)\, x^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$x^m \cdot y'' = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, x^{k+r}$$

Rewrite ODE with series expansions

$$b a_0(-n+r)(-m+r-1)\, x^r + \left(\sum_{k=1}^{\infty} (b a_k(k-n+r)(k-m+r-1) + a a_{k-1}(k-n+r)(k-n$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$b(-n+r)(-m+r-1) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{n, m+1\}$$

- Each term in the series must be 0, giving the recursion relation

$$(k-n+r)(k-m+r-1)(a a_{k-1} + b a_k) = 0$$

- Shift index using $k- >k+1$

$$(k-n+r+1)(k-m+r)(a a_k + b a_{k+1}) = 0$$

- Recursion relation that defines series solution to ODE

$$a_{k+1} = -\frac{a a_k}{b}$$

- Recursion relation for $r = n$

$$a_{k+1} = -\frac{a a_k}{b}$$

- Solution for $r = n$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+n}, a_{k+1} = -\frac{a a_k}{b}\right]$$

- Recursion relation for $r = m+1$

$$a_{k+1} = -\frac{a a_k}{b}$$

- Solution for $r = m+1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+m+1}, a_{k+1} = -\frac{a a_k}{b}\right]$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^{k+n}\right) + \left(\sum_{k=0}^{\infty} d_k x^{k+m+1}\right), c_{1+k} = -\frac{a c_k}{b}, d_{1+k} = -\frac{a d_k}{b}\right]$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-6 Equation of form $(a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 195.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\left(a\,x^3+b\,x^2+cx\right)y''+\left(\alpha\,x^2+\beta x+2c\right)y'+\left(\beta-2b\right)y=0$$

31.14.1 Maple step by step solution

Let's solve

$y''x(a\,x^2+bx+c)+\left(\alpha\,x^2+\beta x+2c\right)y'+\left(\beta-2b\right)y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=\frac{(-\beta+2b)y}{x(a\,x^2+bx+c)}-\frac{(\alpha\,x^2+\beta x+2c)y'}{x(a\,x^2+bx+c)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(\alpha\,x^2+\beta x+2c)y'}{x(a\,x^2+bx+c)}-\frac{(-\beta+2b)y}{x(a\,x^2+bx+c)}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$$\left[P_2(x)=\frac{\alpha x^2+\beta x+2c}{x(a x^2+bx+c)}, P_3(x)=-\frac{-\beta+2b}{x(a x^2+bx+c)}\right]$$

- $x\cdot P_2(x)$ is analytic at $x=0$

  $$\left(x\cdot P_2(x)\right)\Big|_{x=0}=2$$

- $x^2\cdot P_3(x)$ is analytic at $x=0$

  $$\left(x^2\cdot P_3(x)\right)\Big|_{x=0}=0$$

- $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $$y''x(a x^2+bx+c)+(\alpha x^2+\beta x+2c)\,y'+(\beta-2b)\,y=0$$

- Assume series solution for y

  $$y=\sum_{k=0}^{\infty} a_k x^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y'$ to series expansion for $m=0..2$

  $$x^m\cdot y'=\sum_{k=0}^{\infty} a_k(k+r)\,x^{k+r-1+m}$$

- Shift index using $k->k+1-m$

  $$x^m\cdot y'=\sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,x^{k+r}$$

- Convert $x^m\cdot y''$ to series expansion for $m=1..3$

  $$x^m\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$x^m\cdot y''=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$ca_0r(r+1)\,x^{r-1}+\left(ca_1(r+1)\,(2+r)+a_0(r+1)\,(br-2b+\beta)\right)x^r+\left(\sum_{k=1}^{\infty}\left(ca_{k+1}(k+r+1)\,(k\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$cr(r+1) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \{-1, 0\}$$

- Each term must be 0

$$ca_1(r+1)(2+r) + a_0(r+1)(br - 2b + \beta) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$ca_{k+1}(k+r+1)(k+2+r) + ((k+r-2)b+\beta)(k+r+1)a_k + ((k+r-2)a+\alpha)(k+r-1$$

- Shift index using $k- >k+1$

$$ca_{k+2}(k+2+r)(k+3+r) + ((k+r-1)b+\beta)(k+2+r)a_{k+1} + ((k+r-1)a+\alpha)(k+r)$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a\,k^2 a_k + 2akra_k + a\,r^2 a_k + b\,k^2 a_{k+1} + 2bkra_{k+1} + b\,r^2 a_{k+1} - aka_k - ara_k + a_k\alpha k + a_k\alpha r + bka_{k+1} + bra_{k+1} + \beta ka_{k+1} + \beta ra_{k+}}{c(k+2+r)(k+3+r)}$$

- Recursion relation for $r = -1$

$$a_{k+2} = -\frac{a\,k^2 a_k + b\,k^2 a_{k+1} - 3aka_k + a_k\alpha k - bka_{k+1} + \beta ka_{k+1} + 2aa_k - a_k\alpha - 2ba_{k+1} + \beta a_{k+1}}{c(k+1)(k+2)}$$

- Solution for $r = -1$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k-1}, a_{k+2} = -\frac{a\,k^2 a_k + b\,k^2 a_{k+1} - 3aka_k + a_k\alpha k - bka_{k+1} + \beta ka_{k+1} + 2aa_k - a_k\alpha - 2ba_{k+1} + \beta a_{k+1}}{c(k+1)(k+2)}, 0 = 0\right]$$

- Recursion relation for $r = 0$

$$a_{k+2} = -\frac{a\,k^2 a_k + b\,k^2 a_{k+1} - aka_k + a_k\alpha k + bka_{k+1} + \beta ka_{k+1} - 2ba_{k+1} + 2\beta a_{k+1}}{c(k+2)(k+3)}$$

- Solution for $r = 0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a\,k^2 a_k + b\,k^2 a_{k+1} - aka_k + a_k\alpha k + bka_{k+1} + \beta ka_{k+1} - 2ba_{k+1} + 2\beta a_{k+1}}{c(k+2)(k+3)}, 2ca_1 + a_0(\beta - 2b) =\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} d_k x^{k-1}\right) + \left(\sum_{k=0}^{\infty} e_k x^k\right), d_{k+2} = -\frac{a\,k^2 d_k + b\,k^2 d_{1+k} - 3akd_k + \alpha kd_k - bkd_{1+k} + \beta kd_{1+k} + 2ad_k - \alpha d_k - 2bd_{1+}}{c(1+k)(k+2)}\right.$$

$$a_1(1+r)(cr+k) + a_0(r-2)(br-1) = 0$$

- Each term in the series must be 0, giving the recursion relation

$$a_{k+1}(k+1+r)((k+r)c+k) + (k+r-2)\, a_k(-1+(k+r)b) + a a_{k-1}(k+r-2)(k-3+r) =$$

- Shift index using $k->k+1$

$$a_{k+2}(k+2+r)((k+1+r)c+k) + (k+r-1)\, a_{k+1}(-1+(k+1+r)b) + a a_k(k+r-1)(k+$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{a\,k^2 a_k + 2akra_k + a\,r^2 a_k + b\,k^2 a_{k+1} + 2bkra_{k+1} + b\,r^2 a_{k+1} - 3aka_k - 3ara_k + 2a_k a - ba_{k+1} - ka_{k+1} - ra_{k+1} + a_{k+1}}{(k+2+r)(ck+cr+c+k)}$$

- Recursion relation for $r=0$; series terminates at $k=1$

$$a_{k+2} = -\frac{a\,k^2 a_k + b\,k^2 a_{k+1} - 3aka_k + 2a_k a - ba_{k+1} - ka_{k+1} + a_{k+1}}{(k+2)(ck+c+k)}$$

- Solution for $r=0$

$$\left[y = \sum_{k=0}^{\infty} a_k x^k, a_{k+2} = -\frac{a\,k^2 a_k + b\,k^2 a_{k+1} - 3aka_k + 2a_k a - ba_{k+1} - ka_{k+1} + a_{k+1}}{(k+2)(ck+c+k)}, a_1 k + 2a_0 = 0\right]$$

- Recursion relation for $r = \frac{c-k}{c}$

$$a_{k+2} = -\frac{a\,k^2 a_k + \frac{2ak(c-k)a_k}{c} + \frac{a(c-k)^2 a_k}{c^2} + b\,k^2 a_{k+1} + \frac{2bk(c-k)a_{k+1}}{c} + \frac{b(c-k)^2 a_{k+1}}{c^2} - 3aka_k - \frac{3a(c-k)a_k}{c} + 2a_k a - ba_{k+1} - ka_{k+1} - \frac{(}{}}{\left(k+2+\frac{c-k}{c}\right)(ck+2c)}$$

- Solution for $r = \frac{c-k}{c}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{c-k}{c}}, a_{k+2} = -\frac{a\,k^2 a_k + \frac{2ak(c-k)a_k}{c} + \frac{a(c-k)^2 a_k}{c^2} + b\,k^2 a_{k+1} + \frac{2bk(c-k)a_{k+1}}{c} + \frac{b(c-k)^2 a_{k+1}}{c^2} - 3aka_k - \frac{3a(c-k)a_k}{c}}{\left(k+2+\frac{c-k}{c}\right)(ck+2c)}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{m=0}^{\infty} d_m x^m\right) + \left(\sum_{m=0}^{\infty} e_m x^{m+\frac{c-k}{c}}\right), d_{m+2} = -\frac{a\,m^2 d_m + b\,m^2 d_{m+1} - 3amd_m + 2ad_m - bd_{m+1} - md_{m+1} + d_{m+1}}{(m+2)(cm+c+k)}\right.$$

$$\boxed{2y''x\left(a\,x^2+bx+c\right)+\left(a\,x^2-c\right)y'+\lambda\,x^2y=0}$$

31.21.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(2a\,x^3+2b\,x^2+2cx\right)y''+\left(a\,x^2-c\right)y'+\lambda\,x^2y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{a\,x^2-c}{2a\,x^3+2b\,x^2+2cx} \\ q(x) &= \frac{\lambda x}{2a\,x^2+2bx+2c} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{a\,x^2-c}{2a\,x^3+2b\,x^2+2cx}dx\right)} dx \\
&= \int e^{\frac{\ln(x)}{2}-\frac{\ln\left(a\,x^2+bx+c\right)}{2}} dx \\
&= \int \frac{\sqrt{x}}{\sqrt{a\,x^2+bx+c}} dx \\
&= -\frac{\left(b+\sqrt{-4ac+b^2}\right)\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\sqrt{\frac{-2ax+\sqrt{-4ac+b^2}-b}{\sqrt{-4ac+b^2}}}\sqrt{-\frac{ax}{b+\sqrt{-4ac+b^2}}}\left(2\sqrt{-4ac+b^2}\ \mathrm{EllipticE}\left(\right.\right.}{}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{\lambda x}{2a\,x^2+2bx+2c}}{\frac{x}{a\,x^2+bx+c}} \\
&= \frac{\lambda}{2}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{\lambda y(\tau)}{2} &= 0
\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = \frac{\lambda}{2}$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda\tau} + \frac{\lambda\, e^{\lambda\tau}}{2} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + \frac{\lambda}{2} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \frac{\lambda}{2}$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\left(\frac{\lambda}{2}\right)}\\
&= \pm\frac{\sqrt{-2\lambda}}{2}
\end{aligned}$$

Hence

$$\lambda_1 = +\frac{\sqrt{-2\lambda}}{2}$$
$$\lambda_2 = -\frac{\sqrt{-2\lambda}}{2}$$

Which simplifies to

$$\lambda_1 = \frac{\sqrt{2}\,\sqrt{-\lambda}}{2}$$
$$\lambda_2 = -\frac{\sqrt{2}\,\sqrt{-\lambda}}{2}$$

Since roots are real and distinct, then the solution is

$$y(\tau) = c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau}$$
$$y(\tau) = c_1 e^{\left(\frac{\sqrt{2}\,\sqrt{-\lambda}}{2}\right)\tau} + c_2 e^{\left(-\frac{\sqrt{2}\,\sqrt{-\lambda}}{2}\right)\tau}$$

Or

$$
y(\tau) = c_1 \mathrm{e}^{\frac{\sqrt{2}\,\sqrt{-\lambda}\,\tau}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{2}\,\sqrt{-\lambda}\,\tau}{2}}
$$

The above solution is now transformed back to y using (6) which results in

$$
y = c_1 \mathrm{e}^{-\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b \cdots}}{2(\cdots}\right.\right. \cdots}{2\sqrt{a\,x^2+bx+c}\,\sqrt{x}\,a^2 \cdots}}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 \mathrm{e}^{-\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2 \cdots}}{2(-4a \cdots}\right.\right. \cdots}{2\sqrt{a\,x^2+bx+c}\,\sqrt{x}\,a^2 \cdots}} \\
&\quad + c_2 \mathrm{e}^{\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+ \cdots}}{2(- \cdots}\right.\right. \cdots}{2\sqrt{a\,x^2+bx+c}\,\sqrt{x}\,a^2 \cdots}}
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 \mathrm{e}^{-\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2 \cdots}}{2(-4a \cdots}\right.\right. \cdots}{2\sqrt{a\,x^2+bx+c}\,\sqrt{x}\,a^2 \cdots}} \\
&\quad + c_2 \mathrm{e}^{\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\sqrt{2b+ \cdots}}{2(- \cdots}\right.\right. \cdots}{2\sqrt{a\,x^2+bx+c}\,\sqrt{x}\,a^2 \cdots}}
\end{aligned}
$$

Verified OK.

31.21.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(2a\,x^{3}+2b\,x^{2}+2cx\right) y''+\left(a\,x^{2}-c\right) y'+\lambda\,x^{2} y = 0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{a\,x^{2}-c}{2x\left(a\,x^{2}+bx+c\right)}\\ q(x) &= \frac{\lambda x}{2a\,x^{2}+2bx+2c} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^{2}}{d\tau^{2}}y(\tau)+p_{1}\left(\frac{d}{d\tau}y(\tau)\right)+q_{1}y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_{1}(\tau) = \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'\left(x\right)^{2}} \tag{4}$$

$$q_{1}(\tau) = \frac{q(x)}{\tau'\left(x\right)^{2}} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q}\\ &= \frac{\sqrt{\frac{\lambda x}{2a\,x^{2}+2bx+2c}}}{c} \\ \tau'' &= \frac{\frac{\lambda}{2a\,x^{2}+2bx+2c}-\frac{\lambda x(4ax+2b)}{\left(2a\,x^{2}+2bx+2c\right)^{2}}}{2c\sqrt{\frac{\lambda x}{2a\,x^{2}+2bx+2c}}} \end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned} p_{1}(\tau) &= \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'\left(x\right)^{2}}\\ &= \frac{\frac{\frac{\lambda}{2a\,x^{2}+2bx+2c}-\frac{\lambda x(4ax+2b)}{\left(2a\,x^{2}+2bx+2c\right)^{2}}}{2c\sqrt{\frac{\lambda x}{2a\,x^{2}+2bx+2c}}}+\frac{a\,x^{2}-c}{2x(a\,x^{2}+bx+c)}\frac{\sqrt{\frac{\lambda x}{2a\,x^{2}+2bx+2c}}}{c}}{\left(\frac{\sqrt{\frac{\lambda x}{2a\,x^{2}+2bx+2c}}}{c}\right)^{2}}\\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned} y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\ \frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0 \end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c} \sqrt{q}\, dx \\ &= \frac{\int \sqrt{\frac{\lambda x}{2a\,x^2+2bx+2c}} dx}{c} \\ &= -\frac{\sqrt{\frac{\lambda x}{a\,x^2+bx+c}} \left(a\,x^2+bx+c\right) \left(b+\sqrt{-4ac+b^2}\right) \sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}} \sqrt{\frac{-2ax+\sqrt{-4ac+b^2}-b}{\sqrt{-4ac+b^2}}} \sqrt{-\frac{2ax}{b+\sqrt{-4ac+b^2}}} \Bigg(}{} \end{aligned}$$

Substituting the above into the solution obtained gives

$$\begin{aligned} y &= c_1 \cos\left(\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}} \left(\frac{\left(b-\sqrt{-4ac+b^2}\right) \operatorname{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2} + \sqrt{-4ac+b^2}\, \operatorname{EllipticE}\right.}{2\sqrt{a\,x^2}}\right. \\ &\quad - c_2 \sin\left(\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}} \left(\frac{\left(b-\sqrt{-4ac+b^2}\right) \operatorname{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2} + \sqrt{-4ac+b^2}\, \operatorname{Elliptic}\right.}{2\sqrt{a\,x}}\right. \end{aligned}$$

Summary

The solution(s) found are the following

$$
y = c_1 \cos\left(\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\operatorname{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2} + \sqrt{-4ac+b^2}\ \operatorname{EllipticE}\cdots}{2\sqrt{a\,x^2 \cdots}}\right) - c_2 \sin\left(\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\operatorname{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2} + \sqrt{-4ac+b^2}\ \operatorname{Elliptic}\cdots}{2\sqrt{a\,x \cdots}}\right) \tag{1}
$$

Verification of solutions

$$
y = c_1 \cos\left(\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\operatorname{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2} + \sqrt{-4ac+b^2}\ \operatorname{EllipticE}\cdots}{2\sqrt{a\,x^2 \cdots}}\right) - c_2 \sin\left(\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\operatorname{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\sqrt{2b+2\sqrt{-4ac+b^2}}}{2\left(-4ac+b^2\right)^{\frac{1}{4}}}\right)}{2} + \sqrt{-4ac+b^2}\ \operatorname{Elliptic}\cdots}{2\sqrt{a\,x \cdots}}\right)
$$

Warning, solution could not be verified

31.21.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(2a\,x^3+2b\,x^2+2cx\right)y''+\left(a\,x^2-c\right)y'+\lambda\,x^2y=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A&=2a\,x^3+2b\,x^2+2cx\\B&=a\,x^2-c\\C&=\lambda\,x^2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned}r&=\frac{s}{t}\\&=\frac{2AB'-2BA'+B^2-4AC}{4A^2}\end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{-8a\lambda\,x^5-3a^2x^4-8b\lambda\,x^4-8c\lambda\,x^3+14ac\,x^2+8bcx+5c^2}{16\left(a\,x^3+b\,x^2+cx\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned}s&=-8a\lambda\,x^5-3a^2x^4-8b\lambda\,x^4-8c\lambda\,x^3+14ac\,x^2+8bcx+5c^2\\t&=16\left(a\,x^3+b\,x^2+cx\right)^2\end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{-8a\lambda\,x^5-3a^2x^4-8b\lambda\,x^4-8c\lambda\,x^3+14ac\,x^2+8bcx+5c^2}{16\left(a\,x^3+b\,x^2+cx\right)^2}\right)z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y=z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 188: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 6 - 5 \\
&= 1
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 16(a\,x^3 + b\,x^2 + cx)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = -\frac{b-\sqrt{-4ac+b^2}}{2a}$ of order 2. There is a pole at $x = -\frac{b+\sqrt{-4ac+b^2}}{2a}$ of order 2. Since there is a pole of order 2 then necessary conditions for case two are met. Therefore

$$
L = [2]
$$

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{\frac{\left(-b+\sqrt{-4ac+b^2}\right)^3 b}{4a} - \frac{\left(-b+\sqrt{-4ac+b^2}\right)^3 c\lambda}{a^2} - 2\left(-b+\sqrt{-4ac+b^2}\right)^2 c + \frac{\left(-b+\sqrt{-4ac+b^2}\right)^2 b^2}{a} - \frac{2\left(-b+\sqrt{-4ac+b^2}\right)^2 bc\lambda}{a^2} \cdots}{16c\left(-4ac+b^2\right)\left(x - \frac{-b+\sqrt{-4ac \cdots}}{2a}\right.}$$

$$+ \frac{-\frac{\left(b+\sqrt{-4ac+b^2}\right)^3 b}{4a} + \frac{\left(b+\sqrt{-4ac+b^2}\right)^3 c\lambda}{a^2} - 2\left(b+\sqrt{-4ac+b^2}\right)^2 c + \frac{\left(b+\sqrt{-4ac+b^2}\right)^2 b^2}{a} - \frac{2\left(b+\sqrt{-4ac+b^2}\right)^2 bc\lambda}{a^2} + 3 \cdots}{16c\left(-4ac+b^2\right)\left(x + \frac{b+\sqrt{-4ac+b^2}}{2a}\right.}$$

$$+ \frac{\frac{\left(-b+\sqrt{-4ac+b^2}\right)^3 b}{2} - \frac{2\left(-b+\sqrt{-4ac+b^2}\right)^3 c\lambda}{a} - 2a\left(-b+\sqrt{-4ac+b^2}\right)^2 c + \frac{7\left(-b+\sqrt{-4ac+b^2}\right)^2 b^2}{4} - \frac{5\left(-b+\sqrt{-4ac+b^2}\right. \cdots}{a}}{8c\left(-4ac+b^2 \cdots\right.}$$

$$- \frac{-\frac{\left(b+\sqrt{-4ac+b^2}\right)^3 b}{2} + \frac{2\left(b+\sqrt{-4ac+b^2}\right)^3 c\lambda}{a} - 2\left(b+\sqrt{-4ac+b^2}\right)^2 ac + \frac{7\left(b+\sqrt{-4ac+b^2}\right)^2 b^2}{4} - \frac{5\left(b+\sqrt{-4ac+b^2}\right)^2 bc\lambda}{a} \cdots}{8c\left(-4ac+b^2\right)^{\frac{3}{2}}\left(\cdots\right.}$$

$$+ \frac{5}{16x^2} - \frac{b}{8cx}$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{5}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{-1, 2, 5\} \end{aligned}$$

For the pole at $x = -\frac{b-\sqrt{-4ac+b^2}}{2a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b-\sqrt{-4ac+b^2}}{2a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -\frac{b+\sqrt{-4ac+b^2}}{2a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b+\sqrt{-4ac+b^2}}{2a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is $1 < 2$ then

$$E_\infty = \{1\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
0	2	$\{-1, 2, 5\}$
$-\frac{b-\sqrt{-4ac+b^2}}{2a}$	2	$\{1, 2, 3\}$
$-\frac{b+\sqrt{-4ac+b^2}}{2a}$	2	$\{1, 2, 3\}$

Order of r at ∞	E_∞
1	$\{1\}$

Using the family $\{e_1, e_2, \ldots, e_\infty\}$ given by

$$e_1 = -1,\ e_2 = 1,\ e_3 = 1,\ e_\infty = 1$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(1 - (-1 + (1) + (1))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{-1}{(x-(0))} + \frac{1}{\left(x - \left(-\frac{b-\sqrt{-4ac+b^2}}{2a}\right)\right)} + \frac{1}{\left(x - \left(-\frac{b+\sqrt{-4ac+b^2}}{2a}\right)\right)}\right) \\ &= -\frac{1}{2x} + \frac{1}{2x + \frac{b-\sqrt{-4ac+b^2}}{a}} + \frac{1}{2x + \frac{b+\sqrt{-4ac+b^2}}{a}} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= -\frac{1}{2x} + \frac{1}{2x + \frac{b-\sqrt{-4ac+b^2}}{a}} + \frac{1}{2x + \frac{b+\sqrt{-4ac+b^2}}{a}}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(-\frac{1}{2x} + \frac{1}{2x + \frac{b-\sqrt{-4ac+b^2}}{a}} + \frac{1}{2x + \frac{b+\sqrt{-4ac+b^2}}{a}}\right) w + \frac{\left(8a\lambda\, x^5 + (a^2 + 8b\lambda)\, x^4 + 8c\lambda\, x^3 - 2ac\, x^2 + c^2\right) a^2}{x^2 \left(2ax + b - \sqrt{-4ac+b^2}\right)^2 \left(2ax + \sqrt{-4ac+b^2} + b\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{a\,x^2 + 2x\sqrt{2}\,\sqrt{-\lambda x\,(a\,x^2 + bx + c)} - c}{4x\,(a\,x^2 + bx + c)}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\, dx} \\ &= \mathrm{e}^{\int \frac{a\,x^2 + 2x\sqrt{2}\,\sqrt{-\lambda x\left(a\,x^2+bx+c\right)} - c}{4x\left(a\,x^2+bx+c\right)} dx} \\ &= \frac{(a\,x^2 + bx + c)^{\frac{1}{4}}\, \mathrm{e}^{\frac{\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}\,\sqrt{2}\,\sqrt{-\frac{ax}{b+\sqrt{-4ac+b^2}}}\,\lambda\sqrt{\frac{-2ax+\sqrt{-4ac+b^2}-b}{\sqrt{-4ac+b^2}}}\,\left(b+\sqrt{-4ac+b^2}\right)\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2a \cdots}{}}\right.}{\cdots}\right.}{2\sqrt{-\lambda x\left(a\,x^2+bx \cdots\right)}}}}{x^{\frac{1}{4}}}\end{aligned}$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{a\,x^2-c}{2a\,x^3+2b\,x^2+2cx}\,dx} \\
&= z_1 e^{\frac{\ln(x)}{4}-\frac{\ln\left(a\,x^2+bx+c\right)}{4}} \\
&= z_1\left(\frac{x^{\frac{1}{4}}}{(a\,x^2+bx+c)^{\frac{1}{4}}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}}\sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\frac{\left(-\left(4ac-b^2\right)^{\cdots}\right.}{\cdots}\right.\right.}{a^2}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{a\,x^2-c}{2a\,x^3+2b\,x^2+2cx}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{\ln(x)}{2}-\frac{\ln\left(a\,x^2+bx+c\right)}{2}}}{(y_1)^2}\,dx
\end{aligned}
$$

$$= y_1 \left(\int \frac{\sqrt{x}\, \mathrm{e}^{-\frac{2\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right) \mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}} \sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2} + \sqrt{-4ac+b^2}\, \mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4a \cdots}}{b+\sqrt{-4a \cdots}}} \cdots \right)\right)}{a^2}}}{\sqrt{a\, x^2+bx+c}} \cdots \right.$$

Therefore the solution is

$$y = c_1 y_1 + c_2 y_2$$

$$= c_1 \left(\mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right) \mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}} \sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2} + \sqrt{-4ac+b^2}\, \mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\, \frac{\left(-\left(4 \cdots\right.\right.}{\cdots} \cdots \right)\right)}{a^2}} \cdots \right.$$

$$+ c_2 \left(\mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right) \mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}} \sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2} + \sqrt{-4ac+b^2}\, \mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}},\, \frac{\left(\cdots\right.}{\cdots} \cdots \right)\right)}{a^2}} \cdots \right.$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}}\sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2}+\sqrt{-4ac+b^2}\;\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4ac-b\right.\right.}{}\right.\right.}{a^2}} + c_2 \mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}}\sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2}+\sqrt{-4ac+b^2}\;\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4a\right.\right.}{}\right.\right.}{a^2}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}}\sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4ac-b\right.\right.}{}\right.}{a^2}} + c_2 \mathrm{e}^{\frac{\sqrt{2}\left(\frac{\left(b-\sqrt{-4ac+b^2}\right)\mathrm{EllipticF}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4ac-b^2\right)^3\right)^{\frac{1}{4}}\sqrt{2b+2\sqrt{-4ac+b^2}}}{8ac-2b^2}\right)}{2}+\sqrt{-4ac+b^2}\,\mathrm{EllipticE}\left(\sqrt{\frac{2ax+\sqrt{-4ac+b^2}+b}{b+\sqrt{-4ac+b^2}}}, \frac{\left(-\left(4a\right.\right.}{}\right.}{a^2}}$$

Verified OK.

31.21.4 Maple step by step solution

Let's solve

$(2a\,x^3+2b\,x^2+2cx)\,y''+(a\,x^2-c)\,y'+\lambda\,x^2y=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{\lambda xy}{2(a\,x^2+bx+c)}-\frac{(a\,x^2-c)y'}{2x(a\,x^2+bx+c)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(a\,x^2-c)y'}{2x(a\,x^2+bx+c)}+\frac{\lambda xy}{2(a\,x^2+bx+c)}=0$

☐ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=\frac{a\,x^2-c}{2x(a\,x^2+bx+c)}, P_3(x)=\frac{\lambda x}{2(a\,x^2+bx+c)}\right]$

  ◦ $x\cdot P_2(x)$ is analytic at $x=0$

$(x \cdot P_2(x))\Big|_{x=0} = -\frac{1}{2}$

- $x^2 \cdot P_3(x)$ is analytic at $x = 0$

  $(x^2 \cdot P_3(x))\Big|_{x=0} = 0$

- $x = 0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = 0$

- Multiply by denominators

  $2y''x(a\,x^2 + bx + c) + (a\,x^2 - c)\,y' + \lambda\,x^2 y = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

- Convert $x^2 \cdot y$ to series expansion

  $x^2 \cdot y = \sum_{k=0}^{\infty} a_k x^{k+r+2}$

- Shift index using $k- > k - 2$

  $x^2 \cdot y = \sum_{k=2}^{\infty} a_{k-2} x^{k+r}$

- Convert $x^m \cdot y'$ to series expansion for $m = 0..2$

  $x^m \cdot y' = \sum_{k=0}^{\infty} a_k (k + r)\, x^{k+r-1+m}$

- Shift index using $k- > k + 1 - m$

  $x^m \cdot y' = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k + 1 - m + r)\, x^{k+r}$

  Check to see if x_0 is a regular singular point

  $x_0 = \frac{\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a-108d\,a^2+36abc-8b^3\right)^{\frac{1}{3}}}{6a} - \frac{2(3ac-b^2)}{3a\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a-\right.}$

- Multiply by denominators

  $(a\,x^3+b\,x^2+cx+d)\,y''+(\lambda^2-x^2)\,y'+(\lambda+x)\,y=0$

- Change variables using $x = u + \frac{\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a-108d\,a^2+36abc-8b^3\right)^{\frac{1}{3}}}{6a} - \frac{}{3a\left(12\sqrt{3}\,\sqrt{\right.}}$

  $\left(\frac{d}{2} - \frac{8uc\,b^2}{\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a-108d\,a^2+36abc-8b^3\right)^{\frac{2}{3}}} + \frac{\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}}{18a} + \frac{u\,b^2}{3a}\right.$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot y(u)$ to series expansion for $m = 0..1$

$$u^m \cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$

- Shift index using $k- >k-m$

$$u^m \cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 0..2$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\, u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

$$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\, u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 0..3$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$0 = 0$$

- Values of r that satisfy the indicial equation

$$r = r$$

- The coefficients of each power of u must be 0

$$\left[\frac{a_0 r\left(240b^2ca-48b^4-48a\,b^4-432a^3c^2-\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a-108d\,a^2+36abc-8b^3\right)^{\frac{4}{3}}-12\left(12\sqrt{3}\,\sqrt{27a^2d^2\cdots\right.\right.}{\cdots}\right.$$

- Each term in the series must be 0, giving the recursion relation

$$-\frac{54\left(\left(-\frac{a_{k-1}(k+r-1)(k-2+r)a^3}{54}+\left(\frac{(k+1+r)\left(ck+cr-\lambda^2\right)a_{k+1}}{54}+\frac{ka_{k-1}}{54}-\frac{a_k\lambda}{54}+\frac{ra_{k-1}}{54}-\frac{a_{k-1}}{27}\right)a^2+\left(-\frac{(k+1+r)\left((k+r)b^2+2c\right)a_{k+1}}{162}-\cdots\right.\right.\right.}{\cdots}$$

- Shift index using $k- >k+1$

$$-\frac{54\left(\left(-\frac{a_k(k+r)(k+r-1)a^3}{54}+\left(\frac{(k+2+r)\left(c(k+1)+cr-\lambda^2\right)a_{k+2}}{54}+\frac{(k+1)a_k}{54}-\frac{a_{k+1}\lambda}{54}+\frac{a_k r}{54}-\frac{a_k}{27}\right)a^2+\left(-\frac{(k+2+r)\left((k+1+r)b^2+2c\right)a_{k+2}}{162}-\right.\right.\right.}{}$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-6 Equation of form $(a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 206.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{2\left(a\,x^3 + b\,x^2 + cx + d\right) y'' + \left(3a\,x^2 + 2bx + c\right) y' + y\lambda = 0}$$

31.25.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$y''\left(2a\,x^3 + 2b\,x^2 + 2cx + 2d\right) + \left(3a\,x^2 + 2bx + c\right) y' + y\lambda = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3a\,x^2 + 2bx + c}{2a\,x^3 + 2b\,x^2 + 2cx + 2d} \\ q(x) &= \frac{\lambda}{2a\,x^3 + 2b\,x^2 + 2cx + 2d} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{3a\,x^2+2bx+c}{2a\,x^3+2b\,x^2+2cx+2d}dx\right)}dx \\
&= \int e^{-\frac{\ln\left(a\,x^3+b\,x^2+cx+d\right)}{2}}\,dx \\
&= \int \frac{1}{\sqrt{a\,x^3+b\,x^2+cx+d}}dx \\
&= \text{Expression too large to display}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}{\frac{1}{a\,x^3+b\,x^2+cx+d}} \\
&= \frac{\lambda}{2}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\begin{aligned}
\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + \frac{\lambda y(\tau)}{2} &= 0
\end{aligned}$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = \frac{\lambda}{2}$. Let the solution be $y(\tau) = e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau} + \frac{\lambda\, \mathrm{e}^{\lambda\tau}}{2} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2 + \frac{\lambda}{2} = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = \frac{\lambda}{2}$ into the above gives

$$\begin{aligned}
\lambda_{1,2} &= \frac{0}{(2)\,(1)} \pm \frac{1}{(2)\,(1)}\sqrt{0^2 - (4)\,(1)\left(\frac{\lambda}{2}\right)} \\
&= \pm\frac{\sqrt{-2\lambda}}{2}
\end{aligned}$$

Hence

$$\begin{aligned}
\lambda_1 &= +\frac{\sqrt{-2\lambda}}{2} \\
\lambda_2 &= -\frac{\sqrt{-2\lambda}}{2}
\end{aligned}$$

Which simplifies to

$$\begin{aligned}
\lambda_1 &= \frac{\sqrt{2}\,\sqrt{-\lambda}}{2} \\
\lambda_2 &= -\frac{\sqrt{2}\,\sqrt{-\lambda}}{2}
\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}
y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau} \\
y(\tau) &= c_1 e^{\left(\frac{\sqrt{2}\,\sqrt{-\lambda}}{2}\right)\tau} + c_2 e^{\left(-\frac{\sqrt{2}\,\sqrt{-\lambda}}{2}\right)\tau}
\end{aligned}$$

Or

$$y(\tau) = c_1 \mathrm{e}^{\frac{\sqrt{2}\,\sqrt{-\lambda}\,\tau}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{2}\,\sqrt{-\lambda}\,\tau}{2}}$$

The above solution is now transformed back to y using (6) which results in

$$y = \text{Expression too large to display}$$

Summary

The solution(s) found are the following

$$\text{Expression too large to display} \tag{1}$$

Verification of solutions

$$\text{Expression too large to display}$$

Warning, solution could not be verified

31.25.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$y''(2a\,x^3 + 2b\,x^2 + 2cx + 2d) + (3a\,x^2 + 2bx + c)\,y' + y\lambda = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{3a\,x^2 + 2bx + c}{2a\,x^3 + 2b\,x^2 + 2cx + 2d} \\ q(x) &= \frac{\lambda}{2a\,x^3 + 2b\,x^2 + 2cx + 2d} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\tau' = \frac{1}{c}\sqrt{q} = \frac{\sqrt{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}}{c} \tag{6}$$
$$\tau'' = -\frac{\lambda(6a\,x^2+4bx+2c)}{2c\sqrt{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}\,(2a\,x^3+2b\,x^2+2cx+2d)^2}$$

Substituting the above into (4) results in

$$\begin{aligned} p_1(\tau) &= \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'(x)^2} \\ &= \frac{-\frac{\lambda(6a\,x^2+4bx+2c)}{2c\sqrt{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}\,(2a\,x^3+2b\,x^2+2cx+2d)^2}+\frac{3a\,x^2+2bx+c}{2a\,x^3+2b\,x^2+2cx+2d}\frac{\sqrt{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}}{c}}{\left(\frac{\sqrt{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}}{c}\right)^2} \\ &= 0 \end{aligned}$$

Therefore ode (3) now becomes

$$y(\tau)''+p_1y(\tau)'+q_1y(\tau)=0$$
$$\frac{d^2}{d\tau^2}y(\tau)+c^2y(\tau)=0 \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau)=c_1\cos(c\tau)+c_2\sin(c\tau)$$

Now from (6)

$$\begin{aligned} \tau &= \int \frac{1}{c}\sqrt{q}\,dx \\ &= \frac{\int \sqrt{\frac{\lambda}{2a\,x^3+2b\,x^2+2cx+2d}}dx}{c} \\ &= \text{Expression too large to display} \end{aligned}$$

Substituting the above into the solution obtained gives

$$y = \text{Expression too large to display}$$

Summary

The solution(s) found are the following

$$\text{Expression too large to display} \tag{1}$$

Verification of solutions

$$\text{Expression too large to display}$$

Warning, solution could not be verified

31.25.3 Maple step by step solution

Let's solve

$y''(2a\,x^3+2b\,x^2+2cx+2d)+(3a\,x^2+2bx+c)\,y'+y\lambda=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{\lambda y}{2(a\,x^3+b\,x^2+cx+d)}-\frac{(3a\,x^2+2bx+c)\,y'}{2(a\,x^3+b\,x^2+cx+d)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{(3a\,x^2+2bx+c)\,y'}{2(a\,x^3+b\,x^2+cx+d)}+\frac{\lambda y}{2(a\,x^3+b\,x^2+cx+d)}=0$

□ Check to see if x_0 is a regular singular point

- ○ Define functions

  $\left[P_2(x)=\frac{3a\,x^2+2bx+c}{2(a\,x^3+b\,x^2+cx+d)},P_3(x)=\frac{\lambda}{2(a\,x^3+b\,x^2+cx+d)}\right]$

- ○ $\left(x-\frac{\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a-108d\,a^2+36abc-8b^3\right)^{\frac{1}{3}}}{6a}+\frac{2(3ac-b^2)}{3a\left(12\sqrt{3}\,\sqrt{27a^2d^2-18abcd+4a\,c^3+4b^3d-c^2b^2}\,a \cdots\right.}\right.$

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^4y'' + ay = 0}$$

32.1.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{ay}{x^2} = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= \sqrt{a} \\
n &= \frac{1}{2} \\
\gamma &= -1
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}}
$$

Verified OK.

32.1.2 Solving using Kovacic algorithm

Writing the ode as

$$
x^4 y'' + ay = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= x^4 \\
B &= 0 \\
C &= a
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a}{x^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a \\ t &= x^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{a}{x^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1, 2\}$,$\{1, 3\}$,$\{2\}$,$\{3\}$,$\{3, 4\}$,$\{1, 2, 5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 195: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

<u>Attempting to find a solution using case $n = 1$.</u>

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_2^v \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = -\frac{a}{x^4}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{i\sqrt{a}}{x^2} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{i\sqrt{a}}{x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = i\sqrt{a}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be 0. Therefore

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{i\sqrt{a}}{x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) &= \frac{1}{2}\left(\frac{0}{i\sqrt{a}} + 2\right) &= 1 \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) &= \frac{1}{2}\left(-\frac{0}{i\sqrt{a}} + 2\right) &= 1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{a}{x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{i\sqrt{a}}{x^2}$	1	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^-\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{i\sqrt{a}}{x^2} + \frac{1}{x} + (-)\,(0) \\
&= -\frac{i\sqrt{a}}{x^2} + \frac{1}{x} \\
&= \frac{-i\sqrt{a} + x}{x^2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right)p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{i\sqrt{a}}{x^2} + \frac{1}{x}\right)(0) + \left(\left(\frac{2i\sqrt{a}}{x^3} - \frac{1}{x^2}\right) + \left(-\frac{i\sqrt{a}}{x^2} + \frac{1}{x}\right)^2 - \left(-\frac{a}{x^4}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega\, dx} \\
&= \mathrm{e}^{\int \left(-\frac{i\sqrt{a}}{x^2} + \frac{1}{x}\right) dx} \\
&= x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}} \end{aligned}$$

Which simplifies to

$$y_1 = x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}} \int \frac{1}{x^2 \mathrm{e}^{\frac{2i\sqrt{a}}{x}}}\,dx \\ &= x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}} \left(-\frac{i\mathrm{e}^{-\frac{2i\sqrt{a}}{x}}}{2\sqrt{a}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1\left(x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}}\right) + c_2\left(x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}}\left(-\frac{i\mathrm{e}^{-\frac{2i\sqrt{a}}{x}}}{2\sqrt{a}}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 x\,\mathrm{e}^{\frac{i\sqrt{a}}{x}} - \frac{i c_2 x\,\mathrm{e}^{-\frac{i\sqrt{a}}{x}}}{2\sqrt{a}} \tag{1}$$

Verification of solutions

$$y = c_1 x \,\mathrm{e}^{\frac{i\sqrt{a}}{x}} - \frac{i c_2 x \,\mathrm{e}^{-\frac{i\sqrt{a}}{x}}}{2\sqrt{a}}$$

Verified OK.

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 212.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^4y'' + \left(a\,x^2 + bx + c\right)y = 0}$$

32.2.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(a + \frac{b}{x} + \frac{c}{x^2}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1\,\mathrm{BesselJ}\left(n, \beta\,x^{\gamma}\right) + c_2\,\mathrm{BesselY}\left(n, \beta\,x^{\gamma}\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = 2$$
$$n = \sqrt{1-4a}$$
$$\gamma = \frac{1}{2}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\sqrt{1-4a}, 2\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\sqrt{1-4a}, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\sqrt{1-4a}, 2\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\sqrt{1-4a}, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\sqrt{1-4a}, 2\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\sqrt{1-4a}, 2\sqrt{x}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^4y'' - (a+b)\,x^2y' + ((a+b)\,x + ab)\,y = 0}$$

32.3.1 Solving using Kovacic algorithm

Writing the ode as

$$x^4y'' - (a+b)\,x^2y' + (a(x+b) + bx)\,y = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4 \\ B &= -x^2(a+b) \\ C &= a(x+b) + bx \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$
\begin{aligned}
r &= \frac{s}{t} \\
&= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2}
\end{aligned} \tag{5}
$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$
r = \frac{a^2 - 2ab + b^2}{4x^4} \tag{6}
$$

Comparing the above to (5) shows that

$$
\begin{aligned}
s &= a^2 - 2ab + b^2 \\
t &= 4x^4
\end{aligned}
$$

Therefore eq. (4) becomes

$$
z''(x) = \left(\frac{a^2 - 2ab + b^2}{4x^4}\right) z(x) \tag{7}
$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$
y = z(x)\, e^{-\int \frac{B}{2A}\, dx}
$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 196: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_{2}^{v} \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\begin{aligned} \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) \end{aligned}$$

The partial fraction decomposition of r is

$$r = \frac{\frac{1}{4}a^2 - \frac{1}{2}ab + \frac{1}{4}b^2}{x^4}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{\sqrt{a^2 - 2ab + b^2}}{2x^2} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{\sqrt{a^2 - 2ab + b^2}}{2x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = \frac{\sqrt{a^2 - 2ab + b^2}}{2}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be 0. Therefore

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{\sqrt{a^2 - 2ab + b^2}}{2x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a} + v\right) &&= \frac{1}{2}\left(\frac{0}{\frac{\sqrt{a^2-2ab+b^2}}{2}} + 2\right) &&= 1 \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a} + v\right) &&= \frac{1}{2}\left(-\frac{0}{\frac{\sqrt{a^2-2ab+b^2}}{2}} + 2\right) &&= 1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a^2 - 2ab + b^2}{4x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{\sqrt{a^2-2ab+b^2}}{2x^2}$	1	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + (-)[\sqrt{r}]_\infty \\ &= -\frac{\sqrt{a^2-2ab+b^2}}{2x^2} + \frac{1}{x} + (-)(0) \\ &= -\frac{\sqrt{a^2-2ab+b^2}}{2x^2} + \frac{1}{x} \\ &= \frac{-\sqrt{(a-b)^2} + 2x}{2x^2} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(-\frac{\sqrt{a^2-2ab+b^2}}{2x^2} + \frac{1}{x}\right)(0) + \left(\left(\frac{\sqrt{a^2-2ab+b^2}}{x^3} - \frac{1}{x^2}\right) + \left(-\frac{\sqrt{a^2-2ab+b^2}}{2x^2} + \frac{1}{x}\right)^2 - \left(\frac{a^2 -}{}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{\sqrt{a^2-2ab+b^2}}{2x^2}+\frac{1}{x}\right) dx} \\
&= x\,\mathrm{e}^{\frac{\operatorname{csgn}(a-b)(a-b)}{2x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{-x^2(a+b)}{x^4}\, dx} \\
&= z_1 e^{-\frac{\frac{a}{2}+\frac{b}{2}}{x}} \\
&= z_1 \left(\mathrm{e}^{-\frac{a+b}{2x}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = x\,\mathrm{e}^{\frac{\operatorname{csgn}(a-b)(a-b)-b-a}{2x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{-x^2(a+b)}{x^4}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{-a-b}{x}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\mathrm{e}^{-\frac{\operatorname{csgn}(a-b)(a-b)}{x}} \operatorname{csgn}(a-b)}{a-b}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x\,\mathrm{e}^{\frac{\operatorname{csgn}(a-b)(a-b)-b-a}{2x}}\right) + c_2 \left(x\,\mathrm{e}^{\frac{\operatorname{csgn}(a-b)(a-b)-b-a}{2x}} \left(\frac{\mathrm{e}^{-\frac{\operatorname{csgn}(a-b)(a-b)}{x}} \operatorname{csgn}(a-b)}{a-b}\right)\right)
\end{aligned}
$$

Simplifying the solution $y = c_1 x \,\mathrm{e}^{\frac{\mathrm{csgn}(a-b)(a-b)-b-a}{2x}} + \frac{c_2 x \,\mathrm{e}^{\frac{(b-a)\,\mathrm{csgn}(a-b)-b-a}{2x}}}{\sqrt{(a-b)^2}}$ to $y = c_1 x \,\mathrm{e}^{-\frac{b}{x}} + \frac{c_2 x \,\mathrm{e}^{-\frac{a}{x}}}{\sqrt{(a-b)^2}}$

Summary
The solution(s) found are the following

$$y = c_1 x \,\mathrm{e}^{-\frac{b}{x}} + \frac{c_2 x \,\mathrm{e}^{-\frac{a}{x}}}{\sqrt{(a-b)^2}} \tag{1}$$

Verification of solutions

$$y = c_1 x \,\mathrm{e}^{-\frac{b}{x}} + \frac{c_2 x \,\mathrm{e}^{-\frac{a}{x}}}{\sqrt{(a-b)^2}}$$

Verified OK.

Problem number: 214.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^4 y'' + 2x^2(x + a)\, y' + yb = 0}$$

32.4.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^4 y'' + 2x^2(x + a)\, y' + yb = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2x + 2a}{x^2} \\ q(x) &= \frac{b}{x^4} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)} dx \\
&= \int \mathrm{e}^{-\left(\int \frac{2x+2a}{x^2} dx\right)} dx \\
&= \int e^{\frac{2a}{x} - 2\ln(x)}\, dx \\
&= \int \frac{\mathrm{e}^{\frac{2a}{x}}}{x^2} dx \\
&= -\frac{\mathrm{e}^{\frac{2a}{x}}}{2a}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{b}{x^4}}{\frac{\mathrm{e}^{\frac{4a}{x}}}{x^4}} \\
&= b\,\mathrm{e}^{-\frac{4a}{x}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + b\,\mathrm{e}^{-\frac{4a}{x}} y(\tau) = 0$$

But in terms of τ

$$b\,\mathrm{e}^{-\frac{4a}{x}} = \frac{b}{4a^2\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{by(\tau)}{4a^2\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)a^2\tau^2 + by(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4a^2\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + b\,\tau^r = 0$$

Simplifying gives

$$4a^2r(r-1)\,\tau^r + 0\,\tau^r + b\,\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4a^2r(r-1) + 0 + b = 0$$

Or

$$4a^2r^2 - 4a^2r + b = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-a + \sqrt{a^2-b}}{2a}$$
$$r_2 = \frac{a + \sqrt{a^2-b}}{2a}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{-\frac{-a+\sqrt{a^2-b}}{2a}} + c_2\tau^{\frac{a+\sqrt{a^2-b}}{2a}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(-\frac{e^{\frac{2a}{x}}}{2a}\right)^{-\frac{-a+\sqrt{a^2-b}}{2a}} + c_2 \left(-\frac{e^{\frac{2a}{x}}}{2a}\right)^{\frac{a+\sqrt{a^2-b}}{2a}}$$

Summary
The solution(s) found are the following

$$y = c_1 \left(-\frac{e^{\frac{2a}{x}}}{2a}\right)^{-\frac{-a+\sqrt{a^2-b}}{2a}} + c_2 \left(-\frac{e^{\frac{2a}{x}}}{2a}\right)^{\frac{a+\sqrt{a^2-b}}{2a}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(-\frac{e^{\frac{2a}{x}}}{2a}\right)^{-\frac{-a+\sqrt{a^2-b}}{2a}} + c_2 \left(-\frac{e^{\frac{2a}{x}}}{2a}\right)^{\frac{a+\sqrt{a^2-b}}{2a}}$$

Verified OK.

32.4.2 Solving using Kovacic algorithm

Writing the ode as

$$x^4 y'' + 2x^2(x+a)\, y' + yb = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= x^4 \\ B &= 2x^2(x+a) \\ C &= b \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{a^2 - b}{x^4} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= a^2 - b \\ t &= x^4 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{a^2 - b}{x^4}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 197: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = x^4$. There is a pole at $x = 0$ of order 4. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Attempting to find a solution using case $n = 1$.

Looking at higher order poles of order $2v \geq 4$ (must be even order for case one).Then for each pole c, $[\sqrt{r}]_c$ is the sum of terms $\frac{1}{(x-c)^i}$ for $2 \leq i \leq v$ in the Laurent series expansion of $\sqrt{r}$ expanded around each pole c. Hence

$$[\sqrt{r}]_c = \sum_2^v \frac{a_i}{(x-c)^i} \tag{1B}$$

Let a be the coefficient of the term $\frac{1}{(x-c)^v}$ in the above where v is the pole order divided by 2. Let b be the coefficient of $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of $\frac{1}{(x-c)^{v+1}}$ in $[\sqrt{r}]_c$. Then

$$\alpha_c^+ = \frac{1}{2}\left(\frac{b}{a} + v\right)$$
$$\alpha_c^- = \frac{1}{2}\left(-\frac{b}{a} + v\right)$$

The partial fraction decomposition of r is

$$r = \frac{a^2 - b}{x^4}$$

There is pole in r at $x = 0$ of order 4, hence $v = 2$. Expanding $\sqrt{r}$ as Laurent series about this pole $c = 0$ gives

$$[\sqrt{r}]_c \approx \frac{\sqrt{a^2 - b}}{x^2} + \dots \tag{2B}$$

Using eq. (1B), taking the sum up to $v = 2$ the above becomes

$$[\sqrt{r}]_c = \frac{\sqrt{a^2 - b}}{x^2} \tag{3B}$$

The above shows that the coefficient of $\frac{1}{(x-0)^2}$ is

$$a = \sqrt{a^2 - b}$$

Now we need to find b. let b be the coefficient of the term $\frac{1}{(x-c)^{v+1}}$ in r minus the coefficient of the same term but in the sum $[\sqrt{r}]_c$ found in eq. (3B). Here c is current pole which is $c = 0$. This term becomes $\frac{1}{x^3}$. The coefficient of this term in the sum $[\sqrt{r}]_c$ is seen to be 0 and the coefficient of this term r is found from the partial fraction decomposition from above to be 0. Therefore

$$\begin{aligned} b &= (0) - (0) \\ &= 0 \end{aligned}$$

Hence

$$\begin{aligned} [\sqrt{r}]_c &= \frac{\sqrt{a^2-b}}{x^2} \\ \alpha_c^+ &= \frac{1}{2}\left(\frac{b}{a}+v\right) &&= \frac{1}{2}\left(\frac{0}{\sqrt{a^2-b}}+2\right) &&= 1 \\ \alpha_c^- &= \frac{1}{2}\left(-\frac{b}{a}+v\right) &&= \frac{1}{2}\left(-\frac{0}{\sqrt{a^2-b}}+2\right) &&= 1 \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = \frac{a^2-b}{x^4}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	4	$\frac{\sqrt{a^2-b}}{x^2}$	1	1

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^- - (\alpha_{c_1}^-) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + (-)[\sqrt{r}]_\infty \\
&= -\frac{\sqrt{a^2 - b}}{x^2} + \frac{1}{x} + (-)(0) \\
&= -\frac{\sqrt{a^2 - b}}{x^2} + \frac{1}{x} \\
&= \frac{-\sqrt{a^2 - b} + x}{x^2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
\begin{aligned}
(0) + 2\left(-\frac{\sqrt{a^2 - b}}{x^2} + \frac{1}{x}\right)(0) + \left(\left(\frac{2\sqrt{a^2 - b}}{x^3} - \frac{1}{x^2}\right) + \left(-\frac{\sqrt{a^2 - b}}{x^2} + \frac{1}{x}\right)^2 - \left(\frac{a^2 - b}{x^4}\right)\right) &= 0 \\
0 &= 0
\end{aligned}
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(-\frac{\sqrt{a^2 - b}}{x^2} + \frac{1}{x}\right) dx} \\
&= x\, \mathrm{e}^{\frac{\sqrt{a^2 - b}}{x}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2x^2(x+a)}{x^4}\,dx} \\
&= z_1 e^{\frac{a}{x}-\ln(x)} \\
&= z_1\left(\frac{e^{\frac{a}{x}}}{x}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = e^{\frac{a+\sqrt{a^2-b}}{x}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2x^2(x+a)}{x^4}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{\frac{2a}{x}-2\ln(x)}}{(y_1)^2}\,dx \\
&= y_1\left(\frac{e^{-\frac{2\sqrt{a^2-b}}{x}}}{2\sqrt{a^2-b}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(e^{\frac{a+\sqrt{a^2-b}}{x}}\right) + c_2\left(e^{\frac{a+\sqrt{a^2-b}}{x}}\left(\frac{e^{-\frac{2\sqrt{a^2-b}}{x}}}{2\sqrt{a^2-b}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{\frac{a+\sqrt{a^2-b}}{x}} + \frac{c_2 e^{\frac{a-\sqrt{a^2-b}}{x}}}{2\sqrt{a^2-b}} \tag{1}
$$

Verification of solutions

$$y = c_1 e^{\frac{a+\sqrt{a^2-b}}{x}} + \frac{c_2 e^{\frac{a-\sqrt{a^2-b}}{x}}}{2\sqrt{a^2-b}}$$

Verified OK.

The type(s) of ODE detected by this program : **"kovacic", "second__order__bessel__ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{x^2(x-a)^2 y'' + yb = 0}$$

32.6.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{by}{x^2} = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta\, x^\gamma) + c_2 \operatorname{BesselY}(n, \beta\, x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= \sqrt{b} \\
n &= \frac{1}{2} \\
\gamma &= -1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}}$$

Verified OK.

32.6.2 Solving using Kovacic algorithm

Writing the ode as

$$y'' x^2 (a - x)^2 + y b = 0 \tag{1}$$

$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}
A &= x^2 (a - x)^2 \\
B &= 0 \\
C &= b
\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-b}{\left(ax - x^2\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -b \\ t &= \left(ax - x^2\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{b}{\left(ax - x^2\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 198: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 0 \\
&= 4
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (ax - x^2)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = a$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{b}{a^2 x^2} - \frac{b}{a^2 (x-a)^2} + \frac{2b}{a^3 (x-a)} - \frac{2b}{a^3 x}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{b}{a^2}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2 - 4b}}{2a} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2 - 4b}}{2a}
\end{aligned}
$$

For the pole at $x = a$ let b be the coefficient of $\frac{1}{(x-a)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{b}{a^2}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2 - 4b}}{2a} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2 - 4b}}{2a}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{b}{\left(ax - x^2\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2}+\frac{\sqrt{a^2-4b}}{2a}$	$\frac{1}{2}-\frac{\sqrt{a^2-4b}}{2a}$
a	2	0	$\frac{1}{2}+\frac{\sqrt{a^2-4b}}{2a}$	$\frac{1}{2}-\frac{\sqrt{a^2-4b}}{2a}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2}-\frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2}+\frac{\sqrt{a^2-4b}}{2a}}{x-a} + (-)\,(0) \\
&= \frac{\frac{1}{2}-\frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2}+\frac{\sqrt{a^2-4b}}{2a}}{x-a} \\
&= \frac{\sqrt{a^2-4b} - a + 2x}{2x\,(x-a)}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x-a}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x^2} - \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{(x-a)^2}\right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x-a}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x-a}\right) dx} \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}
\end{aligned}$$

Which simplifies to

$$y_1 = x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \int \frac{1}{x^{-\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{a}}}\, dx \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}\, dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \right) \\
&\quad + c_2 \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}\, dx \right) \right)
\end{aligned}
$$

<u>Summary</u>
The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \\
&\quad + c_2 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}\, dx \right)
\end{aligned} \tag{1}
$$

<u>Verification of solutions</u>

$$
\begin{aligned}
y &= c_1 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \\
&\quad + c_2 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}\, dx \right)
\end{aligned}
$$

Verified OK.

32.6.3 Maple step by step solution

Let's solve

$y''x^2(a-x)^2 + yb = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{by}{x^2(a-x)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{by}{x^2(a-x)^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = 0, P_3(x) = \frac{b}{x^2(a-x)^2}\right]$

  - $x \cdot P_2(x)$ is analytic at $x = 0$

    $(x \cdot P_2(x))\bigg|_{x=0} = 0$

  - $x^2 \cdot P_3(x)$ is analytic at $x = 0$

    $(x^2 \cdot P_3(x))\bigg|_{x=0} = \frac{b}{a^2}$

  - $x = 0$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = 0$

- Multiply by denominators

  $y''x^2(a-x)^2 + yb = 0$

- Assume series solution for y

  $y = \sum_{k=0}^{\infty} a_k x^{k+r}$

□ Rewrite ODE with series expansions

  - Convert $x^m \cdot y''$ to series expansion for $m = 2..4$

    $x^m \cdot y'' = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, x^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $$x^m\cdot y''=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)(k+1-m+r)\,x^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(a^2r^2-a^2r+b)\,x^r+((a^2r^2+a^2r+b)\,a_1-2a_0r(-1+r)\,a)\,x^{1+r}+\left(\sum_{k=2}^{\infty}(a_k(a^2k^2+2a^2kr+a\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$a^2r^2-a^2r+b=0$$

- Values of r that satisfy the indicial equation

  $$r\in\left\{\frac{\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}}{a},\frac{\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}}{a}\right\}$$

- Each term must be 0

  $$(a^2r^2+a^2r+b)\,a_1-2a_0r(-1+r)\,a=0$$

- Solve for the dependent coefficient(s)

  $$a_1=\frac{2a_0r(-1+r)a}{a^2r^2+a^2r+b}$$

- Each term in the series must be 0, giving the recursion relation

  $$a_k(k+r)(k+r-1)\,a^2-2a_{k-1}(k+r-1)(k-2+r)\,a+k^2a_{k-2}+a_{k-2}(2r-5)\,k+r^2a_{k-2}+a$$

- Shift index using $k->k+2$

  $$a_{k+2}(k+2+r)(k+1+r)\,a^2-2a_{k+1}(k+1+r)(k+r)\,a+(k+2)^2\,a_k+a_k(2r-5)(k+2)+$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2}=\frac{2a\,k^2a_{k+1}+4akra_{k+1}+2a\,r^2a_{k+1}+2aka_{k+1}+2ara_{k+1}-k^2a_k-2kra_k-r^2a_k+a_kk+a_kr}{a^2k^2+2a^2kr+a^2r^2+3a^2k+3a^2r+2a^2+b}$$

- Recursion relation for $r=\frac{\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}}{a}$

  $$a_{k+2}=\frac{2a\,k^2a_{k+1}+4k\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)a_{k+1}+\frac{2\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)^2a_{k+1}}{a}+2aka_{k+1}+2\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)a_{k+1}-k^2a_k-\frac{2k\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)a_k}{a}-}{a^2k^2+2ak\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)+\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)^2+3a^2k+3a\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)+2a^2+b}$$

- Solution for $r=\frac{\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}}{a}$

  $$\left[y=\sum_{k=0}^{\infty}a_kx^{k+\frac{\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}}{a}},a_{k+2}=\frac{2a\,k^2a_{k+1}+4k\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)a_{k+1}+\frac{2\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)^2a_{k+1}}{a}+2aka_{k+1}+2\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)}{a^2k^2+2ak\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)+\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)}\right.$$

- Recursion relation for $r=\frac{\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}}{a}$

$$a_{k+2} = \frac{2a\,k^2 a_{k+1}+4k\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)a_{k+1}+\frac{2\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)^2 a_{k+1}}{a}+2ak a_{k+1}+2\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)a_{k+1}-k^2 a_k-\frac{2k\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)a_k}{a} -}{a^2k^2+2ak\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)+\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)^2+3a^2k+3a\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)+2a^2+b}$$

- Solution for $r = \frac{\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}}{a}$

$$\left[y = \sum_{k=0}^{\infty} a_k x^{k+\frac{\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}}{a}}, a_{k+2} = \frac{2a\,k^2 a_{k+1}+4k\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)a_{k+1}+\frac{2\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)^2 a_{k+1}}{a}+2ak a_{k+1}+2\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)}{a^2k^2+2ak\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)+\left(\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}\right)}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} c_k x^{k+\frac{\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}}{a}}\right)+\left(\sum_{k=0}^{\infty} d_k x^{k+\frac{\frac{a}{2}+\frac{\sqrt{a^2-4b}}{2}}{a}}\right), c_{k+2} = \frac{2a\,k^2 c_{1+k}+4k\left(\frac{a}{2}-\frac{\sqrt{a^2-4b}}{2}\right)c_{1+k}+\frac{2\left(\frac{a}{2}-\frac{\sqrt{a^2}}{2}\right.}{a}}{a^2k^2}\right.$$

Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 217.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _linear, _nonhomogeneous]]`

$$\boxed{x^2(x-a)^2 y'' + yb = c\,x^2(x-a)^2}$$

32.7.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{by}{x^2} = c(a-x)^2 \tag{1}$$

Let the solution be

$$y = y_h + y_p$$

Where y_h is the solution to the homogeneous ODE and y_p is a particular solution to the non-homogeneous ODE. Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= \sqrt{b} \\
n &= \frac{1}{2} \\
\gamma &= -1
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}}$$

Therefore the homogeneous solution y_h is

$$y_h = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}}$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$\begin{aligned}
y_1 &= \frac{\sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}} \\
y_2 &= -\frac{\sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}}{x}}}
\end{aligned}$$

In the Variation of parameters u_1, u_2 are found using

$$u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}$$

$$u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$W = \begin{vmatrix} \frac{\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} & -\frac{\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} \\ \frac{d}{dx}\left(\frac{\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right) & \frac{d}{dx}\left(-\frac{\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right) \end{vmatrix}$$

Which gives

$$W = \begin{vmatrix} \frac{\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} & -\frac{\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} \\ \frac{\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{2\sqrt{x}\,\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} + \frac{\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)\sqrt{b}}{2x^{\frac{3}{2}}\sqrt{\pi}\,\left(\frac{\sqrt{b}}{x}\right)^{\frac{3}{2}}} - \frac{\sqrt{2}\,\sqrt{b}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} & -\frac{\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{2\sqrt{x}\,\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} - \frac{\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)\sqrt{b}}{2x^{\frac{3}{2}}\sqrt{\pi}\,\left(\frac{\sqrt{b}}{x}\right)^{\frac{3}{2}}} - \frac{\sqrt{2}\,\sqrt{b}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} \end{vmatrix}$$

Therefore

$$\begin{aligned} W = {} & \left(\frac{\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right)\left(-\frac{\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{2\sqrt{x}\,\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} - \frac{\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)\sqrt{b}}{2x^{\frac{3}{2}}\sqrt{\pi}\,\left(\frac{\sqrt{b}}{x}\right)^{\frac{3}{2}}} - \frac{\sqrt{2}\,\sqrt{b}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right) \\ & - \left(-\frac{\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right)\left(\frac{\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{2\sqrt{x}\,\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} + \frac{\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)\sqrt{b}}{2x^{\frac{3}{2}}\sqrt{\pi}\,\left(\frac{\sqrt{b}}{x}\right)^{\frac{3}{2}}} - \frac{\sqrt{2}\,\sqrt{b}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{x^{\frac{3}{2}}\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right) \end{aligned}$$

Which simplifies to

$$W = -\frac{2\left(\sin\left(\frac{\sqrt{b}}{x}\right)^2 + \cos\left(\frac{\sqrt{b}}{x}\right)^2\right)}{\pi}$$

Which simplifies to

$$W = -\frac{2}{\pi}$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{-\frac{\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)c(a-x)^2}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}}{-\frac{2x^2}{\pi}} dx$$

Which simplifies to

$$u_1 = -\int \frac{\sqrt{2}\,\sqrt{\pi}\,\cos\left(\frac{\sqrt{b}}{x}\right)c(a-x)^2}{2x^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{x}}} dx$$

Hence

$$u_1 = -\left(\int_0^x \frac{\sqrt{2}\,\sqrt{\pi}\,\cos\left(\frac{\sqrt{b}}{\alpha}\right)c(a-\alpha)^2}{2\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}} d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{\frac{\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)c(a-x)^2}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}}{-\frac{2x^2}{\pi}} dx$$

Which simplifies to

$$u_2 = \int -\frac{\sqrt{2}\,\sqrt{\pi}\,\sin\left(\frac{\sqrt{b}}{x}\right)c(a-x)^2}{2x^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{x}}} dx$$

Hence

$$u_2 = \int_0^x -\frac{\sqrt{2}\,\sqrt{\pi}\,\sin\left(\frac{\sqrt{b}}{\alpha}\right)c(a-\alpha)^2}{2\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}} d\alpha$$

Which simplifies to

$$u_1 = -\frac{\sqrt{2}\,\sqrt{\pi}\,c\left(\int_0^x \frac{\cos\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)}{2}$$

$$u_2 = -\frac{\sqrt{2}\,\sqrt{\pi}\,c\left(\int_0^x \frac{\sin\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)}{2}$$

Therefore the particular solution, from equation (1) is

$$y_p(x) = -\frac{c\left(\int_0^x \frac{\cos\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\sqrt{x}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\frac{\sqrt{b}}{x}}} + \frac{c\left(\int_0^x \frac{\sin\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\sqrt{x}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\frac{\sqrt{b}}{x}}}$$

Which simplifies to

$$y_p(x) = \frac{c\sqrt{x}\left(-\left(\int_0^x \frac{\cos\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\sin\left(\frac{\sqrt{b}}{x}\right) + \left(\int_0^x \frac{\sin\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\cos\left(\frac{\sqrt{b}}{x}\right)\right)}{\sqrt{\frac{\sqrt{b}}{x}}}$$

Therefore the general solution is

$$\begin{aligned}
y &= y_h + y_p \\
&= \left(\frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\right) \\
&\quad + \left(\frac{c\sqrt{x}\left(-\left(\int_0^x \frac{\cos\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\sin\left(\frac{\sqrt{b}}{x}\right) + \left(\int_0^x \frac{\sin\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\cos\left(\frac{\sqrt{b}}{x}\right)\right)}{\sqrt{\frac{\sqrt{b}}{x}}}\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$
\begin{align*}
y &= \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}-\frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\\
&+\frac{c\sqrt{x}\left(-\left(\int_0^x\frac{\cos\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\sin\left(\frac{\sqrt{b}}{x}\right)+\left(\int_0^x\frac{\sin\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\cos\left(\frac{\sqrt{b}}{x}\right)\right)}{\sqrt{\frac{\sqrt{b}}{x}}} \tag{1}
\end{align*}
$$

Verification of solutions

$$
\begin{align*}
y &= \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}-\frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{b}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}}{x}}}\\
&+\frac{c\sqrt{x}\left(-\left(\int_0^x\frac{\cos\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\sin\left(\frac{\sqrt{b}}{x}\right)+\left(\int_0^x\frac{\sin\left(\frac{\sqrt{b}}{\alpha}\right)(a-\alpha)^2}{\alpha^{\frac{3}{2}}\sqrt{\frac{\sqrt{b}}{\alpha}}}d\alpha\right)\cos\left(\frac{\sqrt{b}}{x}\right)\right)}{\sqrt{\frac{\sqrt{b}}{x}}}
\end{align*}
$$

Verified OK.

32.7.2 Solving using Kovacic algorithm

Writing the ode as

$$
\begin{align*}
y''x^2(a-x)^2+yb &= 0 \tag{1}\\
Ay''+By'+Cy &= 0 \tag{2}
\end{align*}
$$

Comparing (1) and (2) shows that

$$
\begin{align*}
A &= x^2(a-x)^2\\
B &= 0 \tag{3}\\
C &= b
\end{align*}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x)=ye^{\int \frac{B}{2A}\,dx}
$$

Then (2) becomes

$$
z''(x)=rz(x) \tag{4}
$$

Where r is given by

$$r = \frac{s}{t} = \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-b}{(ax - x^2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$s = -b$$
$$t = (ax - x^2)^2$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{b}{(ax - x^2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 200: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$
\begin{aligned}
O(\infty) &= \deg(t) - \deg(s) \\
&= 4 - 0 \\
&= 4
\end{aligned}
$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (ax - x^2)^2$. There is a pole at $x = 0$ of order 2. There is a pole at $x = a$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$
L = [1, 2, 4, 6, 12]
$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$
r = -\frac{b}{a^2 x^2} - \frac{b}{a^2 (x-a)^2} + \frac{2b}{a^3 (x-a)} - \frac{2b}{a^3 x}
$$

For the pole at $x = 0$ let b be the coefficient of $\frac{1}{x^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{b}{a^2}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}
\end{aligned}
$$

For the pole at $x = a$ let b be the coefficient of $\frac{1}{(x-a)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{b}{a^2}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a} \\
\alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^+ &= 0 \\
\alpha_\infty^- &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{b}{(ax - x^2)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
0	2	0	$\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}$	$\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}$
a	2	0	$\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}$	$\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c \in \Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c \in \Gamma \cup \infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\ &= \frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x - a} + (-)\,(0) \\ &= \frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x - a} \\ &= \frac{\sqrt{a^2 - 4b} - a + 2x}{2x\,(x - a)} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x-a}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x^2} - \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{(x-a)^2}\right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x-a}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-4b}}{2a}}{x} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-4b}}{2a}}{x-a}\right) dx} \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}
y_1 &= z_1 \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}
\end{aligned}$$

Which simplifies to

$$y_1 = x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2} \, dx \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \int \frac{1}{x^{-\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{a}}} \, dx \\
&= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} \, dx \right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \right) \\
&\quad + c_2 \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} \, dx \right) \right)
\end{aligned}
$$

This is second order nonhomogeneous ODE. Let the solution be

$$
y = y_h + y_p
$$

Where y_h is the solution to the homogeneous ODE $Ay''(x)+By'(x)+Cy(x) = 0$, and y_p is a particular solution to the nonhomogeneous ODE $Ay''(x) + By'(x) + Cy(x) = f(x)$. y_h is the solution to

$$
y'' x^2 (a-x)^2 + yb = 0
$$

The homogeneous solution is found using the Kovacic algorithm which results in

$$
\begin{aligned}
y_h &= c_1 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \\
&\quad + c_2 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} \, dx \right)
\end{aligned}
$$

The particular solution y_p can be found using either the method of undetermined coefficients, or the method of variation of parameters. The method of variation of parameters will be used as it is more general and can be used when the coefficients of the ODE depend on x as well. Let

$$
y_p(x) = u_1 y_1 + u_2 y_2 \tag{1}
$$

Where u_1, u_2 to be determined, and y_1, y_2 are the two basis solutions (the two linearly independent solutions of the homogeneous ODE) found earlier when solving the homogeneous ODE as

$$
\begin{aligned}
y_1 &= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \\
y_2 &= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right)
\end{aligned}
$$

In the Variation of parameters u_1, u_2 are found using

$$
u_1 = -\int \frac{y_2 f(x)}{aW(x)} \tag{2}
$$

$$
u_2 = \int \frac{y_1 f(x)}{aW(x)} \tag{3}
$$

Where $W(x)$ is the Wronskian and a is the coefficient in front of y'' in the given ODE. The Wronskian is given by $W = \begin{vmatrix} y_1 & y_2 \\ y_1' & y_2' \end{vmatrix}$. Hence

$$
W = \begin{vmatrix} x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} & x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx \right. \\ \frac{d}{dx}\left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\right) & \frac{d}{dx}\left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d \right.\right. \end{vmatrix}
$$

Which gives

$$
W = \begin{vmatrix} x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \\ -\frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} \left(-a+\sqrt{a^2-4b}\right)(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}}{2ax} + \frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(a+\sqrt{a^2-4b}\right)}{2a(x-a)} - \frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} \left(-a+\sqrt{a^2-\right.}{} \end{vmatrix}
$$

Therefore

$$W = \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\right)\left(-\frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}\left(-a+\sqrt{a^2-4b}\right)(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)}{2ax} + \frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(a+\sqrt{a^2-4b}\right)\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)}{2a(x-a)} + x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}\right) - \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)\right)\left(-\frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}\left(-a+\sqrt{a^2-4b}\right)(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}}{2ax} + \frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(a+\sqrt{a^2-4b}\right)}{2a(x-a)}\right)$$

Which simplifies to

$$W = (x-a)^{-\frac{a+\sqrt{a^2-4b}}{a}}x^{\frac{-a+\sqrt{a^2-4b}}{a}}x^{-\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{a}}$$

Which simplifies to

$$W = 1$$

Therefore Eq. (2) becomes

$$u_1 = -\int \frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)c\,x^2(a-x)^2}{x^2(a-x)^2}dx$$

Which simplifies to

$$u_1 = -\int x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)c\,dx$$

Hence

$$u_1 = -\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}} (\alpha - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d\alpha\right) c d\alpha\right)$$

And Eq. (3) becomes

$$u_2 = \int \frac{x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} c\, x^2 (a-x)^2}{x^2 (a-x)^2} dx$$

Which simplifies to

$$u_2 = \int x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} c dx$$

Hence

$$u_2 = \int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} c d\alpha$$

Which simplifies to

$$u_1 = -\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}} (\alpha - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d\alpha\right) d\alpha\right) c$$

$$u_2 = c\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} d\alpha\right)$$

Therefore the particular solution, from equation (1) is

$$\begin{aligned} y_p(x) = -\Bigg(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha \\ - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}} (\alpha - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d\alpha\right) d\alpha\Bigg) c\, x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x \\ - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} + c\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} d\alpha\right) x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x \\ - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right) \end{aligned}$$

Which simplifies to

$$y_p(x) = x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} c\left(\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} d\alpha\right)\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right) - \left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}} (\alpha - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d\alpha\right) d\alpha\right)\right)$$

Therefore the general solution is

$$\begin{aligned} y &= y_h + y_p \\ &= \left(c_1 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} + c_2 x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right)\right) \\ &+ \left(x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} c\left(\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} d\alpha\right)\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right) - \left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}} (\alpha - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d\alpha\right) d\alpha\right)\right)\right) \end{aligned}$$

Which simplifies to

$$\begin{aligned} y &= x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(c_1 + c_2\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right)\right) \\ &+ x^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (x - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} c\left(\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}} d\alpha\right)\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}} (x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}} dx\right) - \left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}} (\alpha - a)^{\frac{a+\sqrt{a^2-4b}}{2a}} \left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}} (\alpha - a)^{\frac{-a-\sqrt{a^2-4b}}{a}} d\alpha\right) d\alpha\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(c_1+c_2\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)\right) + x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}c\left(\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}d\alpha\right)\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right) - \left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}}(\alpha-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}d\alpha\right)d\alpha\right)\right) \tag{1}$$

Verification of solutions

$$y = x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(c_1+c_2\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right)\right) + x^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(x-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}c\left(\left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}d\alpha\right)\left(\int x^{\frac{-a+\sqrt{a^2-4b}}{a}}(x-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}dx\right) - \left(\int_0^x \alpha^{-\frac{-a+\sqrt{a^2-4b}}{2a}}(\alpha-a)^{\frac{a+\sqrt{a^2-4b}}{2a}}\left(\int \alpha^{\frac{-a+\sqrt{a^2-4b}}{a}}(\alpha-a)^{\frac{-a-\sqrt{a^2-4b}}{a}}d\alpha\right)d\alpha\right)\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 218.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{a\,x^2(x-1)^2\,y'' + \left(b\,x^2 + cx + d\right)y = 0}$$

32.8.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(\frac{b}{a} + \frac{c}{xa} + \frac{d}{x^2a}\right)y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\,xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1\,\mathrm{BesselJ}\,(n, \beta\,x^{\gamma}) + c_2\,\mathrm{BesselY}\,(n, \beta\,x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= 2 \\
n &= \frac{\sqrt{a\,(a-4b)}}{a} \\
\gamma &= \frac{1}{2}
\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\frac{\sqrt{a\,(a-4b)}}{a}, 2\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\frac{\sqrt{a\,(a-4b)}}{a}, 2\sqrt{x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\frac{\sqrt{a\,(a-4b)}}{a}, 2\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\frac{\sqrt{a\,(a-4b)}}{a}, 2\sqrt{x}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\frac{\sqrt{a\,(a-4b)}}{a}, 2\sqrt{x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\frac{\sqrt{a\,(a-4b)}}{a}, 2\sqrt{x}\right)$$

Verified OK.

32.8.2 Maple step by step solution

Let's solve

$a\,x^2(x-1)^2\,y'' + (b\,x^2+cx+d)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(b\,x^2+cx+d)\,y}{a\,x^2(x-1)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(b\,x^2+cx+d)\,y}{a\,x^2(x-1)^2} = 0$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x)=0, P_3(x)=\frac{b\,x^2+cx+d}{a\,x^2(x-1)^2}\right]$

- $x\cdot P_2(x)$ is analytic at $x=0$

  $(x\cdot P_2(x))\bigg|_{x=0}=0$

- $x^2\cdot P_3(x)$ is analytic at $x=0$

  $(x^2\cdot P_3(x))\bigg|_{x=0}=\frac{d}{a}$

- $x=0$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=0$

- Multiply by denominators

  $a\,x^2(x-1)^2\,y''+(b\,x^2+cx+d)\,y=0$

- Assume series solution for y

  $y=\sum_{k=0}^{\infty} a_k x^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $x^m\cdot y$ to series expansion for $m=0..2$

  $x^m\cdot y=\sum_{k=0}^{\infty} a_k x^{k+r+m}$

- Shift index using $k->k-m$

  $x^m\cdot y=\sum_{k=m}^{\infty} a_{k-m} x^{k+r}$

- Convert $x^m\cdot y''$ to series expansion for $m=2..4$

  $x^m\cdot y''=\sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,x^{k+r-2+m}$

- Shift index using $k->k+2-m$

  $x^m\cdot y''=\sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,x^{k+r}$

  Rewrite ODE with series expansions

  $a_0(a\,r^2-ar+d)\,x^r+((a\,r^2+ar+d)\,a_1-a_0(2a\,r^2-2ar-c))\,x^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_k(a\,k^2+2akr+\right.\right.$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $a\,r^2-ar+d=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{\frac{a+\sqrt{a^2-4ad}}{2a},-\frac{-a+\sqrt{a^2-4ad}}{2a}\right\}$

- Each term must be 0

  $(a\,r^2+ar+d)\,a_1-a_0(2a\,r^2-2ar-c)=0$

- Solve for the dependent coefficient(s)

  $a_1=\frac{a_0(2a\,r^2-2ar-c)}{a\,r^2+ar+d}$

- Each term in the series must be 0, giving the recursion relation

  $((a_k+a_{k-2}-2a_{k-1})\,k^2+((2a_k+2a_{k-2}-4a_{k-1})\,r-a_k-5a_{k-2}+6a_{k-1})\,k+(a_k+a_{k-2}-2a_{k-}$

- Shift index using $k->k+2$

  $\left((a_{k+2}+a_k-2a_{k+1})\,(k+2)^2+((2a_{k+2}+2a_k-4a_{k+1})\,r-a_{k+2}-5a_k+6a_{k+1})\,(k+2)+(a_{k+2}\right.$

- Recursion relation that defines series solution to ODE

  $a_{k+2}=-\frac{a\,k^2a_k-2a\,k^2a_{k+1}+2akra_k-4akra_{k+1}+a\,r^2a_k-2a\,r^2a_{k+1}-aka_k-2aka_{k+1}-ara_k-2ara_{k+1}+a_kb+ca_{k+1}}{a\,k^2+2akr+a\,r^2+3ak+3ar+2a+d}$

- Recursion relation for $r=\frac{a+\sqrt{a^2-4ad}}{2a}$

  $a_{k+2}=-\frac{a\,k^2a_k-2a\,k^2a_{k+1}+k\left(a+\sqrt{a^2-4ad}\right)a_k-2k\left(a+\sqrt{a^2-4ad}\right)a_{k+1}+\frac{\left(a+\sqrt{a^2-4ad}\right)^2a_k}{4a}-\frac{\left(a+\sqrt{a^2-4ad}\right)^2a_{k+1}}{2a}-aka_k-2ak}{a\,k^2+k\left(a+\sqrt{a^2-4ad}\right)+\frac{\left(a+\sqrt{a^2-4ad}\right)^2}{4a}+3ak+\frac{7a}{2}+\frac{3\sqrt{a^2-4ad}}{2}}$

- Solution for $r=\frac{a+\sqrt{a^2-4ad}}{2a}$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k+\frac{a+\sqrt{a^2-4ad}}{2a}},a_{k+2}=-\frac{a\,k^2a_k-2a\,k^2a_{k+1}+k\left(a+\sqrt{a^2-4ad}\right)a_k-2k\left(a+\sqrt{a^2-4ad}\right)a_{k+1}+\frac{\left(a+\sqrt{a^2-4ad}\right)^2a_k}{4a}}{a\,k^2+k\left(a+\sqrt{a^2-4ad}\right)+\frac{(a-}{}}\right.$

- Recursion relation for $r=-\frac{-a+\sqrt{a^2-4ad}}{2a}$

  $a_{k+2}=-\frac{a\,k^2a_k-2a\,k^2a_{k+1}-k\left(-a+\sqrt{a^2-4ad}\right)a_k+2k\left(-a+\sqrt{a^2-4ad}\right)a_{k+1}+\frac{\left(-a+\sqrt{a^2-4ad}\right)^2a_k}{4a}-\frac{\left(-a+\sqrt{a^2-4ad}\right)^2a_{k+1}}{2a}-aka}{a\,k^2-k\left(-a+\sqrt{a^2-4ad}\right)+\frac{\left(-a+\sqrt{a^2-4ad}\right)^2}{4a}+3ak+\frac{7a}{2}-\frac{3\sqrt{c}}{}}$

- Solution for $r=-\frac{-a+\sqrt{a^2-4ad}}{2a}$

  $\left[y=\sum_{k=0}^{\infty}a_kx^{k-\frac{-a+\sqrt{a^2-4ad}}{2a}},a_{k+2}=-\frac{a\,k^2a_k-2a\,k^2a_{k+1}-k\left(-a+\sqrt{a^2-4ad}\right)a_k+2k\left(-a+\sqrt{a^2-4ad}\right)a_{k+1}+\frac{\left(-a+\sqrt{a^2-4}\right.}{4a}}{a\,k^2-k\left(-a+\sqrt{a^2-4ad}\right.}\right.$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} e_k x^{k+\frac{a+\sqrt{a^2-4ad}}{2a}}\right) + \left(\sum_{k=0}^{\infty} f_k x^{k-\frac{-a+\sqrt{a^2-4ad}}{2a}}\right), e_{k+2} = -\frac{a\,k^2 e_k - 2a\,k^2 e_{1+k} + k\left(a+\sqrt{a^2-4ad}\right) e_k - 2k}{}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 220.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second__order__bessel__ode"**

Maple gives the following as the ode type

`[_Halm]`

$$\boxed{\left(x^2+1\right)^2 y''+ay=0}$$

32.10.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y''+\frac{ay}{x^2}=0 \tag{1}$$

Bessel ode has the form

$$x^2y''+y'x+\left(-n^2+x^2\right)y=0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y''+(1-2\alpha)\,xy'+\left(\beta^2\gamma^2x^{2\gamma}-n^2\gamma^2+\alpha^2\right)y=0 \tag{3}$$

With the standard solution

$$y=x^{\alpha}(c_1\,\text{BesselJ}\left(n,\beta\,x^{\gamma}\right)+c_2\,\text{BesselY}\left(n,\beta\,x^{\gamma}\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = \sqrt{a}$$
$$n = \frac{1}{2}$$
$$\gamma = -1$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}}$$

Summary
The solution(s) found are the following

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{a}}{x}}}$$

Verified OK.

32.10.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(x^2+1\right)^2 y'' + ay = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= \left(x^2+1\right)^2 \\ B &= 0 \\ C &= a \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a}{(x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a \\ t &= (x^2+1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{a}{(x^2+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 203: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{a}{4(x-i)^2} + \frac{a}{4(x+i)^2} + \frac{ia}{4x-4i} - \frac{ia}{4(x+i)}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{a}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a+1}}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a+1}}{2}\end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{a}{4}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a+1}}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a+1}}{2}\end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{a}{(x^2+1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
i	2	0	$\frac{1}{2}+\frac{\sqrt{a+1}}{2}$	$\frac{1}{2}-\frac{\sqrt{a+1}}{2}$
$-i$	2	0	$\frac{1}{2}+\frac{\sqrt{a+1}}{2}$	$\frac{1}{2}-\frac{\sqrt{a+1}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2}-\frac{\sqrt{a+1}}{2}}{x-i} + \frac{\frac{1}{2}+\frac{\sqrt{a+1}}{2}}{x+i} + (-)\,(0) \\
&= \frac{\frac{1}{2}-\frac{\sqrt{a+1}}{2}}{x-i} + \frac{\frac{1}{2}+\frac{\sqrt{a+1}}{2}}{x+i} \\
&= \frac{-i\sqrt{a+1}+x}{x^2+1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{a+1}}{2}}{x-i} + \frac{\frac{1}{2} + \frac{\sqrt{a+1}}{2}}{x+i}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{a+1}}{2}}{(x-i)^2} - \frac{\frac{1}{2} + \frac{\sqrt{a+1}}{2}}{(x+i)^2}\right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{a+1}}{2}}{x-i} + \frac{\frac{1}{2} + \frac{\sqrt{a+1}}{2}}{x+i}\right)^2 - \left(-\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \, dx} \\ &= \mathrm{e}^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{a+1}}{2}}{x-i} + \frac{\frac{1}{2} + \frac{\sqrt{a+1}}{2}}{x+i}\right) dx} \\ &= \sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} \end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} \int \frac{1}{(x^2+1)\, \mathrm{e}^{-2i\sqrt{a+1}\, \arctan(x)}}\, dx \\
&= \sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} \left(-\frac{i\mathrm{e}^{2i\sqrt{a+1}\, \arctan(x)}}{2\sqrt{a+1}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)}\right) + c_2\left(\sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} \left(-\frac{i\mathrm{e}^{2i\sqrt{a+1}\, \arctan(x)}}{2\sqrt{a+1}}\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1\sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} - \frac{i c_2\sqrt{x^2+1}\, \mathrm{e}^{i\sqrt{a+1}\, \arctan(x)}}{2\sqrt{a+1}} \tag{1}
$$

Verification of solutions

$$
y = c_1\sqrt{x^2+1}\, \mathrm{e}^{-i\sqrt{a+1}\, \arctan(x)} - \frac{i c_2\sqrt{x^2+1}\, \mathrm{e}^{i\sqrt{a+1}\, \arctan(x)}}{2\sqrt{a+1}}
$$

Verified OK.

ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{\left(x^2-1\right)^2 y''+ay=0}$$

32.11.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y''+\frac{ay}{x^2}=0 \tag{1}$$

Bessel ode has the form

$$x^2y''+y'x+\left(-n^2+x^2\right)y=0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y''+(1-2\alpha)\,xy'+\left(\beta^2\gamma^2x^{2\gamma}-n^2\gamma^2+\alpha^2\right)y=0 \tag{3}$$

With the standard solution

$$y=x^{\alpha}(c_1\,\mathrm{BesselJ}\left(n,\beta\,x^{\gamma}\right)+c_2\,\mathrm{BesselY}\left(n,\beta\,x^{\gamma}\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= \frac{1}{2}\\ \beta &= \sqrt{a}\\ n &= \frac{1}{2}\\ \gamma &= -1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{a}}{x}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{a}}{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{a}}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{\sqrt{a}}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{a}}{x}}}$$

Verified OK.

32.11.2 Solving using Kovacic algorithm

Writing the ode as

$$y''\left(x^4-2x^2+1\right)+ay = 0 \tag{1}$$

$$Ay''+By'+Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= x^4-2x^2+1\\ B &= 0\\ C &= a\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a}{(x^2 - 1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a \\ t &= (x^2 - 1)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{a}{(x^2 - 1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 204: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (x^2 - 1)^2$. There is a pole at $x = 1$ of order 2. There is a pole at $x = -1$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{a}{4x - 4} - \frac{a}{4(x-1)^2} - \frac{a}{4(1+x)^2} - \frac{a}{4(1+x)}$$

For the pole at $x = 1$ let b be the coefficient of $\frac{1}{(x-1)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{a}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-a+1}}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-a+1}}{2} \end{aligned}$$

For the pole at $x = -1$ let b be the coefficient of $\frac{1}{(1+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{a}{4}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{-a+1}}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{-a+1}}{2} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned} [\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1 \end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{a}{(x^2-1)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
1	2	0	$\frac{1}{2}+\frac{\sqrt{-a+1}}{2}$	$\frac{1}{2}-\frac{\sqrt{-a+1}}{2}$
-1	2	0	$\frac{1}{2}+\frac{\sqrt{-a+1}}{2}$	$\frac{1}{2}-\frac{\sqrt{-a+1}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}
d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}}{x-1} + \frac{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}}{1+x} + (-)(0) \\
&= \frac{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}}{x-1} + \frac{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}}{1+x} \\
&= \frac{-\sqrt{-a+1}+x}{x^2-1}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}}{x-1} + \frac{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}}{1+x}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}}{\left(x-1\right)^2} - \frac{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}}{\left(1+x\right)^2}\right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}}{x-1} + \frac{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}}{1+x}\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned} z_1(x) &= p e^{\int \omega \,dx} \\ &= \mathrm{e}^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}}{x-1} + \frac{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}}{1+x}\right) dx} \\ &= (1+x)^{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}} \end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2} \frac{B}{A} \,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= (1+x)^{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}} \end{aligned}$$

Which simplifies to

$$y_1 = (1+x)^{\frac{1}{2} + \frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2} - \frac{\sqrt{-a+1}}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \,dx}}{y_1^2} \,dx$$

Since $B = 0$ then the above becomes

$$
\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= (1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \int \frac{1}{(1+x)^{1+\sqrt{-a+1}} (x-1)^{1-\sqrt{-a+1}}}\, dx \\
&= (1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \left(\int (1+x)^{-1-\sqrt{-a+1}} (x-1)^{-1+\sqrt{-a+1}}\, dx\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left((1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}}\right) \\
&\quad + c_2 \left((1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \left(\int (1+x)^{-1-\sqrt{-a+1}} (x-1)^{-1+\sqrt{-a+1}}\, dx\right)\right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1 (1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \\
&\quad + c_2 (1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \left(\int (1+x)^{-1-\sqrt{-a+1}} (x-1)^{-1+\sqrt{-a+1}}\, dx\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= c_1 (1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \\
&\quad + c_2 (1+x)^{\frac{1}{2}+\frac{\sqrt{-a+1}}{2}} (x-1)^{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}} \left(\int (1+x)^{-1-\sqrt{-a+1}} (x-1)^{-1+\sqrt{-a+1}}\, dx\right)
\end{aligned}
$$

Verified OK.

32.11.3 Maple step by step solution

Let's solve

$y''(x^4-2x^2+1)+ay=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{ay}{x^4-2x^2+1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{ay}{x^4-2x^2+1}=0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

  $\left[P_2(x)=0, P_3(x)=\frac{a}{x^4-2x^2+1}\right]$

  ◦ $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left.((1+x)\cdot P_2(x))\right|_{x=-1}=0$

  ◦ $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left.((1+x)^2\cdot P_3(x))\right|_{x=-1}=\frac{a}{4}$

  ◦ $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=-1$

- Multiply by denominators

  $y''(x^4-2x^2+1)+ay=0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(u^4-4u^3+4u^2)\left(\frac{d^2}{du^2}y(u)\right)+ay(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^{m} \cdot \left(\frac{d^{2}}{d u^{2}}y(u)\right)$ to series expansion for $m = 2..4$

  $$u^{m} \cdot \left(\frac{d^{2}}{d u^{2}}y(u)\right) = \sum_{k=0}^{\infty} a_{k}(k+r)\left(k+r-1\right)u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^{m} \cdot \left(\frac{d^{2}}{d u^{2}}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\left(k+1-m+r\right)u^{k+r}$$

  Rewrite ODE with series expansions

  $$a_{0}(4r^{2}+a-4r)\,u^{r}+\left(\left(4r^{2}+a+4r\right)a_{1}-4a_{0}r(-1+r)\right)u^{1+r}+\left(\sum_{k=2}^{\infty}\left(a_{k}(4k^{2}+8kr+4r^{2}+a-\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$4r^{2}+a-4r = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{\frac{1}{2}-\frac{\sqrt{-a+1}}{2}, \frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right\}$$

- Each term must be 0

  $$\left(4r^{2}+a+4r\right)a_{1}-4a_{0}r(-1+r) = 0$$

- Solve for the dependent coefficient(s)

  $$a_{1} = \frac{4a_{0}r(-1+r)}{4r^{2}+a+4r}$$

- Each term in the series must be 0, giving the recursion relation

  $$\left(4a_{k}+a_{k-2}-4a_{k-1}\right)k^{2}+\left(\left(8a_{k}+2a_{k-2}-8a_{k-1}\right)r-4a_{k}-5a_{k-2}+12a_{k-1}\right)k+\left(4a_{k}+a_{k-2}-\right.$$

- Shift index using $k->k+2$

  $$\left(4a_{k+2}+a_{k}-4a_{k+1}\right)\left(k+2\right)^{2}+\left(\left(8a_{k+2}+2a_{k}-8a_{k+1}\right)r-4a_{k+2}-5a_{k}+12a_{k+1}\right)\left(k+2\right)+\left(4a\right.$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{k^{2}a_{k}-4k^{2}a_{k+1}+2kra_{k}-8kra_{k+1}+r^{2}a_{k}-4r^{2}a_{k+1}-ka_{k}-4ka_{k+1}-ra_{k}-4ra_{k+1}}{4k^{2}+8kr+4r^{2}+a+12k+12r+8}$$

- Recursion relation for $r = \frac{1}{2}-\frac{\sqrt{-a+1}}{2}$

  $$a_{k+2} = -\frac{k^{2}a_{k}-4k^{2}a_{k+1}+2k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)a_{k}-8k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)a_{k+1}+\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)^{2}a_{k}-4\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)^{2}a_{k+1}-ka_{k}-4ka_{k+1}-\left(\right.}{4k^{2}+8k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)+4\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)^{2}+a+12k+14-6\sqrt{-a+1}}$$

- Solution for $r = \frac{1}{2}-\frac{\sqrt{-a+1}}{2}$

  $$\left[y(u) = \sum_{k=0}^{\infty} a_{k}u^{k+\frac{1}{2}-\frac{\sqrt{-a+1}}{2}}, a_{k+2} = -\frac{k^{2}a_{k}-4k^{2}a_{k+1}+2k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)a_{k}-8k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)a_{k+1}+\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)^{2}a_{k}-4}{4k^{2}+8k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)+4\left(\frac{1}{2}-\frac{\sqrt{-a}}{2}\right.}\right.$$

- Revert the change of variables $u = 1+x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{1}{2}-\frac{\sqrt{-a+1}}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 2k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)a_k - 8k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)a_{k+1} + \left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)^2 a}{4k^2 + 8k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right) + 4\left(\frac{1}{2}-\right.}\right.$$

- Recursion relation for $r = \frac{1}{2} + \frac{\sqrt{-a+1}}{2}$

$$a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 2k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)a_k - 8k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)a_{k+1} + \left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)^2 a_k - 4\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)^2 a_{k+1} - k a_k - 4k a_{k+1} - (}{4k^2 + 8k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right) + 4\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)^2 + a + 12k + 14 + 6\sqrt{-a+1}}$$

- Solution for $r = \frac{1}{2} + \frac{\sqrt{-a+1}}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{1}{2}+\frac{\sqrt{-a+1}}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 2k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)a_k - 8k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)a_{k+1} + \left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)^2 a_k - 4}{4k^2 + 8k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right) + 4\left(\frac{1}{2}+\frac{\sqrt{-a}}{2}\right.}\right.$$

- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{1}{2}+\frac{\sqrt{-a+1}}{2}}, a_{k+2} = -\frac{k^2 a_k - 4k^2 a_{k+1} + 2k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)a_k - 8k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)a_{k+1} + \left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right)^2 a}{4k^2 + 8k\left(\frac{1}{2}+\frac{\sqrt{-a+1}}{2}\right) + 4\left(\frac{1}{2}+\right.}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} b_k (1+x)^{k+\frac{1}{2}-\frac{\sqrt{-a+1}}{2}}\right) + \left(\sum_{k=0}^{\infty} c_k (1+x)^{k+\frac{1}{2}+\frac{\sqrt{-a+1}}{2}}\right), b_{k+2} = -\frac{k^2 b_k - 4k^2 b_{1+k} + 2k\left(\frac{1}{2}-\frac{\sqrt{-a+1}}{2}\right)}{}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 222 A.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_Emden, _Fowler]]`

$$\boxed{(a^2 + x^2)^2 y'' + yb^2 = 0}$$

32.12.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{b^2y}{x^2} = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + (-n^2 + x^2) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha) xy' + (\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = \frac{1}{2}$$
$$\beta = b$$
$$n = \frac{1}{2}$$
$$\gamma = -1$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{b}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{b}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{b}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{b}{x}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{b}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{b}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{b}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{b}{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{b}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{b}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{b}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{b}{x}}}$$

Verified OK.

32.12.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(a^2 + x^2\right)^2 y'' + y b^2 = 0 \tag{1}$$
$$A y'' + B y' + C y = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= \left(a^2 + x^2\right)^2 \\ B &= 0 \\ C &= b^2 \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-b^2}{(a^2 + x^2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -b^2 \\ t &= (a^2 + x^2)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{b^2}{(a^2 + x^2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x) e^{-\int \frac{B}{2A} dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 206: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (a^2 + x^2)^2$. There is a pole at $x = ia$ of order 2. There is a pole at $x = -ia$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{b^2}{4a^2 \left(x - \sqrt{-a^2}\right)^2} + \frac{b^2}{4a^2 \left(x + \sqrt{-a^2}\right)^2} + \frac{b^2}{4 \left(-a^2\right)^{\frac{3}{2}} \left(x - \sqrt{-a^2}\right)} - \frac{b^2}{4 \left(-a^2\right)^{\frac{3}{2}} \left(x + \sqrt{-a^2}\right)}$$

For the pole at $x = ia$ let b be the coefficient of $\frac{1}{(-ia+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

For the pole at $x = -ia$ let b be the coefficient of $\frac{1}{(ia+x)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1 + 4b}, 2 - 2\sqrt{1 + 4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

Now since the order of r at ∞ is $4 > 2$ then

$$E_\infty = \{0, 2, 4\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
ia	2	$\{0, 2, 4\}$
$-ia$	2	$\{0, 2, 4\}$

Order of r at ∞	E_∞
4	$\{0, 2, 4\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2, \; e_2 = 2, \; e_\infty = 4$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c \in \Gamma} e_c\right) \\ &= \frac{1}{2}(4 - (2 + (2))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2} \sum_{c \in \Gamma} \frac{e_c}{x - c} \\ &= \frac{1}{2}\left(\frac{2}{(x - (ia))} + \frac{2}{(x - (-ia))}\right) \\ &= \frac{1}{-ia + x} + \frac{1}{ia + x} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{-ia+x} + \frac{1}{ia+x}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{-ia+x} + \frac{1}{ia+x}\right) w + \frac{a^2+b^2+x^2}{\left(a^2+x^2\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{x + \sqrt{-a^2-b^2}}{a^2+x^2}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega \, dx} \\ &= e^{\int \frac{x+\sqrt{-a^2-b^2}}{a^2+x^2} dx} \\ &= \sqrt{a^2+x^2}\, e^{\frac{\sqrt{-a^2-b^2}\, \arctan\left(\frac{x}{a}\right)}{a}}\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1 \\ &= \sqrt{a^2+x^2}\, e^{\frac{\sqrt{-a^2-b^2}\, \arctan\left(\frac{x}{a}\right)}{a}}\end{aligned}$$

Which simplifies to

$$y_1 = \sqrt{a^2+x^2}\, e^{\frac{\sqrt{-a^2-b^2}\, \arctan\left(\frac{x}{a}\right)}{a}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \sqrt{a^2+x^2}\,e^{\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}} \int \frac{1}{(a^2+x^2)\,e^{\frac{2\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}}}\,dx \\
&= \sqrt{a^2+x^2}\,e^{\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}} \left(-\frac{e^{-\frac{2\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}}}{2\sqrt{-a^2-b^2}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1y_1 + c_2y_2 \\
&= c_1\left(\sqrt{a^2+x^2}\,e^{\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}}\right) \\
&\quad + c_2\left(\sqrt{a^2+x^2}\,e^{\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}} \left(-\frac{e^{-\frac{2\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}}}{2\sqrt{-a^2-b^2}}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{a^2+x^2}\,e^{\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}} - \frac{c_2\sqrt{a^2+x^2}\,e^{-\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}}}{2\sqrt{-a^2-b^2}} \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{a^2+x^2}\,e^{\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}} - \frac{c_2\sqrt{a^2+x^2}\,e^{-\frac{\sqrt{-a^2-b^2}\,\arctan\left(\frac{x}{a}\right)}{a}}}{2\sqrt{-a^2-b^2}}$$

Verified OK.

32.12.3 Maple step by step solution

Let's solve

$\left(a^2+x^2\right)^2 y''+y b^2=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{y b^2}{\left(a^2+x^2\right)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{y b^2}{\left(a^2+x^2\right)^2}=0$

- Multiply by denominators of the ODE

  $\left(a^2+x^2\right)^2 y''+y b^2=0$

- Make a change of variables

  $t=\ln(x)$

□ Substitute the change of variables back into the ODE

  ◦ Calculate the 1st derivative of y with respect to x , using the chain rule

    $y'=\left(\frac{d}{dt}y(t)\right)t'(x)$

  ◦ Compute derivative

    $y'=\frac{\frac{d}{dt}y(t)}{x}$

  ◦ Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y''=\left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2+t''(x)\left(\frac{d}{dt}y(t)\right)$

  ◦ Compute derivative

    $y''=\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(a^2+x^2\right)^2\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)+y(t)\,b^2=0$

- Simplify

  $\frac{\left(a^2+x^2\right)^2\left(\frac{d^2}{dt^2}y(t)-\frac{d}{dt}y(t)\right)}{x^2}+y(t)\,b^2=0$

- Isolate 2nd derivative

$$\frac{d^2}{dt^2}y(t) = -\frac{b^2x^2y(t)}{(a^2+x^2)^2} + \frac{d}{dt}y(t)$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^2}{dt^2}y(t) + \frac{b^2x^2y(t)}{(a^2+x^2)^2} - \frac{d}{dt}y(t) = 0$$

- Characteristic polynomial of ODE

$$r^2 + \frac{b^2x^2}{(a^2+x^2)^2} - r = 0$$

- Factor the characteristic polynomial

$$\frac{a^4r^2+2a^2r^2x^2+r^2x^4-a^4r-2a^2r\,x^2-r\,x^4+b^2x^2}{(a^2+x^2)^2} = 0$$

- Roots of the characteristic polynomial

$$r = \left(\frac{\frac{a^2}{2}+\frac{x^2}{2}+\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}}{a^2+x^2}, \frac{\frac{a^2}{2}+\frac{x^2}{2}-\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}}{a^2+x^2}\right)$$

- 1st solution of the ODE

$$y_1(t) = e^{\frac{\left(\frac{a^2}{2}+\frac{x^2}{2}+\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{a^2+x^2}}$$

- 2nd solution of the ODE

$$y_2(t) = e^{\frac{\left(\frac{a^2}{2}+\frac{x^2}{2}-\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{a^2+x^2}}$$

- General solution of the ODE

$$y(t) = c_1y_1(t) + c_2y_2(t)$$

- Substitute in solutions

$$y(t) = c_1 e^{\frac{\left(\frac{a^2}{2}+\frac{x^2}{2}+\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{a^2+x^2}} + c_2 e^{\frac{\left(\frac{a^2}{2}+\frac{x^2}{2}-\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{a^2+x^2}}$$

- Change variables back using $t = \ln(x)$

$$y = c_1 e^{\frac{\left(\frac{a^2}{2}+\frac{x^2}{2}+\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}\right)\ln(x)}{a^2+x^2}} + c_2 e^{\frac{\left(\frac{a^2}{2}+\frac{x^2}{2}-\frac{\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2}\right)\ln(x)}{a^2+x^2}}$$

- Simplify

$$y = c_1 x^{\frac{a^2+x^2+\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2a^2+2x^2}} + x^{\frac{a^2+x^2-\sqrt{a^4+2a^2x^2-4b^2x^2+x^4}}{2a^2+2x^2}} c_2$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 222 B.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(-a^2 + x^2\right)^2 y'' + yb^2 = 0}$$

32.13.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \frac{b^2y}{x^2} = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right)y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha)xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right)y = 0 \tag{3}$$

With the standard solution

$$y = x^\alpha(c_1 \operatorname{BesselJ}(n, \beta x^\gamma) + c_2 \operatorname{BesselY}(n, \beta x^\gamma)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= \frac{1}{2}\\ \beta &= b\\ n &= \frac{1}{2}\\ \gamma &= -1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{b}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{b}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{b}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{b}{x}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{b}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{b}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{b}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{b}{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1\sqrt{x}\,\sqrt{2}\,\sin\left(\frac{b}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{b}{x}}} - \frac{c_2\sqrt{x}\,\sqrt{2}\,\cos\left(\frac{b}{x}\right)}{\sqrt{\pi}\,\sqrt{\frac{b}{x}}}$$

Verified OK.

32.13.2 Solving using Kovacic algorithm

Writing the ode as

$$y''(a-x)^2\,(x+a)^2 + yb^2 = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= (a-x)^2\,(x+a)^2\\ B &= 0\\ C &= b^2\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-b^2}{(a^2 - x^2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -b^2 \\ t &= (a^2 - x^2)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{b^2}{(a^2 - x^2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 208: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (a^2 - x^2)^2$. There is a pole at $x = a$ of order 2. There is a pole at $x = -a$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{b^2}{4a^2 (x+a)^2} - \frac{b^2}{4a^3 (x+a)} - \frac{b^2}{4a^2 (x-a)^2} + \frac{b^2}{4a^3 (x-a)}$$

For the pole at $x = a$ let b be the coefficient of $\frac{1}{(x-a)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{b^2}{4a^2}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2 - b^2}}{2a} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2 - b^2}}{2a} \end{aligned}$$

For the pole at $x = -a$ let b be the coefficient of $\frac{1}{(x+a)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{b^2}{4a^2}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2 - b^2}}{2a} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2 - b^2}}{2a} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$\begin{aligned}[\sqrt{r}]_\infty &= 0 \\ \alpha_\infty^+ &= 0 \\ \alpha_\infty^- &= 1\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r = -\frac{b^2}{(a^2 - x^2)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
a	2	0	$\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}$	$\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}$
$-a$	2	0	$\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}$	$\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned}d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0\end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2}\right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}}{x - a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}}{x + a} + (-)(0) \\
&= \frac{\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}}{x - a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}}{x + a} \\
&= \frac{\sqrt{a^2 - b^2} - x}{a^2 - x^2}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}}{x - a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}}{x + a}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}}{(x - a)^2} - \frac{\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}}{(x + a)^2}\right) + \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}}{x - a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}}{x + a}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-b^2}}{2a}}{x-a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-b^2}}{2a}}{x+a}\right) dx} \\
&= (x - a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x + a)^{\frac{a+\sqrt{a^2-b^2}}{2a}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}
$$

Since $B = 0$ then the above reduces to

$$
\begin{aligned}
y_1 &= z_1 \\
&= (x - a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x + a)^{\frac{a+\sqrt{a^2-b^2}}{2a}}
\end{aligned}
$$

Which simplifies to

$$y_1 = (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \int \frac{1}{(x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{a}}}\, dx \\
&= (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \left(\int (x-a)^{\frac{-a+\sqrt{a^2-b^2}}{a}} (x+a)^{\frac{-a-\sqrt{a^2-b^2}}{a}}\, dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left((x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}}\right) \\
&\quad + c_2\left((x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \left(\int (x-a)^{\frac{-a+\sqrt{a^2-b^2}}{a}} (x+a)^{\frac{-a-\sqrt{a^2-b^2}}{a}}\, dx\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned}
y &= c_1 (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \\
&\quad + c_2 (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \left(\int (x-a)^{\frac{-a+\sqrt{a^2-b^2}}{a}} (x+a)^{\frac{-a-\sqrt{a^2-b^2}}{a}}\, dx\right)
\end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned}
y &= c_1 (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \\
&\quad + c_2 (x-a)^{-\frac{-a+\sqrt{a^2-b^2}}{2a}} (x+a)^{\frac{a+\sqrt{a^2-b^2}}{2a}} \left(\int (x-a)^{\frac{-a+\sqrt{a^2-b^2}}{a}} (x+a)^{\frac{-a-\sqrt{a^2-b^2}}{a}}\, dx\right)
\end{aligned}$$

Verified OK.

32.13.3 Maple step by step solution

Let's solve

$y''(a-x)^2(x+a)^2+yb^2=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{b^2y}{(a-x)^2(x+a)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

    $y'=\left(\frac{d}{dt}y(t)\right)t'(x)$

  - Compute derivative

    $y'=\frac{\frac{d}{dt}y(t)}{x}$

  - Calculate the 2nd derivative of y with respect to x , using the chain rule

    $y''=\left(\frac{d^2}{dt^2}y(t)\right)t'(x)^2+t''(x)\left(\frac{d}{dt}y(t)\right)$

  - Compute derivative

    $y''=\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}$

  Substitute the change of variables back into the ODE

  $\left(\frac{\frac{d^2}{dt^2}y(t)}{x^2}-\frac{\frac{d}{dt}y(t)}{x^2}\right)(a-x)^2(x+a)^2+y(t)\,b^2=0$

- Simplify

  $\frac{\left(\frac{d^2}{dt^2}y(t)-\frac{d}{dt}y(t)\right)(a-x)^2(x+a)^2}{x^2}+y(t)\,b^2=0$

- Isolate 2nd derivative

$$\frac{d^2}{dt^2}y(t) = -\frac{b^2x^2y(t)}{(a-x)^2(x+a)^2} + \frac{d}{dt}y(t)$$

- Group terms with $y(t)$ on the lhs of the ODE and the rest on the rhs of the ODE; ODE is lin

$$\frac{d^2}{dt^2}y(t) + \frac{b^2x^2y(t)}{(a-x)^2(x+a)^2} - \frac{d}{dt}y(t) = 0$$

- Characteristic polynomial of ODE

$$r^2 + \frac{b^2x^2}{(a-x)^2(x+a)^2} - r = 0$$

- Factor the characteristic polynomial

$$\frac{a^4r^2-2a^2r^2x^2+r^2x^4-a^4r+2a^2r\,x^2-r\,x^4+b^2x^2}{(a-x)^2(x+a)^2} = 0$$

- Roots of the characteristic polynomial

$$r = \left(\frac{\frac{a^2}{2}-\frac{x^2}{2}+\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}}{(x+a)(a-x)}, \frac{\frac{a^2}{2}-\frac{x^2}{2}-\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}}{(x+a)(a-x)}\right)$$

- 1st solution of the ODE

$$y_1(t) = \mathrm{e}^{\frac{\left(\frac{a^2}{2}-\frac{x^2}{2}+\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{(x+a)(a-x)}}$$

- 2nd solution of the ODE

$$y_2(t) = \mathrm{e}^{\frac{\left(\frac{a^2}{2}-\frac{x^2}{2}-\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{(x+a)(a-x)}}$$

- General solution of the ODE

$$y(t) = c_1y_1(t) + c_2y_2(t)$$

- Substitute in solutions

$$y(t) = c_1\mathrm{e}^{\frac{\left(\frac{a^2}{2}-\frac{x^2}{2}+\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{(x+a)(a-x)}} + c_2\mathrm{e}^{\frac{\left(\frac{a^2}{2}-\frac{x^2}{2}-\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}\right)t}{(x+a)(a-x)}}$$

- Change variables back using $t = \ln(x)$

$$y = c_1\mathrm{e}^{\frac{\left(\frac{a^2}{2}-\frac{x^2}{2}+\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}\right)\ln(x)}{(x+a)(a-x)}} + c_2\mathrm{e}^{\frac{\left(\frac{a^2}{2}-\frac{x^2}{2}-\frac{\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2}\right)\ln(x)}{(x+a)(a-x)}}$$

- Simplify

$$y = c_1x^{\frac{a^2-x^2+\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2a^2-2x^2}} + x^{\frac{a^2-x^2-\sqrt{a^4-2a^2x^2-4b^2x^2+x^4}}{2a^2-2x^2}}c_2$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 223.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

`[_Halm]`

$$4\left(x^2+1\right)^2 y'' + \left(a\,x^2 + a - 3\right) y = 0$$

32.14.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' + \left(\frac{a}{4} + \frac{a}{4x^2} - \frac{3}{4x^2}\right) y = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= \frac{1}{2}\\ \beta &= \frac{\sqrt{-3+a}}{2}\\ n &= \frac{\sqrt{-a+1}}{2}\\ \gamma &= -1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\frac{\sqrt{-a+1}}{2}, \frac{\sqrt{-3+a}}{2x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\frac{\sqrt{-a+1}}{2}, \frac{\sqrt{-3+a}}{2x}\right)$$

Summary

The solution(s) found are the following

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\frac{\sqrt{-a+1}}{2}, \frac{\sqrt{-3+a}}{2x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\frac{\sqrt{-a+1}}{2}, \frac{\sqrt{-3+a}}{2x}\right) \tag{1}$$

Verification of solutions

$$y = c_1\sqrt{x}\,\text{BesselJ}\left(\frac{\sqrt{-a+1}}{2}, \frac{\sqrt{-3+a}}{2x}\right) + c_2\sqrt{x}\,\text{BesselY}\left(\frac{\sqrt{-a+1}}{2}, \frac{\sqrt{-3+a}}{2x}\right)$$

Verified OK.

32.14.2 Solving using Kovacic algorithm

Writing the ode as

$$4\left(x^2+1\right)^2 y'' + \left(a\,x^2 + a - 3\right) y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= 4\left(x^2+1\right)^2\\ B &= 0\\ C &= a\,x^2 + a - 3\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-a\,x^2 - a + 3}{4\,(x^2+1)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -a\,x^2 - a + 3 \\ t &= 4\big(x^2+1\big)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{-a\,x^2 - a + 3}{4\,(x^2+1)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0,1,2,4,6,8,\cdots\}$	$\{\cdots,-6,-4,-2,0,2,3,4,5,6,\cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1,2\}$	$\{2,3,4,5,6,7,\cdots\}$

Table 210: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 2 \\ &= 2 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(x^2+1)^2$. There is a pole at $x = i$ of order 2. There is a pole at $x = -i$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 2 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 2 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = -\frac{3}{16(x-i)^2} - \frac{3}{16(x+i)^2} + \frac{i\left(\frac{a}{8} - \frac{3}{16}\right)}{x-i} - \frac{i\left(\frac{a}{8} - \frac{3}{16}\right)}{x+i}$$

For the pole at $x = i$ let b be the coefficient of $\frac{1}{(x-i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

For the pole at $x = -i$ let b be the coefficient of $\frac{1}{(x+i)^2}$ in the partial fractions decomposition of r given above. Therefore $b = -\frac{3}{16}$. Hence

$$\begin{aligned} E_c &= \{2, 2 + 2\sqrt{1+4b}, 2 - 2\sqrt{1+4b}\} \\ &= \{1, 2, 3\} \end{aligned}$$

Since the order of r at ∞ is 2 then let b be the coefficient of $\frac{1}{x^2}$ in the Laurent series expansion of r at ∞. which can be found by dividing the leading coefficient of s by the leading coefficient of t from

$$r = \frac{s}{t} = \frac{-a\,x^2 - a + 3}{4\left(x^2+1\right)^2}$$

Since the gcd$(s,t)=1$. This gives $b=-\frac{1}{4}$. Hence

$$\begin{aligned}E_\infty &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\}\\ &= \{2\}\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
i	2	$\{1,2,3\}$
$-i$	2	$\{1,2,3\}$

Order of r at ∞	E_∞
2	$\{2\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 1,\ e_2 = 1,\ e_\infty = 2$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned}d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right)\\ &= \frac{1}{2}(2-(1+(1)))\\ &= 0\end{aligned}$$

We now form the following rational function

$$\begin{aligned}\theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c}\\ &= \frac{1}{2}\left(\frac{1}{(x-(i))}+\frac{1}{(x-(-i))}\right)\\ &= \frac{1}{2x-2i}+\frac{1}{2x+2i}\end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right)p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right)p = 0 \tag{1A}$$

Since $d=0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0=0$$

And solving for p gives

$$p=1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta+\frac{p'}{p}\\ &= \frac{1}{2x-2i}+\frac{1}{2x+2i}\end{aligned}$$

Let ω be the solution of

$$\omega^2-\phi\omega+\left(\frac{1}{2}\phi'+\frac{1}{2}\phi^2-r\right)=0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2-\left(\frac{1}{2x-2i}+\frac{1}{2x+2i}\right)w+\frac{a\,x^2+a-1}{4\left(-x+i\right)^2\left(x+i\right)^2}=0$$

Solving for ω gives

$$\omega=\frac{x+\sqrt{-\left(x^2+1\right)\left(a-1\right)}}{2x^2+2}$$

Therefore the first solution to the ode $z''=rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\,dx}\\ &= \mathrm{e}^{\int \frac{x+\sqrt{-\left(x^2+1\right)\left(a-1\right)}}{2x^2+2}dx}\\ &= \left(x^2+1\right)^{\frac{1}{4}}\mathrm{e}^{-\frac{\sqrt{a-1}\,\arctan\left(\frac{\sqrt{a-1}\,x}{\sqrt{x^2+1}\,\sqrt{-a+1}}\right)}{2}}\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1=z_1e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B=0$ then the above reduces to

$$\begin{aligned}y_1 &= z_1\\ &= \left(x^2+1\right)^{\frac{1}{4}}\mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}}\end{aligned}$$

Which simplifies to

$$y_1 = \left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\
&= \left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}} \int \frac{1}{\sqrt{x^2+1}\,\mathrm{e}^{-i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}}\,dx \\
&= \left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}} \left(-\frac{i\mathrm{e}^{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}}{\sqrt{a-1}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}}\right) \\
&\quad + c_2\left(\left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}} \left(-\frac{i\mathrm{e}^{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}}{\sqrt{a-1}}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1\left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}} - \frac{ic_2\left(x^2+1\right)^{\frac{1}{4}} \mathrm{e}^{\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}}}{\sqrt{a-1}} \tag{1}$$

Verification of solutions

$$y = c_1 (x^2+1)^{\frac{1}{4}} e^{-\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}} - \frac{i c_2 (x^2+1)^{\frac{1}{4}} e^{\frac{i\sqrt{a-1}\,\operatorname{arctanh}\left(\frac{x}{\sqrt{x^2+1}}\right)}{2}}}{\sqrt{a-1}}$$

Verified OK.

$$\boxed{\left(a\,x^{2}+b\right)^{2} y''+2ax\left(a\,x^{2}+b\right) y'+yc=0}$$

32.15.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(a\,x^{2}+b\right)^{2} y''+\left(2x^{3}a^{2}+2abx\right) y'+yc=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2ax}{a\,x^{2}+b}\\ q(x) &= \frac{c}{\left(a\,x^{2}+b\right)^{2}} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{2ax}{a\,x^2+b}dx\right)}dx \\
&= \int e^{-\ln\left(a\,x^2+b\right)}\,dx \\
&= \int \frac{1}{a\,x^2+b}dx \\
&= \frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{c}{\left(a\,x^2+b\right)^2}}{\frac{1}{\left(a\,x^2+b\right)^2}} \\
&= c
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + cy(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau)+By'(\tau)+Cy(\tau)=0$$

Where in the above $A=1, B=0, C=c$. Let the solution be $y(\tau)=e^{\lambda\tau}$. Substituting this into the ODE gives

$$\lambda^2 \mathrm{e}^{\lambda\tau}+c\,\mathrm{e}^{\lambda\tau}=0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda\tau}$ gives

$$\lambda^2+c=0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2}=\frac{-B}{2A}\pm\frac{1}{2A}\sqrt{B^2-4AC}$$

Substituting $A=1, B=0, C=c$ into the above gives

$$\begin{aligned}\lambda_{1,2}&=\frac{0}{(2)(1)}\pm\frac{1}{(2)(1)}\sqrt{0^2-(4)(1)(c)}\\&=\pm\sqrt{-c}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1&=+\sqrt{-c}\\\lambda_2&=-\sqrt{-c}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1&=\sqrt{-c}\\\lambda_2&=-\sqrt{-c}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau)&=c_1e^{\lambda_1\tau}+c_2e^{\lambda_2\tau}\\y(\tau)&=c_1e^{(\sqrt{-c})\tau}+c_2e^{(-\sqrt{-c})\tau}\end{aligned}$$

Or

$$y(\tau)=c_1\mathrm{e}^{\sqrt{-c}\,\tau}+c_2\mathrm{e}^{-\sqrt{-c}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} + c_2 \mathrm{e}^{-\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} + c_2 \mathrm{e}^{-\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} + c_2 \mathrm{e}^{-\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}$$

Verified OK.

32.15.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$\left(a\, x^{2}+b\right)^{2} y''+\left(2 x^{3} a^{2}+2 a b x\right) y'+y c = 0 \tag{1}$$

Becomes

$$y''+p(x)\, y'+q(x)\, y = 0 \tag{2}$$

Where

$$p(x) = \frac{2 a x}{a\, x^{2}+b}$$
$$q(x) = \frac{c}{\left(a\, x^{2}+b\right)^{2}}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^{2}}{d\tau^{2}}y(\tau)+p_{1}\left(\frac{d}{d\tau}y(\tau)\right)+q_{1}y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_{1}(\tau) = \frac{\tau''(x)+p(x)\,\tau'(x)}{\tau'\left(x\right)^{2}} \tag{4}$$

$$q_{1}(\tau) = \frac{q(x)}{\tau'\left(x\right)^{2}} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{\frac{c}{(a\,x^2+b)^2}}}{c} \\
\tau'' &= -\frac{2cax}{c\sqrt{\frac{c}{(a\,x^2+b)^2}}\,(a\,x^2+b)^3}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{-\frac{2cax}{c\sqrt{\frac{c}{(a\,x^2+b)^2}}\,(a\,x^2+b)^3} + \frac{2ax}{a\,x^2+b}\,\frac{\sqrt{\frac{c}{(a\,x^2+b)^2}}}{c}}{\left(\frac{\sqrt{\frac{c}{(a\,x^2+b)^2}}}{c}\right)^2} \\
&= 0
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2}y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{\frac{c}{(a\,x^2+b)^2}}dx}{c} \\
&= \frac{\sqrt{\frac{c}{(a\,x^2+b)^2}}\,(a\,x^2+b)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{c\sqrt{ab}}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos\left(\frac{\sqrt{c}\, \arctan\left(\frac{\sqrt{a}\, x}{\sqrt{b}}\right)}{\sqrt{a}\, \sqrt{b}}\right) + c_2 \sin\left(\frac{\sqrt{c}\, \arctan\left(\frac{\sqrt{a}\, x}{\sqrt{b}}\right)}{\sqrt{a}\, \sqrt{b}}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\frac{\sqrt{c}\, \arctan\left(\frac{\sqrt{a}\, x}{\sqrt{b}}\right)}{\sqrt{a}\, \sqrt{b}}\right) + c_2 \sin\left(\frac{\sqrt{c}\, \arctan\left(\frac{\sqrt{a}\, x}{\sqrt{b}}\right)}{\sqrt{a}\, \sqrt{b}}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cos\left(\frac{\sqrt{c}\, \arctan\left(\frac{\sqrt{a}\, x}{\sqrt{b}}\right)}{\sqrt{a}\, \sqrt{b}}\right) + c_2 \sin\left(\frac{\sqrt{c}\, \arctan\left(\frac{\sqrt{a}\, x}{\sqrt{b}}\right)}{\sqrt{a}\, \sqrt{b}}\right)$$

Verified OK.

32.15.3 Solving using Kovacic algorithm

Writing the ode as

$$\left(a\, x^2 + b\right)^2 y'' + \left(2x^3 a^2 + 2abx\right) y' + yc = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= \left(a\, x^2 + b\right)^2 \\ B &= 2x^3 a^2 + 2abx \\ C &= c \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{ab - c}{(a\,x^2 + b)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= ab - c \\ t &= (a\,x^2 + b)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{ab - c}{(a\,x^2 + b)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 211: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (a\,x^2+b)^2$. There is a pole at $x = \frac{\sqrt{-ab}}{a}$ of order 2. There is a pole at $x = -\frac{\sqrt{-ab}}{a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = &-\frac{ab-c}{4ab\left(x-\sqrt{-\frac{b}{a}}\right)^2}-\frac{ab-c}{4ab\left(x+\sqrt{-\frac{b}{a}}\right)^2} \\ &+\frac{-ab+c}{4\left(-\frac{b}{a}\right)^{\frac{3}{2}}a^2\left(x-\sqrt{-\frac{b}{a}}\right)}-\frac{-ab+c}{4\left(-\frac{b}{a}\right)^{\frac{3}{2}}a^2\left(x+\sqrt{-\frac{b}{a}}\right)} \end{aligned}$$

For the pole at $x = \frac{\sqrt{-ab}}{a}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{-ab}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

For the pole at $x = -\frac{\sqrt{-ab}}{a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{-ab}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

Now since the order of r at ∞ is $4 > 2$ then

$$E_\infty = \{0, 2, 4\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
$\frac{\sqrt{-ab}}{a}$	2	$\{0,2,4\}$
$-\frac{\sqrt{-ab}}{a}$	2	$\{0,2,4\}$

Order of r at ∞	E_∞
4	$\{0,2,4\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2,\ e_2 = 2,\ e_\infty = 4$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(4 - (2 + (2))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$\begin{aligned} \theta &= \frac{1}{2}\sum_{c\in\Gamma} \frac{e_c}{x-c} \\ &= \frac{1}{2}\left(\frac{2}{\left(x - \left(\frac{\sqrt{-ab}}{a}\right)\right)} + \frac{2}{\left(x - \left(-\frac{\sqrt{-ab}}{a}\right)\right)}\right) \\ &= \frac{1}{x - \frac{\sqrt{-ab}}{a}} + \frac{1}{x + \frac{\sqrt{-ab}}{a}} \end{aligned}$$

Now we search for a monic polynomial $p(x)$ of degree $d = 0$ such that

$$p''' + 3\theta p'' + \left(3\theta^2 + 3\theta' - 4r\right) p' + \left(\theta'' + 3\theta\theta' + \theta^3 - 4r\theta - 2r'\right) p = 0 \tag{1A}$$

Since $d = 0$, then letting

$$p = 1 \tag{2A}$$

Substituting p and θ into Eq. (1A) gives

$$0 = 0$$

And solving for p gives

$$p = 1$$

Now that $p(x)$ is found let

$$\begin{aligned}\phi &= \theta + \frac{p'}{p} \\ &= \frac{1}{x - \frac{\sqrt{-ab}}{a}} + \frac{1}{x + \frac{\sqrt{-ab}}{a}}\end{aligned}$$

Let ω be the solution of

$$\omega^2 - \phi\omega + \left(\frac{1}{2}\phi' + \frac{1}{2}\phi^2 - r\right) = 0$$

Substituting the values for ϕ and r into the above equation gives

$$w^2 - \left(\frac{1}{x - \frac{\sqrt{-ab}}{a}} + \frac{1}{x + \frac{\sqrt{-ab}}{a}}\right) w + \frac{a^2x^2 + c}{\left(a\,x^2 + b\right)^2} = 0$$

Solving for ω gives

$$\omega = \frac{ax + \sqrt{-c}}{a\,x^2 + b}$$

Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}z_1(x) &= e^{\int \omega\,dx} \\ &= \mathrm{e}^{\int \frac{ax+\sqrt{-c}}{a\,x^2+b}dx} \\ &= \sqrt{a\,x^2 + b}\,\mathrm{e}^{\frac{\sqrt{-c}\,\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\ &= z_1 e^{-\int \frac{1}{2}\frac{2x^3a^2+2abx}{\left(a\,x^2+b\right)^2}\,dx} \\ &= z_1 e^{-\frac{\ln\left(a\,x^2+b\right)}{2}} \\ &= z_1\left(\frac{1}{\sqrt{a\,x^2 + b}}\right)\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A} \, dx}}{y_1^2} \, dx$$

Substituting gives

$$\begin{aligned} y_2 &= y_1 \int \frac{e^{\int -\frac{2x^3 a^2 + 2abx}{\left(a x^2 + b\right)^2} \, dx}}{\left(y_1\right)^2} \, dx \\ &= y_1 \int \frac{e^{-\ln\left(a x^2 + b\right)}}{\left(y_1\right)^2} \, dx \\ &= y_1 \left(-\frac{\mathrm{e}^{-\frac{2\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}}{2\sqrt{-c}}\right) \end{aligned}$$

Therefore the solution is

$$\begin{aligned} y &= c_1 y_1 + c_2 y_2 \\ &= c_1 \left(\mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}\right) + c_2 \left(\mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} \left(-\frac{\mathrm{e}^{-\frac{2\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}}{2\sqrt{-c}}\right)\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} - \frac{c_2 \mathrm{e}^{-\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}}{2\sqrt{-c}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}} - \frac{c_2 \mathrm{e}^{-\frac{\sqrt{-c}\, \arctan\left(\frac{a x}{\sqrt{a b}}\right)}{\sqrt{a b}}}}{2\sqrt{-c}}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 226.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\left(-x^2+1\right)^2 y'' - 2x\left(-x^2+1\right) y' + \left(\nu(\nu+1)\left(-x^2+1\right) - \mu^2\right) y = 0$$

32.17.1 Maple step by step solution

Let's solve

$y''(x^4 - 2x^2 + 1) + (2x^3 - 2x)\, y' + (-x^2\nu^2 - x^2\nu - \mu^2 + \nu^2 + \nu)\, y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{(x^2\nu^2+x^2\nu+\mu^2-\nu^2-\nu)y}{x^4-2x^2+1} - \frac{2xy'}{x^2-1}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{2xy'}{x^2-1} - \frac{(x^2\nu^2+x^2\nu+\mu^2-\nu^2-\nu)y}{x^4-2x^2+1} = 0$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$$\left[P_2(x) = \frac{2x}{x^2-1}, P_3(x) = -\frac{x^2\nu^2+x^2\nu+\mu^2-\nu^2-\nu}{x^4-2x^2+1}\right]$$

- $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $$\left((1+x)\cdot P_2(x)\right)\Big|_{x=-1} = 1$$

- $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $$\left((1+x)^2\cdot P_3(x)\right)\Big|_{x=-1} = -\frac{\mu^2}{4}$$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $$y''(x^2-1)\left(x^4-2x^2+1\right)+2y'x\left(x^4-2x^2+1\right)-\left(x^2\nu^2+x^2\nu+\mu^2-\nu^2-\nu\right)\left(x^2-1\right)y = 0$$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $$\left(u^6-6u^5+12u^4-8u^3\right)\left(\frac{d^2}{du^2}y(u)\right)+\left(2u^5-10u^4+16u^3-8u^2\right)\left(\frac{d}{du}y(u)\right)+\left(-\nu^2u^4+4\nu^2u^3-\right.$$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

- ☐ Rewrite ODE with series expansions

  - Convert $u^m\cdot y(u)$ to series expansion for $m=1..4$

    $$u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$$

  - Shift index using $k->k-m$

    $$u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$$

  - Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=2..5$

    $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

  - Shift index using $k->k+1-m$

    $$u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=3..6$

$$u^{m}\cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right) = \sum_{k =0}^{\infty} a_{k} \left(k +r \right) \left(k +r -1\right) u^{k +r -2+m}$$

- Shift index using $k->k +2-m$

  $$u^{m}\cdot \left(\frac{d^{2}}{d u^{2}}y \left(u \right)\right) = \sum_{k =-2+m}^{\infty} a_{k +2-m} \left(k +2-m +r \right) \left(k +1-m +r \right) u^{k +r}$$

  Rewrite ODE with series expansions

  $$-2 a_{0} \left(\mu +2 r \right) \left(-\mu +2 r \right) u^{1+r}+\left(-2 a_{1} \left(2+\mu +2 r \right) \left(2-\mu +2 r \right)+a_{0} \left(-\mu^{2}-4 \nu^{2}+12 r^{2}-4 \nu +\right.\right.$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

  $$-2 \left(\mu +2 r \right) \left(-\mu +2 r \right) = 0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{-\frac{\mu}{2}, \frac{\mu}{2}\right\}$$

- The coefficients of each power of u must be 0

  $$\left[-2 a_{1} \left(2+\mu +2 r \right) \left(2-\mu +2 r \right)+a_{0} \left(-\mu^{2}-4 \nu^{2}+12 r^{2}-4 \nu +4 r \right) = 0, -2 a_{2} \left(4+\mu +2 r \right) \left(4-\right.\right.$$

- Solve for the dependent coefficient(s)

  $$\left\{a_{1} = \frac{a_{0} \left(\mu^{2}+4 \nu^{2}-12 r^{2}+4 \nu -4 r \right)}{2 \left(\mu^{2}-4 r^{2}-8 r -4\right)}, a_{2} = \frac{a_{0} \left(\mu^{4}-12 \mu^{2} r^{2}+16 \nu^{4}-64 \nu^{2} r^{2}+96 r^{4}-24 \mu^{2} r +32 \nu^{3}-64 \nu^{2} r -64 \nu \,r^{2}+256 r^{3}-16 \mu^{2}-16\right.}{4 \left(\mu^{4}-8 \mu^{2} r^{2}+16 r^{4}-24 \mu^{2} r +96 r^{3}-20 \mu^{2}+208 r^{2}+192 r +64\right)}\right.$$

- Each term in the series must be 0, giving the recursion relation

  $$\left(a_{k -4}-6 a_{k -3}+12 a_{k -2}-8 a_{k -1}\right) k^{2}+\left(2 \left(a_{k -4}-6 a_{k -3}+12 a_{k -2}-8 a_{k -1}\right) r -7 a_{k -4}+32 a_{k -3}-\right.$$

- Shift index using $k->k +4$

  $$\left(a_{k}-6 a_{k +1}+12 a_{k +2}-8 a_{k +3}\right) \left(k +4\right)^{2}+\left(2 \left(a_{k}-6 a_{k +1}+12 a_{k +2}-8 a_{k +3}\right) r -7 a_{k}+32 a_{k +1}-\right.$$

- Recursion relation that defines series solution to ODE

  $$a_{k +3} = \frac{k^{2} a_{k}-6 k^{2} a_{k +1}+12 k^{2} a_{k +2}+2 k r a_{k}-12 k r a_{k +1}+24 k r a_{k +2}-\mu^{2} a_{k +2}-a_{k} \nu^{2}+4 \nu^{2} a_{k +1}-4 \nu^{2} a_{k +2}+r^{2} a_{k}-6 r^{2} a_{k +1}+12 r^{2} a_{k +}}{2 \left(4 k^{2}+8 k r -\mu^{2}+4 r^{2}+24 k +24\right.}$$

- Recursion relation for $r = -\frac{\mu}{2}$

  $$a_{k +3} = \frac{k^{2} a_{k}-6 k^{2} a_{k +1}+12 k^{2} a_{k +2}-k \mu a_{k}+6 k \mu a_{k +1}-12 k \mu a_{k +2}+\frac{1}{4} a_{k} \mu^{2}-\frac{3}{2} \mu^{2} a_{k +1}+2 \mu^{2} a_{k +2}-a_{k} \nu^{2}+4 \nu^{2} a_{k +1}-4 \nu^{2} a_{k +2}+k a_{k}-}{2 \left(4 k^{2}-4 k \mu +24 k -12 \mu +36\right)}$$

- Solution for $r = -\frac{\mu}{2}$

  $$\left[y \left(u \right) = \sum_{k =0}^{\infty} a_{k} u^{k -\frac{\mu}{2}}, a_{k +3} = \frac{k^{2} a_{k}-6 k^{2} a_{k +1}+12 k^{2} a_{k +2}-k \mu a_{k}+6 k \mu a_{k +1}-12 k \mu a_{k +2}+\frac{1}{4} a_{k} \mu^{2}-\frac{3}{2} \mu^{2} a_{k +1}+2 \mu^{2} a_{k +2}-a_{k} \nu^{2}}{2}\right.$$

- Revert the change of variables $u = 1+x$

  $$\left[y = \sum_{k =0}^{\infty} a_{k} \left(1+x \right)^{k -\frac{\mu}{2}}, a_{k +3} = \frac{k^{2} a_{k}-6 k^{2} a_{k +1}+12 k^{2} a_{k +2}-k \mu a_{k}+6 k \mu a_{k +1}-12 k \mu a_{k +2}+\frac{1}{4} a_{k} \mu^{2}-\frac{3}{2} \mu^{2} a_{k +1}+2 \mu^{2} a_{k +2}-}{}\right.$$

- Recursion relation for $r = \frac{\mu}{2}$

$$a_{k+3} = \frac{k^2a_k - 6k^2a_{k+1} + 12k^2a_{k+2} + k\mu a_k - 6k\mu a_{k+1} + 12k\mu a_{k+2} + \frac{1}{4}a_k\mu^2 - \frac{3}{2}\mu^2a_{k+1} + 2\mu^2a_{k+2} - a_k\nu^2 + 4\nu^2a_{k+1} - 4\nu^2a_{k+2} + ka_k -}{2(4k^2+4k\mu+24k+12\mu+36)}$$

- Solution for $r = \frac{\mu}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{\mu}{2}}, a_{k+3} = \frac{k^2a_k - 6k^2a_{k+1} + 12k^2a_{k+2} + k\mu a_k - 6k\mu a_{k+1} + 12k\mu a_{k+2} + \frac{1}{4}a_k\mu^2 - \frac{3}{2}\mu^2a_{k+1} + 2\mu^2a_{k+2} - a_k\nu^2}{2}\right.$$

- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k(1+x)^{k+\frac{\mu}{2}}, a_{k+3} = \frac{k^2a_k - 6k^2a_{k+1} + 12k^2a_{k+2} + k\mu a_k - 6k\mu a_{k+1} + 12k\mu a_{k+2} + \frac{1}{4}a_k\mu^2 - \frac{3}{2}\mu^2a_{k+1} + 2\mu^2a_{k+2} -}{}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} a_k(1+x)^{k-\frac{\mu}{2}}\right) + \left(\sum_{k=0}^{\infty} b_k(1+x)^{k+\frac{\mu}{2}}\right), a_{k+3} = \frac{k^2a_k - 6k^2a_{1+k} + 12k^2a_{k+2} - k\mu a_k + 6k\mu a_{1+k} - 12k\mu a}{}\right.$$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

Unable to solve or complete the solution.

$$a\left(x^2-1\right)^2 y'' + bx\left(x^2-1\right) y' + \left(c\,x^2+dx+e\right) y = 0$$

32.18.1 Maple step by step solution

Let's solve

$y''a(x-1)^2\,(1+x)^2 + b(x^3-x)\,y' + (c\,x^2+dx+e)\,y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(c\,x^2+dx+e)y}{a(x-1)^2(1+x)^2} - \frac{bxy'}{a(x-1)(1+x)}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{bxy'}{a(x-1)(1+x)} + \frac{(c\,x^2+dx+e)y}{a(x-1)^2(1+x)^2} = 0$

☐ Check to see if x_0 is a regular singular point

- Define functions

  $\left[P_2(x) = \frac{bx}{a(x-1)(1+x)}, P_3(x) = \frac{c\,x^2+dx+e}{a(x-1)^2(1+x)^2}\right]$

- $(1+x)\cdot P_2(x)$ is analytic at $x=-1$

  $\left((1+x)\cdot P_2(x)\right)\bigg|_{x=-1} = \frac{b}{2a}$

- $(1+x)^2\cdot P_3(x)$ is analytic at $x=-1$

  $\left((1+x)^2\cdot P_3(x)\right)\bigg|_{x=-1} = \frac{e-d+c}{4a}$

- $x=-1$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = -1$

- Multiply by denominators

  $y''a(x-1)^2(1+x)^2 + bxy'(x-1)(1+x) + (c\,x^2+dx+e)\,y = 0$

- Change variables using $x=u-1$ so that the regular singular point is at $u=0$

  $(a\,u^4 - 4a\,u^3 + 4a\,u^2)\left(\frac{d^2}{du^2}y(u)\right) + (b\,u^3 - 3b\,u^2 + 2bu)\left(\frac{d}{du}y(u)\right) + (c\,u^2 - 2cu + du + c - d + e)$

- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

☐ Rewrite ODE with series expansions

- Convert $u^m\cdot y(u)$ to series expansion for $m=0..2$

  $u^m\cdot y(u) = \sum_{k=0}^{\infty} a_k u^{k+r+m}$

- Shift index using $k->k-m$

  $u^m\cdot y(u) = \sum_{k=m}^{\infty} a_{k-m} u^{k+r}$

- Convert $u^m\cdot\left(\frac{d}{du}y(u)\right)$ to series expansion for $m=1..3$

  $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$

- Shift index using $k->k+1-m$

  $u^m\cdot\left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 2..4$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$$

  Rewrite ODE with series expansions

  $$a_0(4a\,r^2-4ar+2br+c-d+e)\,u^r + \left((4a\,r^2+4ar+2br+2b+c-d+e)\,a_1 - a_0(4a\,r^2-4ar$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $$4a\,r^2-4ar+2br+c-d+e=0$$

- Values of r that satisfy the indicial equation

  $$r \in \left\{-\frac{-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}}{4a}, \frac{2a-b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}}{4a}\right\}$$

- Each term must be 0

  $$(4a\,r^2+4ar+2br+2b+c-d+e)\,a_1 - a_0(4a\,r^2-4ar+3br+2c-d)=0$$

- Solve for the dependent coefficient(s)

  $$a_1 = \frac{a_0(4a\,r^2-4ar+3br+2c-d)}{4a\,r^2+4ar+2br+2b+c-d+e}$$

- Each term in the series must be 0, giving the recursion relation

  $$((-4a_{k-1}+4a_k+a_{k-2})\,k^2 + ((-8a_{k-1}+8a_k+2a_{k-2})\,r+12a_{k-1}-4a_k-5a_{k-2})\,k + (-4a_{k-1}+$$

- Shift index using $k->k+2$

  $$((-4a_{k+1}+4a_{k+2}+a_k)\,(k+2)^2 + ((-8a_{k+1}+8a_{k+2}+2a_k)\,r+12a_{k+1}-4a_{k+2}-5a_k)\,(k+2)$$

- Recursion relation that defines series solution to ODE

  $$a_{k+2} = -\frac{a\,k^2a_k-4a\,k^2a_{k+1}+2akra_k-8akra_{k+1}+a\,r^2a_k-4a\,r^2a_{k+1}-aka_k-4aka_{k+1}-ara_k-4ara_{k+1}+a_kbk-3bka_{k+1}+a_kbr-}{4a\,k^2+8akr+4a\,r^2+12ak+12ar+2bk+2br+8a+4b+c-d+e}$$

- Recursion relation for $r = -\frac{-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}}{4a}$

  $$a_{k+2} = -\frac{a\,k^2a_k-4a\,k^2a_{k+1}-\frac{k\left(-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}\right)a_k}{2}+2k\left(-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}\right)a_{k+1}+\frac{(-2}{}}{}$$

- Solution for $r = -\frac{-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}}{4a}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}}{4a}}, a_{k+2} = -\frac{a\,k^2 a_k - 4a\,k^2 a_{k+1} - \frac{k\left(-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}\right.}{2}}{}\right.$$

- Revert the change of variables $u = 1+x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k-\frac{-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4ae+b^2}}{4a}}, a_{k+2} = -\frac{a\,k^2 a_k - 4a\,k^2 a_{k+1} - \frac{k\left(-2a+b+\sqrt{4a^2-4ab-4ac+4ad-4\right.}{2}}{}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 228.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(a\,x^2+b\right)^2 y''+(2ax+c)\left(a\,x^2+b\right)y'+yk=0}$$

32.19.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(a\,x^2+b\right)^2 y''+(2ax+c)\left(a\,x^2+b\right)y'+yk=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{2ax+c}{a\,x^2+b}\\ q(x)&=\frac{k}{\left(a\,x^2+b\right)^2}\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{2ax+c}{a\,x^2+b}dx\right)}dx \\
&= \int e^{-\ln\left(a\,x^2+b\right)-\frac{c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}dx \\
&= \int \frac{\mathrm{e}^{-\frac{c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{a\,x^2+b}dx \\
&= -\frac{\mathrm{e}^{-\frac{c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{k}{\left(a\,x^2+b\right)^2}}{\frac{\mathrm{e}^{-\frac{2c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{\left(a\,x^2+b\right)^2}} \\
&= k\,\mathrm{e}^{\frac{2c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + k\,\mathrm{e}^{\frac{2c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}} y(\tau) = 0$$

But in terms of τ

$$k\,\mathrm{e}^{\frac{2c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}} = \frac{k}{c^2\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{k y(\tau)}{c^2\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^2}{d\tau^2}y(\tau)\right)c^2\tau^2 + k y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$c^2\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + k\,\tau^r = 0$$

Simplifying gives

$$c^2 r(r-1)\,\tau^r + 0\,\tau^r + k\,\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$c^2 r(r-1) + 0 + k = 0$$

Or

$$c^2 r^2 - c^2 r + k = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-c + \sqrt{c^2 - 4k}}{2c}$$
$$r_2 = \frac{c + \sqrt{c^2 - 4k}}{2c}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{-\frac{-c+\sqrt{c^2-4k}}{2c}} + c_2 \tau^{\frac{c+\sqrt{c^2-4k}}{2c}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(-\frac{e^{-\frac{c \arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}\right)^{-\frac{-c+\sqrt{c^2-4k}}{2c}} + c_2 \left(-\frac{e^{-\frac{c \arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}\right)^{\frac{c+\sqrt{c^2-4k}}{2c}}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(-\frac{e^{-\frac{c \arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}\right)^{-\frac{-c+\sqrt{c^2-4k}}{2c}} + c_2 \left(-\frac{e^{-\frac{c \arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}\right)^{\frac{c+\sqrt{c^2-4k}}{2c}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(-\frac{e^{-\frac{c \arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}\right)^{-\frac{-c+\sqrt{c^2-4k}}{2c}} + c_2 \left(-\frac{e^{-\frac{c \arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{c}\right)^{\frac{c+\sqrt{c^2-4k}}{2c}}$$

Verified OK.

32.19.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(a\,x^2+b\right)^2 y'' + (2ax+c)\left(a\,x^2+b\right) y' + yk = 0 \tag{1}$$
$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= \left(a\,x^2+b\right)^2 \\ B &= (2ax+c)\left(a\,x^2+b\right) \\ C &= k \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4ab + c^2 - 4k}{4\left(a\,x^2 + b\right)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4ab + c^2 - 4k \\ t &= 4\left(a\,x^2 + b\right)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4ab + c^2 - 4k}{4\left(a\,x^2 + b\right)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 215: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(a\,x^2 + b)^2$. There is a pole at $x = \frac{\sqrt{-ab}}{a}$ of order 2. There is a pole at $x = -\frac{\sqrt{-ab}}{a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Unable to find solution using case one

Attempting to find a solution using case $n = 2$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = &-\frac{4ab + c^2 - 4k}{16ab\left(x - \sqrt{-\frac{b}{a}}\right)^2} - \frac{4ab + c^2 - 4k}{16ab\left(x + \sqrt{-\frac{b}{a}}\right)^2} \\ &+ \frac{-4ab - c^2 + 4k}{16\left(-\frac{b}{a}\right)^{\frac{3}{2}} a^2 \left(x - \sqrt{-\frac{b}{a}}\right)} - \frac{-4ab - c^2 + 4k}{16\left(-\frac{b}{a}\right)^{\frac{3}{2}} a^2 \left(x + \sqrt{-\frac{b}{a}}\right)} \end{aligned}$$

For the pole at $x = \frac{\sqrt{-ab}}{a}$ let b be the coefficient of $\frac{1}{\left(x-\frac{\sqrt{-ab}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

For the pole at $x = -\frac{\sqrt{-ab}}{a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{\sqrt{-ab}}{a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = 0$. Hence

$$\begin{aligned} E_c &= \{2, 2+2\sqrt{1+4b}, 2-2\sqrt{1+4b}\} \\ &= \{0, 2, 4\} \end{aligned}$$

Now since the order of r at ∞ is $4 > 2$ then

$$E_\infty = \{0, 2, 4\}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ for case 2 of Kovacic algorithm.

pole c location	pole order	E_c
$\frac{\sqrt{-ab}}{a}$	2	$\{0, 2, 4\}$
$-\frac{\sqrt{-ab}}{a}$	2	$\{0, 2, 4\}$

Order of r at ∞	E_∞
4	$\{0, 2, 4\}$

Using the family $\{e_1, e_2, \dots, e_\infty\}$ given by

$$e_1 = 2, \; e_2 = 2, \; e_\infty = 4$$

Gives a non negative integer d (the degree of the polynomial $p(x)$), which is generated using

$$\begin{aligned} d &= \frac{1}{2}\left(e_\infty - \sum_{c\in\Gamma} e_c\right) \\ &= \frac{1}{2}(4 - (2 + (2))) \\ &= 0 \end{aligned}$$

We now form the following rational function

$$
\begin{aligned}
\theta &= \frac{1}{2}\sum_{c\in\Gamma}\frac{e_c}{x-c} \\
&= \frac{1}{2}\left(\frac{2}{\left(x-\left(\frac{\sqrt{-ab}}{a}\right)\right)}+\frac{2}{\left(x-\left(-\frac{\sqrt{-ab}}{a}\right)\right)}\right) \\
&= \frac{1}{x-\frac{\sqrt{-ab}}{a}}+\frac{1}{x+\frac{\sqrt{-ab}}{a}}
\end{aligned}
$$

Now we search for a monic polynomial $p(x)$ of degree $d=0$ such that

$$
p'''+3\theta p''+\left(3\theta^2+3\theta'-4r\right)p'+\left(\theta''+3\theta\theta'+\theta^3-4r\theta-2r'\right)p=0 \tag{1A}
$$

Since $d=0$, then letting

$$
p=1 \tag{2A}
$$

Substituting p and θ into Eq. (1A) gives

$$
0=0
$$

And solving for p gives

$$
p=1
$$

Now that $p(x)$ is found let

$$
\begin{aligned}
\phi &= \theta+\frac{p'}{p} \\
&= \frac{1}{x-\frac{\sqrt{-ab}}{a}}+\frac{1}{x+\frac{\sqrt{-ab}}{a}}
\end{aligned}
$$

Let ω be the solution of

$$
\omega^2-\phi\omega+\left(\frac{1}{2}\phi'+\frac{1}{2}\phi^2-r\right)=0
$$

Substituting the values for ϕ and r into the above equation gives

$$
w^2-\left(\frac{1}{x-\frac{\sqrt{-ab}}{a}}+\frac{1}{x+\frac{\sqrt{-ab}}{a}}\right)w+\frac{4a^2x^2-c^2+4k}{4\left(a\,x^2+b\right)^2}=0
$$

Solving for ω gives

$$
\omega=\frac{2ax+\sqrt{c^2-4k}}{2a\,x^2+2b}
$$

Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \frac{2ax+\sqrt{c^2-4k}}{2a\,x^2+2b}dx} \\
&= \sqrt{a\,x^2+b}\,\mathrm{e}^{\frac{\sqrt{c^2-4k}\,\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2\sqrt{ab}}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{(2ax+c)\left(a\,x^2+b\right)}{\left(a\,x^2+b\right)^2}\,dx} \\
&= z_1 e^{-\frac{\ln\left(a\,x^2+b\right)}{2}-\frac{c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2\sqrt{ab}}} \\
&= z_1\left(\frac{\mathrm{e}^{-\frac{c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{2\sqrt{ab}}}}{\sqrt{a\,x^2+b}}\right)
\end{aligned}
$$

Which simplifies to

$$
y_1 = \mathrm{e}^{\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(-c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}}
$$

The second solution y_2 to the original ode is found using reduction of order

$$
y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx
$$

Substituting gives

$$
\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{(2ax+c)\left(a\,x^2+b\right)}{\left(a\,x^2+b\right)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln\left(a\,x^2+b\right)-\frac{c\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{(y_1)^2}\,dx \\
&= y_1\left(-\frac{\mathrm{e}^{-\frac{\sqrt{c^2-4k}\,\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{\sqrt{c^2-4k}}\right)
\end{aligned}
$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(e^{\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(-c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}} \right) + c_2 \left(e^{\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(-c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}} \left(-\frac{e^{-\frac{\sqrt{c^2-4k}\,\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{\sqrt{ab}}}}{\sqrt{c^2-4k}} \right) \right)
\end{aligned}
$$

Summary

The solution(s) found are the following

$$
y = c_1 e^{\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(-c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}} - \frac{c_2 e^{-\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}}}{\sqrt{c^2-4k}} \tag{1}
$$

Verification of solutions

$$
y = c_1 e^{\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(-c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}} - \frac{c_2 e^{-\frac{\arctan\left(\frac{ax}{\sqrt{ab}}\right)\left(c+\sqrt{c^2-4k}\right)}{2\sqrt{ab}}}}{\sqrt{c^2-4k}}
$$

$$\xi'' - (\xi\, p)' + \xi q = 0$$
$$\xi'' - \left(\frac{(c\,x^2+d)\,\xi(x)}{a\,x^2+b}\right)' + \left(-\frac{2(ad-bc)\,x\xi(x)}{\left(a\,x^2+b\right)^2}\right) = 0$$
$$\xi''(x) - \frac{(c\,x^2+d)\,\xi'(x)}{a\,x^2+b} + \left(-\frac{2cx}{a\,x^2+b} + \frac{2(c\,x^2+d)\,ax}{\left(a\,x^2+b\right)^2} - \frac{2(ad-bc)\,x}{\left(a\,x^2+b\right)^2}\right)\xi(x) = 0$$

Which is solved for $\xi(x)$. This is second order ode with missing dependent variable $\xi(x)$. Let

$$p(x) = \xi'(x)$$

Then

$$p'(x) = \xi''(x)$$

Hence the ode becomes

$$p'(x)\left(a\,x^2+b\right) + \left(-c\,x^2-d\right)p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned}
p' &= F(x,p)\\
&= f(x)g(p)\\
&= \frac{p(c\,x^2+d)}{a\,x^2+b}
\end{aligned}$$

Where $f(x) = \frac{c\,x^2+d}{a\,x^2+b}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\,dp &= \frac{c\,x^2+d}{a\,x^2+b}\,dx\\
\int \frac{1}{p}\,dp &= \int \frac{c\,x^2+d}{a\,x^2+b}\,dx\\
\ln(p) &= \frac{cx}{a} + \frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}} + c_1\\
p &= \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}+c_1}\\
&= c_1 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}}
\end{aligned}$$

Since $p=\xi'(x)$ then the new first order ode to solve is

$$\xi'(x)=c_1 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}}$$

Integrating both sides gives

$$\begin{aligned}
\xi(x) &= \int c_1 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}}\,\mathrm{d}x \\
&= \int c_1 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2
\end{aligned}$$

The original ode (2) now reduces to first order ode

$$\begin{aligned}
\xi(x)\,y' - y\xi'(x) + \xi(x)\,p(x)\,y &= \int \xi(x)\,r(x)\,dx \\
y' + y\left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)\,r(x)\,dx}{\xi\,(x)} \\
y' + y\left(\frac{c\,x^2+d}{a\,x^2+b} - \frac{c_3 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}}}{\int c_3 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2}\right) &= 0
\end{aligned}$$

Which is now a first order ode. This is now solved for y. In canonical form the ODE is

$$\begin{aligned}
y' &= F(x,y) \\
&= f(x)g(y) \\
&= \frac{y\left(\mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a\,x^2 - \left(\int c_3 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c\,x^2 - c\,x^2 c_2 + \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b}{(a\,x^2+b)\left(\int c_3 \mathrm{e}^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}
\end{aligned}$$

Where $f(x) = \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b - \left(\int c_3 e^{\dots}\right.}{(a x^2+b)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}$

and $g(y) = y$. Integrating both sides gives

$$\frac{1}{y}\,dy = \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c \dots}{(a x^2+b)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}$$

$$\int \frac{1}{y}\,dy = \int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{a\dots}}\right)}{a\sqrt{ab}}} \dots}{(a x^2+b)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}$$

$$\ln(y) = \int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{a\dots}}\right)}{a\sqrt{ab}}} \dots}{(a x^2+b)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}$$

$$y = e^{\int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-\dots}{\dots}}\right.}{\left(a x^2+b\right)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}}$$

$$= c_3 e^{\int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b - \left(\int c_3 e^{\frac{cx}{a}+\frac{(\dots}{\dots}}\right.}{\left(a x^2+b\right)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)}}$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = \int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan}{a\sqrt{ab}}}\right.}{\left(a x^2+b\right)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)} = c_3 e$$

Summary

The solution(s) found are the following

$$y = \int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan}{a\sqrt{ab}}}\right.}{\left(a x^2+b\right)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)} = c_3 e \tag{1}$$

Verification of solutions

$$y = \int \frac{e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 a x^2 - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx\right) c x^2 - c x^2 c_2 + e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} c_3 b - \left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan}{a\sqrt{ab}}}\right.}{\left(a x^2+b\right)\left(\int c_3 e^{\frac{cx}{a}+\frac{(ad-bc)\arctan\left(\frac{ax}{\sqrt{ab}}\right)}{a\sqrt{ab}}} dx + c_2\right)} = c_3 e$$

Verified OK.

Problem number: 232.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x-a)^2 (x-b)^2 y'' - yc = 0}$$

32.23.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - \frac{cy}{x^2} = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1-2\alpha)\, xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta\, x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta\, x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= \sqrt{-c} \\
n &= \frac{1}{2} \\
\gamma &= -1
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{-c}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{-c}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{-c}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{-c}}{x}}}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{-c}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{-c}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{-c}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{-c}}{x}}} \tag{1}
$$

Verification of solutions

$$
y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{-c}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{-c}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{-c}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{-c}}{x}}}
$$

Verified OK.

32.23.2 Solving using Kovacic algorithm

Writing the ode as

$$
y''(a-x)^2 (-x+b)^2 - yc = 0 \tag{1}
$$

$$
Ay'' + By' + Cy = 0 \tag{2}
$$

Comparing (1) and (2) shows that

$$
\begin{aligned}
A &= (a-x)^2 (-x+b)^2 \\
B &= 0 \\
C &= -c
\end{aligned} \tag{3}
$$

Applying the Liouville transformation on the dependent variable gives

$$
z(x) = y e^{\int \frac{B}{2A}\, dx}
$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{c}{(ab - ax - bx + x^2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= c \\ t &= (ab - ax - bx + x^2)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{c}{(ab - ax - bx + x^2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 216: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned}O(\infty) &= \deg(t) - \deg(s)\\ &= 4 - 0\\ &= 4\end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = (ab - ax - bx + x^2)^2$. There is a pole at $x = a$ of order 2. There is a pole at $x = b$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r = \frac{c}{(a-b)^2 (x-b)^2} + \frac{c}{(a-b)^2 (x-a)^2} + \frac{2c}{(a-b)^3 (x-b)} - \frac{2c}{(a-b)^3 (x-a)}$$

For the pole at $x = a$ let b be the coefficient of $\frac{1}{(x-a)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{c}{(a-b)^2}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2 - 2ab + b^2 + 4c}}{2a - 2b}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2 - 2ab + b^2 + 4c}}{2(a-b)}\end{aligned}$$

For the pole at $x = b$ let b be the coefficient of $\frac{1}{(x-b)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{c}{(a-b)^2}$. Hence

$$\begin{aligned}[\sqrt{r}]_c &= 0\\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{a^2 - 2ab + b^2 + 4c}}{2a - 2b}\\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{a^2 - 2ab + b^2 + 4c}}{2(a-b)}\end{aligned}$$

Since the order of r at ∞ is $4>2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= 0\\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{c}{\left(ab - ax - bx + x^2\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
a	2	0	$\frac{1}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}$	$\frac{1}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}$
b	2	0	$\frac{1}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}$	$\frac{1}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s=(s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-}=1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right)\\
&= 1 - (1)\\
&= 0
\end{aligned}
$$

Since d an integer and $d\geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma}\left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c}\right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$\omega = \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x - c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x - c_2}\right) + (-)[\sqrt{r}]_{\infty}$$
$$= \frac{\frac{1}{2} - \frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}}{x-a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}{x-b} + (-)(0)$$
$$= \frac{\frac{1}{2} - \frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}}{x-a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}{x-b}$$
$$= \frac{-a - \sqrt{a^2 - 2ab + b^2 + 4c} + 2x - b}{2(x-a)(x-b)}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}}{x-a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}{x-b}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}}{(x-a)^2} - \frac{\frac{1}{2} + \frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}{(x-b)^2}\right) + \right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$z_1(x) = pe^{\int \omega \, dx}$$
$$= e^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{a^2-2ab+b^2+4c}}{2(a-b)}}{x-a} + \frac{\frac{1}{2} + \frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}{x-b}\right) dx}$$
$$= e^{\frac{(-\ln(x-a)+\ln(x-b))\sqrt{a^2-2ab+b^2+4c}+(\ln(x-a)+\ln(x-b))(a-b)}{2a-2b}}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx}$$

Since $B = 0$ then the above reduces to

$$y_1 = z_1$$
$$= \sqrt{(a-x)(-x+b)} \left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}$$

Which simplifies to

$$y_1 = \sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned}
y_2 &= y_1 \int \frac{1}{y_1^2}\, dx \\
&= \sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}} \int \frac{1}{(a-x)(-x+b)\left(\frac{-x+b}{a-x}\right)^{\frac{2\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}}\, dx \\
&= \sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}} \left(\frac{\left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{a^2-2ab+b^2+4c}}{a-b}}}{\sqrt{a^2-2ab+b^2+4c}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1\left(\sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}\right) \\
&\quad + c_2\left(\sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}} \left(\frac{\left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{a^2-2ab+b^2+4c}}{a-b}}}{\sqrt{a^2-2ab+b^2+4c}}\right)\right)
\end{aligned}$$

Summary

The solution(s) found are the following

$$\begin{aligned}
y &= c_1\sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}} \\
&\quad + \frac{c_2\sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}}{\sqrt{a^2-2ab+b^2+4c}}
\end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 \sqrt{(a-x)(-x+b)} \left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}} + \frac{c_2 \sqrt{(a-x)(-x+b)} \left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{a^2-2ab+b^2+4c}}{2a-2b}}}{\sqrt{a^2-2ab+b^2+4c}}$$

Verified OK.

32.23.3 Maple step by step solution

Let's solve

$y''(a-x)^2(-x+b)^2 - yc = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = \frac{cy}{(a-x)^2(-x+b)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' - \frac{cy}{(a-x)^2(-x+b)^2} = 0$

□ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = 0, P_3(x) = -\frac{c}{(a-x)^2(-x+b)^2}\right]$

  - $(x-a) \cdot P_2(x)$ is analytic at $x = a$

    $\left((x-a) \cdot P_2(x)\right)\Big|_{x=a} = 0$

  - $(x-a)^2 \cdot P_3(x)$ is analytic at $x = a$

    $\left((x-a)^2 \cdot P_3(x)\right)\Big|_{x=a} = -\frac{c}{(b-a)^2}$

  - $x = a$is a regular singular point

    Check to see if x_0 is a regular singular point

    $x_0 = a$

- Multiply by denominators

  $y''(a-x)^2(-x+b)^2 - yc = 0$

- Change variables using $x=u+a$ so that the regular singular point is at $u=0$

$$\left(a^{2}u^{2}-2ab\,u^{2}+2a\,u^{3}+b^{2}u^{2}-2b\,u^{3}+u^{4}\right)\left(\frac{d^{2}}{du^{2}}y(u)\right)-cy(u)=0$$

- Assume series solution for $y(u)$

$$y(u)=\sum_{k=0}^{\infty}a_{k}u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)$ to series expansion for $m=2..4$

$$u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=0}^{\infty}a_{k}(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k->k+2-m$

$$u^{m}\cdot\left(\frac{d^{2}}{du^{2}}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$a_{0}(a^{2}r^{2}-2ab\,r^{2}+b^{2}r^{2}-a^{2}r+2abr-b^{2}r-c)\,u^{r}+\left((a^{2}r^{2}-2ab\,r^{2}+b^{2}r^{2}+a^{2}r-2abr+b^{2}r-$$

- a_{0}cannot be 0 by assumption, giving the indicial equation

$$a^{2}r^{2}-2ab\,r^{2}+b^{2}r^{2}-a^{2}r+2abr-b^{2}r-c=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{\frac{-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^{2}-2ab+b^{2}+4c}}{2}}{a-b},\frac{-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^{2}-2ab+b^{2}+4c}}{2}}{a-b}\right\}$$

- Each term must be 0

$$(a^{2}r^{2}-2ab\,r^{2}+b^{2}r^{2}+a^{2}r-2abr+b^{2}r-c)\,a_{1}+2a_{0}r(-1+r)\,(a-b)=0$$

- Solve for the dependent coefficient(s)

$$a_{1}=-\frac{2a_{0}r(ra-rb-a+b)}{a^{2}r^{2}-2ab\,r^{2}+b^{2}r^{2}+a^{2}r-2abr+b^{2}r-c}$$

- Each term in the series must be 0, giving the recursion relation

$$\left((a-b)^{2}a_{k}+2aa_{k-1}-2ba_{k-1}+a_{k-2}\right)k^{2}+\left(\left(2(a-b)^{2}a_{k}+4aa_{k-1}-4ba_{k-1}+2a_{k-2}\right)r-(a-$$

- Shift index using $k->k+2$

$$\left((a-b)^{2}a_{k+2}+2aa_{k+1}-2ba_{k+1}+a_{k}\right)(k+2)^{2}+\left(\left(2(a-b)^{2}a_{k+2}+4aa_{k+1}-4ba_{k+1}+2a_{k}\right)r-$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{2a\,k^{2}a_{k+1}+4akra_{k+1}+2a\,r^{2}a_{k+1}-2b\,k^{2}a_{k+1}-4bkra_{k+1}-2b\,r^{2}a_{k+1}+2aka_{k+1}+2ara_{k+1}-2bka_{k+1}-2bra_{k+1}+k^{2}a_{k}+}{a^{2}k^{2}+2a^{2}kr+a^{2}r^{2}-2ab\,k^{2}-4abkr-2ab\,r^{2}+b^{2}k^{2}+2b^{2}kr+b^{2}r^{2}+3a^{2}k+3a^{2}r-6abk-6abr+3b^{2}k+3b^{2}r+2a^{2}-}$$

- Recursion relation for $r = \frac{-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}$

$$a_{k+2} = -\frac{2a\,k^2 a_{k+1}+\frac{4ak\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)^2 a_{k+1}}{(a-b)^2}-2b\,k^2 a_{k+1}-\frac{4bk\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-\cdots}}{}\right.}{a-\cdots}}{a^2k^2+\frac{2a^2k\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)}{a-b}+\frac{a^2\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)^2}{(a-b)^2}-2ab\,k^2-\frac{4abk\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2\cdots}}{2}\right.}{a-b}}$$

- Solution for $r = \frac{-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1}+\frac{4ak\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-\cdots}}{}\right.}{(a\cdots}}{a^2k^2+\frac{2a^2k\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)}{a-b}+\frac{a^2\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a\cdots}}{}\right.}{(a-\cdots}}\right.$$

- Revert the change of variables $u = x-a$

$$\left[y = \sum_{k=0}^{\infty} a_k (x-a)^{k+\frac{-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1}+\frac{4ak\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{b}{2}+\frac{a}{2}-\cdots\right.}{}}{a^2k^2+\frac{2a^2k\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)}{a-b}+\frac{a^2\left(-\frac{b}{2}+\frac{a}{2}\cdots\right.}{}}\right.$$

- Recursion relation for $r = \frac{-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}$

$$a_{k+2} = -\frac{2a\,k^2 a_{k+1}+\frac{4ak\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)^2 a_{k+1}}{(a-b)^2}-2b\,k^2 a_{k+1}-\frac{4bk\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-\cdots}}{}\right.}{a-\cdots}}{a^2k^2+\frac{2a^2k\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)}{a-b}+\frac{a^2\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)^2}{(a-b)^2}-2ab\,k^2-\frac{4abk\left(-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2\cdots}}{2}\right.}{a-b}}$$

- Solution for $r = \frac{-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1}+\frac{4ak\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-\cdots}}{}\right.}{(a\cdots}}{a^2k^2+\frac{2a^2k\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)}{a-b}+\frac{a^2\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a\cdots}}{}\right.}{(a-\cdots}}\right.$$

- Revert the change of variables $u = x-a$

$$\left[y = \sum_{k=0}^{\infty} a_k (x-a)^{k+\frac{-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1}+\frac{4ak\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{b}{2}+\frac{a}{2}+\cdots\right.}{}}{a^2k^2+\frac{2a^2k\left(-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}\right)}{a-b}+\frac{a^2\left(-\frac{b}{2}+\frac{a}{2}\cdots\right.}{}}\right.$$

- Combine solutions and rename parameters

$$\left[y = \left(\sum_{k=0}^{\infty} d_k (x-a)^{k+\frac{-\frac{b}{2}+\frac{a}{2}-\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}}\right) + \left(\sum_{k=0}^{\infty} e_k (x-a)^{k+\frac{-\frac{b}{2}+\frac{a}{2}+\frac{\sqrt{a^2-2ab+b^2+4c}}{2}}{a-b}}\right), d_{k+2} = -\frac{2a}{}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 233.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second__order__change__of__variable__on__x__method__2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x-a)^2 (x-b)^2 y'' + (x-a)(x-b)(2x+\lambda) y' + \mu y = 0}$$

32.24.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$y''(a-x)^2 (-x+b)^2 + (2x+\lambda) y'(a-x)(-x+b) + \mu y = 0 \tag{1}$$

Becomes

$$y'' + p(x) y' + q(x) y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= \frac{2x+\lambda}{(a-x)(-x+b)} \\ q(x) &= \frac{\mu}{(a-x)^2 (-x+b)^2} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int \frac{2x+\lambda}{(a-x)(-x+b)}dx\right)}dx \\
&= \int e^{\frac{(-2a-\lambda)\ln(x-a)+2\left(b+\frac{\lambda}{2}\right)\ln(x-b)}{a-b}}dx \\
&= \int (x-a)^{\frac{-2a-\lambda}{a-b}}(x-b)^{\frac{2b+\lambda}{a-b}}dx \\
&= -\frac{(x-b)^{1+\frac{2b+\lambda}{a-b}}(x-a)^{1-\frac{2a+\lambda}{a-b}}}{a+b+\lambda}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{\mu}{(a-x)^2(-x+b)^2}}{(x-b)^{\frac{4b+2\lambda}{a-b}}(x-a)^{\frac{-4a-2\lambda}{a-b}}} \\
&= \mu(x-a)^{\frac{2a+2b+2\lambda}{a-b}}(x-b)^{\frac{-2a-2b-2\lambda}{a-b}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + \mu(x-a)^{\frac{2a+2b+2\lambda}{a-b}}(x-b)^{\frac{-2a-2b-2\lambda}{a-b}}y(\tau) = 0$$

But in terms of τ

$$\mu(x-a)^{\frac{2a+2b+2\lambda}{a-b}} (x-b)^{\frac{-2a-2b-2\lambda}{a-b}} = \frac{\mu}{(a+b+\lambda)^2 \tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{\mu y(\tau)}{(a+b+\lambda)^2 \tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^2}{d\tau^2}y(\tau)\right)(a+b+\lambda)^2 \tau^2 + \mu y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$(a+b+\lambda)^2 \tau^2 (r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \mu\tau^r = 0$$

Simplifying gives

$$(a+b+\lambda)^2 r(r-1)\tau^r + 0\,\tau^r + \mu\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$(a+b+\lambda)^2 r(r-1) + 0 + \mu = 0$$

Or

$$(a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2) r^2 + (-a^2-2ab-2a\lambda-b^2-2b\lambda-\lambda^2) r + \mu = 0 \quad (1)$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-a-b-\lambda+\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a+b+\lambda)}$$
$$r_2 = \frac{a+b+\lambda+\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a+2b+2\lambda}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{-\frac{-a-b-\lambda+\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a+b+\lambda)}} + c_2 \tau^{\frac{a+b+\lambda+\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a+2b+2\lambda}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(-\frac{(x-b)^{\frac{a+b+\lambda}{a-b}} (x-a)^{\frac{-a-b-\lambda}{a-b}}}{a+b+\lambda}\right)^{\frac{a+b+\lambda-\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a+2b+2\lambda}} + c_2 \left(-\frac{(x-b)^{\frac{a+b+\lambda}{a-b}} (x-a)^{\frac{-a-b-\lambda}{a-b}}}{a+b+\lambda}\right)^{a}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & c_1 \left(-\frac{(x-b)^{\frac{a+b+\lambda}{a-b}} (x-a)^{\frac{-a-b-\lambda}{a-b}}}{a+b+\lambda}\right)^{\frac{a+b+\lambda-\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a+2b+2\lambda}} \\ & + c_2 \left(-\frac{(x-b)^{\frac{a+b+\lambda}{a-b}} (x-a)^{\frac{-a-b-\lambda}{a-b}}}{a+b+\lambda}\right)^{\frac{a+b+\lambda+\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a+2b+2\lambda}} \end{aligned} \tag{1}$$

Verification of solutions

$$\begin{aligned} y = {} & c_1 \left(-\frac{(x-b)^{\frac{a+b+\lambda}{a-b}} (x-a)^{\frac{-a-b-\lambda}{a-b}}}{a+b+\lambda}\right)^{\frac{a+b+\lambda-\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a+2b+2\lambda}} \\ & + c_2 \left(-\frac{(x-b)^{\frac{a+b+\lambda}{a-b}} (x-a)^{\frac{-a-b-\lambda}{a-b}}}{a+b+\lambda}\right)^{\frac{a+b+\lambda+\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a+2b+2\lambda}} \end{aligned}$$

Verified OK.

32.24.2 Solving using Kovacic algorithm

Writing the ode as

$$y''(a-x)^2 (-x+b)^2 + (2x+\lambda) y'(a-x)(-x+b) + \mu y = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= (a-x)^2 (-x+b)^2 \\ B &= (2x+\lambda)(a-x)(-x+b) \\ C &= \mu \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A} dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu}{4\,(ab - ax - bx + x^2)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= 4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu \\ t &= 4\big(ab - ax - bx + x^2\big)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(\frac{4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu}{4\,(ab - ax - bx + x^2)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 218: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(ab - ax - bx + x^2)^2$. There is a pole at $x = a$ of order 2. There is a pole at $x = b$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = &\frac{4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu}{4 (a - b)^2 (x - a)^2} - \frac{4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu}{2 (a - b)^3 (x - a)} \\ &+ \frac{4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu}{4 (a - b)^2 (x - b)^2} - \frac{-4ab - 2a\lambda - 2b\lambda - \lambda^2 + 4\mu}{2 (a - b)^3 (x - b)} \end{aligned}$$

For the pole at $x = a$ let b be the coefficient of $\frac{1}{(x-a)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{\lambda^2+(2b+2a)\lambda+4ab-4\mu}{4(a-b)^2}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{\sqrt{a^2 + 2ab + 2a\lambda + b^2 + 2b\lambda + \lambda^2 - 4\mu}}{2a - 2b} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{\sqrt{a^2 + 2ab + 2a\lambda + b^2 + 2b\lambda + \lambda^2 - 4\mu}}{2 (a - b)} \end{aligned}$$

For the pole at $x = b$ let b be the coefficient of $\frac{1}{(x-b)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{\lambda^2+(2b+2a)\lambda+4ab-4\mu}{4(a-b)^2}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1 + 4b} = \frac{1}{2} + \frac{\sqrt{a^2 + 2ab + 2a\lambda + b^2 + 2b\lambda + \lambda^2 - 4\mu}}{2a - 2b} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1 + 4b} = \frac{1}{2} - \frac{\sqrt{a^2 + 2ab + 2a\lambda + b^2 + 2b\lambda + \lambda^2 - 4\mu}}{2 (a - b)} \end{aligned}$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = \frac{4ab + 2a\lambda + 2b\lambda + \lambda^2 - 4\mu}{4\left(ab - ax - bx + x^2\right)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
a	2	0	$\frac{1}{2} + \frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a-2b}$	$\frac{1}{2} - \frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a-b)}$
b	2	0	$\frac{1}{2} + \frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a-2b}$	$\frac{1}{2} - \frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a-b)}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$
\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty
$$

The above gives

$$
\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^{-}}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^{+}}{x-c_2}\right) + (-)[\sqrt{r}]_{\infty} \\
&= \frac{\frac{1}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a-b)}}{x-a} + \frac{\frac{1}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a-2b}}{x-b} + (-)(0) \\
&= \frac{\frac{1}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a-b)}}{x-a} + \frac{\frac{1}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a-2b}}{x-b} \\
&= \frac{-a-\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}+2x-b}{2(x-a)(x-b)}
\end{aligned}
$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d=0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$
p'' + 2\omega p' + (\omega' + \omega^2 - r)\, p = 0 \tag{1A}
$$

Let

$$
p(x) = 1 \tag{2A}
$$

Substituting the above in eq. (1A) gives

$$
(0) + 2\left(\frac{\frac{1}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a-b)}}{x-a} + \frac{\frac{1}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a-2b}}{x-b}\right)(0) + \left(\left(-\frac{\frac{1}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+}}{2(a-b)}}{(x-a)^2}\right.\right.
$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$
\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{\frac{1}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2(a-b)}}{x-a} + \frac{\frac{1}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2a-2b}}{x-b}\right) dx} \\
&= \mathrm{e}^{\frac{(-\ln(x-a)+\ln(x-b))\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}+(\ln(x-a)+\ln(x-b))(a-b)}{2a-2b}}
\end{aligned}
$$

The first solution to the original ode in y is found from

$$
\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\, dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{(2x+\lambda)(a-x)(-x+b)}{(a-x)^2(-x+b)^2}\, dx} \\
&= z_1 e^{-\frac{(-2b-\lambda)\ln(x-b)}{2(a-b)} - \frac{(2a+\lambda)\ln(x-a)}{2(a-b)}} \\
&= z_1 \left((x-b)^{\frac{2b+\lambda}{2a-2b}} (x-a)^{\frac{-2a-\lambda}{2a-2b}}\right)
\end{aligned}
$$

Which simplifies to

$$y_1 = \sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} (x-a)^{\frac{-2a-\lambda}{2a-2b}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\, dx}}{y_1^2}\, dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{(2x+\lambda)(a-x)(-x+b)}{(a-x)^2(-x+b)^2}\, dx}}{(y_1)^2}\, dx \\
&= y_1 \int \frac{e^{\frac{(-2a-\lambda)\ln(x-a)+2\left(b+\frac{\lambda}{2}\right)\ln(x-b)}{a-b}}}{(y_1)^2}\, dx \\
&= y_1 \left(\frac{\left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{a-b}}}{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} (x-a)^{\frac{-2a-\lambda}{2a-2b}}\right) \\
&\quad + c_2 \left(\sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} (x-a)^{\frac{-2a-\lambda}{2a-2b}} \left(\frac{\left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{a-b}}}{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}\right)\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = c_1 \sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} (x-a)^{\frac{-2a-\lambda}{2a-2b}} + \frac{c_2 \sqrt{(a-x)(-x+b)}\,(x-a)^{\frac{-2a-\lambda}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} \left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}}}{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}} \tag{1}$$

Verification of solutions

$$y = c_1 \sqrt{(a-x)(-x+b)}\left(\frac{-x+b}{a-x}\right)^{\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} (x-a)^{\frac{-2a-\lambda}{2a-2b}} + \frac{c_2 \sqrt{(a-x)(-x+b)}\,(x-a)^{\frac{-2a-\lambda}{2a-2b}} (x-b)^{\frac{2b+\lambda}{2a-2b}} \left(\frac{-x+b}{a-x}\right)^{-\frac{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}{2a-2b}}}{\sqrt{\lambda^2+(2b+2a)\lambda+a^2+2ab+b^2-4\mu}}$$

Verified OK.

32.24.3 Maple step by step solution

Let's solve

$y''(a-x)^2(-x+b)^2 + (2x+\lambda)\,y'(a-x)(-x+b) + \mu y = 0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y'' = -\frac{(2x+\lambda)y'}{(a-x)(-x+b)} - \frac{\mu y}{(a-x)^2(-x+b)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y'' + \frac{(2x+\lambda)y'}{(a-x)(-x+b)} + \frac{\mu y}{(a-x)^2(-x+b)^2} = 0$

☐ Check to see if x_0 is a regular singular point

  - Define functions

    $\left[P_2(x) = \frac{2x+\lambda}{(a-x)(-x+b)}, P_3(x) = \frac{\mu}{(a-x)^2(-x+b)^2}\right]$

  - $(x-a)\cdot P_2(x)$ is analytic at $x=a$

    $\left((x-a)\cdot P_2(x)\right)\Big|_{x=a} = -\frac{2a+\lambda}{b-a}$

- $(x-a)^2 \cdot P_3(x)$ is analytic at $x=a$

  $\left((x-a)^2 \cdot P_3(x)\right)\Big|_{x=a} = \frac{\mu}{(b-a)^2}$
- $x=a$is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = a$

- Multiply by denominators

  $y''(a-x)^2(-x+b)^2 + (2x+\lambda)y'(a-x)(-x+b) + \mu y = 0$
- Change variables using $x=u+a$ so that the regular singular point is at $u=0$

  $(a^2u^2 - 2ab\,u^2 + 2a\,u^3 + b^2u^2 - 2b\,u^3 + u^4)\left(\frac{d^2}{du^2}y(u)\right) + (2a^2u - 2abu + a\lambda u + 4a\,u^2 - b\lambda u - 2b$
- Assume series solution for $y(u)$

  $y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$

□ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$
- Shift index using $k->k+1-m$

  $u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$
- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 2..4$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\,u^{k+r-2+m}$
- Shift index using $k->k+2-m$

  $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0(a^2r^2 - 2ab\,r^2 + b^2r^2 + a^2r + a\lambda r - b^2r - b\lambda r + \mu)\,u^r + ((a^2r^2 - 2ab\,r^2 + b^2r^2 + 3a^2r - 4abr$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $a^2r^2 - 2ab\,r^2 + b^2r^2 + a^2r + a\lambda r - b^2r - b\lambda r + \mu = 0$

- Values of r that satisfy the indicial equation

$$r \in \left\{ \frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}, \frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b} \right\}$$

- Each term must be 0

$$(a^2r^2-2ab\,r^2+b^2r^2+3a^2r-4abr+a\lambda r+b^2r-b\lambda r+2a^2-2ab+a\lambda-b\lambda+\mu)\,a_1+a_0r(2ar$$

- Solve for the dependent coefficient(s)

$$a_1 = -\frac{a_0r(2ar-2rb+2a+\lambda)}{a^2r^2-2ab\,r^2+b^2r^2+3a^2r-4abr+a\lambda r+b^2r-b\lambda r+2a^2-2ab+a\lambda-b\lambda+\mu}$$

- Each term in the series must be 0, giving the recursion relation

$$\left((a-b)^2 a_k+2aa_{k-1}-2ba_{k-1}+a_{k-2}\right)k^2+\left(\left(2(a-b)^2 a_k+4aa_{k-1}-4ba_{k-1}+2a_{k-2}\right)r+(a-$$

- Shift index using $k->k+2$

$$\left((a-b)^2 a_{k+2}+2aa_{k+1}-2ba_{k+1}+a_k\right)(k+2)^2+\left(\left(2(a-b)^2 a_{k+2}+4aa_{k+1}-4ba_{k+1}+2a_k\right)r-$$

- Recursion relation that defines series solution to ODE

$$a_{k+2} = -\frac{2a\,k^2a_{k+1}+4akra_{k+1}+2a\,r^2a_{k+1}-2b\,k^2a_{k+1}-4bkra_{k+1}-2b\,r^2a_{k+1}+6aka_{k+1}+6ara_{k+1}-4bka_{k+1}-4bra_{k+1}+k^2a_k+}{a^2k^2+2a^2kr+a^2r^2-2ab\,k^2-4abkr-2ab\,r^2+b^2k^2+2b^2kr+b^2r^2+5a^2k+5a^2r-8abk-8abr+ak\lambda+a\lambda r+}$$

- Recursion relation for $r = \frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}$

$$a_{k+2} = -\frac{2a\,k^2a_{k+1}+\frac{4ak\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}\right)a_{k+1}}{a-b}+\frac{2a\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}\right.}{(a-b)^2}}{\mu+2b^2+6a^2+2a\lambda-2b\lambda-8ab-2ab\,k^2+ak\lambda-bk\lambda-8abk+\frac{a^2\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}\right)^2}{(a-b)^2}+\frac{b^2\left(-\frac{a}{2}-\frac{b}{2}-\right.}{}}$$

- Solution for $r = \frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2a_{k+1}+\frac{4ak\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+\right.}{2}}{a-b}}{\mu+2b^2+6a^2+2a\lambda-2b\lambda-8ab-2ab\,k^2+ak\lambda-bk\lambda-8}\right.$$

- Revert the change of variables $u = x-a$

$$\left[y = \sum_{k=0}^{\infty} a_k (x-a)^{k+\frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1} + \frac{4ak\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}-\frac{\sqrt{a^2+2ab+2}}{}\right.}{a-}}{\mu+2b^2+6a^2+2a\lambda-2b\lambda-8ab-2ab\,k^2+ak\lambda-bk}\right.$$

- Recursion relation for $r = \frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}$

$$a_{k+2} = -\frac{2a\,k^2 a_{k+1} + \frac{4ak\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}\right)a_{k+1}}{a-b} + \frac{2a\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}\right.}{(a-b)^2}}{\mu+2b^2+6a^2+2a\lambda-2b\lambda-8ab-2ab\,k^2+ak\lambda-bk\lambda-8abk+\frac{a^2\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}\right)^2}{(a-b)^2}+\frac{b^2\left(-\frac{a}{2}-\frac{b}{2}-\right.}{}}$$

- Solution for $r = \frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1} + \frac{4ak\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+}}{2}\right.}{a-b}}{\mu+2b^2+6a^2+2a\lambda-2b\lambda-8ab-2ab\,k^2+ak\lambda-bk\lambda-8}\right.$$

- Revert the change of variables $u = x - a$

$$\left[y = \sum_{k=0}^{\infty} a_k (x-a)^{k+\frac{-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2a\lambda+b^2+2b\lambda+\lambda^2-4\mu}}{2}}{a-b}}, a_{k+2} = -\frac{2a\,k^2 a_{k+1} + \frac{4ak\left(-\frac{a}{2}-\frac{b}{2}-\frac{\lambda}{2}+\frac{\sqrt{a^2+2ab+2}}{}\right.}{a-}}{\mu+2b^2+6a^2+2a\lambda-2b\lambda-8ab-2ab\,k^2+ak\lambda-bk}\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-7 Equation of form $(a_4x^4 + a_3x^3 + a_2x^2x + a_1x + a_0)y'' + f(x)y' + g(x)y = 0$
Problem number: 234.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_bessel_ode"**

Maple gives the following as the ode type

`[[_Emden, _Fowler]]`

$$\boxed{\left(a\,x^2+bx+c\right)^2 y''+Ay=0}$$

32.25.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y''+\frac{Ay}{x^2}=0 \tag{1}$$

Bessel ode has the form

$$x^2y''+y'x+\left(-n^2+x^2\right)y=0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y''+(1-2\alpha)\,xy'+\left(\beta^2\gamma^2x^{2\gamma}-n^2\gamma^2+\alpha^2\right)y=0 \tag{3}$$

With the standard solution

$$y=x^{\alpha}(c_1\,\mathrm{BesselJ}\left(n,\beta\,x^{\gamma}\right)+c_2\,\mathrm{BesselY}\left(n,\beta\,x^{\gamma}\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\begin{aligned}\alpha &= \frac{1}{2}\\ \beta &= \sqrt{A}\\ n &= \frac{1}{2}\\ \gamma &= -1\end{aligned}$$

Substituting all the above into (4) gives the solution as

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{A}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{A}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{A}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{A}}{x}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{A}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{A}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{A}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{A}}{x}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \sqrt{x}\, \sqrt{2}\, \sin\left(\frac{\sqrt{A}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{A}}{x}}} - \frac{c_2 \sqrt{x}\, \sqrt{2}\, \cos\left(\frac{\sqrt{A}}{x}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{A}}{x}}}$$

Verified OK.

32.25.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(a\, x^2 + bx + c\right)^2 y'' + Ay = 0 \tag{1}$$

$$Ay'' + By' + Cy = 0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned}A &= \left(a\, x^2 + bx + c\right)^2\\ B &= 0\\ C &= A\end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\, dx}$$

Then (2) becomes

$$z''(x) = rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{-A}{(a\,x^2 + bx + c)^2} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s &= -A \\ t &= (a\,x^2 + bx + c)^2 \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x) = \left(-\frac{A}{(a\,x^2 + bx + c)^2}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 220: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = \left(a\,x^2 + bx + c\right)^2$. There is a pole at $x = -\frac{b-\sqrt{-4ac+b^2}}{2a}$ of order 2. There is a pole at $x = -\frac{b+\sqrt{-4ac+b^2}}{2a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$\begin{aligned} r = &-\frac{A}{\left(-4ac+b^2\right)\left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2} - \frac{A}{\left(-4ac+b^2\right)\left(x + \frac{b+\sqrt{-4ac+b^2}}{2a}\right)^2} \\ &+ \frac{2aA}{\left(-4ac+b^2\right)^{\frac{3}{2}}\left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right)} - \frac{2aA}{\left(-4ac+b^2\right)^{\frac{3}{2}}\left(x + \frac{b+\sqrt{-4ac+b^2}}{2a}\right)} \end{aligned}$$

For the pole at $x = -\frac{b-\sqrt{-4ac+b^2}}{2a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b-\sqrt{-4ac+b^2}}{2a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{A}{4ac-b^2}$. Hence

$$\begin{aligned} [\sqrt{r}]_c &= 0 \\ \alpha_c^+ &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2} \\ \alpha_c^- &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2} \end{aligned}$$

For the pole at $x = -\frac{b+\sqrt{-4ac+b^2}}{2a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b+\sqrt{-4ac+b^2}}{2a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b = \frac{A}{4ac-b^2}$. Hence

$$
\begin{aligned}
[\sqrt{r}]_c &= 0 \\
\alpha_c^{+} &= \frac{1}{2} + \sqrt{1+4b} = \frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2} \\
\alpha_c^{-} &= \frac{1}{2} - \sqrt{1+4b} = \frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}
\end{aligned}
$$

Since the order of r at ∞ is $4 > 2$ then

$$
\begin{aligned}
[\sqrt{r}]_\infty &= 0 \\
\alpha_\infty^{+} &= 0 \\
\alpha_\infty^{-} &= 1
\end{aligned}
$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$
r = -\frac{A}{(a\,x^2 + bx + c)^2}
$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^{+}	α_c^{-}
$-\frac{b-\sqrt{-4ac+b^2}}{2a}$	2	0	$\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}$	$\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}$
$-\frac{b+\sqrt{-4ac+b^2}}{2a}$	2	0	$\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}$	$\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^{+}	α_∞^{-}
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^{\pm}$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^{\pm}$ have also been found, the next step is to determine possible non negative integer d from these using

$$
d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}
$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^{\pm}$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^{-} = 1$ then

$$
\begin{aligned}
d &= \alpha_\infty^{-} - \left(\alpha_{c_1}^{-} + \alpha_{c_2}^{+}\right) \\
&= 1 - (1) \\
&= 0
\end{aligned}
$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c \in \Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x - c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned}
\omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x - c_1} \right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x - c_2} \right) + (-)[\sqrt{r}]_\infty \\
&= \frac{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b+\sqrt{-4ac+b^2}}{2a}} + (-)(0) \\
&= \frac{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b+\sqrt{-4ac+b^2}}{2a}} \\
&= \frac{2ax - \sqrt{-4ac+b^2}\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}} + b}{2a\,x^2 + 2bx + 2c}
\end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b+\sqrt{-4ac+b^2}}{2a}} \right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{\left(x + \frac{b-\sqrt{-4ac+b^2}}{2a}\right)^2} - \frac{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{\left(x + \frac{b+\sqrt{-4ac+b^2}}{2a}\right)^2} \right) + \left(\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= e^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}{x + \frac{b+\sqrt{-4ac+b^2}}{2a}} \right) dx} \\
&= \left(\frac{2ax + \sqrt{-4ac+b^2} + b}{a} \right)^{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \sqrt{\frac{2ax + b - \sqrt{-4ac+b^2}}{a}} \left(\frac{2ax + b - \sqrt{-4ac+b^2}}{a} \right)^{-\frac{\sqrt{4a}}{}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$y_1 = z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx}$$

Since $B = 0$ then the above reduces to

$$\begin{aligned} y_1 &= z_1 \\ &= \left(\frac{2ax + b - \sqrt{-4ac + b^2}}{a}\right)^{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax + \sqrt{-4ac + b^2} + b}{a}\right)^{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \end{aligned}$$

Which simplifies to

$$y_1 = \left(\frac{2ax + b - \sqrt{-4ac + b^2}}{a}\right)^{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax + \sqrt{-4ac + b^2} + b}{a}\right)^{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Since $B = 0$ then the above becomes

$$\begin{aligned} y_2 &= y_1 \int \frac{1}{y_1^2}\,dx \\ &= \left(\frac{2ax + b - \sqrt{-4ac + b^2}}{a}\right)^{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax + \sqrt{-4ac + b^2} + b}{a}\right)^{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \int \frac{}{\left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{1}} \\ &= \left(\frac{2ax + b - \sqrt{-4ac + b^2}}{a}\right)^{\frac{1}{2} - \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax + \sqrt{-4ac + b^2} + b}{a}\right)^{\frac{1}{2} + \frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\int \left(\frac{2ax + b - \sqrt{-}}{a}\right.\right. \end{aligned}$$

Therefore the solution is

$$
\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \right) \\
&\quad + c_2 \left(\left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\int \left(\frac{2ax+b-}{} \right.\right.\right.
\end{aligned}
$$

Summary
The solution(s) found are the following

$$
\begin{aligned}
y = c_1 &\left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \\
- c_2 &\left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \sqrt{\frac{2ax+b-\sqrt{-4ac+b^2}}{a}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{-\frac{\sqrt{\frac{4ac-}{4a}}}{2}} \\
&\quad - \frac{\left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{-\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}}{4a\left(a\,x^2+bx+c\right)} dx \Bigg)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y = {} & c_1 \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \\
& - c_2 \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \sqrt{\frac{2ax+b-\sqrt{-4ac+b^2}}{a}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{-\frac{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}{2}} \left(\int \right. \\
& \left. -\frac{\left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{-\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\sqrt{\frac{4ac-b^2+4A}{4ac-b^2}}}}{4a\left(a\,x^2+bx+c\right)} dx\right)
\end{aligned}
$$

Verified OK.

32.25.3 Maple step by step solution

Let's solve

$\left(a\,x^2+bx+c\right)^2 y''+Ay=0$

- Highest derivative means the order of the ODE is 2

  y''

- Isolate 2nd derivative

  $y''=-\frac{Ay}{\left(a\,x^2+bx+c\right)^2}$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $y''+\frac{Ay}{\left(a\,x^2+bx+c\right)^2}=0$

□ Check to see if x_0 is a regular singular point

- ◦ Define functions

  $\left[P_2(x)=0, P_3(x)=\frac{A}{\left(a\,x^2+bx+c\right)^2}\right]$

- ◦ $\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)\cdot P_2(x)$ is analytic at $x=\frac{-b+\sqrt{-4ac+b^2}}{2a}$

  $\left(\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)\cdot P_2(x)\right)\bigg|_{x=\frac{-b+\sqrt{-4ac+b^2}}{2a}}=0$

- ◦ $\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2\cdot P_3(x)$ is analytic at $x=\frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left(\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2\cdot P_3(x)\right)\Bigg|_{x=\frac{-b+\sqrt{-4ac+b^2}}{2a}}=0$$

- $x=\frac{-b+\sqrt{-4ac+b^2}}{2a}$ is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0=\frac{-b+\sqrt{-4ac+b^2}}{2a}$

- Multiply by denominators

  $(a\,x^2+bx+c)^2\,y''+Ay=0$

- Change variables using $x=u+\frac{-b+\sqrt{-4ac+b^2}}{2a}$ so that the regular singular point is at $u=0$

  $(a^2u^4+2a\,u^3\sqrt{-4ac+b^2}-4ac\,u^2+b^2u^2)\left(\frac{d^2}{du^2}y(u)\right)+Ay(u)=0$

- Assume series solution for $y(u)$

  $y(u)=\sum_{k=0}^{\infty}a_ku^{k+r}$

- ☐ Rewrite ODE with series expansions

  - Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=2..4$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=0}^{\infty}a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$

  - Shift index using $k->k+2-m$

    $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)=\sum_{k=-2+m}^{\infty}a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$

  Rewrite ODE with series expansions

  $a_0(-4ac\,r^2+b^2r^2+4acr-b^2r+A)\,u^r+((-4ac\,r^2+b^2r^2-4acr+b^2r+A)\,a_1+2a_0r(-1+r)$

- $a_0$cannot be 0 by assumption, giving the indicial equation

  $-4ac\,r^2+b^2r^2+4acr-b^2r+A=0$

- Values of r that satisfy the indicial equation

  $r\in\left\{-\frac{-4ac+b^2+\sqrt{16c^2a^2-8b^2ca+b^4+16Aac-4A\,b^2}}{2(4ac-b^2)},\frac{4ac-b^2+\sqrt{16c^2a^2-8b^2ca+b^4+16Aac-4A\,b^2}}{2(4ac-b^2)}\right\}$

- Each term must be 0

  $(-4ac\,r^2+b^2r^2-4acr+b^2r+A)\,a_1+2a_0r(-1+r)\,a\sqrt{-4ac+b^2}=0$

- Solve for the dependent coefficient(s)

  $a_1=-\frac{2a_0r(-1+r)a\sqrt{-4ac+b^2}}{-4ac\,r^2+b^2r^2-4acr+b^2r+A}$

- Each term in the series must be 0, giving the recursion relation

$$2a_{k-1}(k+r-1)(k-2+r)a\sqrt{-4ac+b^2}+a_{k-2}(k-2+r)(k-3+r)a^2-4ca_k(k+r)(k+r$$

- Shift index using $k->k+2$

$$2a_{k+1}(k+1+r)(k+r)a\sqrt{-4ac+b^2}+a_k(k+r)(k+r-1)a^2-4ca_{k+2}(k+2+r)(k+1+r$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=-\frac{a\left(2\sqrt{-4ac+b^2}\,k^2a_{k+1}+4\sqrt{-4ac+b^2}\,kra_{k+1}+2\sqrt{-4ac+b^2}\,r^2a_{k+1}+a\,k^2a_k+2akra_k+a\,r^2a_k+2\sqrt{-4ac+b^2}\,ka_{k+1}+2\sqrt{-}\right.}{-4ac\,k^2-8ackr-4ac\,r^2+b^2k^2+2b^2kr+b^2r^2-12ack-12acr+3b^2k+3b^2r-8ac+2b^2+A}$$

- Recursion relation for $r=-\frac{-4ac+b^2+\sqrt{16c^2a^2-8b^2ca+b^4+16Aac-4A\,b^2}}{2(4ac-b^2)}$

$$a_{k+2}=-\frac{a\left(2\sqrt{-4ac+b^2}\,k^2a_{k+1}-\frac{2\sqrt{-4ac+b^2}\,k\left(-4ac+b^2+\sqrt{16c^2a^2-8b^2ca+b^4+16Aac-4A\,b^2}\right)a_{k+1}}{4ac-b^2}+\frac{\sqrt{-4ac+b^2}\,\left(-4ac+b^2+\sqrt{16c^2a^2}\right.}{2(4ac}\right.}{-4ac\,k^2+\frac{4ack\left(-4ac+b^2+\sqrt{16c^2a^2-8b^2ca+b^4+16Aac-4A\,b^2}\right)}{4ac-b^2}-\frac{ac\left(-4ac+b^2+\sqrt{16c^2a^2-8b^2ca}\right.}{\left(4ac-b^2\right)}}$$

  $$u^m\cdot\left(\frac{d}{du}y(u)\right)=\sum_{k=-1+m}^{\infty}a_{k+1-m}(k+1-m+r)u^{k+r}$$

- Convert $u^m\cdot\left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m=3..6$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)(k+r-1)\, u^{k+r-2+m}$$

- Shift index using $k- > k+2-m$

$$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)(k+1-m+r)\, u^{k+r}$$

Rewrite ODE with series expansions

$$-2a_0(m+2r)(-m+2r)\, u^{1+r} + (-2a_1(2+m+2r)(2-m+2r) + a_0(4a^2 - m^2 + 12r^2 - 4\lambda +$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-2(m+2r)(-m+2r) = 0$$

- Values of r that satisfy the indicial equation

$$r \in \left\{-\frac{m}{2}, \frac{m}{2}\right\}$$

- The coefficients of each power of u must be 0

$$[-2a_1(2+m+2r)(2-m+2r) + a_0(4a^2 - m^2 + 12r^2 - 4\lambda + 4r) = 0, -2a_2(4+m+2r)(4-$$

- Solve for the dependent coefficient(s)

$$\left\{a_1 = -\frac{a_0(4a^2 - m^2 + 12r^2 - 4\lambda + 4r)}{2(m^2 - 4r^2 - 8r - 4)}, a_2 = \frac{a_0(16a^4 + 16a^2m^2 + m^4 - 12m^2r^2 + 96r^4 - 32\lambda a^2 - 64a^2r - 64\lambda r^2 - 24m^2r + 256r^3 - 32}{4(m^4 - 8m^2r^2 + 16r^4 - 24m^2r + 96r^3 - 20m^2 + 208r^2}\right.$$

- Each term in the series must be 0, giving the recursion relation

$$(12a_{k-2} - 8a_{k-1} + a_{k-4} - 6a_{k-3})\, k^2 + (2(12a_{k-2} - 8a_{k-1} + a_{k-4} - 6a_{k-3})\, r - 44a_{k-2} + 16a_{k-1} -$$

- Shift index using $k- > k+6$

$$(12a_{k+4} - 8a_{k+5} + a_{k+2} - 6a_{k+3})(k+6)^2 + (2(12a_{k+4} - 8a_{k+5} + a_{k+2} - 6a_{k+3})\, r - 44a_{k+4} + 16a$$

- Recursion relation that defines series solution to ODE

$$a_{k+5} = \frac{a_k a^2 - 6a^2 a_{k+1} + 13a^2 a_{k+2} - 12a^2 a_{k+3} + 4a^2 a_{k+4} + k^2 a_{k+2} - 6k^2 a_{k+3} + 12k^2 a_{k+4} + 2kra_{k+2} - 12kra_{k+3} + 24kra_{k+4} - m^2 a_{k}}{2(4k^2}$$

- Recursion relation for $r = -\frac{m}{2}$

$$a_{k+5} = \frac{a_k a^2 + 6a_{k+2} - 66a_{k+3} + \frac{1}{4}m^2 a_{k+2} - \frac{3}{2}m^2 a_{k+3} - \frac{5}{2}ma_{k+2} + 20ma_{k+3} - 50ma_{k+4} + 208a_{k+4} - 6a^2 a_{k+1} + 13a^2 a_{k+2} - 12a^2 a_{k+}}{2(}$$

- Solution for $r = -\frac{m}{2}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{m}{2}}, a_{k+5} = \frac{a_k a^2 + 6a_{k+2} - 66a_{k+3} + \frac{1}{4}m^2 a_{k+2} - \frac{3}{2}m^2 a_{k+3} - \frac{5}{2}ma_{k+2} + 20ma_{k+3} - 50ma_{k+4} + 208a_{k+4} - 6a}{}\right.$$

- Revert the change of variables $u = 1 + x$

$$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k-\frac{m}{2}}, a_{k+5} = \frac{a_k a^2 + 6a_{k+2} - 66a_{k+3} + \frac{1}{4}m^2 a_{k+2} - \frac{3}{2}m^2 a_{k+3} - \frac{5}{2}ma_{k+2} + 20ma_{k+3} - 50ma_{k+4} + 208a_{k+}}{}\right.$$

- Recursion relation for $r = \frac{m}{2}$

$a_{k+5} = \frac{a_k a^2+6a_{k+2}-66a_{k+3}+\frac{1}{4}m^2a_{k+2}-\frac{3}{2}m^2a_{k+3}+\frac{5}{2}ma_{k+2}-20ma_{k+3}+50ma_{k+4}+208a_{k+4}-6a^2a_{k+1}+13a^2a_{k+2}-12a^2a_{k+}}{2(4}$

- Solution for $r = \frac{m}{2}$

$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k+\frac{m}{2}}, a_{k+5} = \frac{a_k a^2+6a_{k+2}-66a_{k+3}+\frac{1}{4}m^2a_{k+2}-\frac{3}{2}m^2a_{k+3}+\frac{5}{2}ma_{k+2}-20ma_{k+3}+50ma_{k+4}+208a_{k+4}-6a}{}\right.$

- Revert the change of variables $u = 1+x$

$\left[y = \sum_{k=0}^{\infty} a_k (1+x)^{k+\frac{m}{2}}, a_{k+5} = \frac{a_k a^2+6a_{k+2}-66a_{k+3}+\frac{1}{4}m^2a_{k+2}-\frac{3}{2}m^2a_{k+3}+\frac{5}{2}ma_{k+2}-20ma_{k+3}+50ma_{k+4}+208a_{k+}}{}\right.$

- Combine solutions and rename parameters

$\left[y = \left(\sum_{k=0}^{\infty} b_k (1+x)^{k-\frac{m}{2}}\right) + \left(\sum_{k=0}^{\infty} c_k (1+x)^{k+\frac{m}{2}}\right), b_{k+5} = \frac{-6a^2b_{1+k}+13a^2b_{k+2}-12a^2b_{k+3}+4a^2b_{4+k}+k^2b_{k+2}}{}\right.$

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{\left(a\,x^{2}+bx+c\right)^{2} y''+\left(2ax+k\right)\left(a\,x^{2}+bx+c\right) y'+ym=0}$$

32.28.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$\left(a\,x^{2}+bx+c\right)^{2} y''+\left(2ax+k\right)\left(a\,x^{2}+bx+c\right) y'+ym=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{2ax+k}{a\,x^{2}+bx+c}\\ q(x)&=\frac{m}{\left(a\,x^{2}+bx+c\right)^{2}}\end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int \mathrm{e}^{-\left(\int p(x)dx\right)}dx \\
&= \int \mathrm{e}^{-\left(\int \frac{2ax+k}{a\,x^2+bx+c}dx\right)}dx \\
&= \int e^{-\ln\left(a\,x^2+bx+c\right)+\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}dx \\
&= \int \frac{\mathrm{e}^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{a\,x^2+bx+c}dx \\
&= \frac{\mathrm{e}^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{m}{\left(a\,x^2+bx+c\right)^2}}{\frac{\mathrm{e}^{\frac{4(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\left(a\,x^2+bx+c\right)^2}} \\
&= m\,\mathrm{e}^{-\frac{4(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + m\,\mathrm{e}^{-\frac{4(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}y(\tau) = 0$$

But in terms of τ

$$m\,\mathrm{e}^{-\frac{4(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}} = \frac{m}{(b-k)^2\,\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{my(\tau)}{(b-k)^2\,\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^2}{d\tau^2}y(\tau)\right)(b-k)^2\,\tau^2 + my(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$(b-k)^2\,\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + m\,\tau^r = 0$$

Simplifying gives

$$(b-k)^2\,r(r-1)\,\tau^r + 0\,\tau^r + m\,\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$(b-k)^2\,r(r-1) + 0 + m = 0$$

Or

$$\left(b^2 - 2bk + k^2\right)r^2 + \left(-b^2 + 2bk - k^2\right)r + m = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-b + k + \sqrt{b^2 - 2bk + k^2 - 4m}}{2\,(b-k)}$$

$$r_2 = \frac{b - k + \sqrt{b^2 - 2bk + k^2 - 4m}}{2b - 2k}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1 y_1 + c_2 y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1 \tau^{-\frac{-b+k+\sqrt{b^2-2bk+k^2-4m}}{2(b-k)}} + c_2 \tau^{\frac{b-k+\sqrt{b^2-2bk+k^2-4m}}{2b-2k}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \left(\frac{e^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}\right)^{\frac{b-k-\sqrt{b^2-2bk+k^2-4m}}{2b-2k}} + c_2 \left(\frac{e^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}\right)^{\frac{b-k+\sqrt{b^2-2bk+k^2-4m}}{2b-2k}}$$

Summary

The solution(s) found are the following

$$\begin{aligned} y = {} & c_1 \left(\frac{e^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}\right)^{\frac{b-k-\sqrt{b^2-2bk+k^2-4m}}{2b-2k}} \\ & + c_2 \left(\frac{e^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}\right)^{\frac{b-k+\sqrt{b^2-2bk+k^2-4m}}{2b-2k}} \end{aligned} \tag{1}$$

Verification of solutions

$$y = c_1 \left(\frac{e^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}\right)^{\frac{b-k-\sqrt{b^2-2bk+k^2-4m}}{2b-2k}} + c_2 \left(\frac{e^{\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{b-k}\right)^{\frac{b-k+\sqrt{b^2-2bk+k^2-4m}}{2b-2k}}$$

Verified OK.

32.28.2 Solving using Kovacic algorithm

Writing the ode as

$$\left(a\,x^{2}+bx+c\right)^{2} y''+\left(2ax+k\right)\left(a\,x^{2}+bx+c\right) y'+ym=0 \tag{1}$$

$$Ay''+By'+Cy=0 \tag{2}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A&=\left(a\,x^{2}+bx+c\right)^{2}\\ B&=\left(a\,x^{2}+bx+c\right)\left(2ax+k\right)\\ C&=m \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x)=ye^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x)=rz(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r&=\frac{s}{t}\\ &=\frac{2AB'-2BA'+B^{2}-4AC}{4A^{2}} \end{aligned} \tag{5}$$

Substituting the values of A,B,C from (3) in the above and simplifying gives

$$r=\frac{4ac-2bk+k^{2}-4m}{4\left(a\,x^{2}+bx+c\right)^{2}} \tag{6}$$

Comparing the above to (5) shows that

$$\begin{aligned} s&=4ac-2bk+k^{2}-4m\\ t&=4\left(a\,x^{2}+bx+c\right)^{2} \end{aligned}$$

Therefore eq. (4) becomes

$$z''(x)=\left(\frac{4ac-2bk+k^{2}-4m}{4\left(a\,x^{2}+bx+c\right)^{2}}\right) z(x) \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y=z(x)\,e^{-\int \frac{B}{2A}\,dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 223: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 4 - 0 \\ &= 4 \end{aligned}$$

The poles of r in eq. (7) and the order of each pole are determined by solving for the roots of $t = 4(a\,x^2 + bx + c)^2$. There is a pole at $x = -\frac{b-\sqrt{-4ac+b^2}}{2a}$ of order 2. There is a pole at $x = -\frac{b+\sqrt{-4ac+b^2}}{2a}$ of order 2. Since there is no odd order pole larger than 2 and the order at ∞ is 4 then the necessary conditions for case one are met. Since there is a pole of order 2 then necessary conditions for case two are met. Since pole order is not larger than 2 and the order at ∞ is 4 then the necessary conditions for case three are met. Therefore

$$L = [1, 2, 4, 6, 12]$$

Attempting to find a solution using case $n = 1$.

Looking at poles of order 2. The partial fractions decomposition of r is

$$r=\frac{4ac-2bk+k^2-4m}{4\left(-4ac+b^2\right)\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2}+\frac{4ac-2bk+k^2-4m}{4\left(-4ac+b^2\right)\left(x+\frac{b+\sqrt{-4ac+b^2}}{2a}\right)^2}$$
$$-\frac{\left(4ac-2bk+k^2-4m\right)a}{2\left(-4ac+b^2\right)^{\frac{3}{2}}\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)}+\frac{\left(4ac-2bk+k^2-4m\right)a}{2\left(-4ac+b^2\right)^{\frac{3}{2}}\left(x+\frac{b+\sqrt{-4ac+b^2}}{2a}\right)}$$

For the pole at $x=-\frac{b-\sqrt{-4ac+b^2}}{2a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b-\sqrt{-4ac+b^2}}{2a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{-4ac+2bk-k^2+4m}{16ac-4b^2}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}+\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}\\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}-\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}
\end{aligned}$$

For the pole at $x=-\frac{b+\sqrt{-4ac+b^2}}{2a}$ let b be the coefficient of $\frac{1}{\left(x+\frac{b+\sqrt{-4ac+b^2}}{2a}\right)^2}$ in the partial fractions decomposition of r given above. Therefore $b=\frac{-4ac+2bk-k^2+4m}{16ac-4b^2}$. Hence

$$\begin{aligned}
[\sqrt{r}]_c &= 0\\
\alpha_c^{+} &= \frac{1}{2}+\sqrt{1+4b}=\frac{1}{2}+\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}\\
\alpha_c^{-} &= \frac{1}{2}-\sqrt{1+4b}=\frac{1}{2}-\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}
\end{aligned}$$

Since the order of r at ∞ is $4>2$ then

$$\begin{aligned}
[\sqrt{r}]_\infty &= 0\\
\alpha_\infty^{+} &= 0\\
\alpha_\infty^{-} &= 1
\end{aligned}$$

The following table summarizes the findings so far for poles and for the order of r at ∞ where r is

$$r=\frac{4ac-2bk+k^2-4m}{4\left(a\,x^2+bx+c\right)^2}$$

pole c location	pole order	$[\sqrt{r}]_c$	α_c^+	α_c^-
$-\frac{b-\sqrt{-4ac+b^2}}{2a}$	2	0	$\frac{1}{2}+\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}$	$\frac{1}{2}-\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}$
$-\frac{b+\sqrt{-4ac+b^2}}{2a}$	2	0	$\frac{1}{2}+\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}$	$\frac{1}{2}-\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}$

Order of r at ∞	$[\sqrt{r}]_\infty$	α_∞^+	α_∞^-
4	0	0	1

Now that the all $[\sqrt{r}]_c$ and its associated $\alpha_c^\pm$ have been determined for all the poles in the set Γ and $[\sqrt{r}]_\infty$ and its associated $\alpha_\infty^\pm$ have also been found, the next step is to determine possible non negative integer d from these using

$$d = \alpha_\infty^{s(\infty)} - \sum_{c\in\Gamma} \alpha_c^{s(c)}$$

Where $s(c)$ is either $+$ or $-$ and $s(\infty)$ is the sign of $\alpha_\infty^\pm$. This is done by trial over all set of families $s = (s(c))_{c\in\Gamma\cup\infty}$ until such d is found to work in finding candidate ω. Trying $\alpha_\infty^- = 1$ then

$$\begin{aligned} d &= \alpha_\infty^- - \left(\alpha_{c_1}^- + \alpha_{c_2}^+\right) \\ &= 1 - (1) \\ &= 0 \end{aligned}$$

Since d an integer and $d \geq 0$ then it can be used to find ω using

$$\omega = \sum_{c\in\Gamma} \left(s(c)[\sqrt{r}]_c + \frac{\alpha_c^{s(c)}}{x-c} \right) + s(\infty)[\sqrt{r}]_\infty$$

The above gives

$$\begin{aligned} \omega &= \left((-)[\sqrt{r}]_{c_1} + \frac{\alpha_{c_1}^-}{x-c_1}\right) + \left((+)[\sqrt{r}]_{c_2} + \frac{\alpha_{c_2}^+}{x-c_2}\right) + (-)[\sqrt{r}]_\infty \\ &= \frac{\frac{1}{2}-\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x+\frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2}+\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x+\frac{b+\sqrt{-4ac+b^2}}{2a}} + (-)(0) \\ &= \frac{\frac{1}{2}-\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x+\frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2}+\frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x+\frac{b+\sqrt{-4ac+b^2}}{2a}} \\ &= \frac{2ax - \sqrt{-4ac+b^2}\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}} + b}{2a\,x^2 + 2bx + 2c} \end{aligned}$$

Now that ω is determined, the next step is find a corresponding minimal polynomial $p(x)$ of degree $d = 0$ to solve the ode. The polynomial $p(x)$ needs to satisfy the equation

$$p'' + 2\omega p' + \left(\omega' + \omega^2 - r\right) p = 0 \tag{1A}$$

Let

$$p(x) = 1 \tag{2A}$$

Substituting the above in eq. (1A) gives

$$(0) + 2\left(\frac{\frac{1}{2} - \frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x + \frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2} + \frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x + \frac{b+\sqrt{-4ac+b^2}}{2a}}\right)(0) + \left(\left(-\frac{\frac{1}{2} - \frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{\left(x + \frac{b-\sqrt{-4ac+b^2}}{2a}\right)^2} - \frac{\frac{1}{2} + \frac{\sqrt{-\frac{b^2-2bk+k^2-4}{4ac-b^2}}}{2}}{\left(x + \frac{b+\sqrt{-4ac+b^2}}{2a}\right.}\right.\right.$$

The equation is satisfied since both sides are zero. Therefore the first solution to the ode $z'' = rz$ is

$$\begin{aligned}
z_1(x) &= p e^{\int \omega \, dx} \\
&= \mathrm{e}^{\int \left(\frac{\frac{1}{2} - \frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x + \frac{b-\sqrt{-4ac+b^2}}{2a}} + \frac{\frac{1}{2} + \frac{\sqrt{-\frac{b^2-2bk+k^2-4m}{4ac-b^2}}}{2}}{x + \frac{b+\sqrt{-4ac+b^2}}{2a}}\right) dx} \\
&= \left(\frac{2ax + \sqrt{-4ac+b^2} + b}{a}\right)^{\frac{1}{2} + \frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax + b - \sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2} - \frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}}
\end{aligned}$$

The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A} \, dx} \\
&= z_1 e^{-\int \frac{1}{2} \frac{\left(a\,x^2+bx+c\right)(2ax+k)}{\left(a\,x^2+bx+c\right)^2} \, dx} \\
&= z_1 e^{-\frac{\ln\left(a\,x^2+bx+c\right)}{2} - \frac{(-b+k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}} \\
&= z_1 \left(\frac{\mathrm{e}^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\sqrt{a\,x^2+bx+c}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \frac{\left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \mathrm{e}^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\sqrt{a\,x^2+bx+c}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{(a\,x^2+bx+c)(2ax+k)}{(a\,x^2+bx+c)^2}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\ln(a\,x^2+bx+c)+\frac{2(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{(y_1)^2}\,dx \\
&= y_1 \left(\int \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{-1-\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{-1+\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}} dx\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\frac{\left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \mathrm{e}^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\sqrt{a\,x^2+bx+c}}\right) \\
&\quad + c_2 \left(\frac{\left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \mathrm{e}^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\sqrt{a\,x^2+bx+c}} \left(\int \left(2\right.\right.\right.
\end{aligned}$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= \frac{c_1 \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} e^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\sqrt{a\,x^2+bx+c}} \\
&\quad - \frac{c_2 \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} e^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}} a^2 \left(\int -\frac{(2a \cdots}{\cdots}\right.}{\sqrt{a\,x^2+bx+c}}
\end{aligned}
\tag{1}
$$

Verification of solutions

$$
\begin{aligned}
y &= \frac{c_1 \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} e^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}}}{\sqrt{a\,x^2+bx+c}} \\
&\quad - \frac{c_2 \left(\frac{2ax+\sqrt{-4ac+b^2}+b}{a}\right)^{\frac{1}{2}+\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} \left(\frac{2ax+b-\sqrt{-4ac+b^2}}{a}\right)^{\frac{1}{2}-\frac{\sqrt{\frac{-b^2+2bk-k^2+4m}{4ac-b^2}}}{2}} e^{\frac{(b-k)\arctan\left(\frac{2ax+b}{\sqrt{4ac-b^2}}\right)}{\sqrt{4ac-b^2}}} a^2 \left(\int -\frac{(2a \cdots}{\cdots}\right.}{\sqrt{a\,x^2+bx+c}}
\end{aligned}
$$

Verified OK.

32.28.3 Maple step by step solution

Let's solve

$$\left(a\,x^2+bx+c\right)^2 y''+(2ax+k)\left(a\,x^2+bx+c\right)y'+ym=0$$

- Highest derivative means the order of the ODE is 2

  $$y''$$

- Isolate 2nd derivative

  $$y''=-\frac{(2ax+k)y'}{a\,x^2+bx+c}-\frac{my}{\left(a\,x^2+bx+c\right)^2}$$

- Group terms with y on the lhs of the ODE and the rest on the rhs of the ODE; ODE is linear

  $$y''+\frac{(2ax+k)y'}{a\,x^2+bx+c}+\frac{my}{\left(a\,x^2+bx+c\right)^2}=0$$

□ Check to see if x_0 is a regular singular point

  ◦ Define functions

$$\left[P_2(x) = \frac{2ax+k}{a\,x^2+bx+c}, P_3(x) = \frac{m}{(a\,x^2+bx+c)^2}\right]$$

- $\left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right) \cdot P_2(x)$ is analytic at $x = \frac{-b+\sqrt{-4ac+b^2}}{2a}$

  $$\left(\left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right) \cdot P_2(x)\right)\bigg|_{x=\frac{-b+\sqrt{-4ac+b^2}}{2a}} = 0$$

- $\left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2 \cdot P_3(x)$ is analytic at $x = \frac{-b+\sqrt{-4ac+b^2}}{2a}$

  $$\left(\left(x - \frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^2 \cdot P_3(x)\right)\bigg|_{x=\frac{-b+\sqrt{-4ac+b^2}}{2a}} = 0$$

- $x = \frac{-b+\sqrt{-4ac+b^2}}{2a}$ is a regular singular point

  Check to see if x_0 is a regular singular point

  $x_0 = \frac{-b+\sqrt{-4ac+b^2}}{2a}$

- Multiply by denominators

  $$(a\,x^2+bx+c)^2\,y'' + (2ax+k)\,(a\,x^2+bx+c)\,y' + ym = 0$$

- Change variables using $x = u + \frac{-b+\sqrt{-4ac+b^2}}{2a}$ so that the regular singular point is at $u = 0$

  $$(a^2u^4 + 2a\,u^3\sqrt{-4ac+b^2} - 4ac\,u^2 + b^2u^2)\left(\frac{d^2}{du^2}y(u)\right) + (2a^2u^3 - a\,u^2b + 3a\,u^2\sqrt{-4ac+b^2} + a\,u$$

- Assume series solution for $y(u)$

  $$y(u) = \sum_{k=0}^{\infty} a_k u^{k+r}$$

☐ Rewrite ODE with series expansions

- Convert $u^m \cdot \left(\frac{d}{du}y(u)\right)$ to series expansion for $m = 1..3$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,u^{k+r-1+m}$$

- Shift index using $k- >k+1-m$

  $$u^m \cdot \left(\frac{d}{du}y(u)\right) = \sum_{k=-1+m}^{\infty} a_{k+1-m}(k+1-m+r)\,u^{k+r}$$

- Convert $u^m \cdot \left(\frac{d^2}{du^2}y(u)\right)$ to series expansion for $m = 2..4$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=0}^{\infty} a_k(k+r)\,(k+r-1)\,u^{k+r-2+m}$$

- Shift index using $k- >k+2-m$

  $$u^m \cdot \left(\frac{d^2}{du^2}y(u)\right) = \sum_{k=-2+m}^{\infty} a_{k+2-m}(k+2-m+r)\,(k+1-m+r)\,u^{k+r}$$

Rewrite ODE with series expansions

$$-a_0\left(4ac\,r^2-b^2r^2+\sqrt{-4ac+b^2}\,br-\sqrt{-4ac+b^2}\,kr-m\right)u^r+\left(-a_1\left(4ac+8acr+4ac\,r^2-b^2\right.\right.$$

- $a_0$cannot be 0 by assumption, giving the indicial equation

$$-4ac\,r^2+b^2r^2-\sqrt{-4ac+b^2}\,br+\sqrt{-4ac+b^2}\,kr+m=0$$

- Values of r that satisfy the indicial equation

$$r\in\left\{-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2(4ac-b^2)},-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-}}{}\right.$$

- Each term must be 0

$$-a_1\left(4ac+8acr+4ac\,r^2-b^2-2b^2r-b^2r^2+b\sqrt{-4ac+b^2}+\sqrt{-4ac+b^2}\,br-k\sqrt{-4ac+b^2}-\right.$$

- Solve for the dependent coefficient(s)

$$a_1=\frac{a_0ar\left(2\sqrt{-4ac+b^2}\,r+\sqrt{-4ac+b^2}-b+k\right)}{4ac+8acr+4ac\,r^2-b^2-2b^2r-b^2r^2+b\sqrt{-4ac+b^2}+\sqrt{-4ac+b^2}\,br-k\sqrt{-4ac+b^2}-\sqrt{-4ac+b^2}\,kr-m}$$

- Each term in the series must be 0, giving the recursion relation

$$\left(2\left(k+r-\tfrac{1}{2}\right)a_{k-1}(k+r-1)\,a-a_k(k+r)\,(b-k)\right)\sqrt{-4ac+b^2}+a^2a_{k-2}(k-2+r)\,(k+r-1$$

- Shift index using $k->k+2$

$$\left(2\left(k+\tfrac{3}{2}+r\right)a_{k+1}(k+r+1)\,a-a_{k+2}(k+2+r)\,(b-k)\right)\sqrt{-4ac+b^2}+a^2a_k(k+r)\,(k+r+1$$

- Recursion relation that defines series solution to ODE

$$a_{k+2}=\frac{a\left(2\sqrt{-4ac+b^2}\,k^2a_{k+1}+4\sqrt{-4ac+b^2}\,kra_{k+1}+2\sqrt{-4ac+b^2}\,r^2a_{k+1}+a\,k^2a_k+2akra_k+a\,r^2a_k+5\sqrt{-4ac+b^2}\,ka_{k+1}+5\sqrt{-4a}\right.}{4ac\,k^2+4ac\,r^2-2b^2kr+16ack+16acr+\sqrt{-4ac+b^2}\,bk+\sqrt{-4ac+b^2}\,br-b^2k^2-b^2r^2-4b^2k-4b^2r+16ac-}$$

- Recursion relation for $r=-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2(4ac-b^2)}$

$$a_{k+2}=\frac{a\left(2\sqrt{-4ac+b^2}\,k^2a_{k+1}-\frac{2\sqrt{-4ac+b^2}\,k\left(b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}\right)a_{k+1}}{4ac-b^2}\right.}{4ac\,k^2+\frac{ac\left(b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}\right)^2}{\left(4ac-b^2\right)^2}+\frac{b^2k\left(b\sqrt{}\right.}{}}$$

- Solution for $r=-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2(4ac-b^2)}$

$$\left[y(u)=\sum_{k=0}^{\infty}a_ku^{k-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2\left(4ac-b^2\right)}},a_{k+2}=\frac{a\left(2\sqrt{-4ac+b^2}\,k\right.}{}\right.$$

- Revert the change of variables $u=x-\frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left[y=\sum_{k=0}^{\infty}a_k\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^{k-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}-\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2\left(4ac-b^2\right)}},a_{k+2}=\right.$$

- Recursion relation for $r = -\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2(4ac-b^2)}$

$$a_{k+2} = \frac{a\left(2\sqrt{-4ac+b^2}\,k^2a_{k+1}-\frac{2\sqrt{-4ac+b^2}\,k\left(b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}\right)a_{k+1}}{4ac-b^2}\right.}{4ac\,k^2+\frac{ac\left(b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}\right)^2}{\left(4ac-b^2\right)^2}+\frac{b^2k\left(b\sqrt{\right.}}{}}$$

- Solution for $r = -\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2(4ac-b^2)}$

$$\left[y(u) = \sum_{k=0}^{\infty} a_k u^{k-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2\left(4ac-b^2\right)}}, a_{k+2} = \frac{a\left(2\sqrt{-4ac+b^2}\,k^2\right.}{}\right.$$

- Revert the change of variables $u = x - \frac{-b+\sqrt{-4ac+b^2}}{2a}$

$$\left[y = \sum_{k=0}^{\infty} a_k\left(x-\frac{-b+\sqrt{-4ac+b^2}}{2a}\right)^{k-\frac{b\sqrt{-4ac+b^2}-k\sqrt{-4ac+b^2}+\sqrt{-4b^2ca+8kabc-4k^2ac+b^4-2k\,b^3+k^2b^2+16acm-4b^2m}}{2\left(4ac-b^2\right)}}, a_{k+2} =\right.$$

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-8. Other equations.
Problem number: 238.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_Emden, _Fowler]]
```

$$\boxed{x^6y'' - x^5y' + ay = 0}$$

33.1.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y'' - y'x + \frac{ay}{x^4} = 0 \tag{1}$$

Bessel ode has the form

$$x^2y'' + y'x + \left(-n^2 + x^2\right) y = 0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y'' + (1 - 2\alpha) xy' + \left(\beta^2\gamma^2x^{2\gamma} - n^2\gamma^2 + \alpha^2\right) y = 0 \tag{3}$$

With the standard solution

$$y = x^{\alpha}(c_1 \operatorname{BesselJ}(n, \beta x^{\gamma}) + c_2 \operatorname{BesselY}(n, \beta x^{\gamma})) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$\alpha = 1$$
$$\beta = \frac{\sqrt{a}}{2}$$
$$n = \frac{1}{2}$$
$$\gamma = -2$$

Substituting all the above into (4) gives the solution as

$$y = \frac{2c_1 x \sin\left(\frac{\sqrt{a}}{2x^2}\right)}{\sqrt{\pi}\sqrt{\frac{\sqrt{a}}{x^2}}} - \frac{2c_2 x \cos\left(\frac{\sqrt{a}}{2x^2}\right)}{\sqrt{\pi}\sqrt{\frac{\sqrt{a}}{x^2}}}$$

Summary

The solution(s) found are the following

$$y = \frac{2c_1 x \sin\left(\frac{\sqrt{a}}{2x^2}\right)}{\sqrt{\pi}\sqrt{\frac{\sqrt{a}}{x^2}}} - \frac{2c_2 x \cos\left(\frac{\sqrt{a}}{2x^2}\right)}{\sqrt{\pi}\sqrt{\frac{\sqrt{a}}{x^2}}} \tag{1}$$

Verification of solutions

$$y = \frac{2c_1 x \sin\left(\frac{\sqrt{a}}{2x^2}\right)}{\sqrt{\pi}\sqrt{\frac{\sqrt{a}}{x^2}}} - \frac{2c_2 x \cos\left(\frac{\sqrt{a}}{2x^2}\right)}{\sqrt{\pi}\sqrt{\frac{\sqrt{a}}{x^2}}}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^6y'' + \left(3x^2+a\right)x^3y' + yb = 0}$$

33.2.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$x^6y'' + \left(3x^2+a\right)x^3y' + yb = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = \frac{3x^2+a}{x^3}$$
$$q(x) = \frac{b}{x^6}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int \frac{3x^2+a}{x^3}dx\right)}dx \\
&= \int e^{\frac{a}{2x^2}-3\ln(x)}\,dx \\
&= \int \frac{e^{\frac{a}{2x^2}}}{x^3}dx \\
&= -\frac{e^{\frac{a}{2x^2}}}{a} \qquad (6)
\end{aligned}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{\frac{b}{x^6}}{\frac{e^{\frac{a}{x^2}}}{x^6}} \\
&= b\,e^{-\frac{a}{x^2}} \qquad (7)
\end{aligned}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + b\,e^{-\frac{a}{x^2}}\,y(\tau) = 0$$

But in terms of τ

$$b\,e^{-\frac{a}{x^2}} = \frac{b}{a^2\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{by(\tau)}{a^2\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^2}{d\tau^2}y(\tau)\right)a^2\tau^2 + by(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$a^2\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + b\tau^r = 0$$

Simplifying gives

$$a^2r(r-1)\,\tau^r + 0\,\tau^r + b\,\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$a^2r(r-1) + 0 + b = 0$$

Or

$$a^2r^2 - a^2r + b = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-a + \sqrt{a^2 - 4b}}{2a}$$
$$r_2 = \frac{a + \sqrt{a^2 - 4b}}{2a}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2\tau^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1\left(-\frac{e^{\frac{a}{2x^2}}}{a}\right)^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2\left(-\frac{e^{\frac{a}{2x^2}}}{a}\right)^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

Summary

The solution(s) found are the following

$$y = c_1\left(-\frac{e^{\frac{a}{2x^2}}}{a}\right)^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2\left(-\frac{e^{\frac{a}{2x^2}}}{a}\right)^{\frac{a+\sqrt{a^2-4b}}{2a}} \tag{1}$$

Verification of solutions

$$y = c_1\left(-\frac{e^{\frac{a}{2x^2}}}{a}\right)^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2\left(-\frac{e^{\frac{a}{2x^2}}}{a}\right)^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

Verified OK.

Problem number: 243.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{x^n y'' + (ax+b)\, y' - ay = 0}$$

33.5.1 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned}
y' &= B'v + v'B \\
y'' &= B''v + B'v' + v''B + v'B' \\
&= v''B + 2v' + B' + B''v
\end{aligned}$$

And now the original ode becomes

$$\begin{aligned} A(v''B + 2v'B' + B''v) + B(B'v + v'B) + CBv &= 0 \\ ABv'' + \left(2AB' + B^2\right) v' + (AB'' + BB' + CB)\, v &= 0 \end{aligned} \tag{1}$$

If the term $AB'' + BB' + CB$ is zero, then this method works and can be used to solve

$$ABv'' + \left(2AB' + B^2\right) v' = 0$$

By Using $u = v'$ which reduces the order of the above ode to one. The new ode is

$$ABu' + \left(2AB' + B^2\right) u = 0$$

The above ode is first order ode which is solved for u. Now a new ode $v' = u$ is solved for v as first order ode. Then the final solution is obtain from $y = Bv$.

This method works only if the term $AB'' + BB' + CB$ is zero. The given ODE shows that

$$\begin{aligned} A &= x^n \\ B &= ax + b \\ C &= -a \\ F &= 0 \end{aligned}$$

The above shows that for this ode

$$\begin{aligned} AB'' + BB' + CB &= (x^n)\,(0) + (ax + b)\,(a) + (-a)\,(ax + b) \\ &= 0 \end{aligned}$$

Hence the ode in v given in (1) now simplifies to

$$x^n(ax + b)\, v'' + \left(2a\, x^n + (ax + b)^2\right) v' = 0$$

Now by applying $v' = u$ the above becomes

$$x^n(ax + b)\, u'(x) + \left(2a\, x^n + (ax + b)^2\right) u(x) = 0$$

Which is now solved for u. In canonical form the ODE is

$$\begin{aligned} u' &= F(x, u) \\ &= f(x)g(u) \\ &= -\frac{u(a^2x^2 + 2abx + 2a\, x^n + b^2)\, x^{-n}}{ax + b} \end{aligned}$$

Where $f(x) = -\frac{(a^2x^2+2abx+2a\,x^n+b^2)\,x^{-n}}{ax+b}$ and $g(u) = u$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{u}\,du &= -\frac{(a^2x^2+2abx+2a\,x^n+b^2)\,x^{-n}}{ax+b}\,dx \\
\int \frac{1}{u}\,du &= \int -\frac{(a^2x^2+2abx+2a\,x^n+b^2)\,x^{-n}}{ax+b}\,dx \\
\ln(u) &= \left(\frac{a\,x^2}{n-2}+\frac{bx}{n-1}\right)\mathrm{e}^{-n\ln(x)} - 2\ln(ax+b) + c_1 \\
u &= \mathrm{e}^{\left(\frac{a\,x^2}{n-2}+\frac{bx}{n-1}\right)\mathrm{e}^{-n\ln(x)} - 2\ln(ax+b) + c_1} \\
&= c_1 \mathrm{e}^{\left(\frac{a\,x^2}{n-2}+\frac{bx}{n-1}\right)\mathrm{e}^{-n\ln(x)} - 2\ln(ax+b)}
\end{aligned}$$

Which simplifies to

$$u(x) = \frac{c_1 \mathrm{e}^{\frac{x^2 a\,x^{-n}}{n-2}}\,\mathrm{e}^{\frac{x^{-n} bx}{n-1}}}{(ax+b)^2}$$

The ode for v now becomes

$$\begin{aligned}
v' &= u \\
&= \frac{c_1 \mathrm{e}^{\frac{x^2 a\,x^{-n}}{n-2}}\,\mathrm{e}^{\frac{x^{-n} bx}{n-1}}}{(ax+b)^2}
\end{aligned}$$

Which is now solved for v. Integrating both sides gives

$$\begin{aligned}
v(x) &= \int \frac{c_1 \mathrm{e}^{\frac{x^2 a\,x^{-n}}{n-2}}\,\mathrm{e}^{\frac{x^{-n} bx}{n-1}}}{(ax+b)^2}\,\mathrm{d}x \\
&= \int \frac{c_1 \mathrm{e}^{\frac{x^2 a\,x^{-n}}{n-2}}\,\mathrm{e}^{\frac{x^{-n} bx}{n-1}}}{(ax+b)^2}dx + c_2
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y(x) &= Bv \\
&= (ax+b)\left(\int \frac{c_1 \mathrm{e}^{\frac{x^2 a\,x^{-n}}{n-2}}\,\mathrm{e}^{\frac{x^{-n} bx}{n-1}}}{(ax+b)^2}dx + c_2\right) \\
&= (ax+b)\left(c_1\left(\int \frac{\mathrm{e}^{\frac{(a(n-1)x+b(n-2))x^{1-n}}{(n-2)(n-1)}}}{(ax+b)^2}dx\right) + c_2\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = (ax+b)\left(c_1\left(\int \frac{e^{\frac{(a(n-1)x+b(n-2))x^{1-n}}{(n-2)(n-1)}}}{(ax+b)^2}dx\right)+c_2\right) \tag{1}$$

Verification of solutions

$$y = (ax+b)\left(c_1\left(\int \frac{e^{\frac{(a(n-1)x+b(n-2))x^{1-n}}{(n-2)(n-1)}}}{(ax+b)^2}dx\right)+c_2\right)$$

Verified OK.

33.12 problem 250

Internal problem ID [11074]
Internal file name [`OUTPUT/10330_Wednesday_January_24_2024_10_07_18_PM_82271614/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-8. Other equations.
Problem number: 250.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$
\boxed{\left(a\,x^{n}+bx+c\right)y''-an(n-1)\,x^{n-2}y=0}
$$

33.12.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$
\int \left(\left(a\,x^{n}+bx+c\right)y''-an(n-1)\,x^{n-2}y\right)dx=0
$$

$$
-\frac{\left(x^{n}na+bx\right)y}{x}-\left(-a\,x^{n}-bx-c\right)y'=c_1
$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$
y'+p(x)y=q(x)
$$

Where here

$$
\begin{aligned}
p(x) &= -\frac{x^n n a + b x}{(a\,x^n + b x + c)\,x} \\
q(x) &= \frac{c_1}{a\,x^n + b x + c}
\end{aligned}
$$

Hence the ode is

$$
y' - \frac{(x^n n a + b x)\,y}{(a\,x^n + b x + c)\,x} = \frac{c_1}{a\,x^n + b x + c}
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int -\frac{x^n n a + b x}{(a\,x^n + b x + c)x} dx} \\
&= \frac{1}{a\,\mathrm{e}^{n \ln(x)} + b x + c}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{1}{a\,x^n + b x + c}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{a\,x^n + b x + c}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{a\,x^n + b x + c}\right) &= \left(\frac{1}{a\,x^n + b x + c}\right)\left(\frac{c_1}{a\,x^n + b x + c}\right) \\
\mathrm{d}\left(\frac{y}{a\,x^n + b x + c}\right) &= \left(\frac{c_1}{(a\,x^n + b x + c)^2}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y}{a\,x^n + b x + c} &= \int \frac{c_1}{(a\,x^n + b x + c)^2}\,\mathrm{d}x \\
\frac{y}{a\,x^n + b x + c} &= \frac{x c_1}{(n b x - b x + c n)\,(a\,\mathrm{e}^{n \ln(x)} + b x + c)} + \left(\int \frac{n(n b x - b x + c n - c)}{(n b x - b x + c n)^2\,(a\,\mathrm{e}^{n \ln(x)} + b x + c)} dx\right) c_1 +
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{a\,x^n + b x + c}$ results in

$$
y = (a\,x^n + b x + c)\left(\frac{x c_1}{(n b x - b x + c n)\,(a\,\mathrm{e}^{n \ln(x)} + b x + c)} + \left(\int \frac{n(n b x - b x + c n - c)}{(n b x - b x + c n)^2\,(a\,\mathrm{e}^{n \ln(x)} + b x + c)} dx\right)\right.
$$

which simplifies to

$$
y = (a\,x^n + b x + c)\left(c_1\left(\frac{x}{(a\,x^n + b x + c)\,(n b x - b x + c n)} + n\left(\int \frac{(n-1)\,(b x + c)}{(x\,(n-1)\,b + c n)^2\,(a\,x^n + b x + c)} dx\right)\right.\right.
$$

Summary
The solution(s) found are the following

$$y = (a\,x^n + bx + c)\left(c_1\left(\frac{x}{(a\,x^n + bx + c)\,(nbx - bx + cn)} + n\left(\int \frac{(n-1)\,(bx + c)}{(x\,(n-1)\,b + cn)^2\,(a\,x^n + bx + c)}dx\right)\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (a\,x^n + bx + c)\left(c_1\left(\frac{x}{(a\,x^n + bx + c)\,(nbx - bx + cn)} + n\left(\int \frac{(n-1)\,(bx + c)}{(x\,(n-1)\,b + cn)^2\,(a\,x^n + bx + c)}dx\right)\right) + c_2\right)$$

Verified OK.

33.12.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$(a\,x^n + bx + c)\,y'' - an(n-1)\,x^{n-2}y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\int \left((a\,x^n + bx + c)\,y'' - an(n-1)\,x^{n-2}y\right)dx = 0$$

$$-\frac{(x^n na + bx)\,y}{x} - (-a\,x^n - bx - c)\,y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{x^n na + bx}{(a\,x^n + bx + c)\,x}$$
$$q(x) = \frac{c_1}{a\,x^n + bx + c}$$

Hence the ode is

$$y' - \frac{(x^n na + bx)\,y}{(a\,x^n + bx + c)\,x} = \frac{c_1}{a\,x^n + bx + c}$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= e^{\int -\frac{x^n n a + b x}{(a\,x^n + b x + c) x}dx} \\
&= \frac{1}{a\,e^{n\ln(x)} + b x + c}
\end{aligned}
$$

Which simplifies to

$$
\mu = \frac{1}{a\,x^n + b x + c}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\left(\frac{c_1}{a\,x^n + b x + c}\right) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{a\,x^n + b x + c}\right) &= \left(\frac{1}{a\,x^n + b x + c}\right)\left(\frac{c_1}{a\,x^n + b x + c}\right) \\
\mathrm{d}\left(\frac{y}{a\,x^n + b x + c}\right) &= \left(\frac{c_1}{(a\,x^n + b x + c)^2}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\frac{y}{a\,x^n + b x + c} &= \int \frac{c_1}{(a\,x^n + b x + c)^2}\,\mathrm{d}x \\
\frac{y}{a\,x^n + b x + c} &= \frac{x c_1}{(n b x - b x + c n)\,(a\,e^{n\ln(x)} + b x + c)} + \left(\int \frac{n(n b x - b x + c n - c)}{(n b x - b x + c n)^2\,(a\,e^{n\ln(x)} + b x + c)}dx\right) c_1 +
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \frac{1}{a\,x^n + b x + c}$ results in

$$
y = (a\,x^n + b x + c)\left(\frac{x c_1}{(n b x - b x + c n)\,(a\,e^{n\ln(x)} + b x + c)} + \left(\int \frac{n(n b x - b x + c n - c)}{(n b x - b x + c n)^2\,(a\,e^{n\ln(x)} + b x + c)}dx\right)\right.
$$

which simplifies to

$$
y = (a\,x^n + b x + c)\left(c_1\left(\frac{x}{(a\,x^n + b x + c)\,(n b x - b x + c n)} + n\left(\int \frac{(n-1)\,(b x + c)}{(x\,(n-1)\,b + c n)^2\,(a\,x^n + b x + c)}dx\right)\right)\right.
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y = (a\,x^n + b x + c)\Bigg(c_1\Bigg(&\frac{x}{(a\,x^n + b x + c)\,(n b x - b x + c n)} \\
&+ n\left(\int \frac{(n-1)\,(b x + c)}{(x\,(n-1)\,b + c n)^2\,(a\,x^n + b x + c)}dx\right)\Bigg) + c_2\Bigg)
\end{aligned}
\tag{1}
$$

Verification of solutions

$$y = (a\,x^n + bx + c)\left(c_1\left(\frac{x}{(a\,x^n + bx + c)\,(nbx - bx + cn)} + n\left(\int \frac{(n-1)\,(bx + c)}{(x\,(n-1)\,b + cn)^2\,(a\,x^n + bx + c)}dx\right)\right) + c_2\right)$$

Verified OK.

33.12.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= a\,x^n + bx + c \\ q(x) &= 0 \\ r(x) &= -an(n-1)\,x^{n-2} \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= \frac{a\,x^n n^2}{x^2} - \frac{an\,x^n}{x^2} \\ q'(x) &= 0 \end{aligned}$$

Therefore (1) becomes

$$\frac{a\,x^n n^2}{x^2} - \frac{an\,x^n}{x^2} - (0) + \left(-an(n-1)\,x^{n-2}\right) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$(p(x)\,y' + (q(x) - p'(x))\,y)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\;dx$$

Substituting the above values for p,q,r,s gives

$$(a\,x^n+bx+c)\,y'+\left(-\frac{an\,x^n}{x}-b\right)y=c_1$$

We now have a first order ode to solve which is

$$(a\,x^n+bx+c)\,y'+\left(-\frac{an\,x^n}{x}-b\right)y=c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y'+p(x)y=q(x)$$

Where here

$$\begin{aligned}
p(x)&=-\frac{x^n na+bx}{(a\,x^n+bx+c)\,x}\\
q(x)&=\frac{c_1}{a\,x^n+bx+c}
\end{aligned}$$

Hence the ode is

$$y'-\frac{(x^n na+bx)\,y}{(a\,x^n+bx+c)\,x}=\frac{c_1}{a\,x^n+bx+c}$$

The integrating factor μ is

$$\begin{aligned}
\mu&=\mathrm{e}^{\int -\frac{x^n na+bx}{(a\,x^n+bx+c)x}dx}\\
&=\frac{1}{a\,\mathrm{e}^{n\ln(x)}+bx+c}
\end{aligned}$$

Which simplifies to

$$\mu=\frac{1}{a\,x^n+bx+c}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y)&=(\mu)\left(\frac{c_1}{a\,x^n+bx+c}\right)\\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\frac{y}{a\,x^n+bx+c}\right)&=\left(\frac{1}{a\,x^n+bx+c}\right)\left(\frac{c_1}{a\,x^n+bx+c}\right)\\
\mathrm{d}\left(\frac{y}{a\,x^n+bx+c}\right)&=\left(\frac{c_1}{(a\,x^n+bx+c)^2}\right)\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\frac{y}{a\,x^{n}+bx+c} = \int \frac{c_1}{\left(a\,x^{n}+bx+c\right)^{2}}\, \mathrm{d}x$$

$$\frac{y}{a\,x^{n}+bx+c} = \frac{x c_1}{\left(nbx-bx+cn\right)\left(a\,\mathrm{e}^{n\ln(x)}+bx+c\right)} + \left(\int \frac{n(nbx-bx+cn-c)}{\left(nbx-bx+cn\right)^{2}\left(a\,\mathrm{e}^{n\ln(x)}+bx+c\right)}dx\right) c_1 +$$

Dividing both sides by the integrating factor $\mu = \frac{1}{a\,x^{n}+bx+c}$ results in

$$y = \left(a\,x^{n}+bx+c\right)\left(\frac{x c_1}{\left(nbx-bx+cn\right)\left(a\,\mathrm{e}^{n\ln(x)}+bx+c\right)} + \left(\int \frac{n(nbx-bx+cn-c)}{\left(nbx-bx+cn\right)^{2}\left(a\,\mathrm{e}^{n\ln(x)}+bx+c\right)}dx\right)\right.$$

which simplifies to

$$y = \left(a\,x^{n}+bx+c\right)\left(c_1\left(\frac{x}{\left(a\,x^{n}+bx+c\right)\left(nbx-bx+cn\right)} + n\left(\int \frac{(n-1)\left(bx+c\right)}{\left(x\left(n-1\right)b+cn\right)^{2}\left(a\,x^{n}+bx+c\right)}dx\right)\right.\right.$$

Summary

The solution(s) found are the following

$$y = \left(a\,x^{n}+bx+c\right)\left(c_1\left(\frac{x}{\left(a\,x^{n}+bx+c\right)\left(nbx-bx+cn\right)} + n\left(\int \frac{(n-1)\left(bx+c\right)}{\left(x\left(n-1\right)b+cn\right)^{2}\left(a\,x^{n}+bx+c\right)}dx\right)\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \left(a\,x^{n}+bx+c\right)\left(c_1\left(\frac{x}{\left(a\,x^{n}+bx+c\right)\left(nbx-bx+cn\right)} + n\left(\int \frac{(n-1)\left(bx+c\right)}{\left(x\left(n-1\right)b+cn\right)^{2}\left(a\,x^{n}+bx+c\right)}dx\right)\right) + c_2\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_x_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{x\left(x^{2n}+a\right)y''+\left(x^{2n}+a-an\right)y'-b^{2}x^{-1+2n}y=0}$$

33.14.1 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$x\left(x^{2n}+a\right)y''+\left(x^{2n}+a-an\right)y'-b^{2}x^{-1+2n}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=0 \tag{2}$$

Where

$$p(x)=\frac{x^{2n}+a-an}{x\left(x^{2n}+a\right)}$$
$$q(x)=-\frac{b^{2}x^{2n-2}}{x^{2n}+a}$$

Applying change of variables $\tau=g(x)$ to (2) results

$$\frac{d^{2}}{d\tau^{2}}y(\tau)+p_{1}\left(\frac{d}{d\tau}y(\tau)\right)+q_{1}y(\tau)=0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned}
\tau' &= \frac{1}{c}\sqrt{q} \\
&= \frac{\sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}}{c} \\
\tau'' &= \frac{-\frac{b^2 x^{2n-2}(2n-2)}{x(x^{2n}+a)} + \frac{2b^2 x^{2n-2} x^{2n} n}{(x^{2n}+a)^2 x}}{2c\sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}}
\end{aligned} \tag{6}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{\frac{-\frac{b^2 x^{2n-2}(2n-2)}{x\left(x^{2n}+a\right)} + \frac{2b^2 x^{2n-2} x^{2n} n}{\left(x^{2n}+a\right)^2 x}}{2c\sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}} + \frac{x^{2n}+a-an}{x(x^{2n}+a)} \frac{\sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}}{c}}{\left(\frac{\sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}}{c}\right)^2} \\
&= 0
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0
\end{aligned} \tag{7}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\tau = \int \frac{1}{c}\sqrt{q}\, dx$$
$$= \frac{\int \sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}dx}{c}$$
$$= \frac{\int \sqrt{-\frac{b^2 x^{2n-2}}{x^{2n}+a}}dx}{c}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cosh\left(\frac{b \operatorname{arcsinh}\left(\frac{x^n}{\sqrt{a}}\right)}{n}\right) + i c_2 \sinh\left(\frac{b \operatorname{arcsinh}\left(\frac{x^n}{\sqrt{a}}\right)}{n}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cosh\left(\frac{b \operatorname{arcsinh}\left(\frac{x^n}{\sqrt{a}}\right)}{n}\right) + i c_2 \sinh\left(\frac{b \operatorname{arcsinh}\left(\frac{x^n}{\sqrt{a}}\right)}{n}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \cosh\left(\frac{b \operatorname{arcsinh}\left(\frac{x^n}{\sqrt{a}}\right)}{n}\right) + i c_2 \sinh\left(\frac{b \operatorname{arcsinh}\left(\frac{x^n}{\sqrt{a}}\right)}{n}\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.2-8. Other equations.
Problem number: 255.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_bessel_ode"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(x^n+a)^2 y''-b\,x^{n-2}((b-1)\,x^n+(n-1)\,a)\,y=0}$$

33.17.1 Solving as second order bessel ode ode

Writing the ode as

$$x^2y''+\left(-\frac{b^2x^{2n}}{x^2}-\frac{x^n abn}{x^2}+\frac{x^{2n}b}{x^2}+\frac{ab\,x^n}{x^2}\right)y=0 \tag{1}$$

Bessel ode has the form

$$x^2y''+y'x+\left(-n^2+x^2\right)y=0 \tag{2}$$

The generalized form of Bessel ode is given by Bowman (1958) as the following

$$x^2y''+(1-2\alpha)\,xy'+\left(\beta^2\gamma^2x^{2\gamma}-n^2\gamma^2+\alpha^2\right)y=0 \tag{3}$$

With the standard solution

$$y=x^\alpha(c_1\,\text{BesselJ}\left(n,\beta\,x^\gamma\right)+c_2\,\text{BesselY}\left(n,\beta\,x^\gamma\right)) \tag{4}$$

Comparing (3) to (1) and solving for α, β, n, γ gives

$$
\begin{aligned}
\alpha &= \frac{1}{2} \\
\beta &= \frac{2\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)} \\
n &= -\frac{\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)} \\
\gamma &= \frac{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}{2\ln(x)}
\end{aligned}
$$

Substituting all the above into (4) gives the solution as

$$
y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(-\frac{\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}, \frac{2\ln(x)\,x^{\frac{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}{2\ln(x)}}}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}\right)
$$

Summary

The solution(s) found are the following

$$
\begin{aligned}
y &= c_1\sqrt{x}\,\mathrm{BesselJ}\left(-\frac{\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}, \frac{2\ln(x)\,x^{\frac{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}{2\ln(x)}}}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}\right) \\
&\quad + c_2\sqrt{x}\,\mathrm{BesselY}\left(-\frac{\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}, \frac{2\ln(x)\,x^{\frac{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}{2\ln(x)}}}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}\right)
\end{aligned} \tag{1}
$$

Verification of solutions

$$y = c_1\sqrt{x}\,\mathrm{BesselJ}\left(-\frac{\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}, \frac{2\ln(x)\,x^{\frac{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}{2\ln(x)}}}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}\right) + c_2\sqrt{x}\,\mathrm{BesselY}\left(-\frac{\ln(x)}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}, \frac{2\ln(x)\,x^{\frac{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}{2\ln(x)}}}{\ln\left(-\frac{b\left(b\,\mathrm{e}^{n\ln(x)}+an-\mathrm{e}^{n\ln(x)}-a\right)}{x^2}\right)+n\ln(x)}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{(a\,x^n+b)^2\,y''+(a\,x^n+b)\,(x^n c+d)\,y'+n(-ad+bc)\,x^{n-1}y=0}$$

33.18.1 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$y''\left(x^{2n}a^2+2ab\,x^n+b^2\right)+\left(x^{2n}ac+da\,x^n+bc\,x^n+bd\right)y'+n(-ad+bc)\,x^{n-1}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=r(x) \tag{2}$$

Where

$$\begin{aligned}p(x)&=\frac{x^{2n}ac+da\,x^n+bc\,x^n+bd}{x^{2n}a^2+2ab\,x^n+b^2}\\ q(x)&=\frac{n\,x^{n-1}(-ad+bc)}{x^{2n}a^2+2ab\,x^n+b^2}\\ r(x)&=0\end{aligned}$$

The Lagrange adjoint ode is given by

$$\xi'' - \left(\frac{(x^{2n}ac + da\,x^n + b}{x^{2n}a^2 + 2ab}\right.$$

$$\xi''(x) - \frac{(x^{2n}ac + da\,x^n + bc\,x^n + bd)\,\xi'(x)}{x^{2n}a^2 + 2ab\,x^n + b^2} + \left(\frac{(x^{2n}ac + da\,x^n + bc\,x^n + bd)\left(\frac{2x^{2n}n\,a^2}{x} + \frac{2abn\,x^n}{x}\right)}{(x^{2n}a^2 + 2ab\,x^n + b^2)^2} - \frac{\frac{2x^{2n}nac}{x}}{x^{2n}a}\right.$$

Which is solved for $\xi(x)$. The ODE is

$$x\left(x^{4n}a^4 + 4b\,x^{3n}a^3 + 6x^{2n}a^2b^2 + 4a\,b^3x^n + b^4\right)\xi''(x) - x\left(\left(3a^2bd + 3b^2ca\right)x^{2n} + \left(a^3d + 3a^2bc\right)x^{3n} + x^{4n}a^3c\right.$$

Or

$$x\left(6x^{2n}\xi''(x)\,a^2b^2 - 3x^{2n}\xi'(x)\,a^2bd - 3x^{2n}\xi'(x)\,a\,b^2c + 4x^n\xi''(x)\,a\,b^3 - 3x^n\xi'(x)\,a\,b^2d - x^n\xi'(x)\,b^3c + 4x^{3n}\xi\right.$$

For $x \neq 0$ the above simplifies to

$$\xi''(x)\left(x^{4n}a^4 + 4b\,x^{3n}a^3 + 6x^{2n}a^2b^2 + 4a\,b^3x^n + b^4\right) - \left(\left(3a^2bd + 3b^2ca\right)x^{2n} + \left(a^3d + 3a^2bc\right)x^{3n} + x^{4n}a^3c + \right.$$

This is second order ode with missing dependent variable $\xi(x)$. Let

$$p(x) = \xi'(x)$$

Then

$$p'(x) = \xi''(x)$$

Hence the ode becomes

$$x\left(x^{4n}a^4 + 4b\,x^{3n}a^3 + 6x^{2n}a^2b^2 + 4a\,b^3x^n + b^4\right)p'(x) - x\left(\left(3a^2bd + 3b^2ca\right)x^{2n} + \left(a^3d + 3a^2bc\right)x^{3n} + x^{4n}a^3\right.$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned} p' &= F(x,p) \\ &= f(x)g(p) \\ &= \frac{p(x^{4n}a^3c + d\,x^{3n}a^3 + 3bc\,x^{3n}a^2 + 3x^{2n}a^2bd + 3x^{2n}a\,b^2c + 3a\,b^2x^nd + b^3c\,x^n + b^3d)}{x^{4n}a^4 + 4b\,x^{3n}a^3 + 6x^{2n}a^2b^2 + 4a\,b^3x^n + b^4} \end{aligned}$$

Where $f(x) = \frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}$ and $g(p) = p$. Integrating both sides gives

$$\frac{1}{p}\,dp = \frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}\,dx$$

$$\int\frac{1}{p}\,dp = \int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}\,dx$$

$$\ln(p) = \int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx + c_1$$

$$p = \mathrm{e}^{\int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx+c_1}$$

$$= c_1\mathrm{e}^{\int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}$$

Since $p = \xi'(x)$ then the new first order ode to solve is

$$\xi'(x) = c_1\mathrm{e}^{\int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}$$

Writing the ode as

$$\xi'(x) = c_1\mathrm{e}^{\int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}$$
$$\xi'(x) = \omega(x,\xi)$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_\xi - \xi_x) - \omega^2\xi_\xi - \omega_x\xi - \omega_\xi\eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = xa_2 + \xi a_3 + a_1 \tag{1E}$$
$$\eta = xb_2 + \xi b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + c_1\mathrm{e}^{\int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}(b_3 - a_2) \tag{5E}$$
$$- c_1^2\mathrm{e}^{\int\frac{2x^{4n}a^3c+2d\,x^{3n}a^3+6bc\,x^{3n}a^2+6x^{2n}a^2bd+6x^{2n}a\,b^2c+6a\,b^2x^n d+2b^3c\,x^n+2b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}a_3$$
$$- \frac{c_1(x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d)\,\mathrm{e}^{\int\frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a}{x^{4n}a^4+4b}}}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}$$
$$= 0$$

Putting the above in normal form gives

$$\text{Expression too large to display}$$

Setting the numerator to zero gives

$$\text{Expression too large to display} \tag{6E}$$

Simplifying the above gives

$$\text{Expression too large to display} \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, \xi\}$ in them.

$$\left\{x, \xi, x^{n}, x^{2n}, x^{3n}, x^{4n}, \int \frac{x^{4n}a^{3}c + d\,x^{3n}a^{3} + 3bc\,x^{3n}a^{2} + 3x^{2n}a^{2}bd + 3x^{2n}a\,b^{2}c + 3a\,b^{2}x^{n}d + b^{3}c\,x^{n} + b^{3}d}{x^{4n}a^{4} + 4b\,x^{3n}a^{3} + 6x^{2n}a^{2}b^{2} + 4a\,b^{3}x^{n} + b^{4}} d$$

The following substitution is now made to be able to collect on all terms with $\{x, \xi\}$ in them

$$\left\{x = v_{1}, \xi = v_{2}, x^{n} = v_{3}, x^{2n} = v_{4}, x^{3n} = v_{5}, x^{4n} = v_{6}, \int \frac{x^{4n}a^{3}c + d\,x^{3n}a^{3} + 3bc\,x^{3n}a^{2} + 3x^{2n}a^{2}bd + 3x^{2n}a\,b^{2}}{x^{4n}a^{4} + 4b\,x^{3n}a^{3} + 6x^{2n}a^{2}b^{2} + 4a}$$

The above PDE (6E) now becomes

$$\begin{aligned}
&-a^{4}c_{1}^{2}a_{3}v_{3}^{4}v_{8} - a^{3}cc_{1}a_{2}v_{1}v_{3}^{4}v_{9} - a^{3}cc_{1}a_{3}v_{2}v_{3}^{4}v_{9} - a^{4}c_{1}a_{2}v_{3}^{4}v_{9} \\

&- b^{4}c_{1}a_{2}v_{9} + b^{4}c_{1}b_{3}v_{9} - b^{3}c_{1}da_{1}v_{9} + 4v_{3}a\,b^{3}b_{2} + b^{4}b_{2} = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_{1}, v_{2}, v_{3}, v_{4}, v_{5}, v_{6}, v_{7}, v_{8}, v_{9}\}$$

Equation (7E) now becomes

$$\begin{aligned}
&-b^4c_1^2a_3v_8+b^4b_2+\left(-a^3c_1da_2-3a^2bcc_1a_2\right)v_1v_3^3v_9\\
&+\left(-3a^2bc_1da_2-3a\,b^2cc_1a_2\right)v_1v_3^2v_9+\left(-3a\,b^2c_1da_2-b^3cc_1a_2\right)v_1v_3v_9\\
&+\left(-a^3c_1da_3-3a^2bcc_1a_3\right)v_2v_3^3v_9+\left(-b^4c_1a_2+b^4c_1b_3-b^3c_1da_1\right)v_9\\
&+\left(-3a^2bc_1da_3-3a\,b^2cc_1a_3\right)v_2v_3^2v_9\\
&+\left(-3a\,b^2c_1da_3-b^3cc_1a_3\right)v_2v_3v_9+v_3^4a^4b_2+6v_3^2a^2b^2b_2\\
&+\left(-4a\,b^3c_1a_2+4a\,b^3c_1b_3-3a\,b^2c_1da_1-b^3cc_1a_1\right)v_3v_9\\
&+\left(-a^4c_1a_2+a^4c_1b_3-a^3cc_1a_1\right)v_3^4v_9\\
&+\left(-4a^3bc_1a_2+4a^3bc_1b_3-a^3c_1da_1-3a^2bcc_1a_1\right)v_3^3v_9\\
&+\left(-6a^2b^2c_1a_2+6a^2b^2c_1b_3-3a^2bc_1da_1-3a\,b^2cc_1a_1\right)v_3^2v_9\\
&+4v_3^3a^3bb_2+4v_3a\,b^3b_2-a^4c_1^2a_3v_3^4v_8-a^3cc_1a_2v_1v_3^4v_9\\
&-a^3cc_1a_3v_2v_3^4v_9-4a^3b\,c_1^2a_3v_3^3v_8-6a^2b^2c_1^2a_3v_3^2v_8\\
&-4a\,b^3c_1^2a_3v_3v_8-b^3c_1da_2v_1v_9-b^3c_1da_3v_2v_9=0
\end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
a^4 b_2 &= 0\\
b^4 b_2 &= 0\\
-c_1^2 a^4 a_3 &= 0\\
-c_1^2 b^4 a_3 &= 0\\
4a\, b^3 b_2 &= 0\\
6a^2 b^2 b_2 &= 0\\
4a^3 b b_2 &= 0\\
-c_1 a^3 c a_2 &= 0\\
-c_1 a^3 c a_3 &= 0\\
-c_1 b^3 d a_3 &= 0\\
-4c_1^2 a\, b^3 a_3 &= 0\\
-6c_1^2 a^2 b^2 a_3 &= 0\\
-4c_1^2 a^3 b a_3 &= 0\\
-b^3 d a_2 c_1 &= 0\\
-3a\, b^2 c_1 d a_2 - b^3 c c_1 a_2 &= 0\\
-3a^2 b c_1 d a_2 - 3a\, b^2 c c_1 a_2 &= 0\\
-a^3 c_1 d a_2 - 3a^2 b c c_1 a_2 &= 0\\
-3a\, b^2 c_1 d a_3 - b^3 c c_1 a_3 &= 0\\
-3a^2 b c_1 d a_3 - 3a\, b^2 c c_1 a_3 &= 0\\
-a^3 c_1 d a_3 - 3a^2 b c c_1 a_3 &= 0\\
-a^4 c_1 a_2 + a^4 c_1 b_3 - a^3 c c_1 a_1 &= 0\\
-b^4 c_1 a_2 + b^4 c_1 b_3 - b^3 c_1 d a_1 &= 0\\
-4a\, b^3 c_1 a_2 + 4a\, b^3 c_1 b_3 - 3a\, b^2 c_1 d a_1 - b^3 c c_1 a_1 &= 0\\
-6a^2 b^2 c_1 a_2 + 6a^2 b^2 c_1 b_3 - 3a^2 b c_1 d a_1 - 3a\, b^2 c c_1 a_1 &= 0\\
-4a^3 b c_1 a_2 + 4a^3 b c_1 b_3 - a^3 c_1 d a_1 - 3a^2 b c c_1 a_1 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= b_1 \\ b_2 &= 0 \\ b_3 &= 0 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\begin{aligned} \xi &= 0 \\ \eta &= 1 \end{aligned}$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, \xi) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{d\xi}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial \xi}\right) S(x, \xi) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{1} dy \end{aligned}$$

Which results in

$$S = \xi$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x, \xi) S_\xi}{R_x + \omega(x, \xi) R_\xi} \tag{2}$$

Where in the above R_x, R_ξ, S_x, S_ξ are all partial derivatives and $\omega(x,\xi)$ is the right hand side of the original ode given by

$$\omega(x,\xi) = c_1 \mathrm{e}^{\int \frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_\xi &= 0 \\ S_x &= 0 \\ S_\xi &= 1 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = c_1 \mathrm{e}^{\int \frac{(3a^2bd+3b^2ca)x^{2n}+(a^3d+3a^2bc)x^{3n}+x^{4n}a^3c+(3a\,b^2d+b^3c)x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, ξ in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = c_1 \mathrm{e}^{\int \frac{(3a^2bd+3b^2ca)R^{2n}+(a^3d+3a^2bc)R^{3n}+R^{4n}a^3c+(3a\,b^2d+b^3c)R^n+b^3d}{R^{4n}a^4+4b\,R^{3n}a^3+6R^{2n}a^2b^2+4a\,b^3R^n+b^4}dR}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int c_1 \mathrm{e}^{\int \frac{3R^{2n}a^2bd+3R^{2n}a\,b^2c+R^{3n}a^3d+3R^{3n}a^2bc+R^{4n}a^3c+3R^n a\,b^2d+R^n b^3c+b^3d}{R^{4n}a^4+4b\,R^{3n}a^3+6R^{2n}a^2b^2+4a\,b^3R^n+b^4}dR}dR + c_2 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, ξ coordinates. This results in

$$\xi(x) = \int c_1 \mathrm{e}^{\int \frac{x^{4n}a^3c+d\,x^{3n}a^3+3bc\,x^{3n}a^2+3x^{2n}a^2bd+3x^{2n}a\,b^2c+3a\,b^2x^n d+b^3c\,x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}dx + c_2$$

Which simplifies to

$$\xi(x) - c_1\left(\int \mathrm{e}^{\int \frac{(3a^2bd+3b^2ca)x^{2n}+(a^3d+3a^2bc)x^{3n}+x^{4n}a^3c+(3a\,b^2d+b^3c)x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}dx\right) - c_2 = 0$$

Which gives

$$\xi(x) = c_1\left(\int \mathrm{e}^{\int \frac{(3a^2bd+3b^2ca)x^{2n}+(a^3d+3a^2bc)x^{3n}+x^{4n}a^3c+(3a\,b^2d+b^3c)x^n+b^3d}{x^{4n}a^4+4b\,x^{3n}a^3+6x^{2n}a^2b^2+4a\,b^3x^n+b^4}dx}dx\right) + c_2$$

The original ode (2) now reduces to first order ode

$$\xi(x)\, y' - y\xi'(x) + \xi(x)\, p(x$$

$$y' + y\left(p(x) - \frac{\xi'(x)}{\xi(x)}\right.$$

$$y' + y\left(\frac{x^{2n}ac + da\, x^n + bc\, x^n + bd}{x^{2n}a^2 + 2ab\, x^n + b^2} - \frac{c_3 e^{\int \frac{\left(3a^2bd+3b^2ca\right)x^{2n}+\left(a^3d+3a^2bc\right)x^{3n}+x^{4n}a^3c+\left(3a\, b^2d+b^3c\right)x^n+b^3d}{x^{4n}a^4+4b\, x^{3n}a^3+6x^{2n}a^2b^2+4a\, b^3x^n+b^4}dx}}{c_3\left(\int e^{\int \frac{\left(3a^2bd+3b^2ca\right)x^{2n}+\left(a^3d+3a^2bc\right)x^{3n}+x^{4n}a^3c+\left(3a\, b^2d+b^3c\right)x^n+b^3d}{x^{4n}a^4+4b\, x^{3n}a^3+6x^{2n}a^2b^2+4a\, b^3x^n+b^4}dx}dx\right) + c_2}\right.$$

Which is now a first order ode. This is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-c_3(x^{2n}ac + (ad+bc)\, x^n + bd)\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right) + c_3(x^{2n}a^2 + 2ab\, x^n + b^2)\, e^{\int \frac{x^nc+d}{a\, x^n+b}dx} - (x^{2n}ac +}{\left(c_3\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right) + c_2\right)(x^{2n}a^2 + 2ab\, x^n + b^2)}$$

$$q(x) = 0$$

Hence the ode is

$$y' - \frac{\left(-c_3(x^{2n}ac + (ad+bc)\, x^n + bd)\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right) + c_3(x^{2n}a^2 + 2ab\, x^n + b^2)\, e^{\int \frac{x^nc+d}{a\, x^n+b}dx} - (x^{2n}ac + (a\right.}{\left(c_3\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right) + c_2\right)(x^{2n}a^2 + 2ab\, x^n + b^2)}$$

The integrating factor μ is

$$\mu = e^{\int -\frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\, x^n+b^2\right)e^{\int \frac{x^nc+d}{a\, x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\, x^n+b^2\right)}dx}$$

The ode becomes

$$\frac{d}{dx}\mu y = 0$$

$$\frac{d}{dx}\left(e^{\int -\frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\, x^n+b^2\right)e^{\int \frac{x^nc+d}{a\, x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^nc+d}{a\, x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\, x^n+b^2\right)}dx} y\right) = 0$$

Integrating gives

$$e^{\int -\frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\,x^n+b^2\right)e^{\int \frac{x^n c+d}{a\,x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\,x^n+b^2\right)}dx}\,y = c_3$$

Dividing both sides by the integrating factor $\mu = e^{\int -\frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\,x^n+b^2\right)e^{\int \frac{x^n c+d}{a\,x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\,x^n+b^2\right)}dx}$ results in

$$y = c_3 e^{\int \frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\,x^n+b^2\right)e^{\int \frac{x^n c+d}{a\,x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\,x^n+b^2\right)}dx}$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = c_3 e^{\int \frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\,x^n+b^2\right)e^{\int \frac{x^n c+d}{a\,x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\,x^n+b^2\right)}dx}$$

<u>Summary</u>

The solution(s) found are the following

$$y = c_3 e^{\int \frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\,x^n+b^2\right)e^{\int \frac{x^n c+d}{a\,x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\,x^n+b^2\right)}dx} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_3 e^{\int \frac{-c_3\left(x^{2n}ac+(ad+bc)x^n+bd\right)\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_3\left(x^{2n}a^2+2ab\,x^n+b^2\right)e^{\int \frac{x^n c+d}{a\,x^n+b}dx}-\left(x^{2n}ac+(ad+bc)x^n+bd\right)c_2}{\left(c_3\left(\int e^{\int \frac{x^n c+d}{a\,x^n+b}dx}dx\right)+c_2\right)\left(x^{2n}a^2+2ab\,x^n+b^2\right)}dx}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_ode_non_constant_coeff_transformation_on_B"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{(a\,x^n + b\,x^m + c)\,y'' + (\lambda - x)\,y' + y = 0}$$

33.23.1 Solving as second order ode non constant coeff transformation on B ode

Given an ode of the form

$$Ay'' + By' + Cy = F(x)$$

This method reduces the order ode the ODE by one by applying the transformation

$$y = Bv$$

This results in

$$\begin{aligned} y' &= B'v + v'B \\ y'' &= B''v + B'v' + v''B + v'B' \\ &= v''B + 2v' + B' + B''v \end{aligned}$$

And now the original ode becomes

$$
\begin{aligned}
A(v''B+2v'B'+B''v)+B(B'v+v'B)+CBv&=0\\
ABv''+\left(2AB'+B^2\right)v'+\left(AB''+BB'+CB\right)v&=0 \qquad (1)
\end{aligned}
$$

If the term $AB''+BB'+CB$ is zero, then this method works and can be used to solve

$$
ABv''+\left(2AB'+B^2\right)v'=0
$$

By Using $u=v'$ which reduces the order of the above ode to one. The new ode is

$$
ABu'+\left(2AB'+B^2\right)u=0
$$

The above ode is first order ode which is solved for u. Now a new ode $v'=u$ is solved for v as first order ode. Then the final solution is obtain from $y=Bv$.

This method works only if the term $AB''+BB'+CB$ is zero. The given ODE shows that

$$
\begin{aligned}
A&=a\,x^n+b\,x^m+c\\
B&=\lambda-x\\
C&=1\\
F&=0
\end{aligned}
$$

The above shows that for this ode

$$
\begin{aligned}
AB''+BB'+CB&=\left(a\,x^n+b\,x^m+c\right)(0)+(\lambda-x)(-1)+(1)(\lambda-x)\\
&=0
\end{aligned}
$$

Hence the ode in v given in (1) now simplifies to

$$
\left(a\,x^n+b\,x^m+c\right)(\lambda-x)\,v''+\left(-2a\,x^n-2b\,x^m-2c+(\lambda-x)^2\right)v'=0
$$

Now by applying $v'=u$ the above becomes

$$
\left(a\,x^n+b\,x^m+c\right)(\lambda-x)\,u'(x)-2\left(a\,x^n+b\,x^m-\frac{x^2}{2}+\lambda x-\frac{\lambda^2}{2}+c\right)u(x)=0
$$

Which is now solved for u. In canonical form the ODE is

$$
\begin{aligned}
u'&=F(x,u)\\
&=f(x)g(u)\\
&=\frac{u(2b\,x^m+2a\,x^n-\lambda^2+2\lambda x-x^2+2c)}{x^m b\lambda-x^m bx+x^n a\lambda-ax\,x^n+c\lambda-cx}
\end{aligned}
$$

Where $f(x) = \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}$ and $g(u) = u$. Integrating both sides gives

$$
\begin{aligned}
\frac{1}{u}\,du &= \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}\,dx\\
\int \frac{1}{u}\,du &= \int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}\,dx\\
\ln\left(u\right) &= \int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx+c_{1}\\
u &= \mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx+c_{1}}\\
&= c_{1}\mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx}
\end{aligned}
$$

The ode for v now becomes

$$
\begin{aligned}
v' &= u\\
&= c_{1}\mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx}
\end{aligned}
$$

Which is now solved for v. Writing the ode as

$$
\begin{aligned}
v'(x) &= c_{1}\mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx}\\
v'(x) &= \omega(x,v)
\end{aligned}
$$

The condition of Lie symmetry is the linearized PDE given by

$$
\eta_x+\omega(\eta_v-\xi_x)-\omega^2\xi_v-\omega_x\xi-\omega_v\eta=0 \tag{A}
$$

The type of this ode is not in the lookup table. To determine ξ,η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$
\xi = va_{3}+xa_{2}+a_{1} \tag{1E}
$$

$$
\eta = vb_{3}+xb_{2}+b_{1} \tag{2E}
$$

Where the unknown coefficients are

$$
\{a_{1}, a_{2}, a_{3}, b_{1}, b_{2}, b_{3}\}
$$

Substituting equations (1E,2E) and ω into (A) gives

$$
\begin{aligned}
&b_{2}+c_{1}\mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx}(b_{3}-a_{2})-c_{1}^{2}\mathrm{e}^{\int \frac{4b\,x^{m}+4a\,x^{n}-2\lambda^{2}+4\lambda x-2x^{2}+4c}{x^{m}b\lambda-b\,x^{m+1}+x^{n}a\lambda-a\,x^{n+1}+c\lambda-cx}dx}a_{3}\\
&-\frac{c_{1}\left(2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c\right)\mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}dx}(va_{3}+xa_{2}+a_{1})}{x^{m}b\lambda-x^{m}bx+x^{n}a\lambda-ax\,x^{n}+c\lambda-cx}\\
&=0
\end{aligned} \tag{5E}
$$

Putting the above in normal form gives

Expression too large to display

Setting the numerator to zero gives

Expression too large to display (6E)

Simplifying the above gives

Expression too large to display (6E)

Looking at the above PDE shows the following are all the terms with $\{v, x\}$ in them.

$$\left\{v, x, x^{m}, x^{n}, \int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m} b\lambda -x^{m} b x+x^{n} a\lambda -a x\,x^{n}+c\lambda -c x}d x, \mathrm{e}^{2\left(\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m} b\lambda -x^{m} b x+x^{n} a\lambda -a x\,x^{n}+c\lambda -c x}d x\right)}, \mathrm{e}^{\int \frac{2b\,x^{m}+2a\,x}{x^{m} b\lambda -x^{m} b x-}}\right.$$

The following substitution is now made to be able to collect on all terms with $\{v, x\}$ in them

$$\left\{v = v_{1}, x = v_{2}, x^{m} = v_{3}, x^{n} = v_{4}, \int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x-x^{2}+2c}{x^{m} b\lambda -x^{m} b x+x^{n} a\lambda -a x\,x^{n}+c\lambda -c x}d x = v_{5}, \mathrm{e}^{2\left(\int \frac{2b\,x^{m}+2a\,x^{n}-\lambda^{2}+2\lambda x}{x^{m} b\lambda -x^{m} b x+x^{n} a\lambda -a x}\right.}\right.$$

The above PDE (6E) now becomes

$$\begin{aligned}
&-a\,c_{1}^{2} \lambda a_{3} v_{4} v_{6}+a\,c_{1}^{2} a_{3} v_{2} v_{4} v_{6}-b\,c_{1}^{2} \lambda a_{3} v_{3} v_{6}+b\,c_{1}^{2} a_{3} v_{2} v_{3} v_{6}-a c_{1} \lambda a_{2} v_{4} v_{7}\\
&+a c_{1} \lambda b_{3} v_{4} v_{7}-a c_{1} a_{2} v_{2} v_{4} v_{7}-2 a c_{1} a_{3} v_{1} v_{4} v_{7}-a c_{1} b_{3} v_{2} v_{4} v_{7}-b c_{1} \lambda a_{2} v_{3} v_{7}\\
&+b c_{1} \lambda b_{3} v_{3} v_{7}-b c_{1} a_{2} v_{2} v_{3} v_{7}-2 b c_{1} a_{3} v_{1} v_{3} v_{7}-b c_{1} b_{3} v_{2} v_{3} v_{7}-c\,c_{1}^{2} \lambda a_{3} v_{6}\\
&+c\,c_{1}^{2} a_{3} v_{2} v_{6}+c_{1} \lambda^{2} a_{2} v_{2} v_{7}+c_{1} \lambda^{2} a_{3} v_{1} v_{7}-2 c_{1} \lambda a_{2} v_{2}^{2} v_{7}-2 c_{1} \lambda a_{3} v_{1} v_{2} v_{7}\\
&+c_{1} a_{2} v_{2}^{3} v_{7}+c_{1} a_{3} v_{1} v_{2}^{2} v_{7}-2 a c_{1} a_{1} v_{4} v_{7}-2 b c_{1} a_{1} v_{3} v_{7}-c c_{1} \lambda a_{2} v_{7}+c c_{1} \lambda b_{3} v_{7}\\
&-c c_{1} a_{2} v_{2} v_{7}-2 c c_{1} a_{3} v_{1} v_{7}-c c_{1} b_{3} v_{2} v_{7}+c_{1} \lambda^{2} a_{1} v_{7}-2 c_{1} \lambda a_{1} v_{2} v_{7}+c_{1} a_{1} v_{2}^{2} v_{7}\\
&+v_{4} a \lambda b_{2}-v_{4} a v_{2} b_{2}+v_{3} b \lambda b_{2}-v_{3} b v_{2} b_{2}-2 c c_{1} a_{1} v_{7}+c \lambda b_{2}-c v_{2} b_{2} = 0
\end{aligned} \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_{1}, v_{2}, v_{3}, v_{4}, v_{5}, v_{6}, v_{7}\}$$

Equation (7E) now becomes

$$
\begin{aligned}
&(-bc_1a_2 - bc_1b_3)\, v_2v_3v_7 + (-ac_1a_2 - ac_1b_3)\, v_2v_4v_7 + c\lambda b_2 \\
&\; - a\, c_1^2\lambda a_3v_4v_6 + a\, c_1^2a_3v_2v_4v_6 - b\, c_1^2\lambda a_3v_3v_6 + b\, c_1^2a_3v_2v_3v_6 \\
&\; + c_1a_3v_1v_2^2v_7 - 2ac_1a_3v_1v_4v_7 - 2bc_1a_3v_1v_3v_7 - 2c_1\lambda a_3v_1v_2v_7 \\
&\; - c\, c_1^2\lambda a_3v_6 + c\, c_1^2a_3v_2v_6 - cv_2b_2 + \left(c_1\lambda^2a_3 - 2cc_1a_3\right) v_1v_7 \\
&\; + (-2c_1\lambda a_2 + c_1a_1)\, v_2^2v_7 + \left(c_1\lambda^2a_2 - cc_1a_2 - cc_1b_3 - 2c_1\lambda a_1\right) v_2v_7 \\
&\; + (-bc_1\lambda a_2 + bc_1\lambda b_3 - 2bc_1a_1)\, v_3v_7 + (-ac_1\lambda a_2 + ac_1\lambda b_3 - 2ac_1a_1)\, v_4v_7 \\
&\; + v_3b\lambda b_2 - v_3bv_2b_2 + v_4a\lambda b_2 - v_4av_2b_2 + c_1a_2v_2^3v_7 \\
&\; + \left(-cc_1\lambda a_2 + cc_1\lambda b_3 + c_1\lambda^2a_1 - 2cc_1a_1\right) v_7 = 0
\end{aligned}
\tag{8E}
$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$
\begin{aligned}
c_1 a_2 &= 0 \\
c_1 a_3 &= 0 \\
c_1^2 a a_3 &= 0 \\
c_1^2 b a_3 &= 0 \\
a \lambda b_2 &= 0 \\
b \lambda b_2 &= 0 \\
c\, c_1^2 a_3 &= 0 \\
c \lambda b_2 &= 0 \\
-a b_2 &= 0 \\
-b b_2 &= 0 \\
-b_2 c &= 0 \\
-2 c_1 a a_3 &= 0 \\
-2 c_1 b a_3 &= 0 \\
-2 c_1 \lambda a_3 &= 0 \\
-c_1^2 a \lambda a_3 &= 0 \\
-c_1^2 b \lambda a_3 &= 0 \\
-c_1^2 c \lambda a_3 &= 0 \\
-a c_1 a_2 - a c_1 b_3 &= 0 \\
-b c_1 a_2 - b c_1 b_3 &= 0 \\
c_1 \lambda^2 a_3 - 2 c c_1 a_3 &= 0 \\
-2 c_1 \lambda a_2 + c_1 a_1 &= 0 \\
-a c_1 \lambda a_2 + a c_1 \lambda b_3 - 2 a c_1 a_1 &= 0 \\
-b c_1 \lambda a_2 + b c_1 \lambda b_3 - 2 b c_1 a_1 &= 0 \\
c_1 \lambda^2 a_2 - c c_1 a_2 - c c_1 b_3 - 2 c_1 \lambda a_1 &= 0 \\
-c c_1 \lambda a_2 + c c_1 \lambda b_3 + c_1 \lambda^2 a_1 - 2 c c_1 a_1 &= 0
\end{aligned}
$$

Solving the above equations for the unknowns gives

$$
\begin{aligned}
a_1 &= 0 \\
a_2 &= 0 \\
a_3 &= 0 \\
b_1 &= b_1 \\
b_2 &= 0 \\
b_3 &= 0
\end{aligned}
$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$
\begin{aligned}
\xi &= 0 \\
\eta &= 1
\end{aligned}
$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x, v) \to (R, S)$ where (R, S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$
\frac{dx}{\xi} = \frac{dv}{\eta} = dS \tag{1}
$$

The above comes from the requirements that $\left(\xi \frac{\partial}{\partial x} + \eta \frac{\partial}{\partial v}\right) S(x, v) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$
R = x
$$

S is found from

$$
\begin{aligned}
S &= \int \frac{1}{\eta} dy \\
&= \int \frac{1}{1} dy
\end{aligned}
$$

Which results in

$$
S = v
$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$
\frac{dS}{dR} = \frac{S_x + \omega(x, v) S_v}{R_x + \omega(x, v) R_v} \tag{2}
$$

Where in the above R_x, R_v, S_x, S_v are all partial derivatives and $\omega(x,v)$ is the right hand side of the original ode given by

$$\omega(x,v) = c_1 \mathrm{e}^{\int \frac{2b\,x^m+2a\,x^n-\lambda^2+2\lambda x-x^2+2c}{x^m b\lambda - x^m bx + x^n a\lambda - ax\,x^n + c\lambda - cx}dx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_v &= 0 \\ S_x &= 0 \\ S_v &= 1 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = c_1 \mathrm{e}^{\int \frac{-2b\,x^m-2a\,x^n+\lambda^2-2\lambda x+x^2-2c}{(a\,x^n+b\,x^m+c)(-\lambda+x)}dx} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, v in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = c_1 \mathrm{e}^{\int \frac{-2b\,R^m-2a\,R^n+\lambda^2-2\lambda R+R^2-2c}{(a\,R^n+b\,R^m+c)(-\lambda+R)}dR}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int c_1 \mathrm{e}^{-\left(\int \frac{2b\,R^m+2a\,R^n-R^2+2\lambda R-\lambda^2+2c}{(a\,R^n+b\,R^m+c)(-\lambda+R)}dR\right)}dR + c_2 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, v coordinates. This results in

$$v(x) = \int c_1 \mathrm{e}^{-\left(\int \frac{2b\,x^m+2a\,x^n-\lambda^2+2\lambda x-x^2+2c}{(a\,x^n+b\,x^m+c)(-\lambda+x)}dx\right)}dx + c_2$$

Which simplifies to

$$v(x) - c_1\left(\int \mathrm{e}^{\int \frac{-2b\,x^m-2a\,x^n+\lambda^2-2\lambda x+x^2-2c}{(a\,x^n+b\,x^m+c)(-\lambda+x)}dx}dx\right) - c_2 = 0$$

Which gives

$$v(x) = c_1\left(\int \mathrm{e}^{\int \frac{-2b\,x^m-2a\,x^n+\lambda^2-2\lambda x+x^2-2c}{(a\,x^n+b\,x^m+c)(-\lambda+x)}dx}dx\right) + c_2$$

Therefore the solution is

$$\begin{aligned} y(x) &= Bv \\ &= (\lambda - x)\left(c_1\left(\int \mathrm{e}^{\int \frac{-2b\,x^m - 2a\,x^n + \lambda^2 - 2\lambda x + x^2 - 2c}{(a\,x^n + b\,x^m + c)(-\lambda + x)}dx}dx\right) + c_2\right) \\ &= (\lambda - x)\left(c_1\left(\int \mathrm{e}^{\int \frac{-2b\,x^m - 2a\,x^n + \lambda^2 - 2\lambda x + x^2 - 2c}{(a\,x^n + b\,x^m + c)(-\lambda + x)}dx}dx\right) + c_2\right) \end{aligned}$$

Summary

The solution(s) found are the following

$$y = (\lambda - x)\left(c_1\left(\int \mathrm{e}^{\int \frac{-2b\,x^m - 2a\,x^n + \lambda^2 - 2\lambda x + x^2 - 2c}{(a\,x^n + b\,x^m + c)(-\lambda + x)}dx}dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = (\lambda - x)\left(c_1\left(\int \mathrm{e}^{\int \frac{-2b\,x^m - 2a\,x^n + \lambda^2 - 2\lambda x + x^2 - 2c}{(a\,x^n + b\,x^m + c)(-\lambda + x)}dx}dx\right) + c_2\right)$$

Verified OK.

$$\boxed{(a\,x^n+b)^{m+1}\,y''+(a\,x^n+b)\,y'-anm\,x^{n-1}y=0}$$

33.26.1 Solving as second order ode lagrange adjoint equation method ode

In normal form the ode

$$(a\,x^n+b)^{m+1}\,y''+(a\,x^n+b)\,y'-anm\,x^{n-1}y=0 \tag{1}$$

Becomes

$$y''+p(x)\,y'+q(x)\,y=r(x) \tag{2}$$

Where

$$\begin{aligned}p(x)&=(a\,x^n+b)^{-m}\\ q(x)&=-anm\,x^{n-1}(a\,x^n+b)^{-m-1}\\ r(x)&=0\end{aligned}$$

The Lagrange adjoint ode is given by

$$\xi''-(\xi\,p)'+\xi q=0$$
$$\xi''-\left((a\,x^n+b)^{-m}\,\xi(x)\right)'+\left(-anm\,x^{n-1}(a\,x^n+b)^{-m-1}\,\xi(x)\right)=0$$
$$\xi''(x)-(a\,x^n+b)^{-m}\,\xi'(x)+\left(\frac{anm\,x^n(a\,x^n+b)^{-m}}{x\,(a\,x^n+b)}-anm\,x^{n-1}(a\,x^n+b)^{-m-1}\right)\xi(x)=0$$

Which is solved for $\xi(x)$. This is second order ode with missing dependent variable $\xi(x)$. Let

$$p(x) = \xi'(x)$$

Then

$$p'(x) = \xi''(x)$$

Hence the ode becomes

$$x(-a\,x^n - b)\,p'(x) + x(a\,x^n + b)^{-m+1}\,p(x) = 0$$

Which is now solve for $p(x)$ as first order ode. In canonical form the ODE is

$$\begin{aligned}
p' &= F(x,p)\\
&= f(x)g(p)\\
&= \frac{(a\,x^n + b)^{-m+1}\,p}{a\,x^n + b}
\end{aligned}$$

Where $f(x) = \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}$ and $g(p) = p$. Integrating both sides gives

$$\begin{aligned}
\frac{1}{p}\,dp &= \frac{(a\,x^n + b)^{-m+1}}{a\,x^n + b}\,dx\\
\int \frac{1}{p}\,dp &= \int \frac{(a\,x^n + b)^{-m+1}}{a\,x^n + b}\,dx\\
\ln(p) &= \int \frac{(a\,x^n + b)^{-m+1}}{a\,x^n + b}dx + c_1\\
p &= e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx + c_1}\\
&= c_1 e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx}
\end{aligned}$$

Since $p = \xi'(x)$ then the new first order ode to solve is

$$\xi'(x) = c_1 e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx}$$

Writing the ode as

$$\begin{aligned}
\xi'(x) &= c_1 e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx}\\
\xi'(x) &= \omega(x,\xi)
\end{aligned}$$

The condition of Lie symmetry is the linearized PDE given by

$$\eta_x + \omega(\eta_\xi - \xi_x) - \omega^2 \xi_\xi - \omega_x \xi - \omega_\xi \eta = 0 \tag{A}$$

The type of this ode is not in the lookup table. To determine ξ, η then (A) is solved using ansatz. Making bivariate polynomials of degree 1 to use as anstaz gives

$$\xi = x a_2 + \xi a_3 + a_1 \tag{1E}$$

$$\eta = x b_2 + \xi b_3 + b_1 \tag{2E}$$

Where the unknown coefficients are

$$\{a_1, a_2, a_3, b_1, b_2, b_3\}$$

Substituting equations (1E,2E) and ω into (A) gives

$$b_2 + c_1 \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} (b_3 - a_2) - c_1^2 \mathrm{e}^{\int 2(a\,x^n+b)^{-m}dx} a_3 - \frac{c_1 (a\,x^n + b)^{-m+1} \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} (x a_2 + \xi a_3 + a_1)}{a\,x^n + b} = 0 \tag{5E}$$

Putting the above in normal form gives

$$-\frac{\mathrm{e}^{\int 2(a\,x^n+b)^{-m}dx} x^n c_1^2 a a_3 + \mathrm{e}^{\int 2(a\,x^n+b)^{-m}dx} c_1^2 b a_3 + \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} x^n c_1 a a_2 - \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} x^n c_1 a b_3 + \mathrm{e}^{\int \frac{(a}{}}{}$$

$$= 0$$

Setting the numerator to zero gives

$$\begin{aligned}
&-\mathrm{e}^{\int 2(a\,x^n+b)^{-m}dx} x^n c_1^2 a a_3 - \mathrm{e}^{\int 2(a\,x^n+b)^{-m}dx} c_1^2 b a_3 - \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} x^n c_1 a a_2 \\
&+ \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} x^n c_1 a b_3 - \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} (a\,x^n + b)^{-m+1} c_1 x a_2 \\
&- \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} (a\,x^n + b)^{-m+1} c_1 \xi a_3 - \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} (a\,x^n + b)^{-m+1} c_1 a_1 \\
&- \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b a_2 + \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b b_3 + x^n a b_2 + b b_2 = 0
\end{aligned} \tag{6E}$$

Simplifying the above gives

$$-\left(x^n e^{2\left(\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx\right)} c_1^2 a a_3 (a\,x^n+b)^m + x^n e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 a a_2 (a\,x^n+b)^m - x^n e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 a b_3 (a\,x^n+b)^m + x^n e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 a x a_2 + x^n e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 a \xi a_3 + e^{2\left(\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx\right)} c_1^2 b a_3 (a\,x^n+b)^m + x^n e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 a a_1 + e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b a_2 (a\,x^n+b)^m - e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b b_3 (a\,x^n+b)^m + e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b x a_2 + e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b \xi a_3 - x^n a b_2 (a\,x^n+b)^m + e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} c_1 b a_1 - b b_2 (a\,x^n+b)^m\right) (a\,x^n+b)^{-m} = 0 \tag{6E}$$

Looking at the above PDE shows the following are all the terms with $\{x, \xi\}$ in them.

$$\left\{x, \xi, x^n, (a\,x^n+b)^m, (a\,x^n+b)^{-m+1}, \int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx, e^{2\left(\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx\right)}, e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx}\right\}$$

The following substitution is now made to be able to collect on all terms with $\{x, \xi\}$ in them

$$\left\{x = v_1, \xi = v_2, x^n = v_3, (a\,x^n+b)^m = v_4, (a\,x^n+b)^{-m+1} = v_5, \int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx = v_6, e^{2\left(\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx\right)} = v_7, e^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx} = v_8\right\}$$

The above PDE (6E) now becomes

$$-\frac{a\,c_1^2 a_3 v_3 v_4 v_7 + a c_1 a_2 v_1 v_3 v_8 + a c_1 a_2 v_3 v_4 v_8 + a c_1 a_3 v_2 v_3 v_8 - a c_1 b_3 v_3 v_4 v_8 + b\,c_1^2 a_3 v_4 v_7 + a c_1 a_1 v_3 v_8 + b c_1 a_2 \cdots}{v_4} = 0 \tag{7E}$$

Collecting the above on the terms v_i introduced, and these are

$$\{v_1, v_2, v_3, v_4, v_5, v_6, v_7, v_8\}$$

Equation (7E) now becomes

$$\begin{aligned} &-\frac{c_1 a a_2 v_8 v_1 v_3}{v_4} - \frac{c_1 b a_2 v_8 v_1}{v_4} - \frac{c_1 a a_3 v_8 v_2 v_3}{v_4} - \frac{c_1 b a_3 v_8 v_2}{v_4} \\ &- c_1^2 a a_3 v_7 v_3 + (-a c_1 a_2 + a c_1 b_3) v_8 v_3 + a b_2 v_3 - \frac{c_1 a a_1 v_8 v_3}{v_4} \\ &- c_1^2 b a_3 v_7 + (-b c_1 a_2 + b c_1 b_3) v_8 + b b_2 - \frac{v_8 c_1 b a_1}{v_4} = 0 \end{aligned} \tag{8E}$$

Setting each coefficients in (8E) to zero gives the following equations to solve

$$\begin{aligned} a b_2 &= 0 \\ b b_2 &= 0 \\ -c_1 a a_1 &= 0 \\ -a c_1 a_2 &= 0 \\ -c_1 a a_3 &= 0 \\ -c_1 b a_1 &= 0 \\ -b c_1 a_2 &= 0 \\ -c_1 b a_3 &= 0 \\ -c_1^2 a a_3 &= 0 \\ -c_1^2 b a_3 &= 0 \\ -a c_1 a_2 + a c_1 b_3 &= 0 \\ -b c_1 a_2 + b c_1 b_3 &= 0 \end{aligned}$$

Solving the above equations for the unknowns gives

$$\begin{aligned} a_1 &= 0 \\ a_2 &= 0 \\ a_3 &= 0 \\ b_1 &= b_1 \\ b_2 &= 0 \\ b_3 &= 0 \end{aligned}$$

Substituting the above solution in the anstaz (1E,2E) (using 1 as arbitrary value for any unknown in the RHS) gives

$$\xi = 0$$
$$\eta = 1$$

The next step is to determine the canonical coordinates R, S. The canonical coordinates map $(x,\xi) \to (R,S)$ where (R,S) are the canonical coordinates which make the original ode become a quadrature and hence solved by integration.

The characteristic pde which is used to find the canonical coordinates is

$$\frac{dx}{\xi} = \frac{d\xi}{\eta} = dS \tag{1}$$

The above comes from the requirements that $\left(\xi\frac{\partial}{\partial x} + \eta\frac{\partial}{\partial \xi}\right) S(x,\xi) = 1$. Starting with the first pair of ode's in (1) gives an ode to solve for the independent variable R in the canonical coordinates, where $S(R)$. Since $\xi = 0$ then in this special case

$$R = x$$

S is found from

$$\begin{aligned} S &= \int \frac{1}{\eta} dy \\ &= \int \frac{1}{1} dy \end{aligned}$$

Which results in

$$S = \xi$$

Now that R, S are found, we need to setup the ode in these coordinates. This is done by evaluating

$$\frac{dS}{dR} = \frac{S_x + \omega(x,\xi)S_\xi}{R_x + \omega(x,\xi)R_\xi} \tag{2}$$

Where in the above R_x, R_ξ, S_x, S_ξ are all partial derivatives and $\omega(x,\xi)$ is the right hand side of the original ode given by

$$\omega(x,\xi) = c_1 \mathrm{e}^{\int \frac{(a\,x^n+b)^{-m+1}}{a\,x^n+b}dx}$$

Evaluating all the partial derivatives gives

$$\begin{aligned} R_x &= 1 \\ R_\xi &= 0 \\ S_x &= 0 \\ S_\xi &= 1 \end{aligned}$$

Substituting all the above in (2) and simplifying gives the ode in canonical coordinates.

$$\frac{dS}{dR} = c_1 \mathrm{e}^{\int (a\,x^n+b)^{-m}dx} \tag{2A}$$

We now need to express the RHS as function of R only. This is done by solving for x, ξ in terms of R, S from the result obtained earlier and simplifying. This gives

$$\frac{dS}{dR} = c_1 \mathrm{e}^{\int (a\,R^n+b)^{-m}dR}$$

The above is a quadrature ode. This is the whole point of Lie symmetry method. It converts an ode, no matter how complicated it is, to one that can be solved by integration when the ode is in the canonical coordiates R, S. Integrating the above gives

$$S(R) = \int c_1 \mathrm{e}^{\int (a\,R^n+b)^{-m}dR} dR + c_2 \tag{4}$$

To complete the solution, we just need to transform (4) back to x, ξ coordinates. This results in

$$\xi(x) = \int c_1 \mathrm{e}^{\int (a\,x^n+b)^{-m}dx} dx + c_2$$

Which simplifies to

$$\xi(x) = \int c_1 \mathrm{e}^{\int (a\,x^n+b)^{-m}dx} dx + c_2$$

Which gives

$$\xi(x) = \int c_1 \mathrm{e}^{\int (a\,x^n+b)^{-m}dx} dx + c_2$$

The original ode (2) now reduces to first order ode

$$\begin{aligned} \xi(x)\,y' - y\xi'(x) + \xi(x)\,p(x)\,y &= \int \xi(x)\,r(x)\,dx \\ y' + y\left(p(x) - \frac{\xi'(x)}{\xi\,(x)}\right) &= \frac{\int \xi(x)\,r(x)\,dx}{\xi\,(x)} \end{aligned}$$

$$y' + y\left((a\,x^n+b)^{-m} - \frac{c_3 \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{\int c_3 \mathrm{e}^{\int (a\,x^n+b)^{-m}dx} dx + c_2}\right) = 0$$

Which is now a first order ode. This is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$p(x) = -\frac{-(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3 - (a\,x^n+b)^{-m}c_2 + c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2}$$

$$q(x) = 0$$

Hence the ode is

$$y' - \frac{\left(-(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3 - (a\,x^n+b)^{-m}c_2 + c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}\right)y}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2} = 0$$

The integrating factor μ is

$$\mu = \mathrm{e}^{\int -\frac{-(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3-(a\,x^n+b)^{-m}c_2+c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2}dx}$$

The ode becomes

$$\frac{\mathrm{d}}{\mathrm{d}x}\mu y = 0$$

$$\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\int -\frac{-(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3-(a\,x^n+b)^{-m}c_2+c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2}dx}y\right) = 0$$

Integrating gives

$$\mathrm{e}^{\int -\frac{-(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3-(a\,x^n+b)^{-m}c_2+c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2}dx}y = c_3$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\int -\frac{-(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3-(a\,x^n+b)^{-m}c_2+c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2}dx}$ results in

$$y = c_3\mathrm{e}^{-\left(\int \frac{(a\,x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)c_3+(a\,x^n+b)^{-m}c_2-c_3\mathrm{e}^{\int (a\,x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a\,x^n+b)^{-m}dx}dx\right)+c_2}dx\right)}$$

Hence, the solution found using Lagrange adjoint equation method is

$$y = c_3 \mathrm{e}^{-\left(\int \frac{(a x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a x^n+b)^{-m}dx}dx\right)c_3+(a x^n+b)^{-m}c_2-c_3\mathrm{e}^{\int (a x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a x^n+b)^{-m}dx}dx\right)+c_2}dx\right)}$$

Summary

The solution(s) found are the following

$$y = c_3 \mathrm{e}^{-\left(\int \frac{(a x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a x^n+b)^{-m}dx}dx\right)c_3+(a x^n+b)^{-m}c_2-c_3\mathrm{e}^{\int (a x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a x^n+b)^{-m}dx}dx\right)+c_2}dx\right)} \tag{1}$$

Verification of solutions

$$y = c_3 \mathrm{e}^{-\left(\int \frac{(a x^n+b)^{-m}\left(\int \mathrm{e}^{\int (a x^n+b)^{-m}dx}dx\right)c_3+(a x^n+b)^{-m}c_2-c_3\mathrm{e}^{\int (a x^n+b)^{-m}dx}}{c_3\left(\int \mathrm{e}^{\int (a x^n+b)^{-m}dx}dx\right)+c_2}dx\right)}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_bessel_ode_form_A"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \mathrm{e}^{\lambda x} y a = 0}$$

34.1.1 Solving as second order bessel ode form A ode

Writing the ode as

$$y'' + \mathrm{e}^{\lambda x} y a = 0 \tag{1}$$

An ode of the form

$$a y'' + b y' + (c e^{rx} + m) y = 0 \tag{1}$$

can be transformed to Bessel ode using the transformation

$$\begin{aligned} x &= \ln(t) \\ e^x &= t \end{aligned}$$

Where a, b, c, m are not functions of x and where b and m are allowed to be be zero. Using this transformation gives

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{dt}\frac{dt}{dx} \\ &= \frac{dy}{dt} e^x \\ &= t\frac{dy}{dt} \end{aligned} \tag{2}$$

And

$$\begin{aligned}
\frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{dy}{dx}\right)\\
&= \frac{d}{dx}\left(t\frac{dy}{dt}\right)\\
&= \frac{d}{dt}\frac{dt}{dx}\left(t\frac{dy}{dt}\right)\\
&= \frac{dt}{dx}\frac{d}{dt}\left(t\frac{dy}{dt}\right)\\
&= t\frac{d}{dt}\left(t\frac{dy}{dt}\right)\\
&= t\left(\frac{dy}{dt}+t\frac{d^2y}{dt^2}\right) \qquad (3)
\end{aligned}$$

Substituting (2,3) into (1) gives

$$\begin{aligned}
at\left(\frac{dy}{dt}+t\frac{d^2y}{dt^2}\right)+bt\frac{dy}{dt}+(ce^{rx}+m)y &= 0\\
(aty'+at^2y'')+bty'+(ct^r+m)y &= 0\\
at^2y''+(b+a)\,ty'+(ct^r+m)y &= 0\\
t^2y''+\frac{b+a}{a}ty'+\left(\frac{c}{a}t^r+\frac{m}{a}\right)y &= 0 \qquad (4)
\end{aligned}$$

Which is Bessel ODE. Comparing the above to the general known Bowman form of Bessel ode which is

$$t^2y''+(1-2\alpha)\,ty'+\left(\beta^2\gamma^2t^{2\gamma}-\left(n^2\gamma^2-\alpha^2\right)\right)y=0 \qquad \text{(C)}$$

And now comparing (4) and (C) shows that

$$\begin{aligned}
(1-2\alpha) &= \frac{b+a}{a} \qquad (5)\\
\beta^2\gamma^2 &= \frac{c}{a} \qquad (6)\\
2\gamma &= r \qquad (7)\\
\left(n^2\gamma^2-\alpha^2\right) &= -\frac{m}{a} \qquad (8)
\end{aligned}$$

(5) gives $\alpha=\frac{1}{2}-\frac{b+a}{2a}$. (7) gives $\gamma=\frac{r}{2}$. (8) now becomes $\left(n^2\left(\frac{r}{2}\right)^2-\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2\right)=-\frac{m}{a}$ or $n^2=\frac{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}{\left(\frac{r}{2}\right)^2}$. Hence $n=\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}$ by taking the positive root.

And finally (6) gives $\beta^2 = \frac{c}{a\gamma^2}$ or $\beta = \sqrt{\frac{c}{a}\frac{1}{\gamma}} = \sqrt{\frac{c}{a}\frac{2}{r}}$ (also taking the positive root). Hence

$$
\begin{aligned}
\alpha &= \frac{1}{2} - \frac{b+a}{2a} \\
n &= \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2} \\
\beta &= \sqrt{\frac{c}{a}\frac{2}{r}} \\
\gamma &= \frac{r}{2}
\end{aligned}
$$

But the solution to (C) which is general form of Bessel ode is known and given by

$$
y(t) = t^\alpha (c_1 J_n(\beta t^\gamma) + c_2 Y_n(\beta t^\gamma))
$$

Substituting the above values found into this solution gives

$$
y(t) = t^{\frac{1}{2} - \frac{b+a}{2a}} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} t^{\frac{r}{2}} \right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} t^{\frac{r}{2}} \right) \right)
$$

Since $e^x = t$ then the above becomes

$$
\begin{aligned}
y(x) &= e^{x\left(\frac{1}{2} - \frac{b+a}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) \right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{-b}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{-b}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) \right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \frac{b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \frac{b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) \right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) \right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{1}{ra}\sqrt{-4ma+b^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) + c_2 Y_{\frac{1}{ra}\sqrt{-4ma+b^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}} \right) \right) \qquad (9)
\end{aligned}
$$

Equation (9) above is the solution to $ay'' + by' + (ce^{rx} + m)y = 0$. Therefore we just need now to compare this form to the ode given and use (9) to obtain the final solution.

Comparing form (1) to the ode we are solving shows that

$$
\begin{aligned}
a &= 1 \\
b &= 0 \\
c &= a \\
r &= \lambda \\
m &= 0
\end{aligned}
$$

Substituting these in (9) gives the solution as

$$y = c_1 \operatorname{BesselJ}\left(0, \frac{2\sqrt{a}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) + c_2 \operatorname{BesselY}\left(0, \frac{2\sqrt{a}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \operatorname{BesselJ}\left(0, \frac{2\sqrt{a}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) + c_2 \operatorname{BesselY}\left(0, \frac{2\sqrt{a}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \operatorname{BesselJ}\left(0, \frac{2\sqrt{a}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) + c_2 \operatorname{BesselY}\left(0, \frac{2\sqrt{a}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_bessel_ode_form_A"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

$$\boxed{y'' + (a\,\mathrm{e}^{x} - b)\,y = 0}$$

34.2.1 Solving as second order bessel ode form A ode

Writing the ode as

$$y'' + (a\,\mathrm{e}^{x} - b)\,y = 0 \tag{1}$$

An ode of the form

$$ay'' + by' + (ce^{rx} + m)y = 0 \tag{1}$$

can be transformed to Bessel ode using the transformation

$$\begin{aligned} x &= \ln(t) \\ e^{x} &= t \end{aligned}$$

Where a, b, c, m are not functions of x and where b and m are allowed to be be zero. Using this transformation gives

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{dt}\frac{dt}{dx} \\ &= \frac{dy}{dt}e^{x} \\ &= t\frac{dy}{dt} \end{aligned} \tag{2}$$

And

$$\begin{aligned}
\frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{dy}{dx}\right) \\
&= \frac{d}{dx}\left(t\frac{dy}{dt}\right) \\
&= \frac{d}{dt}\frac{dt}{dx}\left(t\frac{dy}{dt}\right) \\
&= \frac{dt}{dx}\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\
&= t\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\
&= t\left(\frac{dy}{dt}+t\frac{d^2y}{dt^2}\right) \qquad (3)
\end{aligned}$$

Substituting (2,3) into (1) gives

$$\begin{aligned}
at\left(\frac{dy}{dt}+t\frac{d^2y}{dt^2}\right)+bt\frac{dy}{dt}+(ce^{rx}+m)y &= 0 \\
\left(aty'+at^2y''\right)+bty'+(ct^r+m)y &= 0 \\
at^2y''+(b+a)\,ty'+(ct^r+m)y &= 0 \\
t^2y''+\frac{b+a}{a}ty'+\left(\frac{c}{a}t^r+\frac{m}{a}\right)y &= 0 \qquad (4)
\end{aligned}$$

Which is Bessel ODE. Comparing the above to the general known Bowman form of Bessel ode which is

$$t^2y''+(1-2\alpha)\,ty'+\left(\beta^2\gamma^2t^{2\gamma}-\left(n^2\gamma^2-\alpha^2\right)\right)y=0 \qquad (C)$$

And now comparing (4) and (C) shows that

$$\begin{aligned}
(1-2\alpha) &= \frac{b+a}{a} \qquad (5) \\
\beta^2\gamma^2 &= \frac{c}{a} \qquad (6) \\
2\gamma &= r \qquad (7) \\
\left(n^2\gamma^2-\alpha^2\right) &= -\frac{m}{a} \qquad (8)
\end{aligned}$$

(5) gives $\alpha=\frac{1}{2}-\frac{b+a}{2a}$. (7) gives $\gamma=\frac{r}{2}$. (8) now becomes $\left(n^2\left(\frac{r}{2}\right)^2-\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2\right)=-\frac{m}{a}$ or $n^2=\frac{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}{\left(\frac{r}{2}\right)^2}$. Hence $n=\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}$ by taking the positive root.

And finally (6) gives $\beta^2 = \frac{c}{a\gamma^2}$ or $\beta = \sqrt{\frac{c}{a}\frac{1}{\gamma}} = \sqrt{\frac{c}{a}\frac{2}{r}}$ (also taking the positive root). Hence

$$\begin{aligned}
\alpha &= \frac{1}{2} - \frac{b+a}{2a} \\
n &= \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2} \\
\beta &= \sqrt{\frac{c}{a}\frac{2}{r}} \\
\gamma &= \frac{r}{2}
\end{aligned}$$

But the solution to (C) which is general form of Bessel ode is known and given by

$$y(t) = t^\alpha(c_1 J_n(\beta t^\gamma) + c_2 Y_n(\beta t^\gamma))$$

Substituting the above values found into this solution gives

$$y(t) = t^{\frac{1}{2}-\frac{b+a}{2a}}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}t^{\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}t^{\frac{r}{2}}\right)\right)$$

Since $e^x = t$ then the above becomes

$$\begin{aligned}
y(x) &= e^{x\left(\frac{1}{2}-\frac{b+a}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{-b}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{-b}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\frac{b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\frac{b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{1}{ra}\sqrt{-4ma+b^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{1}{ra}\sqrt{-4ma+b^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \quad (9)
\end{aligned}$$

Equation (9) above is the solution to $ay'' + by' + (ce^{rx} + m)y = 0$. Therefore we just need now to compare this form to the ode given and use (9) to obtain the final solution.

Comparing form (1) to the ode we are solving shows that

$$\begin{aligned}
a &= 1 \\
b &= 0 \\
c &= a \\
r &= 1 \\
m &= -b
\end{aligned}$$

Substituting these in (9) gives the solution as

$$y = c_1 \operatorname{BesselJ}\left(2\sqrt{b}, 2\sqrt{a}\, e^{\frac{x}{2}}\right) + c_2 \operatorname{BesselY}\left(2\sqrt{b}, 2\sqrt{a}\, e^{\frac{x}{2}}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \operatorname{BesselJ}\left(2\sqrt{b}, 2\sqrt{a}\, e^{\frac{x}{2}}\right) + c_2 \operatorname{BesselY}\left(2\sqrt{b}, 2\sqrt{a}\, e^{\frac{x}{2}}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \operatorname{BesselJ}\left(2\sqrt{b}, 2\sqrt{a}\, e^{\frac{x}{2}}\right) + c_2 \operatorname{BesselY}\left(2\sqrt{b}, 2\sqrt{a}\, e^{\frac{x}{2}}\right)$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_bessel_ode_form_A"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + ay' + b\,\mathrm{e}^{2ax} y = 0}$$

34.8.1 Solving as second order bessel ode form A ode

Writing the ode as

$$y'' + ay' + b\,\mathrm{e}^{2ax} y = 0 \tag{1}$$

An ode of the form

$$ay'' + by' + (ce^{rx} + m)y = 0 \tag{1}$$

can be transformed to Bessel ode using the transformation

$$\begin{aligned} x &= \ln(t) \\ e^x &= t \end{aligned}$$

Where a, b, c, m are not functions of x and where b and m are allowed to be be zero. Using this transformation gives

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{dt}\frac{dt}{dx} \\ &= \frac{dy}{dt}e^x \\ &= t\frac{dy}{dt} \end{aligned} \tag{2}$$

And

$$
\begin{aligned}
\frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{dy}{dx}\right) \\
&= \frac{d}{dx}\left(t\frac{dy}{dt}\right) \\
&= \frac{d}{dt}\frac{dt}{dx}\left(t\frac{dy}{dt}\right) \\
&= \frac{dt}{dx}\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\
&= t\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\
&= t\left(\frac{dy}{dt} + t\frac{d^2y}{dt^2}\right) \qquad (3)
\end{aligned}
$$

Substituting (2,3) into (1) gives

$$
\begin{aligned}
at\left(\frac{dy}{dt} + t\frac{d^2y}{dt^2}\right) + bt\frac{dy}{dt} + (ce^{rx} + m)y &= 0 \\
(aty' + at^2y'') + bty' + (ct^r + m)y &= 0 \\
at^2y'' + (b+a)\,ty' + (ct^r + m)y &= 0 \\
t^2y'' + \frac{b+a}{a}ty' + \left(\frac{c}{a}t^r + \frac{m}{a}\right)y &= 0 \qquad (4)
\end{aligned}
$$

Which is Bessel ODE. Comparing the above to the general known Bowman form of Bessel ode which is

$$
t^2y'' + (1-2\alpha)\,ty' + \left(\beta^2\gamma^2t^{2\gamma} - \left(n^2\gamma^2 - \alpha^2\right)\right)y = 0 \qquad (C)
$$

And now comparing (4) and (C) shows that

$$
\begin{aligned}
(1-2\alpha) &= \frac{b+a}{a} \qquad (5) \\
\beta^2\gamma^2 &= \frac{c}{a} \qquad (6) \\
2\gamma &= r \qquad (7) \\
\left(n^2\gamma^2 - \alpha^2\right) &= -\frac{m}{a} \qquad (8)
\end{aligned}
$$

(5) gives $\alpha = \frac{1}{2} - \frac{b+a}{2a}$. (7) gives $\gamma = \frac{r}{2}$. (8) now becomes $\left(n^2\left(\frac{r}{2}\right)^2 - \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2\right) = -\frac{m}{a}$ or $n^2 = \frac{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}{\left(\frac{r}{2}\right)^2}$. Hence $n = \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}$ by taking the positive root.

And finally (6) gives $\beta^2 = \frac{c}{a\gamma^2}$ or $\beta = \sqrt{\frac{c}{a}\frac{1}{\gamma}} = \sqrt{\frac{c}{a}\frac{2}{r}}$ (also taking the positive root). Hence

$$\begin{aligned}
\alpha &= \frac{1}{2} - \frac{b+a}{2a} \\
n &= \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2} \\
\beta &= \sqrt{\frac{c}{a}\frac{2}{r}} \\
\gamma &= \frac{r}{2}
\end{aligned}$$

But the solution to (C) which is general form of Bessel ode is known and given by

$$y(t) = t^{\alpha}(c_1 J_n(\beta t^{\gamma}) + c_2 Y_n(\beta t^{\gamma}))$$

Substituting the above values found into this solution gives

$$y(t) = t^{\frac{1}{2}-\frac{b+a}{2a}}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}t^{\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}t^{\frac{r}{2}}\right)\right)$$

Since $e^x = t$ then the above becomes

$$\begin{aligned}
y(x) &= e^{x\left(\frac{1}{2}-\frac{b+a}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{-b}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{-b}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\frac{b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\frac{b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{1}{ra}\sqrt{-4ma+b^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{1}{ra}\sqrt{-4ma+b^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}e^{x\frac{r}{2}}\right)\right) \qquad (9)
\end{aligned}$$

Equation (9) above is the solution to $ay'' + by' + (ce^{rx} + m)y = 0$. Therefore we just need now to compare this form to the ode given and use (9) to obtain the final solution.

Comparing form (1) to the ode we are solving shows that

$$\begin{aligned}
a &= 1 \\
b &= a \\
c &= b \\
r &= 2a \\
m &= 0
\end{aligned}$$

Substituting these in (9) gives the solution as

$$y = \frac{c_1 \mathrm{e}^{-\frac{ax}{2}} \sqrt{2}\, \sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} - \frac{c_2 \mathrm{e}^{-\frac{ax}{2}} \sqrt{2}\, \cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}}$$

Summary

The solution(s) found are the following

$$y = \frac{c_1 \mathrm{e}^{-\frac{ax}{2}} \sqrt{2}\, \sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} - \frac{c_2 \mathrm{e}^{-\frac{ax}{2}} \sqrt{2}\, \cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} \tag{1}$$

Verification of solutions

$$y = \frac{c_1 \mathrm{e}^{-\frac{ax}{2}} \sqrt{2}\, \sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} - \frac{c_2 \mathrm{e}^{-\frac{ax}{2}} \sqrt{2}\, \cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\, \sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_bessel_ode_form_A", "second_order_change_of_variable_on_x_method_1", "second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries], [_2nd_order, _linear, `
   _with_symmetry_[0,F(x)]`]]
```

$$\boxed{y'' - ay' + b\,\mathrm{e}^{2ax}y = 0}$$

34.9.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$y'' - ay' + b\,\mathrm{e}^{2ax}y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -a \\ q(x) &= b\,\mathrm{e}^{2ax} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)}dx \\
&= \int e^{-\left(\int -adx\right)}dx \\
&= \int e^{ax}\,dx \\
&= \int e^{ax}dx \\
&= \frac{e^{ax}}{a}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{b\,e^{2ax}}{e^{2ax}} \\
&= b
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$
$$\frac{d^2}{d\tau^2}y(\tau) + by(\tau) = 0$$

The above ode is now solved for $y(\tau)$.This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Ay''(\tau) + By'(\tau) + Cy(\tau) = 0$$

Where in the above $A = 1, B = 0, C = b$. Let the solution be $y(\tau) = e^{\lambda \tau}$. Substituting this into the ODE gives

$$\lambda^2 e^{\lambda \tau} + b\, e^{\lambda \tau} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda \tau}$ gives

$$\lambda^2 + b = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 1, B = 0, C = b$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(1)} \pm \frac{1}{(2)(1)}\sqrt{0^2 - (4)(1)(b)}\\ &= \pm\sqrt{-b}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\sqrt{-b}\\ \lambda_2 &= -\sqrt{-b}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \sqrt{-b}\\ \lambda_2 &= -\sqrt{-b}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}y(\tau) &= c_1 e^{\lambda_1 \tau} + c_2 e^{\lambda_2 \tau}\\ y(\tau) &= c_1 e^{(\sqrt{-b})\tau} + c_2 e^{(-\sqrt{-b})\tau}\end{aligned}$$

Or

$$y(\tau) = c_1 e^{\sqrt{-b}\,\tau} + c_2 e^{-\sqrt{-b}\,\tau}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-b}\,\mathrm{e}^{ax}}{a}} + c_2 \mathrm{e}^{-\frac{\sqrt{-b}\,\mathrm{e}^{ax}}{a}}$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-b}\,\mathrm{e}^{ax}}{a}} + c_2 \mathrm{e}^{-\frac{\sqrt{-b}\,\mathrm{e}^{ax}}{a}} \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{\frac{\sqrt{-b}\,\mathrm{e}^{ax}}{a}} + c_2 \mathrm{e}^{-\frac{\sqrt{-b}\,\mathrm{e}^{ax}}{a}}$$

Verified OK.

34.9.2 Solving as second order change of variable on x method 1 ode

In normal form the ode

$$y'' - ay' + b\,\mathrm{e}^{2ax} y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -a \\ q(x) &= b\,\mathrm{e}^{2ax} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) results

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $q_1 = c^2$ where c is some constant. Therefore from (5)

$$\begin{aligned} \tau' &= \frac{1}{c}\sqrt{q} \\ &= \frac{\sqrt{b\,\mathrm{e}^{2ax}}}{c} \end{aligned} \tag{6}$$

$$\tau'' = \frac{b\,\mathrm{e}^{2ax} a}{c\sqrt{b\,\mathrm{e}^{2ax}}}$$

Substituting the above into (4) results in

$$\begin{aligned}
p_1(\tau) &= \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \\
&= \frac{\frac{b\,\mathrm{e}^{2ax} a}{c\sqrt{b\,\mathrm{e}^{2ax}}} - a\frac{\sqrt{b\,\mathrm{e}^{2ax}}}{c}}{\left(\frac{\sqrt{b\,\mathrm{e}^{2ax}}}{c}\right)^2} \\
&= 0
\end{aligned}$$

Therefore ode (3) now becomes

$$\begin{aligned}
y(\tau)'' + p_1 y(\tau)' + q_1 y(\tau) &= 0 \\
\frac{d^2}{d\tau^2} y(\tau) + c^2 y(\tau) &= 0 \qquad (7)
\end{aligned}$$

The above ode is now solved for $y(\tau)$. Since the ode is now constant coefficients, it can be easily solved to give

$$y(\tau) = c_1 \cos(c\tau) + c_2 \sin(c\tau)$$

Now from (6)

$$\begin{aligned}
\tau &= \int \frac{1}{c}\sqrt{q}\,dx \\
&= \frac{\int \sqrt{b\,\mathrm{e}^{2ax}}dx}{c} \\
&= \frac{\sqrt{b\,\mathrm{e}^{2ax}}}{ca}
\end{aligned}$$

Substituting the above into the solution obtained gives

$$y = c_1 \cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right) + c_2 \sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right) + c_2 \sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right) \qquad (1)$$

Verification of solutions

$$y = c_1 \cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right) + c_2 \sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)$$

Verified OK.

34.9.3 Solving as second order bessel ode form A ode

Writing the ode as

$$y'' - ay' + b\,e^{2ax}y = 0 \tag{1}$$

An ode of the form

$$ay'' + by' + (ce^{rx} + m)y = 0 \tag{1}$$

can be transformed to Bessel ode using the transformation

$$\begin{aligned} x &= \ln(t) \\ e^x &= t \end{aligned}$$

Where a, b, c, m are not functions of x and where b and m are allowed to be be zero. Using this transformation gives

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{dt}\frac{dt}{dx} \\ &= \frac{dy}{dt}e^x \\ &= t\frac{dy}{dt} \end{aligned} \tag{2}$$

And

$$\begin{aligned} \frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{dy}{dx}\right) \\ &= \frac{d}{dx}\left(t\frac{dy}{dt}\right) \\ &= \frac{d}{dt}\frac{dt}{dx}\left(t\frac{dy}{dt}\right) \\ &= \frac{dt}{dx}\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\ &= t\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\ &= t\left(\frac{dy}{dt} + t\frac{d^2y}{dt^2}\right) \end{aligned} \tag{3}$$

Substituting (2,3) into (1) gives

$$\begin{aligned} at\left(\frac{dy}{dt} + t\frac{d^2y}{dt^2}\right) + bt\frac{dy}{dt} + (ce^{rx} + m)y &= 0 \\ (aty' + at^2y'') + bty' + (ct^r + m)y &= 0 \\ at^2y'' + (b+a)\,ty' + (ct^r + m)y &= 0 \\ t^2y'' + \frac{b+a}{a}ty' + \left(\frac{c}{a}t^r + \frac{m}{a}\right)y &= 0 \end{aligned} \tag{4}$$

Which is Bessel ODE. Comparing the above to the general known Bowman form of Bessel ode which is

$$t^2y'' + (1-2\alpha)\,ty' + \left(\beta^2\gamma^2 t^{2\gamma} - \left(n^2\gamma^2 - \alpha^2\right)\right)y = 0 \tag{C}$$

And now comparing (4) and (C) shows that

$$(1-2\alpha) = \frac{b+a}{a} \tag{5}$$
$$\beta^2\gamma^2 = \frac{c}{a} \tag{6}$$
$$2\gamma = r \tag{7}$$
$$\left(n^2\gamma^2 - \alpha^2\right) = -\frac{m}{a} \tag{8}$$

(5) gives $\alpha = \frac{1}{2} - \frac{b+a}{2a}$. (7) gives $\gamma = \frac{r}{2}$. (8) now becomes $\left(n^2\left(\frac{r}{2}\right)^2 - \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2\right) = -\frac{m}{a}$ or $n^2 = \frac{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}{\left(\frac{r}{2}\right)^2}$. Hence $n = \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}$ by taking the positive root. And finally (6) gives $\beta^2 = \frac{c}{a\gamma^2}$ or $\beta = \sqrt{\frac{c}{a}\frac{1}{\gamma}} = \sqrt{\frac{c}{a}\frac{2}{r}}$ (also taking the positive root). Hence

$$\alpha = \frac{1}{2} - \frac{b+a}{2a}$$
$$n = \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}$$
$$\beta = \sqrt{\frac{c}{a}\frac{2}{r}}$$
$$\gamma = \frac{r}{2}$$

But the solution to (C) which is general form of Bessel ode is known and given by

$$y(t) = t^{\alpha}(c_1 J_n(\beta t^{\gamma}) + c_2 Y_n(\beta t^{\gamma}))$$

Substituting the above values found into this solution gives

$$y(t) = t^{\frac{1}{2}-\frac{b+a}{2a}}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}t^{\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}\frac{2}{r}}t^{\frac{r}{2}}\right)\right)$$

Since $e^x = t$ then the above becomes

$$
\begin{aligned}
y(x) &= e^{x\left(\frac{1}{2}-\frac{b+a}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)+c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{1}{2}-\frac{b+a}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{-b}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)+c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\left(\frac{-b}{2a}\right)^2}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a}+\frac{b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)+c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a}+\frac{b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)+c_2 Y_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)}\left(c_1 J_{\frac{1}{ra}\sqrt{-4ma+b^2}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)+c_2 Y_{\frac{1}{ra}\sqrt{-4ma+b^2}}\left(\sqrt{\frac{c}{a}}\frac{2}{r}e^{x\frac{r}{2}}\right)\right) \qquad (9)
\end{aligned}
$$

Equation (9) above is the solution to $ay'' + by' + (ce^{rx} + m)y = 0$. Therefore we just need now to compare this form to the ode given and use (9) to obtain the final solution.

Comparing form (1) to the ode we are solving shows that

$$
\begin{aligned}
a &= 1 \\
b &= -a \\
c &= b \\
r &= 2a \\
m &= 0
\end{aligned}
$$

Substituting these in (9) gives the solution as

$$
y = \frac{c_1 \mathrm{e}^{\frac{ax}{2}}\sqrt{2}\,\sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} - \frac{c_2 \mathrm{e}^{\frac{ax}{2}}\sqrt{2}\,\cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}}
$$

Summary

The solution(s) found are the following

$$
y = \frac{c_1 \mathrm{e}^{\frac{ax}{2}}\sqrt{2}\,\sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} - \frac{c_2 \mathrm{e}^{\frac{ax}{2}}\sqrt{2}\,\cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} \qquad (1)
$$

Verification of solutions

$$
y = \frac{c_1 \mathrm{e}^{\frac{ax}{2}}\sqrt{2}\,\sin\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}} - \frac{c_2 \mathrm{e}^{\frac{ax}{2}}\sqrt{2}\,\cos\left(\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}\right)}{\sqrt{\pi}\,\sqrt{\frac{\sqrt{b}\,\mathrm{e}^{ax}}{a}}}
$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.3-1. Equations with exponential functions
Problem number: 10.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second__order__bessel__ode__form__A"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + ay' + \left(b\,\mathrm{e}^{\lambda x} + c\right) y = 0}$$

34.10.1 Solving as second order bessel ode form A ode

Writing the ode as

$$y'' + ay' + \left(b\,\mathrm{e}^{\lambda x} + c\right) y = 0 \tag{1}$$

An ode of the form

$$ay'' + by' + (ce^{rx} + m)y = 0 \tag{1}$$

can be transformed to Bessel ode using the transformation

$$\begin{aligned} x &= \ln(t) \\ e^x &= t \end{aligned}$$

Where a, b, c, m are not functions of x and where b and m are allowed to be be zero. Using this transformation gives

$$\begin{aligned} \frac{dy}{dx} &= \frac{dy}{dt}\frac{dt}{dx} \\ &= \frac{dy}{dt}e^x \\ &= t\frac{dy}{dt} \end{aligned} \tag{2}$$

And

$$
\begin{aligned}
\frac{d^2y}{dx^2} &= \frac{d}{dx}\left(\frac{dy}{dx}\right) \\
&= \frac{d}{dx}\left(t\frac{dy}{dt}\right) \\
&= \frac{d}{dt}\frac{dt}{dx}\left(t\frac{dy}{dt}\right) \\
&= \frac{dt}{dx}\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\
&= t\frac{d}{dt}\left(t\frac{dy}{dt}\right) \\
&= t\left(\frac{dy}{dt} + t\frac{d^2y}{dt^2}\right) \qquad (3)
\end{aligned}
$$

Substituting (2,3) into (1) gives

$$
\begin{aligned}
at\left(\frac{dy}{dt} + t\frac{d^2y}{dt^2}\right) + bt\frac{dy}{dt} + (ce^{rx} + m)y &= 0 \\
(aty' + at^2y'') + bty' + (ct^r + m)y &= 0 \\
at^2y'' + (b+a)\,ty' + (ct^r + m)y &= 0 \\
t^2y'' + \frac{b+a}{a}ty' + \left(\frac{c}{a}t^r + \frac{m}{a}\right)y &= 0 \qquad (4)
\end{aligned}
$$

Which is Bessel ODE. Comparing the above to the general known Bowman form of Bessel ode which is

$$
t^2y'' + (1-2\alpha)\,ty' + \left(\beta^2\gamma^2t^{2\gamma} - \left(n^2\gamma^2 - \alpha^2\right)\right)y = 0 \qquad \text{(C)}
$$

And now comparing (4) and (C) shows that

$$
\begin{aligned}
(1-2\alpha) &= \frac{b+a}{a} \qquad (5) \\
\beta^2\gamma^2 &= \frac{c}{a} \qquad (6) \\
2\gamma &= r \qquad (7) \\
\left(n^2\gamma^2 - \alpha^2\right) &= -\frac{m}{a} \qquad (8)
\end{aligned}
$$

(5) gives $\alpha = \frac{1}{2} - \frac{b+a}{2a}$. (7) gives $\gamma = \frac{r}{2}$. (8) now becomes $\left(n^2\left(\frac{r}{2}\right)^2 - \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2\right) = -\frac{m}{a}$ or $n^2 = \frac{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}{\left(\frac{r}{2}\right)^2}$. Hence $n = \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}$ by taking the positive root.

And finally (6) gives $\beta^2 = \frac{c}{a\gamma^2}$ or $\beta = \sqrt{\frac{c}{a}\frac{1}{\gamma}} = \sqrt{\frac{c}{a}\frac{2}{r}}$ (also taking the positive root). Hence

$$
\begin{aligned}
\alpha &= \frac{1}{2} - \frac{b+a}{2a} \\
n &= \frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2} \\
\beta &= \sqrt{\frac{c}{a}\frac{2}{r}} \\
\gamma &= \frac{r}{2}
\end{aligned}
$$

But the solution to (C) which is general form of Bessel ode is known and given by

$$
y(t) = t^{\alpha}(c_1 J_n(\beta t^{\gamma}) + c_2 Y_n(\beta t^{\gamma}))
$$

Substituting the above values found into this solution gives

$$
y(t) = t^{\frac{1}{2} - \frac{b+a}{2a}} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} t^{\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} t^{\frac{r}{2}}\right)\right)
$$

Since $e^x = t$ then the above becomes

$$
\begin{aligned}
y(x) &= e^{x\left(\frac{1}{2} - \frac{b+a}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{1}{2} - \frac{b+a}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{-b}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \left(\frac{-b}{2a}\right)^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{m}{a} + \frac{b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{m}{a} + \frac{b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{2}{r}\sqrt{-\frac{4ma+b^2}{4a^2}}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right)\right) \\
&= e^{x\left(\frac{-b}{2a}\right)} \left(c_1 J_{\frac{1}{ra}\sqrt{-4ma+b^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right) + c_2 Y_{\frac{1}{ra}\sqrt{-4ma+b^2}} \left(\sqrt{\frac{c}{a}\frac{2}{r}} e^{x\frac{r}{2}}\right)\right) \qquad (9)
\end{aligned}
$$

Equation (9) above is the solution to $ay'' + by' + (ce^{rx} + m)y = 0$. Therefore we just need now to compare this form to the ode given and use (9) to obtain the final solution.

Comparing form (1) to the ode we are solving shows that

$$
\begin{aligned}
a &= 1 \\
b &= a \\
c &= b \\
r &= \lambda \\
m &= c
\end{aligned}
$$

Substituting these in (9) gives the solution as

$$y = c_1 \mathrm{e}^{-\frac{ax}{2}} \operatorname{BesselJ}\left(\frac{\sqrt{a^2-4c}}{\lambda}, \frac{2\sqrt{b}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) + c_2 \mathrm{e}^{-\frac{ax}{2}} \operatorname{BesselY}\left(\frac{\sqrt{a^2-4c}}{\lambda}, \frac{2\sqrt{b}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right)$$

Summary

The solution(s) found are the following

$$y = c_1 \mathrm{e}^{-\frac{ax}{2}} \operatorname{BesselJ}\left(\frac{\sqrt{a^2-4c}}{\lambda}, \frac{2\sqrt{b}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) + c_2 \mathrm{e}^{-\frac{ax}{2}} \operatorname{BesselY}\left(\frac{\sqrt{a^2-4c}}{\lambda}, \frac{2\sqrt{b}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) \tag{1}$$

Verification of solutions

$$y = c_1 \mathrm{e}^{-\frac{ax}{2}} \operatorname{BesselJ}\left(\frac{\sqrt{a^2-4c}}{\lambda}, \frac{2\sqrt{b}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right) + c_2 \mathrm{e}^{-\frac{ax}{2}} \operatorname{BesselY}\left(\frac{\sqrt{a^2-4c}}{\lambda}, \frac{2\sqrt{b}\,\mathrm{e}^{\frac{\lambda x}{2}}}{\lambda}\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.3-1. Equations with exponential functions
Problem number: 13.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"kovacic", "second_order_change_of_variable_on_y_method_1", "linear_second_order_ode_solved_by_an_integrating_factor"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + 2a\,\mathrm{e}^{\lambda x} y' + a\,\mathrm{e}^{\lambda x}\left(a\,\mathrm{e}^{\lambda x} + \lambda\right) y = 0}$$

34.13.1 Solving as linear second order ode solved by an integrating factor ode

The ode satisfies this form

$$y'' + p(x)\,y' + \frac{\left(p(x)^2 + p'(x)\right) y}{2} = f(x)$$

Where $p(x) = 2a\,\mathrm{e}^{\lambda x}$. Therefore, there is an integrating factor given by

$$\begin{aligned}
M(x) &= e^{\frac{1}{2}\int p\,dx} \\
&= e^{\int 2a\,\mathrm{e}^{\lambda x}\,dx} \\
&= \mathrm{e}^{\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}
\end{aligned}$$

Multiplying both sides of the ODE by the integrating factor $M(x)$ makes the left side of the ODE a complete differential

$$(M(x)y)'' = 0$$
$$\left(\mathrm{e}^{\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} y\right)'' = 0$$

Integrating once gives

$$\left(\mathrm{e}^{\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} y\right)' = c_1$$

Integrating again gives

$$\left(\mathrm{e}^{\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} y\right) = c_1 x + c_2$$

Hence the solution is

$$y = \frac{c_1 x + c_2}{\mathrm{e}^{\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}$$

Or

$$y = c_1 x\,\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} + c_2 \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}$$

<u>Summary</u>
The solution(s) found are the following

$$y = c_1 x\,\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} + c_2 \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} \tag{1}$$

<u>Verification of solutions</u>

$$y = c_1 x\,\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} + c_2 \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}$$

Verified OK.

34.13.2 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$p(x) = 2a\,\mathrm{e}^{\lambda x}$$
$$q(x) = a^2 \mathrm{e}^{2\lambda x} + a\lambda\,\mathrm{e}^{\lambda x}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= a^2 e^{2\lambda x} + a\lambda\,e^{\lambda x} - \frac{\left(2a\,e^{\lambda x}\right)'}{2} - \frac{\left(2a\,e^{\lambda x}\right)^2}{4} \\
&= a^2 e^{2\lambda x} + a\lambda\,e^{\lambda x} - \frac{\left(2a\lambda\,e^{\lambda x}\right)}{2} - \frac{\left(4a^2 e^{2\lambda x}\right)}{4} \\
&= a^2 e^{2\lambda x} + a\lambda\,e^{\lambda x} - \left(a\lambda\,e^{\lambda x}\right) - a^2 e^{2\lambda x} \\
&= 0
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\,z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= e^{-\left(\int \frac{p(x)}{2}dx\right)} \\
&= e^{-\int \frac{2a\,e^{\lambda x}}{2}} \\
&= e^{-\frac{a\,e^{\lambda x}}{\lambda}}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\,e^{-\frac{a\,e^{\lambda x}}{\lambda}} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
v''(x)\,e^{-\frac{a\,e^{\lambda x}}{\lambda}} = 0
$$

Which is now solved for $v(x)$ Integrating twice gives the solution

$$
v(x) = c_1 x + c_2
$$

Now that $v(x)$ is known, then

$$
\begin{aligned}
y &= v(x)\,z(x) \\
&= (c_1 x + c_2)\,(z(x))
\end{aligned} \tag{7}
$$

But from (5)

$$
z(x) = e^{-\frac{a\,e^{\lambda x}}{\lambda}}
$$

Hence (7) becomes

$$y = \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}(c_1 x + c_2)$$

Summary
The solution(s) found are the following

$$y = \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}(c_1 x + c_2) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}(c_1 x + c_2)$$

Verified OK.

34.13.3 Solving using Kovacic algorithm

Writing the ode as

$$\begin{aligned} y'' + 2a\,\mathrm{e}^{\lambda x} y' + a\,\mathrm{e}^{\lambda x}\left(a\,\mathrm{e}^{\lambda x} + \lambda\right) y &= 0 & (1)\\ Ay'' + By' + Cy &= 0 & (2) \end{aligned}$$

Comparing (1) and (2) shows that

$$\begin{aligned} A &= 1 \\ B &= 2a\,\mathrm{e}^{\lambda x} \\ C &= \mathrm{e}^{\lambda x} a\left(a\,\mathrm{e}^{\lambda x} + \lambda\right) \end{aligned} \tag{3}$$

Applying the Liouville transformation on the dependent variable gives

$$z(x) = y e^{\int \frac{B}{2A}\,dx}$$

Then (2) becomes

$$z''(x) = r z(x) \tag{4}$$

Where r is given by

$$\begin{aligned} r &= \frac{s}{t} \\ &= \frac{2AB' - 2BA' + B^2 - 4AC}{4A^2} \end{aligned} \tag{5}$$

Substituting the values of A, B, C from (3) in the above and simplifying gives

$$r = \frac{0}{1} \tag{6}$$

Comparing the above to (5) shows that

$$s = 0$$
$$t = 1$$

Therefore eq. (4) becomes

$$z''(x) = 0 \tag{7}$$

Equation (7) is now solved. After finding $z(x)$ then y is found using the inverse transformation

$$y = z(x)\, e^{-\int \frac{B}{2A}\, dx}$$

The first step is to determine the case of Kovacic algorithm this ode belongs to. There are 3 cases depending on the order of poles of r and the order of r at ∞. The following table summarizes these cases.

Case	Allowed pole order for r	Allowed value for $\mathcal{O}(\infty)$
1	$\{0, 1, 2, 4, 6, 8, \cdots\}$	$\{\cdots, -6, -4, -2, 0, 2, 3, 4, 5, 6, \cdots\}$
2	Need to have at least one pole that is either order 2 or odd order greater than 2. Any other pole order is allowed as long as the above condition is satisfied. Hence the following set of pole orders are all allowed. $\{1,2\}$,$\{1,3\}$,$\{2\}$,$\{3\}$,$\{3,4\}$,$\{1,2,5\}$.	no condition
3	$\{1, 2\}$	$\{2, 3, 4, 5, 6, 7, \cdots\}$

Table 225: Necessary conditions for each Kovacic case

The order of r at ∞ is the degree of t minus the degree of s. Therefore

$$\begin{aligned} O(\infty) &= \deg(t) - \deg(s) \\ &= 0 - -\infty \\ &= \infty \end{aligned}$$

There are no poles in r. Therefore the set of poles Γ is empty. Since there is no odd order pole larger than 2 and the order at ∞ is $infinity$ then the necessary conditions for case one are met. Therefore

$$L = [1]$$

Since $r = 0$ is not a function of x, then there is no need run Kovacic algorithm to obtain a solution for transformed ode $z'' = rz$ as one solution is

$$z_1(x) = 1$$

Using the above, the solution for the original ode can now be found. The first solution to the original ode in y is found from

$$\begin{aligned}
y_1 &= z_1 e^{\int -\frac{1}{2}\frac{B}{A}\,dx} \\
&= z_1 e^{-\int \frac{1}{2}\frac{2a\,\mathrm{e}^{\lambda x}}{1}\,dx} \\
&= z_1 e^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} \\
&= z_1 \left(\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}\right)
\end{aligned}$$

Which simplifies to

$$y_1 = \mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}$$

The second solution y_2 to the original ode is found using reduction of order

$$y_2 = y_1 \int \frac{e^{\int -\frac{B}{A}\,dx}}{y_1^2}\,dx$$

Substituting gives

$$\begin{aligned}
y_2 &= y_1 \int \frac{e^{\int -\frac{2a\,\mathrm{e}^{\lambda x}}{1}\,dx}}{(y_1)^2}\,dx \\
&= y_1 \int \frac{e^{-\frac{2a\,\mathrm{e}^{\lambda x}}{\lambda}}}{(y_1)^2}\,dx \\
&= y_1 \left(\frac{\ln\left(\mathrm{e}^{\lambda x}\right)}{\lambda}\right)
\end{aligned}$$

Therefore the solution is

$$\begin{aligned}
y &= c_1 y_1 + c_2 y_2 \\
&= c_1 \left(\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}\right) + c_2 \left(\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}} \left(\frac{\ln\left(\mathrm{e}^{\lambda x}\right)}{\lambda}\right)\right)
\end{aligned}$$

Summary
The solution(s) found are the following

$$y = e^{-\frac{a\,e^{\lambda x}}{\lambda}} c_1 + \frac{c_2 e^{-\frac{a\,e^{\lambda x}}{\lambda}} \ln\left(e^{\lambda x}\right)}{\lambda} \tag{1}$$

Verification of solutions

$$y = e^{-\frac{a\,e^{\lambda x}}{\lambda}} c_1 + \frac{c_2 e^{-\frac{a\,e^{\lambda x}}{\lambda}} \ln\left(e^{\lambda x}\right)}{\lambda}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_x_method_2", "second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' - (a + 2\,\mathrm{e}^{ax} b)\, y' + b^2 \mathrm{e}^{2ax} y = 0}$$

34.17.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$y'' + (-2\,\mathrm{e}^{ax} b - a)\, y' + b^2 \mathrm{e}^{2ax} y = 0 \tag{1}$$

Becomes

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -2\,\mathrm{e}^{ax} b - a \\ q(x) &= b^2 \mathrm{e}^{2ax} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2} y(\tau) + p_1 \left(\frac{d}{d\tau} y(\tau) \right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int (-2\,e^{ax} b - a)dx\right)} dx \\
&= \int e^{\frac{a^2 x + 2\,e^{ax} b}{a}} dx \\
&= \int e^{\frac{a^2 x + 2\,e^{ax} b}{a}} dx \\
&= \frac{e^{\frac{2b\,e^{ax}}{a}}}{2b}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{b^2 e^{2ax}}{e^{\frac{2a^2 x + 4\,e^{ax} b}{a}}} \\
&= b^2 e^{-\frac{4b\,e^{ax}}{a}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2} y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2} y(\tau) + b^2 e^{-\frac{4b\,e^{ax}}{a}} y(\tau) = 0$$

But in terms of τ

$$b^2 e^{-\frac{4b\,e^{ax}}{a}} = \frac{1}{4\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{y(\tau)}{4\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$4\left(\frac{d^2}{d\tau^2}y(\tau)\right)\tau^2 + y(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$4\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + \tau^r = 0$$

Simplifying gives

$$4r(r-1)\,\tau^r + 0\,\tau^r + \tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$4r(r-1) + 0 + 1 = 0$$

Or

$$4r^2 - 4r + 1 = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = \frac{1}{2}$$
$$r_2 = \frac{1}{2}$$

Since the roots are equal, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^r$ and $y_2 = \tau^r \ln(\tau)$. Hence

$$y(\tau) = c_1\sqrt{\tau} + c_2\sqrt{\tau}\,\ln(\tau)$$

The above solution is now transformed back to y using (6) which results in

$$y = \frac{\sqrt{2}\,\sqrt{\frac{e^{\frac{2b\,e^{ax}}{a}}}{b}}\left(c_1 + c_2\ln\left(\frac{e^{\frac{2b\,e^{ax}}{a}}}{b}\right) - c_2\ln(2)\right)}{2}$$

Summary
The solution(s) found are the following

$$y = \frac{\sqrt{2}\, \sqrt{\frac{e^{\frac{2b\, e^{ax}}{a}}}{b}}\, \left(c_1 + c_2 \ln\left(\frac{e^{\frac{2b\, e^{ax}}{a}}}{b}\right) - c_2 \ln(2)\right)}{2} \tag{1}$$

Verification of solutions

$$y = \frac{\sqrt{2}\, \sqrt{\frac{e^{\frac{2b\, e^{ax}}{a}}}{b}}\, \left(c_1 + c_2 \ln\left(\frac{e^{\frac{2b\, e^{ax}}{a}}}{b}\right) - c_2 \ln(2)\right)}{2}$$

Verified OK.

34.17.2 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\, y' + q(x)\, y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= -2\, e^{ax} b - a \\ q(x) &= b^2 e^{2ax} \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$\begin{aligned} Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\ &= b^2 e^{2ax} - \frac{(-2\, e^{ax} b - a)'}{2} - \frac{(-2\, e^{ax} b - a)^2}{4} \\ &= b^2 e^{2ax} - \frac{(-2a\, e^{ax} b)}{2} - \frac{((-2\, e^{ax} b - a)^2)}{4} \\ &= b^2 e^{2ax} - (-a\, e^{ax} b) - \frac{(-2\, e^{ax} b - a)^2}{4} \\ &= -\frac{a^2}{4} \end{aligned}$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$y = v(x)\, z(x) \tag{3}$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$\begin{aligned} z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\ &= e^{-\int \frac{-2\,\mathrm{e}^{ax} b - a}{2}} \\ &= \mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{ax} b}{2a}} \end{aligned} \tag{5}$$

Hence (3) becomes

$$y = v(x)\,\mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{ax} b}{2a}} \tag{4}$$

Applying this change of variable to the original ode results in

$$\mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{ax} b}{2a}} \left(-a^2 v(x) + 4v''(x)\right) = 0$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$Av''(x) + Bv'(x) + Cv(x) = 0$$

Where in the above $A = 4, B = 0, C = -a^2$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$4\lambda^2 \mathrm{e}^{\lambda x} - a^2 \mathrm{e}^{\lambda x} = 0 \tag{1}$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$-a^2 + 4\lambda^2 = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 0, C = -a^2$ into the above gives

$$\begin{aligned} \lambda_{1,2} &= \frac{0}{(2)\,(4)} \pm \frac{1}{(2)\,(4)}\sqrt{0^2 - (4)\,(4)\,(-a^2)} \\ &= \pm\frac{\sqrt{a^2}}{2} \end{aligned}$$

Hence

$$\lambda_1 = +\frac{\sqrt{a^2}}{2}$$

$$\lambda_2 = -\frac{\sqrt{a^2}}{2}$$

Which simplifies to

$$\lambda_1 = \frac{\sqrt{a^2}}{2}$$
$$\lambda_2 = -\frac{\sqrt{a^2}}{2}$$

Since roots are real and distinct, then the solution is

$$v(x) = c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}$$
$$v(x) = c_1 e^{\left(\frac{\sqrt{a^2}}{2}\right)x} + c_2 e^{\left(-\frac{\sqrt{a^2}}{2}\right)x}$$

Or

$$v(x) = c_1 \mathrm{e}^{\frac{\sqrt{a^2}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{a^2}\,x}{2}}$$

Now that $v(x)$ is known, then

$$\begin{aligned} y &= v(x)\, z(x) \\ &= \left(c_1 \mathrm{e}^{\frac{\sqrt{a^2}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{a^2}\,x}{2}}\right)(z(x)) \end{aligned} \tag{7}$$

But from (5)

$$z(x) = \mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{a x} b}{2a}}$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{\frac{\sqrt{a^2}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{a^2}\,x}{2}}\right) \mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{a x} b}{2a}}$$

Summary

The solution(s) found are the following

$$y = \left(c_1 \mathrm{e}^{\frac{\sqrt{a^2}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{a^2}\,x}{2}}\right) \mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{a x} b}{2a}} \tag{1}$$

Verification of solutions

$$y = \left(c_1 \mathrm{e}^{\frac{\sqrt{a^2}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{a^2}\,x}{2}}\right) \mathrm{e}^{\frac{a^2 x + 2\,\mathrm{e}^{a x} b}{2a}}$$

Verified OK.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_x_method_2"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(a\,\mathrm{e}^{\lambda x} - \lambda\right) y' + yb\,\mathrm{e}^{2\lambda x} = 0}$$

34.19.1 Solving as second order change of variable on x method 2 ode

In normal form the ode

$$y'' + \left(a\,\mathrm{e}^{\lambda x} - \lambda\right) y' + yb\,\mathrm{e}^{2\lambda x} = 0 \tag{1}$$

Becomes

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= a\,\mathrm{e}^{\lambda x} - \lambda \\ q(x) &= b\,\mathrm{e}^{2\lambda x} \end{aligned}$$

Applying change of variables $\tau = g(x)$ to (2) gives

$$\frac{d^2}{d\tau^2}y(\tau) + p_1\left(\frac{d}{d\tau}y(\tau)\right) + q_1 y(\tau) = 0 \tag{3}$$

Where τ is the new independent variable, and

$$p_1(\tau) = \frac{\tau''(x) + p(x)\,\tau'(x)}{\tau'(x)^2} \tag{4}$$

$$q_1(\tau) = \frac{q(x)}{\tau'(x)^2} \tag{5}$$

Let $p_1 = 0$. Eq (4) simplifies to

$$\tau''(x) + p(x)\,\tau'(x) = 0$$

This ode is solved resulting in

$$\begin{aligned}
\tau &= \int e^{-\left(\int p(x)dx\right)} dx \\
&= \int e^{-\left(\int (a\,e^{\lambda x}-\lambda)dx\right)} dx \\
&= \int e^{\frac{x\,\lambda^2 - a\,e^{\lambda x}}{\lambda}} dx \\
&= \int e^{\frac{x\,\lambda^2 - a\,e^{\lambda x}}{\lambda}} dx \\
&= -\frac{e^{-\frac{a\,e^{\lambda x}}{\lambda}}}{a}
\end{aligned} \tag{6}$$

Using (6) to evaluate q_1 from (5) gives

$$\begin{aligned}
q_1(\tau) &= \frac{q(x)}{\tau'(x)^2} \\
&= \frac{b\,e^{2\lambda x}}{e^{\frac{2x\,\lambda^2 - 2a\,e^{\lambda x}}{\lambda}}} \\
&= b\,e^{\frac{2a\,e^{\lambda x}}{\lambda}}
\end{aligned} \tag{7}$$

Substituting the above in (3) and noting that now $p_1 = 0$ results in

$$\frac{d^2}{d\tau^2}y(\tau) + q_1 y(\tau) = 0$$

$$\frac{d^2}{d\tau^2}y(\tau) + b\,e^{\frac{2a\,e^{\lambda x}}{\lambda}} y(\tau) = 0$$

But in terms of τ

$$b\,e^{\frac{2a\,e^{\lambda x}}{\lambda}} = \frac{b}{a^2\tau^2}$$

Hence the above ode becomes

$$\frac{d^2}{d\tau^2}y(\tau) + \frac{by(\tau)}{a^2\tau^2} = 0$$

The above ode is now solved for $y(\tau)$. The ode can be written as

$$\left(\frac{d^2}{d\tau^2}y(\tau)\right)a^2\tau^2 + by(\tau) = 0$$

Which shows it is a Euler ODE. This is Euler second order ODE. Let the solution be $y(\tau) = \tau^r$, then $y' = r\tau^{r-1}$ and $y'' = r(r-1)\tau^{r-2}$. Substituting these back into the given ODE gives

$$a^2\tau^2(r(r-1))\tau^{r-2} + 0r\tau^{r-1} + b\,\tau^r = 0$$

Simplifying gives

$$a^2r(r-1)\,\tau^r + 0\,\tau^r + b\,\tau^r = 0$$

Since $\tau^r \neq 0$ then dividing throughout by τ^r gives

$$a^2r(r-1) + 0 + b = 0$$

Or

$$a^2r^2 - a^2r + b = 0 \tag{1}$$

Equation (1) is the characteristic equation. Its roots determine the form of the general solution. Using the quadratic equation the roots are

$$r_1 = -\frac{-a + \sqrt{a^2-4b}}{2a}$$
$$r_2 = \frac{a + \sqrt{a^2-4b}}{2a}$$

Since the roots are real and distinct, then the general solution is

$$y(\tau) = c_1y_1 + c_2y_2$$

Where $y_1 = \tau^{r_1}$ and $y_2 = \tau^{r_2}$. Hence

$$y(\tau) = c_1\tau^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2\tau^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

The above solution is now transformed back to y using (6) which results in

$$y = c_1\left(-\frac{\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}{a}\right)^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2\left(-\frac{\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}{a}\right)^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

Summary

The solution(s) found are the following

$$y = c_1 \left(-\frac{\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}{a}\right)^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2 \left(-\frac{\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}{a}\right)^{\frac{a+\sqrt{a^2-4b}}{2a}} \tag{1}$$

Verification of solutions

$$y = c_1 \left(-\frac{\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}{a}\right)^{-\frac{-a+\sqrt{a^2-4b}}{2a}} + c_2 \left(-\frac{\mathrm{e}^{-\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}}}{a}\right)^{\frac{a+\sqrt{a^2-4b}}{2a}}$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.3-1. Equations with exponential functions
Problem number: 24.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"second_order_change_of_variable_on_y_method_1"**

Maple gives the following as the ode type

```
[[_2nd_order, _with_linear_symmetries]]
```

$$\boxed{y'' + \left(2a\,e^{\lambda x} + b\right)y' + \left(a^2 e^{2\lambda x} + a(b+\lambda)\,e^{\lambda x} + c\right)y = 0}$$

34.24.1 Solving as second order change of variable on y method 1 ode

In normal form the given ode is written as

$$y'' + p(x)\,y' + q(x)\,y = 0 \tag{2}$$

Where

$$\begin{aligned} p(x) &= 2a\,e^{\lambda x} + b \\ q(x) &= ab\,e^{\lambda x} + a\lambda\,e^{\lambda x} + a^2 e^{2\lambda x} + c \end{aligned}$$

Calculating the Liouville ode invariant Q given by

$$
\begin{aligned}
Q &= q - \frac{p'}{2} - \frac{p^2}{4} \\
&= ab\,\mathrm{e}^{\lambda x} + a\lambda\,\mathrm{e}^{\lambda x} + a^2\mathrm{e}^{2\lambda x} + c - \frac{\left(2a\,\mathrm{e}^{\lambda x} + b\right)'}{2} - \frac{\left(2a\,\mathrm{e}^{\lambda x} + b\right)^2}{4} \\
&= ab\,\mathrm{e}^{\lambda x} + a\lambda\,\mathrm{e}^{\lambda x} + a^2\mathrm{e}^{2\lambda x} + c - \frac{\left(2a\lambda\,\mathrm{e}^{\lambda x}\right)}{2} - \frac{\left(\left(2a\,\mathrm{e}^{\lambda x} + b\right)^2\right)}{4} \\
&= ab\,\mathrm{e}^{\lambda x} + a\lambda\,\mathrm{e}^{\lambda x} + a^2\mathrm{e}^{2\lambda x} + c - \left(a\lambda\,\mathrm{e}^{\lambda x}\right) - \frac{\left(2a\,\mathrm{e}^{\lambda x} + b\right)^2}{4} \\
&= c - \frac{b^2}{4}
\end{aligned}
$$

Since the Liouville ode invariant does not depend on the independent variable x then the transformation

$$
y = v(x)\,z(x) \tag{3}
$$

is used to change the original ode to a constant coefficients ode in v. In (3) the term $z(x)$ is given by

$$
\begin{aligned}
z(x) &= \mathrm{e}^{-\left(\int \frac{p(x)}{2} dx\right)} \\
&= e^{-\int \frac{2a\,\mathrm{e}^{\lambda x}+b}{2}} \\
&= \mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}}
\end{aligned} \tag{5}
$$

Hence (3) becomes

$$
y = v(x)\,\mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}} \tag{4}
$$

Applying this change of variable to the original ode results in

$$
\mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}}\left(-b^2 v(x) + 4cv(x) + 4v''(x)\right) = 0
$$

Which is now solved for $v(x)$ This is second order with constant coefficients homogeneous ODE. In standard form the ODE is

$$
Av''(x) + Bv'(x) + Cv(x) = 0
$$

Where in the above $A = 4, B = 0, C = -b^2 + 4c$. Let the solution be $v(x) = e^{\lambda x}$. Substituting this into the ODE gives

$$
4\lambda^2\mathrm{e}^{\lambda x} + \left(-b^2 + 4c\right)\mathrm{e}^{\lambda x} = 0 \tag{1}
$$

Since exponential function is never zero, then dividing Eq(2) throughout by $e^{\lambda x}$ gives

$$-b^2 + 4\lambda^2 + 4c = 0 \tag{2}$$

Equation (2) is the characteristic equation of the ODE. Its roots determine the general solution form.Using the quadratic formula

$$\lambda_{1,2} = \frac{-B}{2A} \pm \frac{1}{2A}\sqrt{B^2 - 4AC}$$

Substituting $A = 4, B = 0, C = -b^2 + 4c$ into the above gives

$$\begin{aligned}\lambda_{1,2} &= \frac{0}{(2)(4)} \pm \frac{1}{(2)(4)}\sqrt{0^2 - (4)(4)(-b^2 + 4c)}\\ &= \pm\frac{\sqrt{b^2 - 4c}}{2}\end{aligned}$$

Hence

$$\begin{aligned}\lambda_1 &= +\frac{\sqrt{b^2 - 4c}}{2}\\ \lambda_2 &= -\frac{\sqrt{b^2 - 4c}}{2}\end{aligned}$$

Which simplifies to

$$\begin{aligned}\lambda_1 &= \frac{\sqrt{b^2 - 4c}}{2}\\ \lambda_2 &= -\frac{\sqrt{b^2 - 4c}}{2}\end{aligned}$$

Since roots are real and distinct, then the solution is

$$\begin{aligned}v(x) &= c_1 e^{\lambda_1 x} + c_2 e^{\lambda_2 x}\\ v(x) &= c_1 e^{\left(\frac{\sqrt{b^2-4c}}{2}\right)x} + c_2 e^{\left(-\frac{\sqrt{b^2-4c}}{2}\right)x}\end{aligned}$$

Or

$$v(x) = c_1 \mathrm{e}^{\frac{\sqrt{b^2-4c}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{b^2-4c}\,x}{2}}$$

Now that $v(x)$ is known, then

$$\begin{aligned}y &= v(x)\,z(x)\\ &= \left(c_1 \mathrm{e}^{\frac{\sqrt{b^2-4c}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{b^2-4c}\,x}{2}}\right)(z(x))\end{aligned} \tag{7}$$

But from (5)

$$z(x) = \mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}}$$

Hence (7) becomes

$$y = \left(c_1 \mathrm{e}^{\frac{\sqrt{b^2-4c}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{b^2-4c}\,x}{2}}\right) \mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}}$$

Summary

The solution(s) found are the following

$$y = \left(c_1 \mathrm{e}^{\frac{\sqrt{b^2-4c}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{b^2-4c}\,x}{2}}\right) \mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}} \tag{1}$$

Verification of solutions

$$y = \left(c_1 \mathrm{e}^{\frac{\sqrt{b^2-4c}\,x}{2}} + c_2 \mathrm{e}^{-\frac{\sqrt{b^2-4c}\,x}{2}}\right) \mathrm{e}^{-\frac{\lambda b x + 2a\,\mathrm{e}^{\lambda x}}{2\lambda}}$$

Verified OK.

Internal file name [`OUTPUT/10376_Wednesday_January_31_2024_08_14_02_PM_16279652/index.tex`]

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.3-1. Equations with exponential functions
Problem number: 32.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"exact linear second order ode", "second_order_integrable_as_is"**

Maple gives the following as the ode type

```
[[_2nd_order, _exact, _linear, _homogeneous]]
```

$$\boxed{y'' + \left(a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c\right) y' + \left(a\lambda\,\mathrm{e}^{\lambda x} + \mu\,\mathrm{e}^{\mu x} b\right) y = 0}$$

34.32.1 Solving as second order integrable as is ode

Integrating both sides of the ODE w.r.t x gives

$$\int \left(y'' + \left(a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c\right) y' + \left(a\lambda\,\mathrm{e}^{\lambda x} + \mu\,\mathrm{e}^{\mu x} b\right) y\right) dx = 0$$
$$\left(a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c\right) y + y' = c_1$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= a\,\mathrm{e}^{\lambda x}+\mathrm{e}^{\mu x} b+c \\
q(x) &= c_1
\end{aligned}
$$

Hence the ode is

$$
\left(a\,\mathrm{e}^{\lambda x}+\mathrm{e}^{\mu x} b+c\right) y+y' = c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int (a\,\mathrm{e}^{\lambda x}+\mathrm{e}^{\mu x} b+c)dx} \\
&= \mathrm{e}^{c x+\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}+\frac{b\,\mathrm{e}^{\mu x}}{\mu}}
\end{aligned}
$$

Which simplifies to

$$
\mu = \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)(c_1) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} y\right) &= \left(\mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}}\right)(c_1) \\
\mathrm{d}\left(\mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} y\right) &= \left(c_1 \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} y &= \int c_1 \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}}\,\mathrm{d}x \\
\mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} y &= \int c_1 \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} dx + c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}}$ results in

$$
y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x} \mu-\lambda (c x \mu+\mathrm{e}^{\mu x} b)}{\mu \lambda}} \left(\int c_1 \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} dx\right) + c_2 \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x} \mu-\lambda (c x \mu+\mathrm{e}^{\mu x} b)}{\mu \lambda}}
$$

which simplifies to

$$
y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x} \mu-\lambda (c x \mu+\mathrm{e}^{\mu x} b)}{\mu \lambda}} \left(c_1 \left(\int \mathrm{e}^{\frac{c x \lambda \mu+a\,\mathrm{e}^{\lambda x} \mu+\mathrm{e}^{\mu x} b \lambda}{\lambda \mu}} dx\right) + c_2\right)
$$

Summary
The solution(s) found are the following

$$y = e^{\frac{-a\,e^{\lambda x}\mu - \lambda\left(cx\mu + e^{\mu x}b\right)}{\mu\lambda}}\left(c_1\left(\int e^{\frac{cx\lambda\mu + a\,e^{\lambda x}\mu + e^{\mu x}b\lambda}{\lambda\mu}}dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = e^{\frac{-a\,e^{\lambda x}\mu - \lambda\left(cx\mu + e^{\mu x}b\right)}{\mu\lambda}}\left(c_1\left(\int e^{\frac{cx\lambda\mu + a\,e^{\lambda x}\mu + e^{\mu x}b\lambda}{\lambda\mu}}dx\right) + c_2\right)$$

Verified OK.

34.32.2 Solving as type second_order_integrable_as_is (not using ABC version)

Writing the ode as

$$y'' + \left(a\,e^{\lambda x} + e^{\mu x}b + c\right)y' + \left(a\lambda\,e^{\lambda x} + \mu\,e^{\mu x}b\right)y = 0$$

Integrating both sides of the ODE w.r.t x gives

$$\begin{aligned}\int \left(y'' + \left(a\,e^{\lambda x} + e^{\mu x}b + c\right)y' + \left(a\lambda\,e^{\lambda x} + \mu\,e^{\mu x}b\right)y\right)dx &= 0\\ \left(a\,e^{\lambda x} + e^{\mu x}b + c\right)y + y' &= c_1\end{aligned}$$

Which is now solved for y.

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$\begin{aligned}p(x) &= a\,e^{\lambda x} + e^{\mu x}b + c\\ q(x) &= c_1\end{aligned}$$

Hence the ode is

$$\left(a\,e^{\lambda x} + e^{\mu x}b + c\right)y + y' = c_1$$

The integrating factor μ is

$$\begin{aligned}\mu &= e^{\int \left(a\,e^{\lambda x} + e^{\mu x}b + c\right)dx}\\ &= e^{cx + \frac{a\,e^{\lambda x}}{\lambda} + \frac{b\,e^{\mu x}}{\mu}}\end{aligned}$$

Which simplifies to

$$\mu = \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}$$

The ode becomes

$$\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\,(c_1) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y\right) &= \left(\mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\right)(c_1) \\
\mathrm{d}\left(\mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y\right) &= \left(c_1 \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\right)\,\mathrm{d}x
\end{aligned}$$

Integrating gives

$$\begin{aligned}
\mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y &= \int c_1 \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,\mathrm{d}x \\
\mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y &= \int c_1 \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx + c_2
\end{aligned}$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}$ results in

$$y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu - \lambda(cx\mu + \mathrm{e}^{\mu x} b)}{\mu\lambda}} \left(\int c_1 \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx\right) + c_2 \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu - \lambda(cx\mu + \mathrm{e}^{\mu x} b)}{\mu\lambda}}$$

which simplifies to

$$y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu - \lambda(cx\mu + \mathrm{e}^{\mu x} b)}{\mu\lambda}} \left(c_1 \left(\int \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx\right) + c_2\right)$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu - \lambda(cx\mu + \mathrm{e}^{\mu x} b)}{\mu\lambda}} \left(c_1 \left(\int \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx\right) + c_2\right) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu - \lambda(cx\mu + \mathrm{e}^{\mu x} b)}{\mu\lambda}} \left(c_1 \left(\int \mathrm{e}^{\frac{cx\lambda\mu + a\,\mathrm{e}^{\lambda x}\mu + \mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx\right) + c_2\right)$$

Verified OK.

34.32.3 Solving as exact linear second order ode ode

An ode of the form

$$p(x)\,y'' + q(x)\,y' + r(x)\,y = s(x)$$

is exact if

$$p''(x) - q'(x) + r(x) = 0 \tag{1}$$

For the given ode we have

$$\begin{aligned} p(x) &= 1 \\ q(x) &= a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c \\ r(x) &= a\lambda\,\mathrm{e}^{\lambda x} + \mu\,\mathrm{e}^{\mu x} b \\ s(x) &= 0 \end{aligned}$$

Hence

$$\begin{aligned} p''(x) &= 0 \\ q'(x) &= a\lambda\,\mathrm{e}^{\lambda x} + \mu\,\mathrm{e}^{\mu x} b \end{aligned}$$

Therefore (1) becomes

$$0 - \left(a\lambda\,\mathrm{e}^{\lambda x} + \mu\,\mathrm{e}^{\mu x} b\right) + \left(a\lambda\,\mathrm{e}^{\lambda x} + \mu\,\mathrm{e}^{\mu x} b\right) = 0$$

Hence the ode is exact. Since we now know the ode is exact, it can be written as

$$\left(p(x)\,y' + (q(x) - p'(x))\,y\right)' = s(x)$$

Integrating gives

$$p(x)\,y' + (q(x) - p'(x))\,y = \int s(x)\,dx$$

Substituting the above values for p, q, r, s gives

$$\left(a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c\right) y + y' = c_1$$

We now have a first order ode to solve which is

$$\left(a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c\right) y + y' = c_1$$

Entering Linear first order ODE solver. In canonical form a linear first order is

$$y' + p(x)y = q(x)$$

Where here

$$
\begin{aligned}
p(x) &= a\,\mathrm{e}^{\lambda x}+\mathrm{e}^{\mu x} b+c \\
q(x) &= c_1
\end{aligned}
$$

Hence the ode is

$$
\left(a\,\mathrm{e}^{\lambda x}+\mathrm{e}^{\mu x} b+c\right) y+y' = c_1
$$

The integrating factor μ is

$$
\begin{aligned}
\mu &= \mathrm{e}^{\int (a\,\mathrm{e}^{\lambda x}+\mathrm{e}^{\mu x} b+c)dx} \\
&= \mathrm{e}^{cx+\frac{a\,\mathrm{e}^{\lambda x}}{\lambda}+\frac{b\,\mathrm{e}^{\mu x}}{\mu}}
\end{aligned}
$$

Which simplifies to

$$
\mu = \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}
$$

The ode becomes

$$
\begin{aligned}
\frac{\mathrm{d}}{\mathrm{d}x}(\mu y) &= (\mu)\,(c_1) \\
\frac{\mathrm{d}}{\mathrm{d}x}\left(\mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y\right) &= \left(\mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\right)(c_1) \\
\mathrm{d}\left(\mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y\right) &= \left(c_1 \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\right)\,\mathrm{d}x
\end{aligned}
$$

Integrating gives

$$
\begin{aligned}
\mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y &= \int c_1 \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,\mathrm{d}x \\
\mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}} y &= \int c_1 \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx+c_2
\end{aligned}
$$

Dividing both sides by the integrating factor $\mu = \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}$ results in

$$
y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu-\lambda(cx\mu+\mathrm{e}^{\mu x} b)}{\mu\lambda}}\left(\int c_1 \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx\right)+c_2 \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu-\lambda(cx\mu+\mathrm{e}^{\mu x} b)}{\mu\lambda}}
$$

which simplifies to

$$
y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu-\lambda(cx\mu+\mathrm{e}^{\mu x} b)}{\mu\lambda}}\left(c_1\left(\int \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x} b\lambda}{\lambda\mu}}\,dx\right)+c_2\right)
$$

Summary

The solution(s) found are the following

$$y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu-\lambda\left(cx\mu+\mathrm{e}^{\mu x}b\right)}{\mu\lambda}}\left(c_1\left(\int \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x}b\lambda}{\lambda\mu}}dx\right)+c_2\right) \tag{1}$$

Verification of solutions

$$y = \mathrm{e}^{\frac{-a\,\mathrm{e}^{\lambda x}\mu-\lambda\left(cx\mu+\mathrm{e}^{\mu x}b\right)}{\mu\lambda}}\left(c_1\left(\int \mathrm{e}^{\frac{cx\lambda\mu+a\,\mathrm{e}^{\lambda x}\mu+\mathrm{e}^{\mu x}b\lambda}{\lambda\mu}}dx\right)+c_2\right)$$

Verified OK.

Book: Handbook of exact solutions for ordinary differential equations. By Polyanin and Zaitsev. Second edition
Section: Chapter 2, Second-Order Differential Equations. section 2.1.3-1. Equations with exponential functions
Problem number: 33.
ODE order: 2.
ODE degree: 1.

The type(s) of ODE detected by this program : **"unknown"**

Maple gives the following as the ode type

`[[_2nd_order, _with_linear_symmetries]]`

Unable to solve or complete the solution.

$$\boxed{y'' + \left(a\,\mathrm{e}^{\lambda x} + \mathrm{e}^{\mu x} b + c\right) y' + \left(ab\,\mathrm{e}^{x(\lambda+\mu)} + \mathrm{e}^{\lambda x} ac + \mu\,\mathrm{e}^{\mu x} b\right) y = 0}$$
